Cavernous angiomas affect roughly 0.5% of the population and are characterized by abnormal enlarged capillary cavities without intervening brain parenchyma. Clinical CCM symptoms include recurrent headaches, focal neurological deficits, hemorrhagic stroke, and seizures Three CCM genes are known: *CCM1/KRIT1*, *CCM2/ MGC4607* and *PDCD10/CCM3,* implicated respectively in about 65%, 20% and 15% of the CCM cases. The phenotypic characterization of *CCM3* mutated patients has been limited by the small number of patients harboring a mutation in this gene.
We report here molecular and clinical data of a large cohort of *CCM3* patients. Molecular screening for point mutations and deletions allowed to identify a mutation in 54 *CCM3* mutated index patients and 22 mutated relatives. Multiple extra-axial, dural based, lesions were detected in 7 unrelated patients and were proved to be meningiomas in 3 patients on pathological examination. Sequencing of the gDNA extracted from a meningioma for one of the patients showed a mutation occurring de novo on the wild type allele within the lesion. This "multiple meningiomas" phenotype is not associated with a specific *CCM3* mutation, and the association of these multiple extra dural lesions and multiple meningiomas was not detected in 189 patients with a *CCM1* mutation or 57 patients with a *CCM2* mutation.
CCM3 gene is as a novel gene involved in multiple meningiomas.

Nursing and genetics: A Brazilian multicenter study about factors of risk for cleft lip and palate

B. H. Bueno[1], *R. Barbosa*[1], *E. M. Ribeiro*[2], *J. SOUZA*[3], *G. F. Leal*[4], *T. M. Félix*[5], *A. C. Fett-Conte*[6], *M. Í. B. Fontes*[7], *I. L. Monlleó*[7], *V. L. G. d. Lopes*[1];
[1]*State University of Campinas, Campinas, Brazil,* [2]*Hospital Infantil Albert Sabin (HIAS), Fortaleza, Brazil,* [3]*Assistance Center for Cleft Lip and Palate (CAIF), Curitiba, Brazil,* [4]*Facial Deformity Care Center (CADEFI), Recife, Brazil,* [5]*Hospital de Clínicas de Porto Alegre (HCPA), Porto Alegre, Brazil,* [6]*Medicine School of São José do Rio Preto (FAMERP/FUNFARME), São José do Rio Preto, Brazil,* [7]*State University of Alagoas (UNCISAL), Maceió, Brazil.*

The nurse participates in consultation family planning and prenatal care and develops health education activities. The cleft lip and palate (CLP) occurs in 1: 600-1000 newborns. The objectives of this study are to describe demographic and clinical characteristics and risk factors in FLP cases registred in the Brazilian Database on Orofacial Clefts (BDOC). It is descriptive and transversal study; used Fisher test and chi-square test, with a significance level of 5% (p <0.05). Of the 640 cases, 384 (60.0%) had at least one recognized risk factor; higher maternal education was associated to lower exposure to environmental risks (p = 0.000) and positive familial history was related to for non-syndromic cleft (p = 0.001). The identification of these and other factors associated with FLP and community profile allow the increase in guidance for family planning and prenatal care. Still, enables health education campaigns for health professionals and community activities related skills of nurses.

EuroGentest Clinical Utility Gene Cards - progress and perspectives 2013

A. Dierking, *J. Schmidtke;*
Institute of Human Genetics, Hannover Medical School, Hannover, Germany.

EuroGentest unit 2, addressing "Genetic testing as part of health care", holds the initiative for the creation of disease-specific, expert-authored genetic testing guidelines, the "Clinical Utility Gene Cards" (CUGCs). CUGCs are dealing with the pros and cons of the usage of genetic tests in a clinical setting. CUGCs give a balanced summary of the analytical and clinical validity, the clinical utility and cost-benefit issues of genetic testing in a disease-specific context. Due to their concise and standardized format, CUGCs offer quick guidance to all stakeholders, including clinicians, clinical geneticists, service providers and payers.
Each CUGC is authored by a multinational expert team. The manuscripts are peer-reviewed and published in the European Journal of Human Genetics (EJHG). All CUGCs are freely accessible on www.eurogentest.org, www.nature.com/ejhg and www.orpha.net. EuroGentest commissions the establishment as well as the annual update of the guidelines. Until now 83 CUGCs have become citable publications and 105 manuscripts are in progress. By the end of 2013, 300 CUGCs are intended to be published.
The CUGCs are well received by the scientific and clinical communities: the average number of downloads per gene card and year is over 1000. CUGCs represent either alternatives or complements to other guideline collections such as GeneReviews (http://www.ncbi.nlm.nih.gov/books/NBK1116/). An analysis of the CUGC commissioning procedure corroborates the experience of all actors in the field of rare diseases: the existence of a limited number of experts, their willingness to contribute, their individual overloading, and the ensuing long process from author invitation to completed review.

P18.19

Elaboration of a tool for assessment and improvement of quality of decision-making at the multidisciplinary oncogenetic committee for colorectal cancer predisposition: a french experience

S. Aissaoui[1,2], *S. Pinson*[3], *S. Giraud*[3], *H. Sobol*[4], *A. Calender*[3];
[1]*Hospices Civils de Lyon, Hôpital Edouard Herriot, Service de génétique moléculaire et Médicale, Lyon 3, France,* [2]*AFCG (Association Française des Conseillers en Génétique), Marseille, France,* [3]*Hospices Civils de Lyon, Hôpital Edouard Herriot, Service de génétique moléculaire et Médicale, lyon 3, France,* [4]*Département d'Oncologie Génétique, de Prévention et Dépistage, Institut Paoli-Calmettes, Marseille, France.*

The most common diseases that predispose for colorectal cancers are Lynch Syndrome and Familial Adenomatous Polyposis. MMR and APC (and MUTYH) genes are respectively responsible. A genetic counselling is imperative for an optimal care making for patients and families. Multidisciplinary committees (MDC) are usually organized, helping professionals to optimize a decision for gene analysis and patient/families follow-up, taking into account relevant experts advices. Our aim is to examine the evaluation and the improvement of quality decision-making for a family suspected for colorectal cancer predisposition. A disparate distribution of decisions has been suspected. In Lyon region we created a database to verify that and harmonize the different participants' work in MDC. Results: the 33 French oncogenetic main consultation centers have been contacted in order to describe the organization of their MDC. Answering rate reached 100%. Among these centers, 76% developed a specific MDC, whereas 24% used standard consultation. About 3.75 different medical specialities are gathered by MDC. Among them, there are oncogeneticists (100%), gastroenterologists (76%), genetic counsellors (84%), surgeons (32%), and biologists (36%). Twenty percent of centers having a specific MDC evaluate all their patient cases, whereas 80% select them. In Lyon region, a computerized tool is elaborated and will be widely disseminated to every collaborating partners of our MDC. It will enable us to standardize our decision-making and, by comparing decisions through quality criteria, to differentiate and categorize some patients/families groups. A better rationalization of care management, families' follow-up and prevention is thus targeted.

P18.20

Complete Androgen Insensitivity Syndrome (CAIS) in a large East African Family

M. M. Alwasiyah[1], *C. Trujillo*[2];
[1]*Aziziah Maternity & Children Hospital, Jeddah, Saudi Arabia,* [2]*Erfan & Bagedo Hospital, Jeddah, Saudi Arabia.*

A 27 year old female, from east Africa, was referred to us for infertility, primary amenorrhea and decreased pubic and axillary hair. She was the second of 9 sibs, 4 other females and 4 males. She had been married for 2 years and she never had a medical consultation for this reason. Testosterone was high. Absence of inguinal masses. There was absence of epididymides and vas deferens. Abdominal testes were seen by MRI; breasts and female adiposity were of normal development. Her karyotype was 46, XY. Her 15 year old sister has the same clinical features, and karyotype 46, XY. We did karyotyping for her 3 other sisters, two of them were 46, XX, and they are clinically normal. The last sister, age 9, was also found to be 46, XY and clinically normal. We offered gonadectomy to the 27 year old female. But it has been rejected. We extracted DNA samples from the mother and all the phenotypical females to provide proper genetic counseling in the carriers. These results will be presented at the meeting.
We haven't disclosed the diagnosis of CAIS to the affected individuals. However, the circumstance in which the diagnosis was done, due to the sociocultural and educational background and after 2 years of marriage, makes this decision extremely difficult. The ethical dilemma faced in revealing a diagnosis with such a devastating social impact for the patient, and the obligation to other carriers in the family, creates quite a unique source of debate.

M.M. Alwasiyah: None. **C. Trujillo:** None.

P18.21

Dynamic Consent - A Tool for Translational Research

J. Kaye[1], *E. Whitley*[2], *D. Lund*[3];
[1]*UNIVERSITY OF OXFORD, Oxford, United Kingdom,* [2]*LSE, London, United Kingdom,* [3]*HW Communications, Lancaster, United Kingdom.*

We have built a patient IT interface which uses a 'dynamic consent' approach. In this model, consent is not a mere communication exercise but a bidirectional, ongoing, interactive process between patients and researchers. Through the interface individuals can make and express preferences about the choices they are given about the use of their data and samples for research. The benefit of this interface is that it enables individuals to exercise their autonomy by giving informed consent for new types of research in real time rather than being asked to give a broad consent at the beginning of the research process when they are recruited into a biobank. The benefits for the research process are that recruitment is easier, less costly and more efficient; the legal and ethical requirements of consent can be met with ease; there is greater transparency and accountability in the research process and research findings can be returned to research participants as part of a personalised medicine approach. Dynamic consent has the potential to enhance patient confidence and enable long term patient-researcher collaborations in research.
This interface moves away from manual, paper-based processes to an e-governance system. We anticipate that the 'dynamic consent' interface will become an essential and sustainable component of research infrastructure and will further advance translational research initiatives. In this paper we present the dynamic consent model and show how it is being used as a tool for translational research and personalised medicine.

SIGN - Slovenian-Italian Genetic Network

M. Cassina[1], *B. Peterlin*[2], *P. Korošec*[3], *A. Viel*[4], *G. Damante*[5], *A. Savoia*[6], *A. Komac*[7], *S. Bigoni*[8], *M. Clementi*[1];
[1]*Clinical Genetics Unit - University of Padova, Padova, Italy,* [2]*Clinical Institute of Medical Genetics - University Medical Center, Ljubljana, Slovenia,* [3]*University Clinic of Respiratory and Allergic Diseases, Golnik, Slovenia,* [4]*Division of Experimental Oncology 1, IRCCS Centro di Riferimento Oncologico, Aviano, Italy,* [5]*Department of Medical and Biological Sciences - University of Udine, Udine, Italy,* [6]*IRCCS ''Burlo Garofolo'', University of Trieste, Trieste, Italy,* [7]*General Hospital, Izola, Slovenia,* [8]*Medical Genetics Unit - University Hospital S. Anna, Ferrara, Italy.*

The "European Directive on the application of patients' rights in cross-border healthcare" allows patients residing in EU countries to receive medical treatments in another Member State and have their expenses reimbursed. Patients affected by rare diseases and in need of specialized care will greatly benefit from this. The directive will have to be enforced by European countries by October 25th 2013. It also aims to ensure quality and safety in health care.
The SIGN project is part of the Cross-border Cooperation Operational Programme between Italy and Slovenia and covers a three year period (2011-2014). Its objective is to improve both the accessibility and the quality of genetic services in the Italy-Slovenia macro-region and to provide patients affected by genetic diseases with equal opportunities of diagnosis and care.
The Institute of Medical Genetics of the University of Ljubljana is the programme leader and seven Slovenian and North-Eastern Italian institutions have joined the project.
The first stage of the project is ongoing and it involves mapping the specific clinical and diagnostic expertises of each participating institution and drafting guidelines to assess patients with genetic diseases.
Further to the EU Directive on cross-border healthcare, the SIGN project aims to develop telemedicine systems in order to provide remote genetics counselling performed by specialized personnel in areas where proper clinical services are lacking.
The project also fosters information spread to raise awareness among the general population and clinical specialists on the cutting edge diagnostic options that can be delivered to patients.

P18.23

Direct-to-consumer genetic testing: development of a decision tool to support patients considering testing and the health professionals involved in their care

H. Skirton[1], *L. Goldsmith*[2], *L. Jackson*[1];
[1]*Plymouth University, Taunton, United Kingdom,* [2]*Plymouth University, Plymouth, United Kingdom.*

Direct-to-consumer genetic tests are available via the Internet. One deliverable for the EuroGentest 2 project was the production of guidelines for 1) individuals who might be considering purchasing such a test and 2) health professionals from whom they might seek advice before or after using such tests. We addressed this task by first conducting three systematic reviews to ascertain the evidence on views and experiences of users and health professionals and the policies of professional and bioethics organisations. From the analysis, it appears that consumers' motivations include: general curiosity, to improve their general health, to ascertain the risk of a particular condition or to plan for future children. However, health professionals and bioethics organisations expressed concerns about potential harms resulting from use of these tests. Using the evidence obtained, we constructed a list of topics that should be included in any guidelines. We used a multidisciplinary expert workshop to produce a clinically relevant and pragmatic set of guidelines in the form of a decision tool. This is based on the health professional asking the initial question 'Why do you wish to have a test?'. According to the patient's response, the health professional and patient are guided through a pathway that includes relevant actions and information on the appropriateness of the test for a number of specific situations. This tool will be made freely accessible to health professionals and patients via the Internet. The rationale for each part of the decision pathway and the information provided will be discussed.

H. Skirton: None. **L. Goldsmith:** None. **L. Jackson:** None.

P18.24

Are you my father? How consumer ancestry DNA testing could undermine the anonymity of sperm donors

O. Rusu[1], *H. C. Howard*[2], ***P. Borry***[1];
[1]*KU Leuven, Leuven, Belgium,* [2]*Inserm, Université de Toulouse 3 Paul Sabatier, UMR 1027, Toulouse, France.*

Direct-to-consumer genetic testing for genealogical or ancestry purposes is a new development that could contribute to undermining privacy and confidentiality of consumers who purchase these services and of individuals who have never even participated in such testing. Recently, various companies have published testimonials on their websites describing how customers have found distant or close (parents, siblings) relatives. The advent of such services and the fact that a number of donor-sperm-conceived (as well as adopted children) have identified their biological father partly with the help of DNA testing raise important questions about whether promises of anonymity, which are still common practice in various countries, can be honored by clinics recruiting sperm donors. Healthcare professionals working in a context where anonymity in gamete donation is still an option for donors enter a new era where promises of absolute privacy become impossible to make. For policy makers, healthcare systems and gamete banks, it questions to what extent anonymity in gamete donations will remain a viable option in the future. It questions whether a few privacy breaches cases might provide sufficient evidence to completely change policies regarding anonymity and whether this might have an impact on the explicit framing of existing privacy risks in the recruitment process of potential gamete donors.

O. Rusu: None. **H.C. Howard:** None. **P. Borry:** None.

P18.25

A thirty-one years retrospective prenatal study of 47,XXX and 47,XYY dysgonosomies.

E. blondeel;
CHI Poissy St germain en Laye, 78300 Poissy, France.

Background: 47,XXX and 47,XYY dysgonosomies are two of the most common chromosomal abnormalities with a 1/1000 frequency. Their prenatal diagnosis (PD) is often fortuitous. We aimed to evaluate the different prenatal diagnosis parameters which enabled these PD and pregnancies outcomes to improve genetic counselling .
Methods: a retrospective collaborative study using data from 21 french laboratories over a period of 31 years from 1981 to 2011 was conducted by collecting the following data for each case: indication of the collection, nature of sample, maternal age, fetal karyotype and pregnancy outcome. All parameters were analyzed according to the implementation of multidisciplinary centers for prenatal diagnosis (MCPD) created since 1997
Results: 291 cases of 47,XXX and 167 cases of 47,XYY syndroms were collected. Karyotype was homogenous in 87.6% of cases. The main indication was advanced maternal age for 47,XXX (53.3%) and ultrasound findings (UF) for 47,XYY (35.9%). Outcome was similar regardless of the karyotype: 78.9% of delivery, 17.9% of termination of pregnancy (TOP), 3.2% pregnancy loss. There is a statistical difference for without UF pregnancies' outcomes in both groups before and after 1997, with a decrease of TOP from 28,6% to 5,4% ($p<0.0001$).
Discussion: As supposed, due to both maternal and paternal inheritance, 47,XXX dysgonosomy is twice more frequent than 47,XYY one. Difference in PD indication was mainly due to maternal age incidence for 47,XXX. Furthermore, we clearly showed that establishment of MCDP permitted to change the outcome of these pregnancies.

E. blondeel: None.

P18.26

RDDR: a Dysmorphology Diagnostic Network for newborn in the central part of Italy

M. Dentici[1], *M. Digilio*[1], *L. Tarani*[2], *G. Zampino*[3], *R. Mingarelli*[1], *A. Baban*[1], *C. Romagnoli*[3], *M. De Curtis*[2], *B. Dallapiccola*[1];
[1]*Bambino Gesú Pediatric Hospital, IRCCS, Rome, Italy., Rome, Italy,* [2]*Department of Pediatrics, University La Sapienza, Rome, Italy,* [3]*Cahtolic University, Rome, Italy.*

***Background*:** Dysmorphology is the study of birth defects or malformations arising from abnormal embryogenesis. A dysmorphology assessment of a newborn focuses on history examination and investigations that may lead to a diagnosis which is essential for patient management and for genetic counselling. In 2011 we developed RDDR network, aiming at improving the diagnosis of dysmorphic conditions in newborn in the central part of Italy.
***RDDR Workflow*:** RDDR (www.rddr.it) is developed on an online electronic software that, to date, links about 20 Centres of Neonatology which re-

present the Submitting Nodes. RDDR Network comprises clinicians from various dysmorphology centres in Lazio region with varying levels of expertise. Submitting Nodes transmit patients' clinical information and photographs. Accepted cases, appropriate for RDDR, are reviewed by RDDR dysmorphology experts throughout a forum section. Summary clinical reports are prepared an average a week after acceptance, depending on the timing and number of reviews, and are sent to the Submitting Nodes, and includes diagnostic suggestions and recommendations for further investigations or management of the patient.

Conclusions: RDDR Network enables clinicians of the submitting cases to access to a range of expert opinions and management advice, to increase individual and collective knowledge about dysmorphic rare conditions, and to raise current standards for the diagnosis, management, and increasing neonatologist skills in recognizing rare dysmorphic syndromes. RDDR was developed based on the experience of related European Dyscerne, A European Network of Centres of Expertise for Dysmorphology.

P18.27

The psychosocial impact of risk-management for hereditary diffuse gastric cancer

N. Hallowell[1], *S. Badger*[1], *J. Lawton*[2], *S. Richardson*[3], *C. Caldas*[4], *R. Fitzgerald*[4];
[1]*PHG Foundation, Cambridge, United Kingdom,* [2]*University of Edinburgh, Edinburgh, United Kingdom,* [3]*Addenbrookes Hospital, Cambridge, United Kingdom,* [4]*University of Cambridge, Cambridge, United Kingdom.*

Between 30%-50% of cases of Hereditary Diffuse Gastric Cancer (HDGC) are caused by mutations in the E-cadeherin gene. *CDH1* mutation carriers have an earlier than average age of disease onset, and greatly increased risks of developing cancer. Individuals identified as at-risk of HDGC, either because of their family history or as a result of DNA testing, need to make decisions about risk management, whether they will have risk-reducing surgery (total gastrectomy) or continue screening. This retrospective qualitative interview project was undertaken to explore i) decisions about risk management, ii) the psychosocial implications of undergoing risk-reducing gastrectomy (RRG), and iii) individuals' information and support needs. The investigation included 42 patients; 27 had undergone RRG and 15 were having endoscopic screening. Factors influencing surgical decisions include: experiences of disease, RR surgery and screening within the family, risk perception, social factors (e.g familial obligations, life course issues) and tolerance of screening. Surgery was reported as having a number of psychological (e.g. impact on body image), social (e.g. impact upon family and earning potential) and physical costs and benefits. A number of information (e.g. impact on social life and reproductive options) and support (e.g. around eating practices) needs were identified.

P18.28

Approaching education in the genomic age - widest possible audience or narrow focus

K. Dunlop[1], *K. Barlow-Stewart*[2];
[1]*The Centre for Genetics Education NSWHealth, Sydney, Australia,* [2]*Sydney Medical School, University of Sydney, Sydney, Australia.*

Education has been proposed for some time as the solution to managing the impact of emerging genetic and genomic technologies. Programs targeting the widest possible audience including the general public, individuals and families affected by genetic conditions, those at risk, schools and the professionals who care for them have been conducted with success by the Centre for Genetics Education NSW Health(CGE) in Australia for over 20 years. However health professionals report great concern for the lack of preparedness for new technologies. Given the enormity and rapid increase in patient and support information now available online, difficulties associated with measuring the impact of community awareness campaigns on health outcomes, the density of information for health professionals in this changing field and the limited resources allocated to education, the best way forward has recently been unclear. In addition approaches to education have significantly changed with the accessibility and popularity of social media, online programs and tools. Following a review in 2012, CGE has adopted a new model to meet this challenge narrowing its focus in order to deliver wider benefits. The approach targets non-genetic trained health professionals to develop skills and knowledge to manage the impact of genetic and genomic technologies and in doing so strengthening and delivering wide patient benefits through their clinical practice including informed decision making, risk assessment, early appropriate referral, testing, detection, prevention, treatment and support. The model and strategies in place for 2013- 2015 are presented.

K. Dunlop: None. **K. Barlow-Stewart:** None.

P18.29

Identification of a Single-Nucleotide Polymorphism of TAS2R38 gene (Bitter receptor gene). Genotype and phenotype characterization of a sample of Ligurian students

B. Zanini[1], *V. Marini*[2], *M. Borriello*[3], *R. Ravazzolo*[2];
[1]*Liceo Scientifico M L King Genova, Genova, Italy,* [2]*University of Genoa, Genova, Italy,* [3]*IPSSAR Marco Polo Genova, Genova, Italy.*

In Liguria region an educational project for teachers and students of last two years of high school has been going on in collaboration with University of Genoa since many years involving lab activities, lectures and training sessions. During the last two meetings of Italian Society of Human Genetics a special session was dedicated to school to disseminate in Italy the Genoa experience. One of the most successful activities was the study of bitter-tasting ability by the analysis of the TAS2R38 gene polymorphisms, a didactic model of genotype-phenotype correlation. Three SNP of this gene - that codes for a transmembrane receptor - cause three amino acids substitutions in P49A, A262Ve I296V, resulting in two common haplotypes, PAV (taster) and AVI (non taster). Individuals who have two dominant alleles (PAV/PAV or PAV/AVI) are sensitives to bitter substances, while those not sensitives (AVI/AVI) are recessive for this trait. The project involves thirty teachers and six hundred students and comprises a first part developed in schools: DNA extraction by mucose buccal cells, Bitter Taste Test by PTC paper, Questionnaire of food preferences, Bioinformatics. The second part takes place in a didactic laboratory of University: amplification of DNA trait including the SNP rs 713598, polymorphism identification by enzyme restriction and gel electrophoresis.
The activity allowed students:
- to evaluate genotype/phenotype correlation
- to calculate the frequences of PAV and AVI genotypes
- to know that a number of SNPs are inherited as a haplotype
- to consider the role of genetic variability of taste perception

P18.30

The Clinical Laboratory Genetics profession in Portugal

L. C. Ramos[1], *P. Jorge*[2], *B. Marques*[2], *M. Avila*[2], *P. Rendeiro*[2], *M. D. Quelhas*[2], *J. B. Melo*[2], *I. M. Carreira*[2];
[1]*President of the Portuguese Society of Human Genetics (SPGH), Coimbra, Portugal,* [2]*Workgroup for the Clinical Laboratory Genetics Speciality (GT-EGCL) – Portuguese Society of Human Genetics (SPGH), Coimbra, Portugal.*

Portugal has several public and private laboratories dedicated to human genetic diagnosis, following high quality standards and professionals with qualifications in accordance with the standards of other European countries. The Clinical Laboratory Genetics profession is included in the career designated *Técnico Superior de Saúde, ramo de Genética (TSS-genética*). To integrate this career a biomedical sciences background is needed (e.g. degree in Biology, Biochemistry, Pharmaceutical Sciences) followed by a 3 year internship that takes place in authorized genetic laboratories. The Portuguese health system is facing significant challenges due to reforms that are under implementation. Alongside the rationalization of expenses, it is very important to regulate the creation of several professions, an issue that has to be addressed by the Portuguese health services authorities.
The Workgroup for the Clinical Laboratory Genetics Specialty (GT-EGCL) designated by the Board of the Portuguese Society of Human Genetics (SPGH) has created a database/registry of the Clinical Laboratory Genetics Specialists working in public and private areas in Portugal. The results obtained by the GT-EGCL that will be presented, allowed the characterization of the Clinical Laboratory Genetics Profession in Portugal.The GT-EGCL fully endorses the inclusion of the Clinical Laboratory Genetics into Directive 2005/EC/36, towards the recognition of this specialty at the European level. This Europe-wide recognition is of tremendous importance not only to maintain the high-standards in clinical practice in human and medical genetics areas, but also for the cross-border mobility/recognition of these Portuguese professionals.

P18.31
Points to consider for prioritizing genetic tests

*F. Severin, **W. Rogowski**;*
Helmholtz Center Munich, Neuherberg, Germany.

Given the need of many European health care systems to contain costs of public health care, decisions have to be made which tests to cover from public budgets if resources are not sufficient to fund them all. This study reports results from EuroGentest activities on fair and reasonable prioritization of genetic tests. It is based on literature searches, interviews and a stakeholder workshop oriented at the ethical principles of accountability for reasonableness. Implicit prioritization of genetic services appears to be prevalent throughout European health care systems. For explicit, fair and reasonable prioritization of genetic tests, a range of criteria need to be considered. These include, in particular, medical benefit of testing, a priori risk of developing the condition, and costs of testing as well as further criteria such as time window for treatment to be effective, severity of the condition or whether the test is diagnostic or predictive. Quantitative methods like discrete-choice experiments can be used to attach relative weights to these criteria. Furthermore, data sources such as the Clinical Utility Gene Cards could be used for operationalizing the criteria and estimating priority scores. However, their validity is limited by the evidence regarding the criteria for most genetic tests. Also, weights attached to the criteria can vary depending on decision context. Theory and practice of explicit, fair and reasonable priority setting of health care resources in Europe are still at an early stage. The results from this study provide important points to consider for their further development.

F. Severin: None. **W. Rogowski:** None.

P18.32
External Quality Assessment of Genetic Counselling: results of a European survey and proposal for a pilot assessment

***C. M. A. van Ravenswaaij-Arts**, C. van Asperen, E. Dequeker, L. Tranebjaerg, L. Garavelli, B. Peterlin, B. Cope, R. Hastings, H. Skirton;*
on behalf of the, Genetic Services Quality Committee of the ESHG, Austria.

One objective of the ESHG Genetic Services Quality Committee (GSQC) is to explore the existing Quality Frameworks and the needs for a European Quality Assessment (EQA) scheme for genetic counselling. A GSQC working group surveyed all European national societies of human genetics by a web-based questionnaire. The working group aimed to obtain an overview of which quality assessments were already in place for genetic counselling, and where they were used. If applicable, national societies were asked to give information on quality assurance for the training of professional counsellors and the counselling process itself. National representatives were asked whether the genetic centres in their country participated in national external quality assessments and whether there was a need for European/international quality assessment (comparable to the EQA schemes for clinical genetic laboratory services). It was not the task of this working group to comment on guidelines, minimal quality criteria, or national quality assessment schemes.
Representatives of 15 out of 32 countries completed the questionnaire. The main outcome was that quality assessment ranged from none (the situation in most countries) to well-organised on a national level (the minority). It is clear that there are few quality assessment activities for genetic counselling and all countries expressed the need for an EQA.
There will be a symposium directly preceding the Paris ESHG 2013 conference, where the challenges and opportunities an EQA scheme may encounter will be discussed. The working group will present a proposal as to how an EQA for genetic counselling could be achieved.

P18.33
Patients' experiences of the FH cascade testing programme in Wales

***j. L. miller**;*
Toulouse University -3 Paul sabatier, Toulouse, France.

Familial hypercholesterolaemia (FH) is an inherited condition giving rise to high blood cholesterol. The heterozygous form is common, affecting 1:500 in the UK, of whom it is estimated that 75% are unaware of the disorder. If left untreated, 50% of males will develop coronary heart disease by the age of 55. It can be effectively treated through the use of statins. The UK department of health 2003 white paper 'Our Inheritance, Our Future' stated that FH cascade testing was a 'paradigm for how to use genetics to improve healthcare outcomes for a complex disorder.'
In 2010, the Welsh Assembly government in conjunction with the British Heart Foundation, funded an all-Wales genetic cascade testing service with lipid clinics, FH specialist nurses, genetic counselors and cascade testing of relatives. Semi-structured interviews were conducted in 2010/2011 with 12 patients (aged 18-70) that were involved in the FH programme.
Many interviewees recounted very strong family stories regarding FH, with several people having had a diagnosis for many years. However there were several examples of problems in receiving appropriate treatment or testing previously and poor understanding of the disorder by GPs. The experience of the all-Wales FH service was generally positive among both the previously and the newly diagnosed. The majority of participants were happy to provide details of their family for cascade testing.
This cascade testing programme is the first to be funded in the UK. It has identified new cases of FH and was also appreciated by participants who had an existing diagnosis.

P18.34
Families' Genetic Counseling Experiences Following a Positive FMR1 Newborn Screen

***M. Roche**[1], C. Powell[1], D. Skinner[1], A. Wheeler[1], D. Bailey[2];*
[1]University of North Carolina, Chapel Hill, NC, United States, [2]Research Triangle Institute International, Research Triangle Park, NC, United States.

Newborn screening for *FMR1* expansions presents unique genetic counseling challenges distinct from those encountered after standard newborn screening. These include a complex inheritance pattern; the variable phenotypes associated with age, gender, and repeat size; the potential for adult-onset disorders in infants and relatives; and the unavailability of medical treatment. We describe the genetic counseling experiences of families with screen positive infants in the Fragile X Newborn Screening Study. Using a PCR-based screening test that detects full mutations (200 repeats or greater) and premutations (55-199 repeats) 3795 infants born at UNC Hospitals were screened. Informed consent from both parents, when the father was reasonably available, was obtained. Twenty-one babies from twenty families screened positive; all had premutations. All twenty families were contacted by phone three months after the birth and invited for a genetic counseling visit for diagnostic and carrier testing. Fourteen families were scheduled, four could not be re-contacted, one withdrew and one is pending. Eleven samples were obtained for diagnostic testing. There were four falsely elevated screening results but only one remained in the carrier range after re-testing. Parents could decide about placing the diagnostic results into the infant's medical record. Before parental testing, we discussed implications for relatives, risks for adult-onset symptoms, and the potential for discrimination. Twelve parents in eleven families requested carrier testing; two parents declined. We will summarize parents' initial reactions to learning the result, factors influencing their subsequent decisions about testing, and their responses to the wider implications of their newborn's results.

Translation and adaptation of the Genetic Counselling Outcome Scale (GCOS-24) to Danish

***B. R. Diness**[1], G. Overbeck[2], T. Duelund[1], T. B. Hammer[1], S. Timshel[1], M. McAllister[3];*
[1]Kennedy Center, Rigshospitalet, Copenhagen University Hospital, Glostrup, Denmark, [2]Department of Scandinavian Studies and Linguistics, University of Copenhagen, Copenhagen, Denmark, [3]Institute of Medical Genetics, Cardiff University, Cardiff, United Kingdom.

Background and aim: The ability to measure patient outcomes from genetic counselling is a prerequisite for evidencebased development of practice. The Genetic Counselling Outcome Scale (GCOS-24) is a recently developed patient reported outcome measure. The aim of this project was to develop a Danish version: GCOS-24-Danish.
Methods: GCOS-24 was translated from English to Danish by two independent translators. The translations were combined and then back-translated by two native English-speakers. All versions were reviewed by an expert committee. Alternative wordings and disagreements between back-translations and the original version were examined. The test developers were consulted regarding ambiguous wording. Forty candidates among patients seen earlier and in our waiting room were asked to fill out the preliminary GCOS-24-Danish. Willing respondents were interviewed about their experience. Distribution of responses and results of interviews were examined and the

GCOS-24-Danish adjusted accordingly. Results: There were differences between the original version and the back translations. Problems in the translation of semantic, conceptual and idiomatic equivalence were identified and resolved. Twenty-one questionnaires were returned and fifteen interviews conducted. Informants' responses and analysis of their understanding as displayed linguistically led to adjustment of two items to ensure cultural adaptation. Discussion: The process was more difficult than anticipated. Each step provided new insight regarding perception of genetic counseling and genetic conditions and led to adjustments of the original translation, leading to development of a tool better-suited to the target population. We would recommend the described approach when attempting translation of patient reported outcome measures.

P18.36

An attempt to evaluate the efficiency of the genetic counseling for families with affected children or relatives

E. E. Baranova[1], *E. K. Ginter*[1], *V. L. Izhevskaya*[2], *A. S. Sergeev*[2];
[1]*Russian Medical Academy of Postgraduated Education, Moscow, Russian Federation,* [2]*Research Centre of Medical Genetics, Moscow, Russian Federation.*

The genetic counseling was essentially directive until recently, its efficiency being often assessed by changes in reproductive plans according to the geneticist's advice. The directive genetic counseling at present tends to be replaced with non-directive one. The efficiency of genetic counseling in Russia is poorly investigated. The current review is dedicated to these problem. The presented qualitative study is aimed to estimate the genetic counseling efficiency by a number of parameters, including satisfaction, reduction of disquietude (stress), the guilt feeling relieving for the birth of affected child. The study was conducted in the outpatient department of the Research Centre of Medical Genetics (RCMG) of the Russian Academy of Medical Sciences (RAMS) from 2007 to 2011. 226 respondents 17 to 67 years old with an affected child/children or affected relatives were interviewed before and after genetic consulting. The interviews were analyzed using Statistica 10.0 software. Most respondents (n=213, 94%) indicated that genetic counseling is important or very important to them. We identified a high level of anxiety and guilt feelings among respondents (60% respondents with affected children experienced guilt feelings and 40% were very concerned about the possibility of the disease recurrence in their family). The level of anxiety is significantly reduced after counseling ($p<0,05$). We are pleased to record a high level of satisfaction with genetic counseling among respondents: 197 (87%) of respondents considered it useful or very useful, 212 (93%) indicated the investment of time and money to be entirely or substantially justified, 181 (80%) reported satisfaction with advice.

P18.37

Palestinian Physicians knowledge of genetics, and their attitudes towards genetic testing and genetic counseling.

E. Tinah, *A. Ayyad, S. Khatib;*
Al-Quds University, Jerusalem, Palestinian Territory.

The Genetic and Metabolic Diseases Center at Al Quds University, provides valuable genetic services for the Palestinian community. As part of the center's mission to improve the knowledge of genetics and genetic testing among health care workers, a survey assessing the knowledge of basic genetics information, practices and genetic counseling was conducted by the center in the fall of 2012.
A cross-sectional survey was used whereby data was gathered from the target population at a single point of time. The target population for this project was physicians in the fields of pediatrics, gynecology, primary care and neurology.
The aim of this survey was to assess multiple criteria regarding physician's knowledge of genetic diseases and genetic testing. Additional aspects included their basic knowledge of genetics and hereditary concepts, awareness of the availability of genetic tests in Palestine, awareness of the importance of genetic counseling and its availability, and the management of patients with genetic diseases.
Surveys were distributed in twelve districts in the West Bank to physicians working in government hospitals, private clinics, and non government health centers. Our sample was about 150 surveys from all the fields mentioned above. The primary results showed a variation in experiences dealing with genetic diseases, and the appropriate response to it. Continuous education about the common genetic diseases is essential. There is a general consensus among the participants on the importance of developing a comprehensive national policy dealing with early genetic screening and genetic diseases management.

French professionals in Genetic Counselor careers

C. Cordier[1,2,3], *N. Taris*[2,1,3], *N. Philip*[4], *M. Voelckel*[4,3];
[1]*Hospital of Strasbourg, Strasbourg, France,* [2]*Centre Paul Strauss, Strasbourg, France,* [3]*A.F.C.G, Marseille, France,* [4]*Hospital of Timone, Marseille, France.*

The profession of genetic counselor in France was recognized in 2004, based on the recommendations of a mandate commissioned by the Health Minister to explore the medical demographics of France. The report predicted a shortage of health professionals in the field of genetics, particularly in light of the rapid development of molecular testing. Development of the profession was supported by a legal framework, and today 107 genetic counselors have graduated from the specific educational program which awards the Professional Master's Degree of Human Pathology, entitled Master in Genetic Counseling and Predictive Medicine. Here we will trace the development of the profession in France and review the demographic characteristics of the students and genetic counselors practicing the profession today.

Genetic counselling data and patient's clinical records: Adapting practice to legislation, in Spain.

M. Rodríguez Pedreira, ***B. P. dos Santos****, A. Mosquera Rey;*
Hospital Teresa Herrera materno infantil-hospital A Coruña-XXI A Coruña, A Coruna, Spain.

According to legislature data derived from gene testing, genetic consultations, and specially genetic counselling; represents a set apart from the rest of the patient's clinical record (CR); for it contains information that can reveal the person's health, ethnicity, and indirectly (i.e. genetic pedigree) about others. That is why under Spanish law it's considered "especially protected personal information" and any media containing such records is subject to what has been termed "reinforced protection."
Unfortunately the Spanish legislation as of today hasn't establish well defined protocols to ensure the protection of said data, therefore the responsibility of designing and implementing strategies towards this end has by default fallen upon health-care providers.
We've compiled the strategies used at both our centre and national institutions with which we maintain communications. These strategies are the following:
• Not including the data into the electronic clinical record so that it is accessible only as hard copy
• Anonymizing the data on the service of origin's terminal
• Having the data in the electronic CR but encrypted
• Restricting access to selected consultants.
• Requiring patient's authorization
• Unrestricted access within electronic CR but with a pop-up style reminder of it's privileged status
• Unrestricted access with user's tracking.
What we advise and have applied to some extent at our institution is a combination of the above namely tracking users, maintaining reminders of its nature and having the patient waive if so wishes the ban on restricting the data from his or her current healthcare providers

M. Rodríguez Pedreira: None. **B.P. dos Santos:** None. **A. Mosquera Rey:** None.

P18.40

Communication of information on genetic studies in paediatric research: what are the present ethical challenges in large scale genomics and longitudinal studies?

V. Anastasova, *A. Mahalatchimy, E. Rial-Sebbag, A. Cambon-Thomsen;*
Inserm, UMR1027, Epidemiology and analyses in Public Health; Université de Toulouse III - Paul Sabatier, Toulouse, France.

The vulnerability of children requires special protection in any type of research, particularly genetic research using large scale sequencing. While genetic data are considered as sensitive data in law, ethical issues raised in genetic studies involving minors are emphasized. Their participation im-

plies ipso facto, the involvement of a third person legally responsible in the decision making process: the legal representative. This is especially relevant in the manner of communicating the information to the legal representative and to the minor in large scale genomics and longitudinal studies because the maturity of the children will increase along with the advancement of the research. Therefore it is necessary to adapt the language in order to gradually involve the children. Such communication raises ethical challenges, in particular those that are related to the informed consent/assent in the decision making process and the communication of results (general and individual) as well as the disclosure of incidental findings. Thus, grounded in our experience acquired in the FP7 EU project MeDALL[1] (Mechanisms of the Development of ALLergy) and practices from the project partners, we argue that the most appropriate way to ensure adequate protection for child participants in paediatric genetic research regarding the issues mentioned above remains the adapted communication of information about the study. We propose models for documents to be used and underline the importance of involvement of patient/family associations in the preparatory process.

EuroGentest E-Courses, a new 'time and money saving' platform for the training of genetic testing laboratories.

S. Delen[1], *S. Berwouts*[1], *M. A. Morris*[2], *A. Herbert*[3], *E. Girodon*[4], *A. Roux*[5], *M. Rodriguez de Alba*[6], *A. Wynants*[7], *D. Radojkovic*[8], *E. Dequeker*[1];

[1]*Biomedical Quality Assurance Research Unit, University of Leuven, Leuven, Belgium,* [2]*Laboratoire de Diagnostic moléculaire, Service de Médecine Génétique, University Hospital, Geneva, Switzerland,* [3]*Wessex Regional Genetics Laboratory, Salisbury, United Kingdom,* [4]*CHU Henri Mondor, Créteil, France,* [5]*CHU Montpellier, Montpellier, France,* [6]*Fundacion Jimenez Diaz, Madrid, Spain,* [7]*Management Consulting & Research, Leuven, Belgium,* [8]*Insitute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia.*

The aim of EuroGentest Workshops is to aid laboratories in the process of implementing and developing a quality system, improving existing quality systems and working towards accreditation (ISO 15189). The workshops also contribute to harmonize the approaches to accreditation of genetic testing services in Europe.

The subjects vary from general topics for those who would like to start up or improve their quality system, to more specific and advanced topics such as validation of diagnostic tests, internal audits, management review and IT support for quality management.

Since 2007, 747 participants took part in the 31 workshops organized up to now. These workshops were organized in 13 different countries, to reach as many participants as possible.

From now on we will try to target a bigger audience of participants worldwide through the organization of e-courses. In this era of fast technological advance and minimization of distance through the use of internet, e-courses provide a 'time and money saving' platform for the training of genetic testing laboratories.

A first pilot e-course on quality management consisted of an online presentation, a quiz and an interactive forum. A total of 36 participants attended, representing 23 countries worldwide. We will evaluate if this pilot and future e-courses represent an added value for participants in sharing experiences with other people and experts in the field and allow them to gain knowledge for improving their current quality systems.

Attitudes toward genetic testing in Japan: National surveys in 2005, 2009 and 2013

Z. Yamagata[1], *K. Muto*[2], *I. Ishiyama*[3], *A. Nagai*[2], *A. Tamakoshi*[4], *T. Maeda*[5];

[1]*University of Yamanashi, Chuo, Japan,* [2]*University of Tokyo, Tokyo, Japan,* [3]*Teikyo-Gakuen Junior College, Yamanashi, Japan,* [4]*Hokkaido Univesity, Sapporo, Japan,* [5]*The Institute of Statistical Mathematics, Tokyo, Japan.*

[Aim] The aim of this study is to explore attitudes toward genome research applied to medicine among the general population of Japan, focusing on willingness to undergo genetic tests for disease susceptibility and pharmacogenetic tests.

[Methods] Postal questionnaire surveys were conducted in 2005, 2009 and 2013 in random samples of the general public in Japan. The questionnaire included items on genetic knowledge, attitudes toward the application of genomic studies to medicine and crop science, basic genomics research, and technology. We analyzed the data with a focus on the attitudes toward the application of genomic studies to medicine.

[Results] There were 2171 participants in 2005 (response rate; 54%), 2005 in 2009 (response rate; 50.1%) and 1161 in 2013 (response rate; 60.3%). In these surveys, most respondents had positive attitudes toward these genetic tests (66.4% of respondents had positive attitudes in 2013). The logistic regression analysis showed that significant predictors of the willingness to undergo both genetic tests were to perceive more benefit and having positive impression and interest in the research. Considering that the use of genetic testing is likely to increase in the near future, we propose that more information about genome and communication between scientists and the public should be provided in Japan.

P18.43

Psychosocial approach in ophtalmic genetics

C. Plumere, *S. Pfeiffer, Y. Perdomo, V. Pelletier, F. Studer, S. Rudzki, H. Dollfus;*
HOPITAUX UNIVERSITAIRES CARGO, STRASBOURG, France.

The Reference Center for Rare Diseases in Ophthalmology in Strasbourg is taking care of patients of all ages with progressive conditions. The latter are diseases such as retintis pigmentosa, Leber's neuropathy, Stargard's maculopathy, leading to visual impairment with sooner or later a major handicap. To date no straight forward therapy is accessible for neither of them eventhougth massive research, often sponsored by patient groups, are currently on going.

In this context, we have observed numerous effects on the psychological and social life of the patients. Indeed, the progression of the disease induces a reorganization of emotional, relational, professional or school life(s). The psychological effects are major as the disease induces a real grief work. The acceptation of a genetic ocular condition is usually very slow and generates a psychological distress that can be major. During the last years, we have offered individual follow up by a social worker and a psychologist. However, the importance of the every-day life problems have led us to consider another therapy option by way of a support group therapy. This novel approach has led us to question about the efficiency of the different methods. We have noticed rapidly that the support group was efficient in respect to the acceptation and care of the disease. The positive impact of the support group seem to us higher compared to the individual follow-up that however should be pursued. The dynamics of the support group appears to be very beneficial for the grief work of most of the patients.

C. Plumere: None. **S. Pfeiffer:** None. **Y. Perdomo:** None. **V. Pelletier:** None. **F. Studer:** None. **S. Rudzki:** None. **H. Dollfus:** None.

Background: Due to new discoveries in genomic medicine, clinical guidelines are increasingly recommending the incorporation of genomic tests or therapeutics into routine care, especially as the transition of genetic knowledge from research laboratories into clinical practice is becoming more and more a part of Western health care systems. Primary care practitioners suffer from inadequate knowledge and skills in medical genetics and many are unaware of the technical, ethical, legal and psychosocial implications of genetic testing.

Methods: We initiated a „genomic education" program for the purpose of teaching primary care practitioners new advanced knowledge on genomic medicine. We emphasized the main take-home messages for physicians, which were: risk calculation for various genetic diseases, recognition of the mode of inheritance from the pedigree, guidelines for decision-making on

which molecular tests to use, and the interpretation of test results and their clinical implications.
Results: To date, 16 physicians have participated in our „genomic education" program, which included lectures, workshops and guided tours in genetic laboratories. In the „pre-course" examination the average score was 54.5% (range 20%-80%), whereas in the „post-course" examination it was 84.5% (range 74%-100%). The average improvement in score as a result of the course was 36% (range 15%-80%). The physicians who participated in our program reported a very high level of satisfaction from the content as well as the concept of a „one-week update".
Conclusion: A one-week „genomic education" program is an effective strategy to update primary care physicians in order to improve their care of patients.

P18.45
Update of the spectrum of GJB2 gene mutations in Tunisian families with autosomal recessive nonsyndromic hearing loss

Z. Riahi[1], *H. Hammami*[2], *H. Ouaraghini*[1], *H. Messai*[3,1], *R. Zainine*[2], *Y. Bouyacoub*[1], *L. Romdhane*[1], *D. Essaid*[1], *R. Kefi*[1], *M. Rhimi*[4], *M. Bedoui*[4], *A. Dhaouadi*[2], *D. Feldmann*[5], *L. Jonard*[5], *G. Besbes*[2], *S. Abdelhak*[1];
[1]*Institut Pasteur de Tunis, Laboratoire de Génomique Biomédicale et Oncogénétique, Tunis, Tunisia,* [2]*Service d'ORL et de Chirurgie Maxillo-Faciale, CHU La Rabta, Tunis, Tunisia,* [3]*Institut Supérieur des Sciences Biologiques Appliquées de Tunis, Tunis, Tunisia,* [4]*Hôpital Public d'El Jem, Mahdia, Tunisia,* [5]*Laboratoire de Biochimie Biologie Moléculaire, Hôpital d'Enfants Armand TROUSSEAU,, Paris, France.*

Hearing loss is the most frequent sensory disorder. It affects 3 in 1000 newborns. It is genetically heterogeneous with 60 causally-related genes identified to date. Mutations in GJB2 gene account for half of all cases of non-syndromic deafness. The aim of this study was to determine the relative frequency of GJB2 allele variants in Tunisia. In this study, we screened 138 patients with congenital hearing loss belonging to 131 families originating from different parts of Tunisia for mutations in GJB2 gene. GJB2 mutations were found in 39% of families (51/131). The most common mutation was c.35delG accounting for 35% of all cases (46/131). The second most frequent mutation was p.E47X present in 3.8% of families. Four identified mutations in our cohort have not been reported in Tunisia; p.V37I, c.235delC, p.G130A and the splice site mutation IVS1+1G>A (0.76%). These previously described mutations were detected only in families originating from Northern and not from other geographic regions in Tunisia. In conclusion we have confirmed the high frequency of c.35delG in Tunisia which represents 85,4% of all GJB2 mutant alleles. We have also extended the mutational spectrum of GJB2 gene in Tunisia and revealed a more pronounced allelic heterogeneity in the North compared to the rest of the country.

P18.46
European guidelines on prenatal diagnostic testing

L. Goldsmith, *L. Jackson, H. Skirton;*
Plymouth University, Plymouth, United Kingdom.

Despite a long history of prenatal testing in Europe, there are no overall guidelines to ensure minimum standards of care for women. With increasing use of non-invasive testing, there is a concern that prenatal testing will become 'routinized'. As part of the EuroGentest2 project, we developed European guidelines on prenatal diagnostic testing, using an Expert Workshop methodology. Sixteen professionals from disciplines including medical genetics, fetal medicine and laboratory genetics from nine different European countries attended, as well as patient representatives.
The guidelines were focussed on prenatal diagnosis, for women with a fetus at increased risk of a specific condition. Screening was therefore not included. The material was organised under four topics: objectives, general principles, logistical issues, and topics for counselling.
The *objective* of prenatal diagnosis counselling is to enable families to make informed choices consistent with their needs and support them in dealing with the outcome. *General principles* include the need for appropriately trained multi-disciplinary teams; ensuring informed decision making and the availability of pre- and post-test counselling. This type of service requires effective communication between multi-disciplinary teams and family, sensitive counselling with interpreters if needed, and consideration of wider family implications. Counselling *topics* should include psychosocial issues as well as information about the condition, the test and available options. The Expert Group concluded that these guidelines for prenatal diagnosis were applicable to both invasive and non-invasive testing.
The guidelines have been subjected to wide consultation in and beyond Europe and are now available on the EuroGentest website.

P18.47
Family matters: How do relatives receive hereditary cancer information? A qualitative study

E. de Geus[1], *J. van der Vloodt*[1], *C. M. Aalfs*[2], *F. H. Menko*[3], *J. C. J. M. de Haes*[1], *E. M. Smets*[1,4];
[1]*AMC department of Medical Psychology, Amsterdam, Netherlands,* [2]*AMC department of Clinical Genetics, Amsterdam, Netherlands,* [3]*VU Medical Centre, department of Clinical Genetics, Amsterdam, Netherlands,* [4]*AMC, department of Clinical Genetics, Amsterdam, Netherlands.*

Background
Genetic counseling for hereditary breast or colon cancer has implications for both counselees and relatives. Counselees are encouraged by genetic counselors to disclose hereditary cancer risk information to their relatives. Yet the question is how at-risk relatives appreciate being informed by counselees and to what extend they understand the information. The aim of this qualitative study was to gain insight in relatives' experiences with receiving hereditary cancer information from counselees.
Methods
A heterogeneous purposefully selected group of first and second degree relatives of counselees visiting the Genetics Department regarding the possibility of hereditary breast or colon cancer were invited to participate in face-to-face, in-depth semi-structured interviews. Counselees could have had a confirmed genetic mutation or an uninformative test result. Relatives' experiences were identified by two independent coders from transcribed interviews. In-depth inductive analysis of 8 interviews provided a coding scheme of major thematic categories used for the analysis of the remaining interviews.
Findings
Overall, interviews with 25 relatives from 16 families (8 colon and 8 breast cancer) were included. Preliminary results show that informing relatives about genetic cancer information is a complex process since the genetic information is difficult to understand for relatives. Especially for relatives of counselees' with an uninformative test result. Family characteristics (perceived closeness) and cancer history play an important role in the communication process between counselees and relatives.
Discussion:
Informing relatives about genetic cancer information is a complex and multi-facetted process. Understanding relatives' experiences may aid clinicians in their provision of family centred genetic counseling.

E. de Geus: None. **J. van der Vloodt:** None. **C.M. Aalfs:** None. **F.H. Menko:** None. **J.C.J.M. de Haes:** None. **E.M. Smets:** None.

P18.48
Rare autosomal recessive syndrome in Yakut children

E. E. Gurinova[1], *N. R. Maximova*[2,3], ***A. L. Suhomyasova***[1];
[1]*Republican Hospital N1-National Center, Yakutsk, Russian Federation,* [2]*Yakutsk Science Center of Russian Academy of Medical Sciences and the Government of the RS(Y), Yakutsk, Russian Federation,* [3]*North Eastern Federal University, Yaktsk, Russian Federation.*

In the Medical and Genetic counseling from 2006 were counseling 10 children with Hurler-like phenotype (7 girls and 3 boys). Eight children died before the 1,5 year old. All the children were from Yakut unrelated families. These children had identical clinical features:
Dysplastic physique. All the children were born at term, full-term.
- A gradual change of the type of person gargoilizm: hydrocephalic head, enlarged parietal tuber, low growth of hair on the forehead, hypertelorism, thick and thick eyebrows, long eyelashes, periorbital edema of the eyelids, broad bridge of the nose, short nose with open nostrils forward, dense at touch the cheeks and nose, macroglossia.
- Skin: thick
- Skeletal deformities: shortened neck, chest wall deformity: barrel-shaped or bell-shaped, the shortening of the chest, stiff, wide aperture, mainly thoracolumbar kyphosis, lumbar spine, stiffness progression of small and large joints to contractures, change the brush-type ,claws „deepening palmar furrows.

- The presence of bronchial obstruction: noisy breathing, shortness of breath rise, auscultation hard breathing, various dry and moist rales, the need for oxygen therapy.
- Cardio-vascular system tachycardia, hypertension, systolic murmur auscultation.
- Gastro-intestinal tract: an enlarged abdomen due to hepatosplenomegaly,different types of hernia: inguinal, umbilical, non-operated.
- The nervous system of all children had delayed motor and static-psycho-verbal development.

Were excluded congenital hypothyroidism, cystic fibrosis, deficiency of alpha-1-antitrypsin, a chromosomal abnormality, MPS I, II, III, IVB, VI, VII types, GM 1, 2-gangliosidosis, Gaucher's disease,classical form of mucolipidosis 2 and 3, Niemann-Pick disease type C / B / A, Zhakena syndrome.

The Progress of the Human Variome Project

R. G. H. Cotton;
Human Variome Project International Limited, Melbourne VIC, Australia.

The Human Variome Project (www.humanvariomeproject.org) was formed to facilitate the collection, curation, interpretation and sharing of genomic knowledge worldwide and to assist its continued integration into research and clinical care. The Human Variome Project Consortium believes that the global knowledge capacity in medical genetics and genomics can be significantly improved if local knowledge is shared in a free and open manner to become global knowledge.
The role of the Human Variome Project is to expand the technical and knowledge capacity around medical genetics across the globe by establishing and maintaining standards, systems and infrastructure; promoting ethical behaviour in the field of medical genetics and genomics; sharing knowledge about our genome and its function in determining health; and assisting individuals and nations build their capacity to address genetics aspects of individual and global health.
This presentation will focus on:
- The Project's vision for a Global Collection Architecture;
- Current standards development work underway;
- Progress by pilot member initiatives: the InSiGHT Database and the Human Variome Project Australian Node;
- Activities of disease-focussed interest groups: cardiac genetics, mitochondrial genetics, neurogenetics and nutrigenomics;
- An ethical framework for data collection and sharing;
- The Project's approach to education and training in response to global pressures and expanding need for skills and knowledge;
- Capacity building work through the Human Variome Project/China Country Development Program.

Does Presymptomatic testing influences Age at Onset in a Negative manner (PAON): follow up of at risk persons for Huntington disease

*M. Gargiulo[1,2], M. Jutras[3], S. Tezenas du Montcel[4], S. Benaich[5], A. Herson[2,6], J. Feingold[5], **A. Durr**[7,5];*
[1]Université Paris Descartes, Laboratoire de Psychologie Clinique et Psychopathologie, Paris, France, [2]Pitié-Salpêtrière Hospital, Institut de Myologie, Paris, France, [3]CRicm UMRS975, Paris, France, [4]Pitié-Salpêtrière Hospital, Department of Biostatistics and Bioinformatics, Paris, France, [5]Pitié-Salpêtrière Hospital, Department of Genetics and Cytogenetics, Paris, France, [6]Pitié-Salpêtrière Hospital, Internal Medecine 1, Paris, France, [7]CRicm UMRS975/NEB, Paris, France.

In PAON we studied prospectively the impact of presymptomatic testing on the onset of symptoms in gene carriers for Huntington disease. 1554 at risk persons requested the test (mean age at request 34.9 ± 11.9 years) between 1992 and 2008 and entered multistep and multidisciplinary care and counseling. 367 (32%) did choose not to take the test, 476 were non-carriers and 307 carriers of an abnormal expanded CAG repeat in the HD gene. Follow-up in 2013 was available for 191 carriers (62%, mean age at follow up 45.3 ± 11.0 years) including 3 who died (1 cancer, 2 suicides). Estimated age at onset will be calculated (Langbehn formula). We collected 48 questionnaires and 46 underwent physical examination, using the UHDRS evaluation score (max worse value 124) at the same time. Mean UHDRS was 12.9 ± 12.7. There were 16 carriers with values 5 years ago, anxiety was still frequently reported (48%) and 8% were currently depressed. Interestingly, 41 % of carriers with signs at examination (UHDRS >4) declare not to show symptoms and 31% of those with normal examination felt that they had signs. All are relying on family/medical support (94%) but knowing their genetic status interfere with daily life activities in 69% of the unaffected carriers and in 33% of the carriers with signs (p<.05). Regardless of the fact that 76% showed increased auto-observation, neurological follow-up was not systematically requested (56%). In addition, 69% declared a need for psychological support.

Doing the right thing of one's children: deciding whether to take the genetic test for Huntington's disease as a moral dilemma.

O. W. J. Quarrell[1]*, M. Stephenson[2], C. Jacobs[3], J. Smith[4];*
[1]Sheffield Children's Hospital, Sheffield, United Kingdom, [2]University of Sheffield, Sheffield, United Kingdom, [3]Guy's and St Thomas' Hospital, London, United Kingdom, [4]Birkbeck College University of London, London, United Kingdom.

A range of reasons are cited for requesting a predictive test for Huntington's disease (HD). One reason which is mentioned frequently is the "need to know for my children". We have analysed transcripts of interviews from 9 participants considering a predictive test for HD and subjected them to interpretative phenomenological analysis. Four participants wanted to take the test and three of them claimed it was to assist their own children's reproductive decision making. Two participants currently opposed to predictive testing cited the same reason as a key factor in their decision making. Three participants were undecided and 2 of these explicitly cited their own children's reproductive decision making as a consideration.
We will present a detailed analysis of this single theme from 3 of the participants to show how they thought through this issue. Four imperatives emerged: wishing to stop HD, doing the right thing for my child, right to chose to have a family, and giving information to others. We will report on the evidence of the participants endorsing, rejecting or not mentioning these. Consideration of these issues resulted in them reaching different decisions regarding predictive testing. We will suggest some ways in which a counsellor may explore the theme of „need to know for my children" during pretest discussions. In addition, we will discuss this result in relation to similar work on communication of genetic information in families with Hereditary Breast and Ovarian Cancer.

Reflecting on earlier experiences with unsolicited findings: Points to consider for next generation sequencing and informed consent in diagnostics

T. Rigter[1]*, L. Henneman[1], U. Kristoffersson[2], A. Hall[3], H. G. Yntema[4], P. M. Borry[5], H. Tönnies[6], Q. Waisfisz[7], M. W. Elting[7], W. J. Dondorp[8], M. C. Cornel[1];*
[1]VU University Medical Center, Department of Clinical Genetics, Section of Community Genetics and the EMGO+ Institute for Health and Care Research, Amsterdam, Netherlands, [2]Lund University, Department of Clinical Genetics, University and Regional Laboratories, Region Skane, Lund, Sweden, [3]PHG foundation, Cambridge, United Kingdom, [4]Radboud University Nijmegen Medical Centre, Department of Human Genetics, Nijmegen, Netherlands, [5]Centre for Biomedical Ethics and Law, Department of Public Health, Leuven, Belgium, [6]Robert Koch-Institut, Geschäftstelle Gendiagnostik-Kommission, Berlin, Germany, [7]VU University Medical Center, Department of Clinical Genetics, Amsterdam, Netherlands, [8]Maastricht University, Department of Healt, Ethics and Society, Research Schools CAPHRI and GROW, Maastricht, Netherlands.

With the recent advent of high-throughput nucleotide sequencing in the clinic for diagnostic purposes, unsolicited findings and informed consent are receiving increased attention. To share experiences and explore dilemmas, an international and multidisciplinary meeting entitled "Exome sequencing in diagnostics: exploring needs for the informed consent procedure" was organized by Workpackage 8 of Eurogentest2 in Amsterdam, the Netherlands in March 2012. The aim was to provide input for the development of guidelines to optimize the informed consent procedure.
Based on the meeting and by exploring recent experiences with unsolicited findings in other medical settings -for example in the context of disclosure of carrier status in neonatal screening, feedback of actionable results in genetic research and the changing informed consent when using array CGH- an attempt is made to describe what can be learned for implementing next ge-

neration sequencing in standard genetic diagnostics. The results show that both ethical and practical dilemmas are encountered when contemplating informed consent for next generation sequencing in diagnostics. Issues that were discussed include: patient rights and professional duties, management of patient expectations, attunement between different actors, a changing role for the lab, feedback of results and involvement of an advisory board for unsolicited findings.
Based on the discussions, a framework has been developed in order to guide decision-making with regard to the return of unsolicited results and the implications for informed consent in clinical diagnostics.

P18.53
Australian life insurance and genetic testing policies 2013 - implications for families and research

K. K. Barlow-Stewart;
University of Sydney, Sydney, Australia.

The Life Insurance industry in Australia's genetic testing policy became a standard (#11) in 2005 making it mandatory practice: genetic testing would not be requested for applicants for new life insurance products or for increases to existing policies for income protection, trauma and permanent and total disability insurance. If however an applicant knew their, or their blood relative's test result, they must disclose it in the application as the contract is one of good faith: the insurer needs to know what the applicant knows. In this context, family health history also needed to be disclosed. In 2011 amendments to standard #16 (Family Medical History) were instituted whereby requirements for disclosure of family history was limited to **only** first degree relatives in recognition of the difficulties some applicants were experiencing. This has significant implications for those with a family history of a genetic condition: it may enable in some cases policies to be assessed at average risk on the basis of family history alone. A further change that however balances this benefit relates to research. While the insurers undertake that their participation in such research will not be into account when underwriting a policy, there is the potential that the requirement will impact on willingness to take part in research projects given issues of public trust and perception regarding life insurance companies. Information about the life insurance requirements for research participants will have to be included in the consent forms. Implications of these changes to policy will be discussed.

Genetic counselling remains challenging in Leber's optic neuropathy

V. PELLETIER[1]*, P. GOSSET*[2]*, M. MIGUET*[3]*, Y. PERDOMO*[1]*, F. REZAIGUIA-STUDER*[1]*, C. PLUMERE*[1]*, S. PFEIFFER*[1]*, H. DOLLFUS*[1]*;*
[1]CARGO, STRASBOURG, France, [2]Laboratoire de Diagnostic Pré-implantatoire, STRASBOURG, France, [3]Service de Génétique Médicale, STRASBOURG, France.

Leber's hereditary optic neuropathy (LHON) is usually characterised by initial unilateral subacute central visual loss with rapid bilateralisation leading to a severe visual handicap.
This optic neuropathy is transmitted exclusively by women because of its mitochondrial inheritance. More than 18 homoplasmics mutations are identified today.
The age of onset varies from infancy to late adulthood. The neuropathy is usually isolated but can be rarely associated to heart conduction disorders or neurologic abnormalities.
Risk of developing this condition differs between sexes from 30% to 83% in men to 5% to 32% in women.
The homoplasmy, the risk of an abrupt severe visual prognosis (four to five times higher in men than in women), the « guilty » feeling of the women who carry LHON mutations and the feeling of a „sword of Damocles" that threaten their children are major issues for genetic counselling that remains a challenge for women who wish to have children.
We present four clinical situations that illustrate the complexity of genetic counselling for LHON : in a context of a prenatal project or during a pregnancy, in the context where another genetic affection coexists. In all cases, questions about prenatal diagnosis (PND) and preimplantation genetic diagnonsis (PGD) were addressed.
What is the place for sexe determination by PGD? What about PND? We will detail the outcomes of each situation that learns us about the deep impact of LHON in the families.

Midwifery issues on induced abortion in Japan

A. Kondo[1,2]*, H. Moriya*[2]*, K. Mitsuzuka*[2]*, K. Takahashi*[2]*, Y. Onuki*[2]*, S. Oda*[2]*, H. Maeda*[2]*, Y. Nakagawa*[1]*, H. Ishimoto*[2]*, S. Izumi*[2]*;*
[1]Kagawa National Children's Hospital, Kagawa, Japan, [2]Tokai University, Isehara, Japan.

Abstract
Background: Induced abortion is one of stressful procedure for both patients and medical specialists. There are a lot of researches on midwifery model care for the patient who is having induced abortion in the world. However, there are only few studies about psychological issues of midwife themselves. In Japan, we cannot give up the pregnancy because of fetal reason and we cannot perform any induced abortion after 22 weeks. Midwives sometimes hold difficult feelings during or after complicated deliveries. The purpose of this study was to explore the concerns of midwives through their duty especially in induced abortion. Methods: A focus group explored issues in induced abortion from the midwife's point of view for twice. Participant midwives were recruited from the maternity ward and their year of experience is three to twelve. Recorded their deliveries were assessed with Interpretative Phenomenological Analysis (IPA). Results: Analysis of the focus group data identified three superordinate themes: 'Ethical Issues as a human', and 'Issues as a midwife, caregiving role' and 'Difficulties in working environment'. Conclusion: These data provide evidence that the midwife have guilt feelings, sorrow and sense of awe in the living life when they care patients having induced abortion. Talking to patients more and talking with colleagues could help them to take care of themselves as sublimation.

P18.57
Misoprostol and teratogenicity. review of 38 cases of vascular disruption defects in Colombia

H. Pachajoa[1]*, W. Saldarriaga*[2]*, C. Isaza*[2]*;*
[1]Universidad Icesi, Cali, Colombia, [2]Universidad del Valle, Cali, Colombia.

Introduction: Misoprostol is a prostaglandin E1 analogue, is used for the prevention of gastric ulcers and has been registered in about 80 countries. Because of Its abortive properties, is used as a method for abortion in countries where abortion is illegal. It has been documented that prenatal exposure to misoprostol has been associated with vascular disruption defects (VDD), mainly Moebius syndrome and transverse reduction defects.
Materials and methods: A case series study where 38 number of cases of VDD (gastroschisis, Moebius sequence, hydranencephaly,) with prenatal history of exposure to misoprostol are reviewed. The cases are mainly identified from the records of the birth defect surveillance system and clinical consultation. A teratogenicity analysis of this drug is made, taken into account dose, gestational age of exposure and type of VDD.
Results: Of the 38 cases of VDD, 27 were Moebius sequence, 4 hydranencephaly, 3 Klippel Feil, 1 Pentalogy of Cantrell, 1 VACTERL association, 1sirenomelia with cyclopia and 1 disruption by amniotic bands. In 7 cases other types of VDD were presented. The average dose of exposure was 652 grams, and gestational age of exposure was 7.2 weeks.
Discussion: The association of prenatal exposure to misoprostol and different types of VDD support the hypothesis of a similar physiopathological mechanism and that the disruptive event is secundary to the teratogenicity of this drug. The presented case series is one of largest in the world and it should raise concerns to the control and surveillance entities in the countries where abortion is illegal.

P18.58
Two cases of Noonan syndrome with neonatal JMML due to PTPN11 mutation p.E139D

C. Courage[1]*, M. Zenker*[2]*, R. Ammann*[3]*, S. Lüer*[3]*, S. Gallati*[1]*, **J. Lemke***[1]*;*
[1]Division of Human Genetics, Bern, Switzerland, [2]Department of Human Genetics, Magdeburg, Germany, [3]Division of Pediatric Hematology/Oncology, Bern, Switzerland.

Noonan syndrome (NS) is a frequent condition characterized by short stature, congenital heart defect, and developmental delay of variable degree. Furthermore, NS is accompanied with an elevated risk of hematologic malignancies, especially juvenile myelomonocytic leukemia (JMML).

Gain of function mutations within the RAS-MAPK pathway have been identified to contribute to NS, among which mutations of PTPN11 play a key role and account for approximately 50% of cases. Genotype phenotype correlations revealed hotspots within exons 3 and 13 of PTPN11 as well as within other genes where mutations specifically predispose to JMML.
We report on two boys with neonatal diagnosis of NS. Both patients showed characteristic features of the disorder including JMML. In both cases, molecular genetic analysis revealed the known de novo mutation PTPN11 p.E139D. According to the literature, only two NS patients carrying this mutation have developed JMML, two further patients developed other malignancies (acute lymphoblastic leukemia and oligodendroglioma). Thus, our two patients strengthens the previously assumed hypothesis of a potentially high risk for hematologic malignancies associated with PTPN11 p.E139D.

P18.59

Osteogenesis imperfecta (type IV) with dentinogenesis imperfecta: 10-year dental follow-up

D. Cogulu[1], *E. Yetkiner*[2], *I. Unal*[2], *H. Ulucan*[3], *O. Cogulu*[4];
[1]*Ege University Faculty of Dentistry Department of Pediatric Dentistry, Izmir, Turkey,* [2]*Ege University Faculty of Dentistry Department of Orthodontics, Izmir, Turkey,* [3]*Cerrahpasa University Faculty of Medicine Department of Medical Genetics, Istanbul, Turkey,* [4]*Ege University Faculty of Medicine Department of Medical Genetics, Izmir, Turkey.*

Osteogenesis imperfecta (OI) is a genetic disorder characterized mainly by varying degrees of bone fragility, osteoporosis, and predisposition to fractures. Common features of affected individuals include blue sclera, hearing loss, dentinogenesis imperfecta, osteoporosis, growth deficiency and joint laxity. It is classified into 13 subtypes and type IV, which is an autosomal dominant form is caused by the mutations in COL1A1 and COL1A2 genes. Here we present 10 year dental follow-up of a 17-year-old female with OI type IV. She had a history of multiple fractures, which have started at 1-year old. She was referred to pediatric dentistry department initially at age 7 because of yellow/brown discoloration of primary teeth with the attrition of the exposed dentin, early loss of primary teeth because of deep caries, anterior cross-bite and class III malocclusion. The clinical and radiographic examinations confirmed the diagnosis of dentinogenesis imperfecta. Throughout the follow-up period all restorative treatments and orthodontic treatment were performed. Physical examination at age 17 showed short stature and pale blue sclera besides dental findings. DEXA revealed osteoporosis. The molecular analysis of the COL1A1 and COL1A2 genes revealed the presence of a heterozygous transition G>C in exon 17 of the COL1A1 gene at position c.1084. In conclusion, it is suggested that dental status of OI cases should be examined as soon as teeth are erupted to prevent loss of tooth structure and to maintain their oral health.

Unexpected Outcomes: Impacting Higher-Education Teaching Practice via Secondary School Outreach

M. Dougherty[1], *P. Bourexis*[2], *J. Kaser*[2];
[1]*American Society of Human Genetics, Bethesda, MD, United States,* [2]*The Study Group, Inc., Kill Devil Hills, NC, United States.*

Funding agencies and the science-education research community have collaborated to implement programs designed to increase outreach from scientists to secondary-school students and teachers, with the goal of improving science learning by younger students. Simultaneously, but independently, they have collaborated on educational research projects to determine effective ways to improve instructional practices and learning in higher-education. However, improving university instruction through secondary-school outreach has never been the explicit goal of an educational research program in the United States. We will present results from a three-year outreach project in the U.S. that demonstrate how secondary school outreach, via partnerships between genetics researchers and high school teachers, can have the unintended and beneficial consequence of motivating instructional change by the research faculty in their own institutions. Although this was a gratifying and positive outcome that should be adopted more broadly, substantive and widespread change in university instruction is unlikely without systemic changes in higher education, such as the incentive system for tenure and promotion.

P18.61

Pallister-Killian syndrome due to mosaicism of two supernumerary isochromosomes (hexasomy 12p) in a girl with relatively mild phenotype

N. Aliu, *C. Rieubland, C. Courage, M. Mamavar, S. Gallati, J. Lemke;*
Division of Human Genetics, Departments of Pediatrics and Clinical Research, Inselspital, University of Bern, 3010 Bern, Switzerland, Bern, Switzerland.

Pallister-Killian syndrome (PKS, OMIM #601803) is a rare and sporadic genetic disorder due to tissue-limited mosaicism for a small supernumerary marker chromosome (sSMC) (isochromsome 12p / i(12p)), which is usually present in fibroblasts but may be absent or at very low level in cultured lymphocytes. PKS was initially described in adults (Pallister et al., 1977) and children (Killian et al., 1981) comprising features of profound mental retardation, diaphragmatic defects and pigmentary skin anomalies.
Vogel et al., 2009 reported a girl with PKS and noted that this was the second case of mosaic hexasomy 12p due to two additional isochromosomes 12p. Van der Veyver et al., 1993 attributed a more severe phenotype in patients with hexasomy to a stronger gene-dosage effect compared to tetrasomy 12p. Since 2009, there have been no further reports on cases of hexasomy 12p.
We report on a 4.5-year-old girl with submucous cleft palate, cranio-facial dysmorphism (hypertelorism, broad nasal root, blepharophimosis, high forehead, sparse hair bilaterally, dental crowding), areas of hyper-/hypopigmentation on trunk and extremities and very mild developmental delay.
The detection of two isochromosomes 12p in 46% of skin fibroblasts but not in cultured lymphocytes confirmed diagnosis of PKS due to mosaic hexasomy. The relatively mild phenotype of our patient is in contradiction to the pure gene-dosage hypothesis previously proposed by others but strengthens the observation from Vogel that the severity of symptoms cannot be predicted by either gene-dosage or the percentage of mosaic cells alone.

Family history of cancer among Ashkenazi pancreatic cancer patients with a BRCA1/2 mutation compared to non-carriers

E. Dagan[1,2], *R. Epelbaum*[3,4], *A. Kurolap*[4], *S. Melikhan*[4], *A. Mory*[4], *R. Gershoni-Baruch*[2,4];
[1]*Department of Nursing, University of Haifa, Haifa, Israel,* [2]*Institute of Human Genetics, Rambam Health Care Campus, Haifa, Israel,* [3]*Department of Oncology, Rambam Health Care Campus, Haifa, Israel,* [4]*The Ruth and Bruce Rappaport Faculty of Medicine, Technion-Institute of Technology, Haifa, Israel.*

Aim: This study investigated the family history of cancer in Ashkenazi pancreatic cancer patients, in carriers compared to non-carriers of a mutation in BRCA1/2 genes. Methods: Cancer family history was available for 90 pancreatic cancer patients, consecutively referred to our hereditary breast-ovarian clinic. Results: Fifteen of them (16.7%) carried a founder Ashkenazi mutation in either of BRCA1or BRCA2: nine (60%) carried the 6174delT mutation in BRCA2; five (33.3%) and one (6.7%) harbored the 185delAG and the 5382insC mutations in BRCA1 gene, respectively. The table illustrates the cancer family history of all 90 patients. Discussion: A family history of breast, ovarian and hepatic cancer is associated with a BRCA1/2 mutation in pancreatic cancer patients. Patients with a family history of breast-ovarian and pancreatic cancer showed a marginally stronger association to BRCA1/2 mutation compared to patients with a family history of cancer other than breast-ovarian-pancreatic cancer (p=0.065). Conclusion: These findings support the addition of pancreatic cancer within the entity of „hereditary breast-ovarian cancer syndrome“ associated with BRCA1/2 mutations.

Type of cancer	BRCA1/2 (n=15)	Non-Carriers (n=75)	Significance

Demonstrating patient benefits from clinical genetics services: pilot studies in six UK centres

M. McAllister[1,2], *A. Clarke*[1,2], *N. Bowen*[1], *G. Scott*[3], *S. Watts*[4], *C. Eddy*[5], *A. Melville*[6], *A. Bruce*[7];

[1]*Cardiff University, Cardiff, United Kingdom,* [2]*Cardiff & Vale University Health Board, Cardiff, United Kingdom,* [3]*West of Scotland Genetic Services, Southern General Hospital, Glasgow, United Kingdom,* [4]*Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,* [5]*Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom,* [6]*NW Thames Regional Genetics Service, North West London Hospitals NHS Trust, London, United Kingdom,* [7]*North East Thames Regional Genetics Service, Great Ormond Street Hospital, London, United Kingdom.*

Background and aims: Patient Reported Outcome Measures (PROMs) have recently taken centre-stage in UK healthcare evaluation, reflecting the NHS quality improvement agenda. PROMs are short self-completion questionnaires that measure healthcare quality from the patient's perspective. UK clinical genetic services have routinely been evaluated using process measures e.g. number of genetic tests done, waiting times, numbers of patients attending. To evaluate services more effectively a new clinical genetics-specific PROM, the Genetic Counselling Outcome Scale (GCOS-24) was developed and validated. This paper reports on pilot studies in six NHS clinical genetics centres that implemented GCOS-24 for service evaluation.

Methods: Patients were asked to complete GCOS-24 before and 4-6 weeks after clinic attendance. Satisfaction data was also collected. Data were analysed using analysis of variance and bivariate correlation. Centres provided feedback on feasibility of using GCOS-24 for service evaluation.

Results: Five centres demonstrated statistically significant improvement in GCOS-24 scores, following clinic attendance with usable samples sizes of 42, 45, 54, 55 and 74 patients respectively ($p<0.001$). Useful sample sizes were limited by less than optimal processes for matching patient's pre-clinic and post-clinic questionnaires, and one centre had insufficient matched pre-clinic and post-clinic questionnaires to enable a useful analysis. GCOS-24 improvement scores correlated significantly with patient satisfaction.

Conclusions: Findings demonstrated that NHS clinical genetics services are delivering significant measurable patient benefits and that GCOS-24 has potential to be a useful supplement to existing methods to evaluate quality of routine clinical genetics services. Consideration needs to be given to how to improve patient response rates.

Vertical transmission of a somatic PKLR mutation leading to non-spherocytic anaemia due to piruvate kinase deficiency: implications on genetic counselling

M. Mañú Pereira[1], *E. González Roca*[1], *R. van Wijk*[2], *H. van Amstel*[2], *L. Montllor*[1], *J. Sevilla Navarro*[3], *J. Vives-Corrons*[1];

[1]*Hospital Clínic of Barcelona, Barcelona, Spain,* [2]*University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Hospital Infantil Universitario Niño Jesús, Madrid, Spain.*

INTRODUCTION

Chronic hemolytic anemia due to pyruvate kinase (PK) deficiency (MIM 609712) is a rare autosomal recessive disorder caused by mutations in the *PKLR* gene. An estimated 3% of PK-deficient patients present with a *de novo* mutation. We report for the first time a case of PK deficiency associated to vertical transmission of a *de novo* somatic mutation in *PKLR*.

METHODS

DNA analysis of *PKLR* was performed by conventional Sanger sequencing. Massive parallel sequencing of *PKLR* was performed on DNA from peripheral blood, mucosal swabs, 24 hours urine, and sperm samples from selected family members.

RESULTS AND DISCUSSION

The proband was an 18 month old boy suffering from severe transfusion-dependent chronic hemolytic anemia due to PK deficiency. PK activity in the mother resembled the PK-deficient carrier state whereas in the father was normal. DNA sequence analysis revealed the proband to be compound heterozygous for two missense mutations in *PKLR*: c.359C>T (p.Ser120Phe) and c.1168G>A (p.Asp390Asn). The c.359C>T change was found to be inherited from the mother. However, the c.1168G>A mutation could not be detected in blood father's DNA, despite confirmed father-mother-child allelic inheritance. Subsequent massive parallel sequencing of the region encompassing nt c.1168 on DNA from different tissues of the father indicated that this mutation has arisen postzygotically, thereby producing parental mosaicism. The methodology used allowed the detection of a somatic mutation in the father that was vertically transmitted to his son. This enabled us to unravel an exceptional case of a rare autosomal disease and, thereby, enabled proper genetic counseling.

A step-wise approach for the implementation of pharmacogenomics in developing countries in Europe

K. Mitropoulos[1], *Z. Zagoriti*[2], *Y. Mai*[2], *A. Vozikis*[3], ***G. P. Patrinos***[2];

[1]*Golden Helix Institute of Biomedical Research, London, United Kingdom,* [2]*University of Patras Faculty Health Sciences Department of Pharmacy, Patras, Greece,* [3]*University of Piraeus, Department of Economics, Piraeus, Greece.*

Pharmacogenomics promises personalized treatment. However, many developing countries currently lack the knowledge or the resources to individualize drug therapy. Here, we propose a multi-step approach for the implementation of pharmacogenomics in developing
countries in Europe, including (a) Collection of DNA samples from healthy volunteers to determine the various pharmacogenomic markers allele frequencies in this population, using a 2-tiered approach (b) Conduct a comprehensive health economic analysis to illustrate the cost-effectiveness of pharmacogenomic testing, (c) Survey the level of awareness of several stakeholders, including genetic laboratories, pharmacists, the general public and healthcare professionals, (d) Organization of education activities to disseminate pharmacogenomics knowledge to society, and (e) Establishment of national guidelines for medication prioritization. Since 2009, we are implementing this approach using the Hellenic population as model. DNA from 45 healthy donors of Hellenic origin was isolated with consent, and subsequently genotyped to determine the allele frequencies in 1,936 pharmacogenomic markers in 220 pharmacogenes, using the DMET+ microarray (Affymetrix, Santa Clara, CA, USA).

We found 46 pharmacogenomic markers that display divert allele frequencies compared to those of the Caucasian population ($p<0.05$), that are currently being confirmed in 500 healthy donors of Hellenic origin. We are also concluding a cost-benefit analysis to demonstrate the usefulness of integrating pharmacogenomics in everyday clinical decision-making process, to adjust the acenocoumarol-dosing scheme, which would lead in the reduction of adverse reactions and the resulting healthcare costs. This approach could be replicated in other developing countries enabling integration of pharmacogenomics in healthcare decision-making at the country level.

Couples' attitudes toward PGD in Greece - Reproduction in crisis

E. Gourna[1,2], *J. Traeger-Synodinos*[1], *K. Kosma*[1], *C. Vrettou*[1], *A. Destouni*[1], *G. Kakourou*[1], *M. Tzetis*[1], *E. Kanavakis*[1], *S. Kitsiou-Tzeli*[1];
[1]*Department of Medical Genetics, Athens University, St Sophia's Children's Hospital, Athens, Greece,* [2]*Post-Graduate Program: „Research in Female Reproduction", Faculty of Medicine, National and Kapodistrian University of Athens, Athens, Greece.*

Objectives: To assess attitudes towards Preimplantation Genetic Diagnosis (PGD) among high-risk or infertile couples in Greece in relation to underlying demographic, medical and reproductive history predictors.
Method: 50 couples who were referred for PGD were interviewed in person after receiving genetic counseling. A semi structured questionnaire was answered based upon socio-demographic, educational, medical and reproductive history variables. The couples' awareness, opinion on advantages/disadvantages of the procedure and opinion of PGD comparing to Prenatal Diagnosis (PND) were also investigated.
Results: The majority of couples have a very burdened medical and reproductive history with β-thalassemia being the main reason for PGD referral (38%). 40% of couples were informed for medical matters directly by doctors, while medical geneticists or another medical specialty initially offered counseling for PGD in 90% of the cases. When comparing PGD to PND most couples consider PGD as a better alternative; for most of the couples having a healthy child and avoiding a selective termination of pregnancy are perceived as the main advantages of PGD. The main recorded disadvantages of PGD are low pregnancy rates and high cost given that financial difficulties were reported in 54,2% of the couples.
Conclusion: Couples' attitudes towards PGD in Greece are mainly positive as are very eager to have a healthy child avoiding PND despite PGD's high cost. Surprisingly they would prefer to avoid having another PGD cycle in the future given the anxiety of the whole procedure.

P18.67

Translational impact of VEGFA variants on the prediction and follow-up of ocular complications in pseudoxanthoma elasticum.

E. De Vilder[1], *M. J. Hosen*[1], *L. Martin*[2], *B. P. Leroy*[1,3], *J. Ebran*[4], *P. J. Coucke*[1], *A. De Paepe*[1], *O. M. Vanakker*[1];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Dermatology, CHU Angers, Angers, France,* [3]*Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium,* [4]*Department of Ophthalmology, CHU Angers, Angers, France.*

Background. Among the phenotypic characteristics of pseudoxanthoma elasticum (PXE), a rare ectopic mineralisation disease affecting skin, eyes and cardiovascular system, the ocular complications (neovascularisation, subretinal haemorrhage and vision loss) result in important morbidity. In the absence of genotype-phenotype correlations with the causal gene ABCC6, it has been suggested that variants in the VEGFA gene, encoding vascular endothelial growth factor, may influence the ocular phenotype. The aim of this study was to evaluate the clinical usefulness of such VEGFA variants in PXE counseling and ophthalmological follow-up.
Methods. The VEGFA coding region, introns and promotor were analysed in 66 molecularly confirmed PXE patients with mild, respectively severe retinopathy. Three categorizing methods were applied to define severe retinopathy: i) visual acuity (VA) <10/10, ii) VA < 5/10 (legal blindness) and iii) VA <5/10 and/or multiple anti-VEGF injections.
Discussion and conclusion. Significant association of 4 VEGFA SNPs with severe retinopathy was found only when using the third categorizing method which also takes into account anti-VEGF treatment, even with (near) normal VA. As such, the identification of these SNPs in a patient does not necessarily imply vision loss with significant impact on activities of daily living but rather an increased necessity for anti-VEGF treatment. This subgroup of patients might thus benefit from a more strict follow-up, emphasizing the importance of regular self-testing, and a more pro-active initiation and duration of anti-VEGF treatment. Whether this will eventually change the outcome will have to be evaluated prospectively.

P18.68

Measuring maternal anxiety during child's development and its effects on psychosocial health and partner relationships

E. Siglen[1,2], *B. Espehaug*[2], *N. Øyen*[1,3], *F. Thuen*[2];
[1]*Helse Bergen, Bergen, Norway,* [2]*Bergen Collage, Bergen, Norway,* [3]*University of Bergen, Bergen, Norway.*

Study aims: This study explores the consequences of being worried about the development of one's child and its association with psychosocial health.

Participants: The Norwegian Mother & Child Cohort Study (MoBa) is a vast resource of epidemiological and biological data collected throughout pregnancy and childhood. Pregnant women from 1999-2009 (N=approximately 100 000) were invited to participate in a national study regarding a diverse number of serious health issues in mother and child.

Methods: This is a cross-sectional study focusing on data (questionnaire) submitted by the mother when their child was 18 months of age. We applied the following tools: The Hopkins Symptom Check-List to measure psychosocial health and Relationship Satisfaction Scale to measure partner relationships quality.

Results: Preliminary results show that being worried about one's child's development has a negative influence on relationship satisfaction and mothers' psychosocial health. There is a statistically significant association between worry about developmental delay in the child and psychosocial problems (OR=5.39).

Conclusions: Findings apply to genetic counsellors, medical doctors and health care workers meeting these parents and assessing the child's development. Parents' psychosocial health needs should be addressed as anxiety may influence understanding and compliance, and to avoid long term implications for the mother and in turn the child. Communication techniques to lower levels of worry and facilitate coping are discussed.

E. Siglen: None. **B. Espehaug:** None. **N. Øyen:** None. **F. Thuen:** None.

P18.69

Professional´s views on quality issues of genetic counselling offered for presymptomatic testing for late-onset neurodegenerative disorders: what is relevant?

A. Mendes[1], *L. Guimarães*[1], *J. Sequeiros*[1], *H. Skirton*[2], ***M. Paneque***[1,2];
[1]*Center for Predictive and Preventive Genetics (CGPP) IBMC, Porto, Portugal,* [2]*Plymouth University, Plymouth, United Kingdom.*

Quality assessment of genetic counselling practice for improving of healthcare is a challenge for genetic services worldwide. However, there is a scarcity of literature regarding quality issues in genetic counselling offered in the context of presymptomatic testing for late-onset neurological diseases. Neither common definitions of quality indicators, nor appropriate guidelines for effective practice exist internationally. The aims of this qualitative study were (1) to explore professionals' views of relevant quality indicators in their own genetic counselling practice; and (2) to describe how presymptomatic testing protocols are currently being implemented in Portugal. We undertook interviews with 18 professionals from the major genetic counselling services for these diseases in Portugal (85% of the professionals currently involved). Core components of genetic counselling encompass providing information and decision-making support, informing the consultand about the protocol and exploring their motivations, anticipated changes, results expectations and personal and familial experience with the disease. Identification of quality indicators for effective practice was less clear. Professionals also discussed some specific challenges in practice, such as the ambiguity of the health/illness status and confirming consultands' autonomy during the process. When questioned about the consultands' views of what would be effective in practice, some reported they had not reflected on the topic previously. Although national guidelines and legislation exist, professionals described concerns regarding heterogeneous standards of practice, mainly due to the lack of regulation regarding genetic counselling outside credited centres and in private services. We conclude that a credible set of quality indicators for presymptomatic testing is required.

A. Mendes: None. **L. Guimarães:** None. **J. Sequeiros:** None. **H. Skirton:** None. **M. Paneque:** None.

P18.70

Centers for rare diseases at the University Hospital Brno, Czech Republic (CZ)

R. Gaillyová[1,2,3], *I. Valášková*[1,2,3], *H. Bučková*[1], *A. Holčíková*[1], *L. Homola*[1], *E. Pokojová*[1], *H. Vinohradská*[1], *L. Fajkusová*[1], *L. Kopečková*[1], *M. Macek jr.*[4];
[1]*University Hospital, Brno, Czech Republic,* [2]*Masaryk Universïty, Department of Biology, Brno, Czech Republic,* [3]*Masaryk University, Department of Laboratory Methods, Brno, Czech Republic,* [4]*University Hospital Motol, Prague, Czech Republic.*

In accordance with the „Council Recommendation on an action in the field of rare diseases" the Government of the CZ approved the National Strategy for rare diseases.
„Interdepartmental and interdisciplinary working group on rare diseases" runs under the czech Ministry of Health, and coordinates the establishment of centers for rare diseases. The main co-ordination center is located in the University Hospital Motol, Prague cooperating with the center at the University Hospital Brno.
In University Hospital Brno the EB Center was established for all 183 patients with Epidermolysis bullosa congenita (EBC) from CZ and CF Center for patients with Cystic fibrosis (CF), one of five CF Centers in the country.
A team of 19 EB specialists provides health care, including genetic counseling and prenatal and postnatal DNA diagnostics. The EB Center cooperates with EB Haus Austria and with Debra CZ, which supports families of patients with EB. EB Center and Debra CZ are involved in various educative activities.
A team of experts from CF Center Brno currently cares for 63 children and 30 adults with CF, provides genetic counseling and DNA analysis of the CFTR gene. University Hospital Brno is also responsible for newborn screening for CF (NSCF) for the Moravia region (about 40,000 newborns/year).
Centers for Orphan cooperate with patient organizations associated in the Czech Association of Rare Diseases. A important part of the work of all experts on rare diseases is an effort to raise awareness about rare diseases among specialists and the public.

Medicinal products for rare diseases in Europe

V. Hivert*, M. Bécas-Garro, A. Rath, S. Aymé;*
ORPHANET - INSERM US14, PARIS, France.

Having knowledge of the development of medicinal products from their preclinical phase to their marketing authorization is of great relevance for the rare disease community. It is for this reason that Orphanet developed a database of orphan designations, medicinal products and clinical trials related to them, allowing for the analysis of trends in clinical research and development. Today 144 drugs have been granted a European Marketing Authorization (MA) through the centralized procedure. Of these, 66 drugs, targeted nearly 70 diseases, are orphan medicinal products (OMP, so-called orphan drugs) that have been granted a European orphan designation (according to the Regulation (EC) No141/2000), and that have then been granted a European MA and - if applicable - a positive evaluation of significant benefit. Ten orphan medicinal products have been granted a European Marketing Authorization in 2012. There are also 78 drugs bearing one or more indications for a rare disease or a group of rare diseases. These OMPs have received a European marketing authorization for one or more indication(s) of use for a rare disease, but they have not been granted a European orphan designation or their designation was withdrawn. In total, more than 120 diseases have a product with an official indication to treat them. On the top of the list of diseases concerned by clinical development are rare cancers, which are widely represented (acute myeloid leukemia, multiple myeloma), as well as some low prevalence (<1/10,000) diseases such as cystic fibrosis, Duchenne muscular dystrophy and pulmonary arterial hypertension.

Support to the International Rare Diseases Research Consortium

S. Aymé[1], ***S. Aymé***[1], *B. Cagniard*[1], *P. Chakraborty*[1], *S. Peixoto*[1], *R. Favresse*[2], *N. Lévy*[2];
[1]*INSERM US14, Paris, France,* [2]*Fondation Maladies Rares, Paris, France.*

The International Rare Diseases Research Consortium (IRDiRC) joins members that share common goals and principles and have agreed to work in a coordinated and collaborative manner within a multinational consortium. The objective is to team up researchers and organisations investing in rare diseases research in order to achieve two main objectives by the year 2020, namely to deliver 200 new therapies for rare diseases and means to diagnose most rare diseases. The members are research funding organizations dedicating over 10 million US$ to research into rare diseases. A number of challenges will need to be addressed through collaborative actions: establishing and providing access to harmonised data and samples, performing the molecular and clinical characterisation of rare diseases, boosting translational, preclinical and clinical research, and streamlining ethical and regulatory procedures. The consortium has established three Scientific Committees. The Diagnostics committee advises on research related to the diagnoses of rare disease, including sequencing and characterization of these diseases. The Interdisciplinary committee provides expertise on cross-cutting aspects of rare diseases research including issues related to ontologies, natural history, biobanking, and registries. The therapies committee gives guidance for the pre-clinical and clinical research aiming to deliver new therapies for rare diseases. The guiding principles, the plan for action and the achievements so far will be presented, as well as the way for the genetic research community to get engaged in this global effort. The scientific secretariat of this International consortium is established at the rare Diseases Platform in Paris.

P18.73

Orphanet.co.uk and Orphanet.ie are for you

I. Gomez Paramio[1,2], *O. Kremp*[3], *H. R. Middleton-Price*[1], *D. Donnai*[1,4];
[1]*Nowgen, Manchester Biomedical Research Centre, Manchester, United Kingdom,* [2]*The University of Manchester, Manchester, United Kingdom,* [3]*INSERM US14, Paris, France,* [4]*Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.*

Orphanet is the reference portal for information on rare diseases and orphan drugs for all audiences. Orphanet provides free and direct online access listing around 6,000 rare diseases, a classification of rare diseases elaborated using existing published expert classifications, a directory of specialised services, an inventory of orphan drugs, an 'assistance to diagnosis' tool, emergency guidelines, the EUCERD's newsletter and the Orphanet Report Series.
The Orphanet entry points for the UK (www.orphanet.co.uk) and Ireland (www.orphanet.ie) were launched on February and March 2011 respectively. They provide specific national information including: the Orphanet team and its Scientific Advisory Boards, collaborators, patient organisations and private not-for-profit funding bodies.
The sources of information and inclusion criteria for the UK were recently added to clarify the registration process. Online registration forms for patient organisations, expert centres, research projects, clinical trials and registries have also been added to simplify and accelerate this process.
Aiming to increase national awareness of rare diseases and the availability (or not) of services, we are now planning to add information about national activities; any patient organisation, funding body, research/clinical group, laboratory or other relevant stakeholder is invited to submit an article for publication on the national home page.
We also aim to promote interaction between the Orphanet national team and the rare disease community (patients/families and/or professionals); work is underway to collect feedback from users, such as "like" buttons, "suggestions" fields, or gathering satisfaction levels on different national events or Orphanet-related matters.

P18.74

Representing the evolution of genetic testing: new services at Orphanet to adequately serve the end users

B. Belloir*, V. Hivert, A. Rath, S. Aymé;*
Orphanet - INSERM US14, Paris, France.

Techniques and processes used to diagnose diseases evolve quickly, creating a challenge for providing access to stakeholders. Over the years, Orphanet has maintained a database of genetic tests in 38 countries, in collaboration with EuroGentest. This must now evolve to meet the professional's needs. Besides the classical representation of the test -gene(s)- disease(s) triplet, which allows one to search for a test by the disease or gene name, it is now necessary to represent new generation of techniques capable of testing an entire panoply of genes.

The techniques/processes will be grouped into 8 categories: molecular genetics, molecular cytogenetics, biochemical tests, immunology, microbiology/virology, hematology, pathology, and Imaging. More specifically, "Molecular genetics" will be split into: mutation targeting or scanning, sequencing of total or partial gene sequences, CNV by array or MLPA, whole genome or exome sequencing, methylation analysis, uniparental disomy study, allowing for a search by techniques.
Furthermore, the purpose for testing will be annotated: antenatal diagnosis, pre-implantation diagnosis, post-natal diagnosis, pre-symptomatic diagnosis, pharmacogenetics, risk assessment and newborn screening.
The search tool currently allows Orphanet websites users to retrieve a specific test for a disease or a gene as well as the quality assessment and the testing site. It will now also offer the possibility to choose the technique / process, or the purpose of the test. Additionally, the ability to find a laboratory by its EUGT number, name of institution, location, technique/process or purpose, without any need for the entry for a specific disease, will be possible.

B. Belloir: None. **V. Hivert:** None. **A. Rath:** None. **S. Aymé:** None.

P18.75

The marketing of gene therapy medicinal products: What are the regulatory challenges?

A. Mahalatchimy[1,2], *W. Meng*[1,3], *A. Cambon-Thomsen*[1], *A. M. Duguet*[1], *E. Rial-Sebbag*[1];
[1]*UMR1027, Inserm and Université de Toulouse III - Paul Sabatier, Toulouse, France,* [2]*IRDEIC Université Toulouse 1 Capitole, Toulouse, France,* [3]*Shandong University, School of law, Jinan, China.*

In 2003 Gendicine (injection to treat head and neck cancers) has been approved by the Chinese State Food and Drug Administration. It became the first gene therapy medicinal products (GTMP) to be marketed in the world. However, the equivalent of Gendicine, Advexin did not reach the European authorisation. Almost ten years later, in October 2012, Glybera (to treat lipoprotein lipase deficiency) was finally granted marketing authorization by the European Commission. After a chaotic regulatory process it became the first GTMP to be approved in Western countries. Although approvals of these GTMP have mainly been seen as a huge step for patients and for the future of gene therapy, both regulatory processes have been challenged. On the one hand, the relevance of assessment's criteria by the relevant institutions is questioned. China and the European Union do not have the same eligibility criteria for marketing authorization. But in any case, the balance benefit/risk is particularly difficult to assess for GTMP. Beyond the safety criteria, efficacy raised high concerns. It led Gendicine to be seen as a quite controversial drug for Western countries while Glybera suffers from several negative opinions at the European Medicine Agency's relevant committees. On the other hand, going through the whole regulatory process requires a very substantial investment for companies, especially in time and costs. Based on the experience of Gendicine, Glybera and Advexin, this paper aims to highlight the regulatory challenges that GTMP faced to be marketed.

Experiences and attitudes of Flemish pharmacists towards (genetic and non-genetic) self-testing. An interview study

E. Sleurs, *K. Thys, L. Demeester, C. Desmet, A. Heeren, F. Van Wonterghem, I. Huys, P. Borry;*
KU Leuven, Leuven, Belgium.

An increasing number of medical 'self-tests' with the goal of detecting the risk for certain conditions are becoming available to consumers. Although various of these (genetic and non-genetic) self-tests are available through the Internet, pharmacists are increasingly confronted with the availability of these self-tests and the consumers who purchase them.The objective of this study was to explore the experiences of community pharmacists with regard to (genetic and non-genetic) self-tests and their attitudes towards those self-tests, as well as their role towards consumers and other health care professionals. 29 community pharmacists spread over Flanders were interviewed. A semi-structured interview was designed that incorporated open-ended questions regarding their knowledge about self-tests, their experiences with self-tests, their views with regard to self-tests, and their perspectives on their role related to the provision of self-tests as well as their relation to other health care professionals. Overall, community pharmacists had only limited experiences with consumers asking for self-tests. Although community pharmacists advanced potential benefits of self-tests, they emphasized as well potential concerns such as the limited predictive value, false positive and false negative test results, misuse of the device, the psychological impact of the result, or the absence of a medical framework. Most community pharmacists see an important role for their profession in relation to self-tests, especially in the provision of information when delivering a self-test and in the interpretation of the results. However, they underlined as well the non-diagnostic purpose of their role and the importance of consumers interacting with physicians.

When a patient sends you a 'friend request': Social networking in the context of Genetic Counselling.

T. Delikurt[1], *E. Spanou*[1], *A. Kotti*[2], *G. A. Tanteles*[1], *V. Anastasiadou*[3];
[1]*The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus,* [2]*Makarios III Hospital, Nicosia, Cyprus,* [3]*Makarios III Hospital & The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus.*

Internet-technology (IT) is a major part of everyday-life, both professionally and personally. As an "engine" of globalisation, its use revolutionised the way we communicate with others, distribute and access information. Although beneficial, just like any other innovation, IT
has certain disadvantages. The use of IT has been integrated into healthcare through novel approaches like *internet-based-telemedicine (IBT)*. IBT creates opportunities for underserved patients to access healthcare which can positively influence the patient/healthcare professional (HCP) interaction. Unfortunately, there are instances that can risk the dynamics of this interaction. HCPs have ethical responsibilities towards their patients including the preservation of a professional relationship with a patient within moral boundaries. Social-networking websites, such as facebook, can put HCPs in difficult situations e.g. being "facebook-friends" with patients can potentially blur the boundaries of their relationship. The small bi-communal composition of Cyprus, culturally, has a "close-nit" characteristic, where everyone knows everyone". The Clinical Genetics Clinic (CGC) has substantial experience in providing genetic services in a relatively small community, where balancing the equilibrium of patient/HCP relationship can be a delicate issue. In the recent years, with the popularity of facebook, a new dilemma has emerged in terms of whether it is appropriate for HCPs to be "facebook friends" with patients. Although this issue is addressed in medical literature mainly for physicians, it hasn't been addressed for genetic specialists such as genetic counsellors and/or clinical geneticists. This poster will reflect on the experiences of CGC-team in the added effect of facebook upon genetic counselling in a small-community.

15 years of education and volunteering service with Down Syndrome groups

M. Gafencu, *V. Stan, S. Per, Z. Andrei, G. Doros;*
Univ. of medicine and pharmacy V. Babes Timisoara, Timisoara, Romania.

Introduction: Aim of this paper is to describe the changes in life quality of people with this syndrome, after 15 years of multidisciplinary volunteer work with groups from Western part of Romania. We work together with other NGO from Romania and founded an association - ANBRaRo - dedicated to all support groups of people that start occupied with genetic transmitted diseases.Material: In 1997 Save the Children - Timisoara formed support group for children with Down syndrome- a "club". We worked with high school volunteers from 1997 and after 2005 together with students from our medical university - they made teams around 5-10 persons. Around 35 people with Down syndrome were our beneficiaries in all these years. In our Down club we start one by one relation with volunteers. In specific moments we performed psychological evaluation and motor testing using kinethoterapic observation. Results: Assessment of their advancement might establish the exact role of communication among the Down Club. Parents have observed important cognitive changes in their children - at the beginning was the only method of evaluating their progress, but emotional and social improvement. Psychological evaluation was performed in specialized centers. Conclusions: The former children from "Down club" evolved in social life easier and have established professional contacts and school relationships much faster. Continue monitoring and participation to support programs led to easy integration in the community. In the absence of a coherent state policy, input from various NGOs is crucial for good independent life skills to this category of beneficiaries.

Telemedicine use in Clinical Genetics; a European survey

E. Otten[1], *E. Birnie*[1], *A. V. Ranchor*[2], *I. M. Van Langen*[1];
[1]*Department of Clinical Genetics, University of Groningen, University Medical Center Groningen, Groningen, Netherlands,* [2]*Department of Health Psychology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.*

Introduction: The demand for genetic counseling is increasing, while simultaneously health care resources are scarce.
US and Australian reports show that Telecounseling (TC, real-time counseling via internet and webcam) can save time and costs, when it is used as an alternative for traditional face-to-face outpatient counseling. TC also allows for a more flexible planning of consultations for both patient and counselor. We successfully completed a TC pilot study in oncogenetics and cardiogenetics at our department. Our aim was to inventorise if comparable TC-programs in Europe are initiated and what their characteristics are, to allow for exchange of experiences and collaboration.
Methods: We set up a cross-sectional survey in collaboration with the American Telegenetics Workgroup. The survey was spread amongst 927 clinically and non-clinically working ESHG-members of whom email-addresses were available for use between November 2012 and January 2013.
Results: 120 ESHG members (92 institutions in 39 different countries) completed the survey. Members reported the use of telephone-only counseling (20%) and various web-based counseling methods (6-14%). 24% of respondents indicated videoconferencing facilities being available at their departments, though 78% of them do not use these. 56% of respondents indicated to be interested in joining a meeting or participating in a working group on Telegenetics.
Conclusion: While TC seems a promising modality to meet increasing health care demands, only about 20% of respondents use some form of TC. Setup of an ESHG working group is recommended to support the use of TC, collaboration and exchange of experiences.

Congenital lamellar ichthyosis in Tunisia is caused by a founder nonsense mutation in the TGM1 gene

N. Louhichi[1], *I. Hadj Salem*[1], *S. Marrakchi*[2], *F. Trabelsi*[1], *A. Masmoudi*[2], *H. Turki*[2], *F. Fakhfakh*[1];
[1]*(1) Human Molecular Genetic Laboratory, Sfax, Tunisia,* [2]*(2) Department of Dermatology ; Hedi Chaker Hospital, Sfax, Tunisia.*

Lamellar ichthyosis (LI, MIM# 242300) is a severe autosomal recessive genodermatosis present at birth in the form of collodion membrane covering the neonate. Mutations in the TGM1 gene encoding transglutaminase-1 are a major cause of LI. In this study molecular analysis of two LI Tunisian patients revealed a common nonsense c.788G>A mutation in TGM1 gene. The identification of a cluster of LI pedigrees carrying the c.788G>A mutation in a specific area raises the question of the origin of this mutation from a common ancestor. We carried out a haplotype-based analysis by way of genotyping 4 microsatellite markers and 8 SNPs flanking and within the TGM1 gene spanning a region of 6 Mb. Haplotype reconstruction from genotypes of all members of the affected pedigrees indicated that all carriers for the mutation c.788G>A harbored the same haplotype, indicating common ancestor. The finding of a founder effect in a rare disease is essential for the genetic diagnosis and the genetic counselling of affected LI pedigrees in Tunisia.

Thalassemia genetic counselling in Greece: an initial evaluation.

A. Kafassi[1], *M. Papadakis*[1], *E. Boutou*[1], *V. Aleporou*[2], *P. Kollia*[2], *E. Voskaridou*[1], *A. Balassopoulou*[1];
[1]*laikon Hospital, Athens, Greece,* [2]*athens University, Athens, Greece.*

Genetic counselling consists a vital part of prenatal decision making and this should be performed according to international guidelines, adopted to ethnic necessities. Thalassaemia and haemoglobinopathies are the most frequent genetic diseases in Greece. The National Thalassaemia Prevention Program, established thirty years ago, proved to be quite effective as it led to a severe reduction of affected births. A slight increase in affected newborns, observed recently, prompt us to evaluate the efficacy of the genetic counselling offered. Towards evaluation of the counselling services provided, two questionnaires were completed by 100 individuals requesting prenatal testing for thalassaemia. Remarkably, a noteworthy proportion of the participants did not adequately comprehend the provided information. Our results showed that certain fields require more detailed, intensive and simplified communication. The percentages of areas less understandable and thus requiring improvement are: mode of inheritance (~60%), combination of disease causing mutations (~25%) as well as knowledge about severity of the disease in terms of life expectancy (~30%) and lack of radical treatment (~35%). Furthermore, the majority of people declared not informed about prenatal diagnosis options as well as the necessity of prenatal testing for other high prevalence genetic diseases.
These results are contradictory to the long life time of the national prevention program in the country. It is worth mentioning that genetic counselling in Greece is provided by healthcare professionals, not specialised accordingly. These data suggest the urge for the official establishment of genetic counselling specialty in Greece, as a distinct specialty in human / medical genetics.

Trichorhinophalangeal syndrome type I (TRPSI) is a genetic disorder characterized by sparse hair, a bulbous nasal tip, short stature with severe generalized shortening of all phalanges, metacarpal and metatarsal bones and cone-shaped epiphyses. This syndrome is caused by autosomal dominant mutations in the TRPS1 gene. However because recurrence has been observed in siblings from healthy parents, an autosomal recessive mode of inheritance has also been suggested.
We report on a male patient, born to healthy unrelated parents, with TRPSI. Using Sanger sequencing, we identified a mutation in the TRPS1 gene (c.2735G>A, p.Cys912Tyr). The same mutation was detected as a 10% mosaic mutation by Pyrosequencing in blood-derived DNA from his healthy mother.
To our knowledge, this is the first time that somatic mosaicism has been identified in TRPSI. This data combined with the observations of recurrences in siblings from healthy parents modifies the genetic counselling for TRPSI which should discuss a 5 to 10 percent recurrence risk for healthy parents with an affected child because of the possibility of germinal mosaicism.

TRPC6 mutation is a rare cause of steroid-resistant nephrotic syndrome in children

M. Lion[1,2], *O. Boyer*[1,3,2], *P. Niaudet*[1,2], *M. Charbit*[1], *F. Névo*[3], *P. Eckart*[4], *P. Krug-Tricot*[1], *R. Salomon*[1,3,2], *M. Gubler*[3], *C. Antignac*[5,3,2];
[1]*Néphrologie pédiatrique et MARHEA - Hôpital Necker - Enfants malades, Paris, France,* [2]*Université Paris Descartes - Sorbonne Paris Cité, Paris, France,* [3]*Inserm U983 - Institut Imagine, Paris, France,* [4]*Service de pédiatrie - CHU de Caen, Caen, France,* [5]*Génétique médicale - Hôpital Necker - Enfants malades, Paris, France.*

Heterozygous mutations of the TRPC6 gene have been reported in ~5% of autosomal-dominant podocytopathies with focal segmental glomerulosclerosis (FSGS). Most patients present with nephrotic range proteinuria in their thirties-fifties, and progress to end-stage renal failure within 10 years. Recently, TRPC6 mutations have been identified in 4 children; one of them had severe collapsing FSGS at 2 years of age.
A boy, born to non-consanguineous parents presented at the age of 6 years with nephrotic syndrome, chronic kidney disease and hypertension. The renal biopsy showed collapsing FSGS with 50% of sclerotic glomeruli. The

renal function rapidly worsened despite steroid therapy, and peritoneal dialysis was started within 2 months. He was transplanted one year later, with no recurrence. The eGFR remained stable around until the last follow-up 20 years later.
Genetic testing revealed a de novo heterozygous mutation c.2678G>A (p.Ser893Asn) in the exon 13 of the TRPC6 gene. This missense mutation is predicted to be "probably damaging" by the Polyphen2 software with a score of 1. The TRPC6 gene encodes a non-selective cation-channel highly expressed in podocytes. It mediates intra-cellular calcium influx and plays a major role in signaling cascades of the slit diaphragm where TRPC6 interacts with nephrin and podocin. The mutation involves a highly-conserved residue located in the last cytoplasmic domain of the protein, that could participate in the assembly of subunits of TRPC6 and its interaction with membrane phospholipids.
In conclusion, TRPC6 mutations can be detected in early-onset and severe forms of familial and sporadic
steroid-resistant nephrotic syndromes.

P18.84
A systematic approach to clinical classification of DNA sequence variants in mismatch repair genes: the InSiGHT initiative

M. Genuardi[1,2], *B. Thompson*[3,2], *A. Spurdle*[3,2], *F. Macrae*[4,2], *J. P. Plazzer*[4,2];
[1]*Medical Genetics, Dept Biomedical, Experimental and Clinical Sciences,University of Florence, Florence, Italy,* [2]*Variant Interpretation Committee, International Society for Gastrointestinal Hereditary Tumors, London, United Kingdom,* [3]*Queensland Institute of Medical Research, Genetics and Computational Biology Division, Brisbane, Australia,* [4]*Dept of Colorectal Medicine and Genetics, The Royal Melbourne Hospital, Melbourne, Australia.*

Sequence variants of uncertain significance are common in genetic test reports. Several parameters can be evaluated to assess their significance, but usually none of them can be used on its own to obtain clinically useful interpretation. The Variant Interpretation Committeee of the International Society for Gastrointestinal Hereditary Tumors (InSiGHT), comprised of a multidisciplinary panel of 41 experts, has undertaken a collaborative effort to establish interpretation guidelines, to encourage data submission and to provide objective assessment of available variant information for the mismatch repair (MMR) genes. Guidelines matching the five-tiered classification scheme proposed by the IARC Unclassified Genetic Variants Working Group were devised based on scientific evidence and expert opinion. The scheme was tested on different sets of MMR variants. Data for evaluation included co-segregation with phenotype, family history, co-occurrence with clearly pathogenic variants, frequency in controls, tumor molecular characteristics (microsatellite instability and immunohistochemistry of MMR proteins), effects on RNA (assessed on patient samples or by minigene splicing assays) and in vitro functional consequences. Data were retrieved from the LOVD database (http://www.insight-group.org/mutations/); submission of unpublished information from InSiGHT members was encouraged, leading to accrual of substantial amounts of novel data. The approach was applied to all 2,759 variants listed in the database, including 129 with discordant interpretation provided by difefrent submitters. This large-scale endeavour has important implications for the clinical management of suspected Lynch syndrome families and provides an important model of international multidisciplinary collaboration for DNA variant interpretation.
Presented on behalf of the InSiGHT Variant Interpretation Committee.

P18.85
The Challenges of Genetic Counselling in Vascular Ehlers Danlos Syndrome

J. H. Tocher, *J. M. Bowen;*
Sheffield Children's Hospital, Sheffield, United Kingdom.

Vascular Ehlers Danlos Syndrome (Vascular EDS) is a dominantly inherited connective tissue disorder. Mutations in the COL3A1 gene affect collagen type III which is found mainly in the walls of hollow organs and blood vessels. The main clinical features of Vascular EDS include:
- a tendency to very easy bruising
- thin skin
- fragile blood vessels which can lead to complications due to rupture of arteries
- hollow organ rupture
- premature death

The National Diagnostic Service for EDS has now been running since April 2009 and was set up to diagnose complex cases of EDS. Genetic testing for Vascular EDS has been available in the UK since 2007 with a 99% pick up rate. Over 30 patients have now been diagnosed with Vascular EDS by the National Diagnostic Service. Some of these individuals did not present with the classical phenotype or clinical history. We have also seen a number of individuals who were referred with the diagnosis for specialist advice on the condition. We review recent data gathered from the clinic and discuss cases which highlight some of the issues that have emerged and to share our experiences of genetic counselling with patients who are newly diagnosed with Vascular EDS.

P18.86
Challenges of clinical whole exome sequencing and practical considerations for genetic counseling

A. Bytyci Telegrafi[1], *C. Applegate*[1], *N. Beck*[1], *R. McClellan*[2], *L. Jamal*[2], *J. Cohen*[2], *Y. Alade*[1];
[1]*McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD, United States,* [2]*Department of Neurogenetics, Kennedy Krieger Institute, Baltimore, MD, United States.*

Objective: Our objective is to demonstrate how clinical whole exome sequencing (WES) testing has impacted our genetic counseling (GC) practice.
Methods: Between Johns Hopkins Hospital (JHH) and Kennedy Krieger Institute (KKI), 93 cases have been sent for clinical WES from Nov 2011-Feb 2013. For each case data was gathered for result types and time spent in case management. Data was analyzed using STATA Statistical Software.
Results: Of the 29 genetic counselors at both JHH and KKI, only 6(21%) have thus far sent clinical WES for various indications. The use of this testing has been utilized by the pediatric, general genetics and neurogenetics clinics. Of the 93 cases sent for WES, results of 33 have come back thus far: 12 Negative (36.36%); 13 Positive (39.39%); and 8 with Variants of Unknown Clinical significance (VUS) (24.24%). The time spent in each category required for case management is as follows: time spent pre-test counseling N=84 (Mean 56±16.0 min); time spent researching results in light of patient phenotype N=18 (88±58.4 min); time spent post test GC N=13 (65.8±28.4 min); time spent writing result notes N=16 (71.2± 43.3 min).
Conclusions: The above preliminary data demonstrate an increased time required in patient case management. An increased amount of time was spent in interpreting the results in light of the patient's phenotype and medical documentation of results, which are non-billable time. Though major conclusions cannot be generated from this preliminary data, it suggests that many results, whether classified as "Positive" or "VUS", only partially explained patients' phenotypes.

P18.87
Genetic basis of Xeroderma pigmentosum in MENA region: consequences for patient management and care

O. MESSAOUD[1], *M. Ben Rekaya*[1], *M. Jerbi*[1], *N. Laroussi*[1], *H. Yacoub*[1], *S. Boubaker*[1], *H. Boussen*[1,2], *M. Mokni*[3,4], *M. Zghal*[5], *S. Abdelhak*[1];
[1]*Université de Tunis El Manar, Institut Pasteur de Tunis, LR11IPT05 Génomique biomédicale et oncogénétique, Tunis, Tunisia,* [2]*Medical Oncology Department, Salah Azaïez Institute, Tunis, Tunisia,* [3]*Dermatology Department, La Rabta Hospital, Tunis, Tunisia,* [4]*Study of Hereditary Keratinization Disorders" Research Unit, La Rabta Hospital, Tunis, Tunisia,* [5]*Dermatology Department, Charles Nicolle Hospital, Tunis, Tunisia.*

Xeroderma pigmentosum (XP) is a rare autosomal recessive disorder characterized by a high skin sun-sensitivity predisposing to skin cancers. In Tunisia, the frequency of the disease was estimated to 1/10000. Tunisian XP patients have been classified in three forms: severe, intermediate and moderate.
In the present study, 114 patients were investigated by direct sequencing or genotyped using STR to confirm linkage by homozygosity mapping strategy. Our preliminary molecular investigation showed homogeneity of the mutational spectrum for *XPA* and *XPC* genes. Indeed, among studied cases, 24 patients (21%) affected by intermediate cutaneous and neurological manifestations shared the same mutation in the *XPA* gene: p.R228X and 44 patients (38.6%) with the severe clinical form have the same mutation in the *XPC* gene: p.V548AfsX25. These are two founder mutations as they segregate each in a single haplotype. Twelve patients (10.5%) with the moderate clinical form are linked to the *XPV* gene with four different haplotypes. For

the remaining cases, the aetiology of XP is still unknown.
Having only two recurrent mutations that are responsible for the majority of explored patients made it easier to propose genetic counselling and prenatal diagnosis for the investigated families. Indeed, six consanguineous XP Tunisian families (4 XP-A and 2 XP-C) and one XP-C Libyan family have benefited from a prenatal diagnosis.
Based on a common history of settlement and the share of a similar genetic background, the mutations identified in the present study could be prioritized for mutation screening in other similar populations particularly from the MENA region.

Heterogeneity of XP-C group in Tunisian families: two novel mutations

*M. Jerbi[1], M. Ben Rekaya[1], O. Messaoud[1], A. Ben Brick[1], M. Zghal[1], C. Mbarek[1], A. Chadli-Debbiche[1], M. Jones[1], M. Mokni[1], H. Boussen[1], M. Boubaker[1], B. Fazaa[1], **H. Yacoub-Youssef**[2], S. Abdelhak[1];*
[1]Pasteur Institut of Tunis, TUNIS, Tunisia, [2]Pasteur Institut of Tunis, Tunis, Tunisia.

Xeroderma Pigmentosum (XP) is a rare recessive autosomal cancer prone disease, characterized by UV hypersensitivity and early appearance of cutaneous and ocular malignancies.
In the present study we investigated four patients suspected to be affected by XP-C group. These patients were from consanguineous unrelated families. Among them, three patients developed cancers: two patients (XP45 and XP50) developed melanoma. Internal tumors was also observed in patient XP28 and XP45: Thyroid cancer and benign articular tumor of the knee respectively.
Sequencing of the exon 9 showed absence of the frequent mutation XPC p.V548AlafsX25 in these patients. However genotyping and linkage analysis revealed possible involvement of XPC gene, this gene was screened for mutation by direct sequencing
Mutation analysis revealed the presence of two novel mutations. The first mutation is a splice site transition in intron 6 present in XP50 patient that abolishes the splice donor site and leads to a premature stop codon. The second one is a nonsense mutation located in exon 7 that has been identified in the three remaining patients. These originating from three cities of Southern Tunisia and bearing the same haplotype, in favor of a founder effect. Reverse Transciptase PCR revealed the absence of the mRNA of the XPC gene in all patients, thus confirming the hypothesis of mRNA degradation by the Non sense Mediated mRNA Decay system.
We concluded that in Tunisia, XP-C group seems to be homogeneous with some pockets of heterogeneity, that should be taking into account to improve molecular diagnosis of this disease.

Corpus Callosum Malformations: a neuropathological description and classification in a series of 105 fetuses

***C. ALBY**[1,2], K. Burkhardt[3], B. Bessieres[4], M. Bonnière[4], N. Bahi-Buisson[1,5,6], P. Sonigo[7], A. Millischer[7], V. Malan[4,6], Y. Ville[2,6], M. Vekemans[1,4,6], T. Attie Bitach[1,4,1], F. Encha Razavi[1,4];*
[1]INSERM U781, Hôpital Necker-Enfants Malades, Paris, France, [2]Obstetrics and gynecology, Hôpital Necker-Enfants Malades, Paris, France, [3]Neuropathology, Hôpitaux Universitaires de Genève, Genève, Switzerland, [4]Histology-Embryology-Cytogenetics, Hôpital Necker-Enfants Malades, Paris, France, [5]Neuropediatrics, Hôpital Necker-Enfants Malades, Paris, France, [6]Paris Descartes University, Paris, France, [7]Radiology, Hôpital Necker-Enfants Malades, Paris, France.

Corpus callosum (CC) is the major brain commissure connecting the homologous areas of both hemispheres at the midline. CC malformations (CCM) are the most frequent brain malformations with an incidence of 1/4000 newborn often associated with chromosomal anomalies or mendelian syndromes with recessive and dominant inheritance. Recurrence is observed in 5 % of cases. Children with CCM have an uncertain neuro-developmental outcome. Therefore, counseling remains challenging. A monocentric retrospective study was carried out between 2000 and 2012, on fetuses whose pregnancy was terminated for CCM observed on US and/or MRI. In 105 fetuses, neuropathological examinations permit distinction of four groups: I: abnormal decussation of callosal fibres (48 cases); II: cortical malformations (34); III: abnormal growth of CC (7) and IV: dysplasia of CC (16). Most importantly, among 61 cases where CCM was thought to be isolated antenatally, another brain and/or extraneurological signs were found in 32 cases (50%). To date, chromosomal and molecular screenings permit identification of a cause in 18 cases of this cohort (17%). This includes trisomy 18, der(7)t(7;8), add(1)(q43), add(8)(q11.21), 1q44, 3q13.2, 11p13, 14q12 and 17p (*LIS1*) deletions respectively, dup(19)(p13), tetrasomy 9p, as well as mutations in *TUBA1*, *TUBB2B* and *OFD1* genes. In this heterogeneous cohort, morphological approach based on steps of callosal development provides valuable insight into the underlying mechanisms of CCM. This study will be instrumental for genotype-phenotype correlations and identification of the causal underlying molecular defect in unexplained cases that will be undertaken using a high throughput sequencing approach.

Objective: The 22q11 deletion (del22q11.2) is one of the most common human microdeletions and is associated with a wide spectrum of abnormalities. The objective of the present study was to evaluate the number of pregnancies diagnosed with a del22q11.2 in French laboratories and to describe the corresponding prenatal, clinical features.
Methods: 27 laboratories collaborated to perform a retrospective analysis of data on fetuses with a del22q11.2.
Results: 204 fetuses with a del22q11.2 were identified. The mean time of diagnosis was 25.6wg. Diagnosis was mainly performed after an ultrasound examination. The most frequent malformations were congenital heart defects (CHDs, in 82.4% of cases). The other typical 22q11 deletion syndrome features were polyhydramnios (n=21), kidney abnormalities (n=16), thymus abnormalities (n=8) and cleft palate (n=6). The mean time of diagnosis was significantly shorter for the 69.8% of couples who decided to terminate their pregnancy than for those who decided to continue (24.8wg vs 28.2wg; p=0.0015). Interestingly, the del22q11.2 was inherited in 24.3% of cases. A fetal pathological examination was performed in 56 cases. Even though CHD was still the most frequently observed disease feature, thymus abnormalities were detected more frequently in the pathological examination (n=26 (46.4%), only two of which had been identified on ultrasound). The facial dysmorphism observed in 42 fetuses (75%) with del22q11.2 had not been detected on ultrasound.
Conclusion: Out of CHD that prompt a del22q11 analysis, we found that polyhydramnios and kidney abnormalities are the most frequent. Furthermore, the time of pregnancy termination depended on the time of diagnosis.

P19.03

Application of molecular methodologies for the identification of genetic abnormalities in aborted fetuses/ intrauterine deaths that failed to grow in vitro

C. Sismani, *P. Evangelidou, N. Salameh, C. Ioannidou, E. Panayiotou, E. Constantinou, A. Alexandrou, M. Moutafi, P. C. Patsalis;*
The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Of all the recognized pregnancies, about 10-15% ends in clinical miscarriage/spontaneous abortion, usually towards the end of the first trimester. Of these 50% have a chromosomal abnormality, if they are all successfully cultured. Cytogenetic analysis of abortion samples can be limited by culture failure and this is attributed to the in vivo death of tissue. Genome-wide array-CGH in combination with QF-PCR can be implemented as an alternative to chromosomal analysis for samples that failed to grow. In addition, using array-CGH it is possible not only to detect aneuploidies but also aberrations that are beyond the resolution of chromosomal analysis.
Here we present our results from application of combined genome-wide array-CGH and QF-PCR analyses in 66 selected samples from first and second trimester Product of Conception/Intrauterine deaths/Stillbirths which failed to grow in vitro. Abnormalities were identified in 32 samples (48.4%).
Twenty-one autosomal full trisomies, seven sex-chromosome aneuploidies and four triploidies were detected. No submicroscopic copy number changes were detected.
The benefits these methods offer, in POC/intrauterine death/stillbirths samples are evident considering the fact that around 30% of the total of these samples received by the laboratory over a year would have failed. Moreover, the turnaround time is dramatically decreased compared to chromosomal analysis.
Finally, a very small amount of DNA is required for both of the analyses to be carried out. The limitations of the combined methodology lie with the fact that they cannot detect balanced rearrangements, therefore chromosomal analysis of parental samples is required when an aneuploidy is detected.

P19.04

Diagnosis by a Camerounese-Swiss collaboration of a 610 kb MECP2 duplication leading to a prenatal diagnosis in a Camerounese woman.

C. NGONGANG[1], S. GIMELLI[2], I. MOIX[2], M. MORRIS[2], H. ZAMBO[1], S. DAHOUN[2], A. WONKAM[3], ***F. SLOAN-BENA[2]****;*
[1]Faculty of Medicine and Biomedical Sciences, Yaoundé, Cameroon, [2]University Geneva Hospitals, Geneva, Switzerland, [3]Division of Human Genetics, Faculty of Health Sciences, CapeTown, South Africa.

A 610Kb duplication in the Xq28 region encompassing *L1CAM, IRAK1* and *MECP2* genes resulting in a functional disomy, was diagnosed by Array-CGH in a 5 years old boy with global severe devopmental delay, hypotonia, recurrent infection and hypoplastic genitalia/cryorchidism. He was the second of a sibship of 2 and the first boy, affected by the same clinical symptoms, died within a seizures context. The mother was found to be carrier of the same Xq28 duplication with a biais of X-chromosome inactivation of 100%. Prenatal diagnosis was done for a pregnancy showing a girl carrier of the maternal duplication and X-chromosome 100% inactivated. At 6 month's old, the girl has a satisfactory development. More of 45 patients have been described in the literature showing Xq28 duplications ranging from 0.2 to 22 Mb. *MECP2*, is a dosage sensitive gene described in X-linked mental retardation syndrome, with typical features of infantile hypotonia, poor speech development, recurrent infections, epilepsy, and progressive spasticity. Duplications Xq28 lead to a slighter phenotype in women, as a consequence of a normal random inactivation.
The clinical service of Genetic Medecine exits in Cameroun since 2007. The consultations identified a large number or patients with mental retardation. The coverage of the affected patients quickly highlighted a lack of local resources also technical as human. This case put in evidence the efficiency of an international collaboration tightening the links between European laboratories and the African country. The training of local teams and the patient's access to diagnosis remain the priority.

Prenatal Diagnosis by aCGH on Uncultured Prenatal Samples, Validation Study

E. Ordoñez*, L. Rueda, E. Lloveras, A. Plaja, V. Cirigliano;*
Labco General Lab, Barcelona, Spain.

Objective: We aimed to assess the suitability of using small aliquots of uncultured prenatal samples for routine aCGH analysis using a targeted BAC array.
Methods: The Cytochip Focus Constitutional array (Cambridge Bluegnome) was evaluated with an automated DNA extraction method (Qiagen) using 70 consecutive amniotic fluids (2ml) and CVS samples (0.5ml of cell suspension). DNAs were tested by QF-PCR to confirm extraction efficiency and to exclude maternal contamination. Hybridisations were performed with slight modifications of the manufacturer protocol and data analysed using Bluefuse V2.6 software. All samples were also cultured and karyotyped.
Results: Auto-passed QC check were obtained in all cases, suboptimal pass was observed in 5% (up to 2 parameters outside optimal range) while 3 samples failed. Five chromosome abnormalities were identified 3 of which were also detectable by cytogenetic analysis (one mosaic trisomy and 2 unbalanced rearrangements). Two abnormalities (1 microdeletion and 1 mosaic trisomy) were detected in the group of samples with suboptimal data. Results were confirmed by either FISH or cytogenetic analysis. Seven benign CNVs were observed, none of uncertain significance using default smoothing values of 3 clones.
Conclusions: The Cytochip Focus provided clear and easily interpretable results. It allowed detecting 2 chromosome abnormalities otherwise invisible by cytogenetic analysis without exposure of CNV with uncertain clinical outcome. The assay was robust enough to also detect abnormalities in presence of suboptimal data. In our experience only 2ml uncultured AF provided enough DNA to perform up to 4 hybridisations thus easily allowing confirmation of abnormal results.

P19.06

Non-invasive prenatal detection of achondroplasia using cell-free fetal DNA: 2 case reports from the prenatal centre in Czech Republic.

D. Grochova*[1], L. Durcova[1], J. Kadlecova[1], I. Grochova[1,2], D. Leznarova[3], P. Vlasin[3];*
[1]Cytogenetic laboratory Brno, s.r.o., Brno, Czech Republic, [2]Centre of Prenatal Diagnosics, Brno, Czech Republic, [3]Centre of Prenatal Diagnostics, Brno, Czech Republic.

Background: Achondroplasia is one of the most common form of short limb dwarfism with incidence ranges from 1/10 000 to 1/30 000 life birth. The majority of cases is sporadic and results from a *de novo* mutation c.G1138A in *FGFR3* gene (98% cases). Prenatal ultrasound examination of achondroplasia often fails but sometimes it is suspected during the last trimester of pregnancy mainly by evidence of short limbs. Our aim is to improve prenatal diagnosis of this condition by implementation of cell-free fetal DNA analysis (cffDNA).
Methods: cffDNA was extracted from maternal plasma between 17 and 36 gestation weeks. PCR combined with restriction analysis and followed by fragmentation analysis was used for c.G1138A mutation detection. The presence of cffDNA was confirmed by real-time PCR detection of DYS14 marker (male fetus) or methylation status analysis of marker RASSF1A (female fetus).
Results: Nine cases at risk of achondroplasia were scanned in our centre. In two pregnancies (27 and 36 gestation week) mutation c.G1138A was detected in cffDNA. Both cases exhibited reduced ossification and shortening of long limbs, slight hypoplasia of the chest and frontal bossing. Mutation was confirmed by genomic fetal or newborn DNA analysis.
Conclusion: Non-invasive prenatal diagnosis of achondroplasia using cffDNA is a safe alternative approach to invasive testing. Accurate diagnosis is important for parental counselling as well as for clinical management in time of delivery and for the newborn with achondroplasia. It has also an important psychological aspect since the family can be prepared for the child with this condition.

Recurrence of an adjacent-2 segregation of a non-Robertsonian reciprocal translocation t(14;21)(q11.2;q11.2)

M. Maurin[1], *O. Raoul*[1], *M. Bonnière*[1], *T. Attié-Bitach*[1,2,3], *C. Alby*[4], *F. Encha-Razavi*[1], *H. Der Sarkissian*[1], *S. Chevallier*[1], *S. Romana*[1,2,3], *C. Turleau*[1,2], *M. Vekemans*[1,2,3], *V. Malan*[1,2,3];

Adjacent-2 segregation is a very rare type of segregation of balanced reciprocal translocations during meiosis. One of the derivative chromosome is transmitted with its counterpart. Thus, there is a trisomy and a monosomy for the centric segments of the derived chromosomes without genomic imbalance of the translocated segments. We report on the recurrence of an adjacent-2 segregation of a reciprocal translocation. Ultrasound examination in the first pregnancy of a 30-year old woman at 30 weeks' gestation showed intrauterine growth restriction associated with a right-sided pelvic kidney. The fetal karyotype performed on cultured amniocytes showed an abnormal chromosome 21. This chromosome was shown to be a derivative chromosome 14 of a non-Robertsonian translocation between a chromosome 14 and of a chromosome 21. Thus, the fetus had a partial proximal 14q trisomy and a partial proximal 21q monosomy. The pregnancy was terminated at 33 weeks' gestation. The father's karyotype showed a reciprocal balanced translocation t(14;21)(q11.2;q11.2). Thus, the fetus had inherited the derivative chromosome 14 from an adjacent-2 segregation. During the fourth pregnancy, after two miscarriages, the fetal karyotype performed on trophoblastic cells showed the same derivative chromosome 14. In carrier of balanced reciprocal translocation, the formation of unbalanced gametes due to adjacent-2 segregation is rarely observed. This type of segregation has been observed when the translocation involves at least one acrocentric chromosome or a chromosome with a short centric segment. This observation shows that this cytogenetic diagnosis should be considered when an abnormal acrocentric chromosome is detected, especially in prenatal diagnosis.

Prenatal diagnosis using array-CGH: a French experience.

D. Cailley[1], *J. Toutain*[1], *M. Vuillaume*[2,1], *J. Bouron*[1], *J. Horovitz*[3], *D. Lacombe*[2,1], *B. Arveiler*[2,1], *R. Saura*[1], ***C. Rooryck***[2,1];
[1]*Bordeaux Univ Hospital, Medical Genetics, Bordeaux, France,* [2]*Univ. Bordeaux, Maladies Rares : Génétique et Métabolisme (MRGM), EA 4576, Bordeaux, France,* [3]*Bordeaux Univ Hospital, Gynecology and Obstetrics, Bordeaux, France.*

Array-CGH or Chromosomal Microarray Analysis (CMA) is increasingly used in prenatal diagnosis throughout the world. However, routine practices are very different among centers and countries, regarding CMA indications, design and resolution of microarrays, notification and interpretation of Copy Number Alterations (CNA). We present our data and experience from our Fetal Medecine Center on 224 prospective prenatal diagnoses, using FISH, karyotype and CMA. Rapid FISH analyses enabled to identify 64 common aneuploïdies (trisomies 13, 18, 21, Turner and triploïdies) in 213 fetus presenting with ultrasound abnormal features (30%). Conventional karyotyping confirmed these 64 aneuploïdies and detected 7 other chromosomal anomalies (+3%). In parallele, conventional karyotyping identified 11 other chromosomal anomalies among a group with other prenatal indications (advanced maternel age, abnormal first or second trimester screen). CMA was carried out in 160 samples: in the 18 fetus with chromosomal anomalies identified by karyotyping in order to characterize these rearrangements, and in the 142 fetuses with no karyotype anomaly. Among the 142 fetus with ultrasound abnormal findings, the anomaly rate fluctuated from 5.3% (Group of fetuses with isolated increased nuchal translucy) to 16.6% (Group of fetuses with 2nd and 3rd trimester minor ultrasound anomalies). Our approach is practical, and aims to propose a strategy to offer Chromosomal Microarray Analysis (CMA) to selected fetuses, and to help to interpret CNA. We hope that this publication could encourage development of CMA in centers that have not started yet this activity in prenatal routine, and could contribute to edict guidelines in this field.

P19.09

A very rare case detected by array-CGH

C. Garrido[1], *D. Escué*[1], *M. A. Caamaño*[1], *A. Torrents*[1], *S. Franco*[2], *E. Gean*[3];
[1]*Reference Laboratory, L'Hospitalet de Llobregat (Barcelona), Spain,* [2]*Hospital Materno-infantil de Málaga, Málaga, Spain,* [3]*Hospital Sant Joan de Déu, Esplugues de Llobregat (Barcelona), Spain.*

Extensive experience gained in the past decades has shown that prenatal karyotyping is a robust technique to detect the majority of chromosomal anomalies. But there is a growing request for arrays in the prenatal setting. Array-CGH showed an increased diagnostic yield compared to karyotyping, varying from 1-5%, depending on the reason for referral.
The higher abnormality detection yield and its amenability to automation render array-CGH suitable for prenatal diagnosis.
We report a case with pathological cytogenetic results and normal ultrasound scan at 16+2 weeks pregnancy woman. A cytogenetic study in amniotic fluid cell cultures revealed structural abnormality, consisting of an isochromosome of the short arm of an X chromosome: 46,X,i(X)(p10). This diagnostic was performed in another laboratory.
Array-CGH from fetus DNA, revealed a terminal deletion of about 33.66Mb in the long arm of chromosome X, and a partial trisomy of 535 Kb in the terminal segment of the long arm of chromosome 21.
Subtelomeric FISH probes showed that trisomy of 21qtel region is located in long arm of deleted X chromosome.
Karyotype: 46,X,der(X)t(X,21)(?;q22.3).ish der(X)t(X;21)(q28-;q22.3+).arr 21q22.3(46,358,908-46,894,371)x3,Xq25q28(121,214,280-154,878,101)x1.
Parents cytogenetic studies were normal, therefore fetus abnormalities were de novo.
Genetic counselling was performed by a Clinical Genetics Consultation and an obstetrician, and parents decided to continue the pregnancy, which is still on course.
Specific techniques revealed the existence of several chromosomal abnormalities than conventional karyotype study could not be found to observe a isochromosome Xp wrong.
Combination of cytogenetic techniques, FISH and CGH-array must be considered as the best choice in difficult cases.

P19.10

Perinatal & childhood outcomes in ART children: Experience from a Medical Genetics Department

H. Fryssira, *D. Vasileiadou, S. Psoni, A. Syrmou, E. Kanavakis;*
Medical Genetics, University of Athens Medical School, "Aghia Sophia" Children's Hospital, Athens, Greece.

In developed countries, 1-3% of births involve some form of assisted reproductive technology (ART). However, ART has been associated with a 30-40% increased risk of major congenital anomalies, compared with natural conceptions.
Over a period of 10 years, 147 children and fetuses who had been artificially conceived were examined in our Medical Genetics Department.
Regarding the demographic features, 53.7% of the patients were male and 46.2% female. The median age at diagnosis was 19 months. The mean maternal age was 34.7 ± 5.5 (mean ± SD) and the mean paternal age was 38.7 ± 5.8 (mean ± SD).
Most patients presented with congenital anomalies, the most common being craniofacial, musculoskeletal and genitourinary. Psychomotor delay was reported in 51.02% of cases. Several patients were diagnosed with syndromes such as Sotos, Noonan, Down, Williams, Prader - Willi, Angelman, Kabuki or others. A positive family history was reported in 21.9% of cases.
In most cases (64%), a total of two embryos were transferred. Almost in all cases (96.7%), a cesarean section was performed, with the main reasons being premature rupture of membranes, IUGR or oligohydramnios. Perinatal complications occurred in 51.7% of cases and included respiratory distress syndrome, jaundice and neonatal infections.
The increased risk of congenital anomalies in children who have been artificially conceived has been partly attributed to the ART itself, micromanipulations during ICSI, periconceptional drug administration or underlying genetic reasons of infertility. Therefore, more research needs to be conducted in order to help counseling couples who are considering treatment for infertility.

P19.11

Atypical prenatal case of cat eye syndrome

*A. RECEVEUR[1], **G. JEDRASZAK**[1,2,3], S. KANAFANI[1], J. ANDRIEUX[4], M. MATHIEU[5], P. NAEPELS[6], H. SEVESTRE[7], B. DEMEER[5], T. DERY[5], G. MORIN[5], H. COPIN[1];*
[1]Laboratoire de cytogénétique, AMIENS, France, [2]Laboratoire de génétique moléculaire médicale, Amiens, France, [3]Unité de génétique clinique et oncogénétique, Amiens, France, [4]Laboratoire de génétique médicale, LILLE, France, [5]Unité de génétique clinique et oncogénétique, AMIENS, France, [6]Centre de gynécologie-obstétrique - Unité de diagnostic prénatal, AMIENS, France, [7]Service d'anatomie et de cytologie pathologiques, AMIENS, France.

Cat-Eye syndrome (CES) is a rare malformation syndrome mainly due to a partial tetrasomy of chromosome 22. CES is characterized by a high phenotypic variability. The main characteristic signs are : abnormal ears, coloboma, and anal malformations.
CES is often discovered postnatally when characteristic signs are associated. In the litterature, only one case was antenatally diagnosed based on ultrasonographic anomalies.
We report the second fetal case of CES who presented several signs at the ultrasound examination : intra-uterine growth retardation (cephalic circummference and femoral length below the 10th percentile), miroretrognathia, cerebellum hypoplasia, and low-set ears at the three-dimensional ultrasonography.
An amniocentesis was performed. The fetal karyotype was established using RHG banding and result was : 47,XX,+idic(22)(q11.21). This result has been confirmed by array-CGH, which concluded to a typical type I CES chromosome.
Fetal autopsy confirmed the ultrasonographic features. No coloboma and no anal malformation were found.
Fetal diagnosis of CES is difficult because of variability of the phenotype. Compared to the other reported cases, our observation is atypical. The fetus did not present coloboma or anal malformation. He had a cerebellum hypoplasia which was reported in one case only. Prenatal diagnosis of CES is even not easy because of difficulty to detect the characteristics signs at ultrasonography. This explains why only one prenatally case has been reported up today. On these two cases, ears anomalies detected on three-dimensional ultrasonography were crucial for the diagnosis.
Diagnosis of CES and other polymalformation syndromes will be facilitated by progress in fetal ultrasound examination.

Heterochromatin variants of chromosome 9: clinical aspects and method of molecular cytogenetic examination

***A. Šípek jr.**[1], A. Panczak[1], R. Mihalová[1], L. Hrčková[1], E. Suttrová[1], A. Šípek[2,3], P. Lonský[2], M. Janashia[1], M. Kohoutová[1];*
[1]Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Department of Medical Genetics, Pronatal Sanatorium, Prague, Czech Republic, [3]Department of Medical Genetics, Thomayer Hospital, Prague, Czech Republic.

Heterochromatin abnormalities of human chromosomes are mostly believed to be clinically insignificant variants of the human karyotype. However, several authors have studied the possible association of heterochromatin variants (including those of chromosome 9 which are the most common) with certain clinical diagnoses, primarily with reproduction failure (sterility and/or repeated abortions).
We provide an overview of diagnoses in the large group of 405 chromosome 9 variant carriers that were karyotyped between 1986 and 2012. Idiopathic sterility was the most common clinical indication with frequency 43.5%. In the control group of 700 individuals with normal karyotype (without any kind of variant), the referral incidence of idiopathic infertility was significantly lower - only 30.0% (p<0.0001).
We also present a special molecular cytogenetic procedure which we use for more precise analysis of heterochromatin area of chromosome 9. Three different FISH probes - centromeric alpha-satellite, centromeric III-DNA satellite and a specific BAC probe (hybridizing on 9p12 and 9q13 homologous sequences) - are involved. By this method we investigated in detail the chromosome 9 variant in 12 carriers. We have proven, that this molecular cytogenetic examination is able to distinguish among different (sub)variants of chromosome 9 much better than standard G-banding. Although believed to be harmless, the variants of chromosome 9 have been repeatedly mentioned as potentially associated with reproduction failure. Since the majority of these variants are undoubtedly truly benign, we present a possible tool for their further investigation.
This study was supported by the GAUK 523456 grant project.

P19.13

Detection of high recurrence risk ciliopathies in a cohort of intrauterine fetal death conceptuses of unknown cause: a functional genomic approach

*R. Oegema, L. van Unen, J. M. A. Verhagen, K. M. E. Diderich, M. L. T. van der Sterre, **G. M. S. Mancini**, F. W. Verheijen;*
ErasmusMC, Rotterdam, Netherlands.

The wide application of prenatal ultrasound often leads to the detection of multiple congenital anomalies and consequently to termination of pregnancy (TOP) without a definitive diagnosis.
Severe congenital anomalies at ultrasounds, such as (cranial) neural tube defects, ventriculomegaly, cerebellar and kidney dysplasia, skeletal abnormalities and heart-loop lateralization defects are also frequent in defects of the primary cilium (ciliopathies), mostly recessively inherited, such as Meckel syndrome or hydrolethalus syndrome, but establishing a diagnosis in a fetus can be challenging. Ciliopathies have an incidence of >1 in 1,000 conceptuses and around 2500 genes are expected to be related to function and/or structure of the cilia. We therefore sought to develop a diagnostic screening assay and subsequent workflow for ciliopathies in fetuses of pregnancies, terminated on the basis of the ultrasound findings. Initially, immunostaining of the primary cilium and basal body in cultured skin fibroblasts proved to accurately diagnose patients with known ciliopathies (such as Joubert syndrome, Meckel syndrome, Rotatin mutation). Additionally, Shh-mediated Gli response was used as functional test for cilia-related pathways and confidently detected patients with known mutations, even with minor/no cilia structural anomalies. In a cohort of TOP fetal fibroblasts derived from fetuses with above mentioned malformations, we detected a high percentage of structural and functional cilia abnormalities. In fetuses with undefined ciliopathy, this approach complements the use of targeted NGS panels for ciliopathy genes, useful for both patient selection and confirmation of genomic variants. This approach also detects high recurrence risk pregnancies, offering the possibility of early prenatal diagnosis.

P19.14

Managing a complex chromosomal rearrangement in prenatal diagnosis

***M. Volk**, Ž. I. Remec, K. Writzl, L. Lovrečić, B. Peterlin;*
Institute of Medical Genetics, UMC Ljubljana, Ljubljana, Slovenia.

Complex chromosomal rearrangements (CCR) are structural rearrangements, involving at least three breakpoints on two or more chromosomes. A de novo cytogenetically balanced CCR have been associated with increased risk for developmental delay/intellectual disability (DD/ID) and multiple congenital anomalies, however normal children have also been born. The risk increases with the number of breakpoints and is estimated to be approximately 3% per breakage.
Herein, we report on an amniocentesis performed because of increased nuchal translucency that revealed a cytogenetically de novo balanced complex translocation involving chromosome 7, 8 and 12 (46,XY,t(7;8;12)(q34;q21.1;q12)dn). Array CGH analysis revealed a 3.7Mb deletion of 12p12, unrelated to the breakpoint (arr 12p12.1(21,356,582-25,062,714)×1), which involved 8 genes (SLC1A2, RECQL, GYS2, LDHB, ABCC9, ST8SIA1, ETNK1 and SOX5). Deletions containing whole SOX5 and some adjacent genes have been associated with DD/ID, speech delay, dysmorphic features, skeletal abnormalities and congenital heart defects. The ultrasound scans (USS) of fetal morphology and heart were normal. Nevertheless, the risk for abnormal phenotype was high and the parents decided to terminate pregnancy. Post mortem examination was normal.
To our knowledge this is the first case of de novo 12p12.1 deletion in the prenatal setting. This report highlights the usefulness of array CGH for the specification of de novo CCR in prenatal diagnosis, facilitating the detection of other genomic imbalances and the establishment of risk for abnormal phenotype.

P19.15

5 probes PGD-FISH strategy for a surprising complex chromosomal rearrangement.

C. Retter, J. Lauer-Zillhardt, S. Casalanguida, C. Moutou, ***P. Gosset****;*
Laboratoire de Biologie de la Reproduction, CMCO - Hôpitaux Universitaires de Strasbourg, Schiltigheim, France.

Pre-implantation Genetic Diagnosis (PGD) can benefit to couples carrying chromosomal anomalies, to avoid the birth of children with imbalanced rearrangements.
Fluorescent in situ hybridisation (FISH) is the technique of choice to detect chromosome imbalances in one or two biopsied blastomeres. Usually, 2 probes are used for PGD of Robertsonian translocations and 3 for reciprocal ones. PGD is more difficult for complex chromosomal rearrangement (CCR) because more probes are required, simultaneously or sequentially, to detect all imbalances.
A couple was referred to our PGD centre for CCR. The woman carries a balanced three-break rearrangement, ISCN: 46,XX,t(4;11;6)(q28;q14;q16).
Five probes were combined to adjust our FISH technique: three directly fluorescent labelled probes on 11 centromere (blue), 11q (green), 6q (red) and two hapten-labelled probes on 6 centromere and 4q which are detected by fluorescents antibody (green) and streptavidin (red) in a second step. This set can identify any possible imbalance in the offspring.
When testing these probes on patient's lymphocytes chromosomes, we identified an unexpected additional anomaly: a small piece of the translocated 11q region was found inserted at the breakpoint of derivative chromosome 4. In total, this leads to a complex anomaly involving 5 breakpoints on 3 chromosomes. Here we report the workup for the final PGD test, combining only 5 probes but detecting almost all possible imbalances in embryos.

P19.16

Confined placental mosaicism and pregnancy outcome: a distinction needs to be made between types 2 and 3

J. Horovitz[1]*, J. Toutain*[2]*, F. Pelluard*[3]*, D. Lacombe*[2,4]*, R. Saura*[2]*;*
[1]*CHU Bordeaux, Gynécologie-obstétrique et médecine fœtale, Bordeaux, France,* [2]*CHU Bordeaux, Génétique médicale, Bordeaux, France,* [3]*CHU Bordeaux, Anatomo-pathologie, Bordeaux, France,* [4]*Univ. Bordeaux, Maladies Rares: Génétique et Métabolisme (MRGM), Bordeaux, France.*

Objective: To study the influence of types 2 and 3 confined placental mosaicism (CPM) on pregnancy outcome. *Method*: From 13 809 chorionic villus samplings (CVSs), karyotype after long-term cultured villi (LTC-villi) was systematically performed. Next, in case of suspicion of CPM, karyotype after short-term cultured villi (STC-villi) was established to define type 2 CPM (chromosomal abnormality limited to the mesenchymal core) or type 3 CPM (chromosomal abnormality found both in the cytotrophoblast and the mesenchymal core). Confirmatory amniocentesis was performed to exclude fetal mosaicism. Uniparental disomy (UPD) testing was carried out when the abnormal cell line involved chromosomes with imprinting genes. Fetal growth was assessed using term and birth weight, and adverse pregnancy outcomes were defined by the occurrence of fetal loss or perinatal death. Results were compared with those obtained in a control population of 198 patients. *Results:* Fifty-seven CPM cases were observed (57/13 809 = 0.41%) and of these, 37 were type 2 and 20 were type 3 CPM. Incidence of preterm infants, neonatal hypotrophy and adverse pregnancy outcome were comparable between patients in whom type 2 CPM was demonstrated and the control population. In contrast, for the type 3 CPM the incidence of these factors was higher than for the control population. *Conclusion:* When a CPM is suspected, it appears essential to determine type, since type 2 has no effect on fetal development and type 3 is associated with preterm infants, low birth weight and adverse pregnancy outcome, even in the absence of UPD.

Characterization of novel GNRHR gene mutations underlying congenital hypogonadotropic hypogonadism

K. Vaaralahti[1,2]*, J. Tommiska*[1,2]*, J. Känsäkoski*[1]*, E. Laitinen*[1,2]*, T. Raivio*[1,2]*;*
[1]*University of Helsinki, Institute of Biomedicine/Physiology, Helsinki, Finland,* [2]*Children's Hospital, Helsinki University Central Hospital, Helsinki, Finland.*

Mutations in GNRHR, the gene encoding for GnRH receptor, cause autosomal recessive form of normosmic congenital hypogonadotropic hypogonadism (nHH). Prevalence estimates of biallelic GNRHR mutations in nHH patients vary from 3.5 to 40%, and to date, 24 different mutations have been reported. Patients with biallelic GNRHR mutations display variable reproductive phenotypes ranging from severe hypogonadism to reversal of nHH later in life.
We are characterizing functional consequences of two recently identified GNRHR mutations. A heterozygous c.924_926delCTT (p.del309F) mutation, located in the 7th transmembrane-domain of the receptor, was first identified in a Finnish family, in which it segregated with delayed puberty. Subsequently, the same mutation was found in a compound heterozygous state (del309F/R262Q) in a Finnish male with nHH who underwent reversal of HH. The c.714T>G (p.L238R) mutation, located in the 3rd intracellular loop of GNRHR which is responsible for G-protein coupling, was found in a compound heterozygous (L238R/R262Q) state in a Finnish female nHH patient. Assessment of cell-surface expression, ligand-binding properties and intracellular signaling properties of the mutant receptors are on-going.
We expect that characterization of the functional properties of these mutations will help in understanding how these mutations contribute to the nHH phenotype of the patients and whether the del309F mutation alone is severe enough to cause delayed puberty. In addition, these results provide us with a better knowledge on the roles of different domains in receptor function.

Population-based carrier screening for Cystic Fibrosis in Sicily: Three years experience

C. Liuzzo*, I. Loddo, V. Procopio, M. A. La Rosa, L. Rigoli, C. Salpietro;*
UOC Genetics and Pediatric Immunology, University of Messina, Messina, Italy.

Background: Cystic Fibrosis (CF) is an inherited disease caused by mutations in the *CFTR* gene (OMIM #602421). In this study we report our cases performed during a 3-year period on couples as preconception carrier screening, or on infertile couples from Southern Italy (Sicily). The aim of this paper is to report our experience of carrier screening for CF.
Materials and methods: Data were collected from January 2010 through January 2013 on 295 individuals. Screening of the most important mutations and polymorphisms into the CFTR gene was performed by molecular analysis on strips (reverse dot blot).
Results: A total of 295 individuals were screened. Out of them, 275 were wild type (93,2%).
We identified 20 heterozygous carriers (6,8%) for the following gene mutations: F508del (8; 2,7%), N1303K (4), I148T (3), W1282X (1), G542X (1), 621+3 A>G (1), 711+1G>T (1), 3849+10kbC>T (1).
Poly-T variant in intron 8 (IVS-8 poly-T) was also analyzed and we found: 7T/7T (186), 7T/9T (73), 5T/7T (22), 5T/9T (6), 5T/5T (4), 9T/9T (4). 5T variant was carried by 28 individuals (9,5%).
Conclusion: To date, more than 1800 mutations and polymorphisms have been identified in the CFTR gene. The combination of various mutations can give different phenotypes. Polymorphisms associated with poly-T variant of the CFTR gene may have an important prognostic value.
The goal of CF carrier screening is to identify couples at risk. Genetic counseling is important to discern whether the combination of mutations and variants would cause classic or atypical CF.

Cystic Fibrosis (CF) is the most common lethal autosomal recessive disease affecting the Caucasian population. For couples at risk of having children affected with CF, preimplantation genetic diagnosis (PGD) is an alternati-

ve to prenatal diagnosis, giving couples the opportunity to have unaffected children without having to consider termination of pregnancy. The rapid increase of PGD over the last 20 years and the wide practical experience of different PGD laboratories over the world on CF, one of the most common indication of PGD, prompted the EuroGentest Network (www.eurogentest.org) to grant the organization a meeting dedicated to establish European Best Practice Guidelines for CF-PGD. Even though general best practice guidelines for amplification-based PGD have been already established by ESHRE (European Society of Human Reproduction and Embryology), the goal of this meeting was to edit CF-specific guidelines in order to harmonize inclusion criteria, genetic counselling, PGD strategy and technical protocols, and to provide the high standards of result reporting, across Europe (EGT2, Unit 3, WP 10). Sixteen experts in PGD and molecular diagnosis of CF from 7 countries attended the meeting, which was held in Montpellier, France, on December 14th 2011. Several topics were discussed and focused on mutation nomenclature, inclusion criteria (according to severity of mutations), genetic counselling (according to transferable embryos), PGD strategy (direct and/or indirect diagnosis) and results reporting (there is currently no formal consensus regarding the PGD reports, as it depends on legislation of each country). Hereby we present a summary of the consensus achieved.

OOBJECTIVE: To determine the incidence of abnormal array CGH and Noonan syndrome spectrum mutations in fetal nuchal cystic hygroma with a normal karyotype.
METHODS: We analyzed the results of array CGH and DNA mutation analysis for Noonan syndrome spectrum on cases with fetal nuchal cystic hygroma and normal karyotypes, detected prenatally on 11-14 weeks ultrasound, between January 2011 to December 2012.
RESULTS: 49 cases of fetal cystic hygroma with normal karyotypes were included in the data collection. 46 cases had DNA analysis for both Noonan syndrome spectrum and microarray analysis. In 3 aCGH was not done since a mutation was detected on DNA analysis on Noonan syndrome spectrum.
6/49 (12.2%) were found to have mutations associated Noonan syndrome spectrum: 2 PTPN11, 2 RAF 1, 1 SOS1 and 1 MAP2K1 mutations. In addition a novel missense change, M117R was identified in the BRAF gene, predicted to be a benign variant. 2/46 (4.3%) cases were identified as having clinically significant array CGH abnormalities.
CONCLUSION: In our population with karyotypically normal fetal nuchal cystic hygroma detected prenatally 12.2 % were found to have a mutation in the Noonan syndrome spectrum and 4.3% were found to have aCGH abnormalities.

Circulating fetal DNA (cfDNA) constitutes approximately 6-10% of the cell-free DNA in maternal plasma and is a proper source of fetal material for non-invasive prenatal diagnosis (NIDP). Since 2008, a routine facility for prenatal fetal sex determination based upon the detection of Y chromosome-specific gene SRY by quantitative PCR (qPCR) has been proposed in Cochin hospital (AP-HP, Paris, France). However, cfDNA circulating concentrations are close to the detection limits of PCR methods, especially during first weeks of pregnancy (<7 weeks). The objective of this study was to determine the suitability and reliability of using digital PCR (dPCR) for NIPD of fetal gender against already established qPCR Taqman assay. The fractional cfDNA concentration was assessed for each case, and the male DNA was detected and/or quantified with both standard qPCR and dPCR, which were compared for sensitivity and specificity. Fetal gender was confirmed by the result of ultrasound observation. Until now, fetal gender was determined correctly in 100% of the cases with cfDNA concentrations >7% using either method, but dPCR allowed a more accurate quantification. We confirm that, after an essential step of optimization of the fractional fetal DNA concentration, digital PCR can be used successfully for non invasive fetal sex determination, and may be adapted for single gene disorder detection.

P19.22

Reduction of bias in non-invasive prenatal karyotyping

K. Karlsson, *S. Linnarsson;*
Karolinska Institutet, Stockholm, Sweden.

Karyotyping for trisomy aberrations in non-invasive prenatal diagnostics using maternal cell free DNA (cfDNA) has proven to be difficult. There are probability tests on the market, but still no diagnostic test. The main problem is to distinguish fetal cfDNA from the large background of maternal cfDNA. The bias inherent in current library preparation methods, and especially library amplification, prohibits accurate testing.
We have developed a method reduce amplification bias by making all molecules unique before library amplification. This can be done either by attaching a unique molecular identifier (UMI), or by diluting the sample so that each molecule gets a unique starting position with high probability. The library is then amplified and sequenced to a depth where each molecule is seen at least two times, to make sure that all molecules present in the pre-amplified library are seen.
Using UMI we have shown that we can remove a large part of the GC bias from amplification and we get an even distribution of reads on all chromosomes including high GC content chromosome 19 and low GC content chromosome 13, not just from chromosomes with a normal GC distribution (e.g. chr 21). We have also shown that using UMI we can distingiush fetal trisomy samples down to 3% fetal cfDNA content.

Fetoplacental discrepancy involving complex structural rearrangement of chromosome 13 : first case of constitutionnal chromothripsis ascertained by prenatal diagnosis

N. Marle[1,2], *D. Sanlaville*[3], *A. Mosca-Boidron*[1,2], *P. Callier*[1,2], *C. Thauvin-Robinet*[4,2], *S. El Chehadeh*[4,2], *S. Pigeonnat*[5], *C. Ragon*[1,2], *M. Payet*[1,2], *N. Laurent*[5], *T. Rousseau*[6], *L. Faivre*[4,2], *F. Mugneret*[1];

[1]*Laboratoire de Cytogénétique, CHU Le Bocage, Dijon, France,* [2]*Equipe GAD EA 4271, IFR Santé STIC, Université de Bourgogne, Dijon, France,* [3]*Laboratoire de Cytogénétique Constitutionnelle, CHU de Lyon-GH Est, Lyon, France,* [4]*Département de Génétique, Hôpital d'Enfants, Dijon, France,* [5]*Laboratoire d'Anatomo-Pathologie, CHU Le Bocage, Dijon, France,* [6]*Maternité du Bocage, Dijon, France.*

Karyotype disparities between cytotrophoblast and fetal cells are detected in 1 to 2% of pregnancies undergoing first-trimester chorionic villi sampling (CVS). Cases involving structural rearrangement are very rare.
In the present report, CVS was performed on a 31-year-old woman because of a 3,37 mm cystic hygroma at 15 weeks of gestation (WG). Direct preparations showed a female karyotype harboring a robertsonian translocation between chromosomes 13 and 15 with duplication of the der(13;15), leading to trisomy 13 and trisomy 15 : 46,XX,rob(q10;q10),+der(13;15)(q10;q10). Cytogenetics analysis after long-term CVS culture displayed balanced karyotype with rob(13;15), except for one metaphase with supernumerary chromosome 13 : 45,XX,rob(13;15)(q10;q10)[20]/46,idem,+13[1]. Mosaic trisomy 13 was confirmed on FISH analysis (15% of nuclei). Amniocentesis was therefore performed and karyotype from amniocytes showed a robertsonian translocation between a structurally abnormal chromosome 13 and a chromosome 15. Array-CGH analysis (Agilent®, 4x44K) performed

on DNA extracted from amniotic fluid cell cultures confirmed the highly complex rearrangement of chromosome 13 with seven duplicated regions and four deleted regions.
After genetic counselling, parents opted for termination of the pregnancy at 19 WG. Fetal autopsy showed a eutrophic female fetus presenting with dysmorphic features, cerebral abnormalities, congenital heart defect with transposition of the great vessels and skeletal abnormalities.
Recently, it has been suggested that chromothripsis, a chromosome catastrophe phenomenon described in 2%-3% of cancers, in which numerous genomic rearrangements are acquired in one single catastrophic event, could explain constitutional complex genomic rearrangements. Thereby, this report could be the first case of constitutional chromothripsis ascertained in prenatal.

P19.24
N680S polymorphism on the FSHR gene and its effect on ovarian donor follicle stimulating hormone stimulation.

J. A. Ortiz[1], *A. Turienzo*[1], *B. Lledo*[1], *R. Morales*[1], *J. Guerrero*[2], *J. Ten*[2], *J. Llacer*[2], *R. Bernabeu*[2];
[1]*INSTITUTO BERNABEU BIOTECH, Alicante, Spain,* [2]*INSTITUTO BERNABEU, Alicante, Spain.*

INTRODUCTION: Genetic factors could explain differences in response to drugs. Clinical studies have demonstrated that N680S polymorphism on FSHR gene determines ovarian response to FSH stimulation in patients undergoing IVF. Patients with the S680 allele need more FSH during the stimulation phase. The aim of this work was Investigate whether N680S FSHR polymorphism has a predictive value for ovarian response to stimulation with gonadotropins and cycle outcome in our egg donor program.
MATERIAL AND METHODS: FSHR polymorphism N680S has been studied in 145 oocyte donors at Instituto Bernabeu and underwent ovarian stimulation (n=355). The main outcome measures were oocyte yield, stimulation days, gonadotropin dosages, biochemical pregnancy, ongoing pregnancy and miscarriage rates.
RESULTS: Significant differences were reported in antral follicles count (16.5 + 5.0 for NN, 14.5+4.7 for NS and 14.1+3.8 for SS), number of eggs retrieved (21.5 + 9.2 for NN, 18.5 + 8.2 for NS and 19.8 + 8.9 for SS) and gonadotropin doses (2098.5 + 639.4 IU for NN, 2023 +490.1 IU for NS and 2149.5 + 552.3 IU for SS) between genotypes. Differences in cycle outcome were not affected by the N680S polymorphism on FSHR gene.
DISCUSSION: In spite of the final clinical outcome is not different, this investigation reveals that in a population of fertile egg donors, FSHR gene polymorphism at position 680 is associated with different ovarian response to COH. Genotyping FSHR N680S together with some additional markers may therefore provide a means of identifying a group of poor responders before infertility treatment is initiated.

P19.25
Study of triple CGG repeats (*FMR1* gene) in 157 patients with ovarian failure of unknown origin

M. Tejada[1], *H. Maortua*[1], *R. Mendoza*[2], *B. Prieto*[2], *C. Martinez-Bouzas*[1], *M. Díez-Zapirain*[2], *N. Martínez-Zilloniz*[2], *R. Matorras*[2];
[1]*Molecular Genetics Laboratory, Genetics Service, BioCruces Health Research Institute, Cruces University Hospital, Barakaldo-Bizkaia, Spain,* [2]*Human Reproduction Unit, BioCruces Health Research Institute, Cruces University Hospital, Barakaldo-Bizkaia, Spain.*

Fragile X-associated primary ovarian insufficiency (FXPOI) is characterized by a large spectrum of ovarian dysfunction phenotypes and possible early menopause as the end stage. FXPOI is due to a premutation (PM) - 55 to 200 CGGs- in the *FMR1* gene and recent studies have even suggested that women with ovarian failure might be at risk of carrying alleles in the intermediate range.
This study was designed in order to find out the frequency of PM and intermediate alleles in our population of women with different types of ovarian failure.
We studied 157 women with ovarian failure, 67 of them already had early menopause and the others still don't. All participants were informed regarding the purpose of the study and signed the written informed consent.
DNA from patients was analysed using a commercial triplet CGG assay (AmplideX FMR1 PCR kit from Asuragen).
Nine (5,73%) of the 157 women studied had FMR1 alleles >44 repeats; five of them (3,18%) with PM and four (2,55%) with intermediate alleles. Three of the women with PM (95, 88 and 75 CGG repeats) presented with a very early menopause (21, 28 and 28 years old respectively). The other two women with PM (64 and 56 CGG repeats) had an ovarian poor response.
This study demonstrates that women in the midsize range of the PM have the highest risk of having FXPOI and the need to study the triplet CGG repeat in patients with ovarian failure and/or early menopause.
Work financially supported: FIS (ISCIII) grant No. PI10/00550.

P19.26
Paternal *NF1* germ cell mosaicism: should parental sperm analysis be offered for recurrence risk assessment in de novo cases of NF1?

A. Wernstedt[1], *F. Laccone*[2], *S. Tinschert*[1], *J. Zschocke*[1], ***K. Wimmer***[1];
[1]*Division Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [2]*Institute of Medical Genetics, Medical University Vienna, Vienna, Austria.*

The neurofibromatosis type 1 (*NF1*) gene exhibits one of the highest mutation rates of human disease genes, and ~ 50% of NF1 index patients occur sporadically. At least 10% of them are suspected mosaics. Somatic and gonado-somatic NF1 mosaicism may clinically present as (mild) generalized, segmental or oligo-symptomatic NF1. However, germline mosaicism typically only comes to attention in families with more than one affected child born to unaffected parents. Very few of such families have been described and only in two of them germline mosaicism was molecularly confirmed.
We identified a third case in the course of prenatal testing. The first child of unaffected parents was diagnosed with NF1 caused by a recurrent *NF1* mutation (p.Arg304*). Having been made aware of the rare possibility of germline mosaicism, the couple opted for prenatal testing in the second pregnancy despite the absence of the mutation in their blood lymphocytes. Unexpectedly, the *NF1* mutation p.Arg304* was also present in chorionic villi sampling of the second pregnancy. Sanger sequencing confirmed presence of the mutation in the father's sperm cells. Quantitative evaluation showed that ~9% of sperm cells carried the mutation. Even a more sensitive allele-specific PCR-assay was unable to detect the mutation in somatic cells of the father's blood, buccal mucosa and urothel.
The majority of intragenic *NF1* mutations are expected to arise in paternal germ cells. Hence, offering analysis of the father's spermatozoa should improve recurrence risk assessment in future cases and will uncover the frequency of NF1 germline mosaicism.

Mondor, Créteil, France,* [8]*Unité de Fœtopathologie, Hôpitaux Universitaires Paris-Sud, Site Antoine Béclère, Clamart, France,* [9]*Service de Gynécologie Obstétrique, Hôpital Antoine Béclère, Clamart, France.*

HMGA2 is known to have multiple functions in development and cellular growth. Here we report the prenatal detection of its deletion, associated with a complex chromosomal rearrangement, in a fetus with growth delay and phenotypic abnormalities.
A nonconsanguineous couple was referred to our center at 30 weeks of gestation after an ultrasound revealing growth retardation and bilateral cataract. Cytogenetic analyses revealed a complex *de novo* rearrangement. After genetic counseling and according to the French law the pregnancy was terminated at 32.5 weeks of gestation. Fetopathologic examination confirmed ultrasound abnormalities.
Standard karyotype and FISH analyses on amniotic fluid revealed a complex *de novo* translocation, resulting in a formula 46,XY,t(1;12;14)(q42;q14;q32).

CGH-array study showed one significant deletion of 387Kb on chromosome 12 in q14.3 only 200 to 700Kb distant from the breakpoint in 12q14, that encompassed the *HMGA2* gene and occurred *de novo*. To date, this is the smallest described, that confirms the already suspected role of *HMGA2* loss of function in growth retardation.
The link between cataract and genotype is less easy to draw. Among the genes disrupted by the breakpoint in 12q14, *GRIP1* has been associated with mice abnormal eye development, including lens degeneration (Schwiergiel *et al* 2000). Interestingly enough, *HMGA2* could also be involved: Peng *et al* (2012) showed a decreased *HMGA2* expression in elderly's lens, correlated with the severity of lens opacity, and Lord-Grignon *et al* (2006) identified *HMGA2* expression in the mice developing lens. Further studies are in process to better determine correlation between genotype and lens opacification.

P19.28
Severe prenatal renal anomalies associated with mutations *HNF1B* and *PAX2* genes

L. Madariaga[1], *V. Morinière*[1,2], *C. Antignac*[1,2], *T. Attié-Bitach*[1], *R. Salomon*[1,3,2], *S. SoFFœt*[4], *L. Heidet*[1,2];
[1]*Hôpital Necker-Enfants Malades, Paris, France,* [2]*Centre de Réf des Maladies Rénales Héréditaires (MARHEA), Paris, France,* [3]*Université Paris Descartes, Paris, France,* [4]*SOFFOET, Paris and other cities, France.*

Introduction: Mutations in *HNF1B* and *PAX2* can be associated with congenital anomalies of the kidney and urinary tract of variable severity and with extra-renal anomalies.
The aim of our study was to estimate the prevalence of these mutations in a series of 103 foetuses with severe isolated prenatal renal anomalies, which led to termination of pregnancy, and to describe associated extra-renal anomalies and genotype-phenotype correlations.
Patients: Renal phenotypes of the 103 foetuses were the following: bilateral multicystic dysplasia in 22, bilateral dysplasia with cysts in 24, bilateral hypodysplasia in 5, a combination of the previous phenotypes in 5, unilateral agenesis in 18 and bilateral agenesis in 27.
HNF1B was analyzed in 90 unrelated foetuses. A mutation was identified in 12 cases from 11 unrelated families: 3 complete and 1 partial heterozygous deletions, and 8 point mutations. Parents were tested 9 times: mutations were inherited in 6 cases.
PAX2 was tested in 75 unrelated foetuses. A point mutation was identified in 4 cases. All were inherited, one parent carrying a somatic mosaicism for the mutation.
Conclusions: Our study shows that mutations in genes involved in syndromic CAKUT with a Mendelian inheritance are not rare in fetal cases with severe CAKUT appearing as isolated at prenatal US. The severity of the renal phenotype was not correlated with the type or the position of the mutation. This phenotypic variability makes genetic counselling particularly difficult in the inherited forms.

Understanding the genetic mechanisms of intra-uterine growth retardation (IUGR) constitutes a major issue in prenatal diagnosis and fetal medicine. We report the observation of the second pregnancy of a non-consanguineous healthy couple. The beginning of the pregnancy was uneventful. No drug or toxic was reported. Fetal hypotrophy (biometry below the 5th percentile) was detected at 23 weeks of amenorrhea. Sonographic examination was normal furthermore and doppler investigations excluded a vascular etiology. Karyotype from amniocytes and *in situ* hybridization of 4p16.3 locus (Wolf-Hirschhorn syndrome) were performed at 28 WA and showed normal results.
A fetal CGH-array was decided to be performed by the Multidisciplinary Centre for Prenatal Diagnosis. Micro-Array using Affymetrix Cytoscan HD Array detected a *de novo* 5.2 Mb microdeletion arr[hg19]3q27.1q28(182.877.291-188.090.034)x1 (3q26.33) to 185.786.898
(3q27.2). This deletion was confirmed by FISH and occurred *de novo*. After information, the parents opted for termination of pregnancy.
To our knowledge, we describe here the first prenatal case of 3q27.1q28 microdeletion. Very recently, a first report of three children has been reported about three children with growth retardation and moderate to severe mental retardation and an overlapping 3q26.33-3q27.2 microdeletion. This disorder is considered to constitute a possible contiguous gene deletion. At least 40 genes are located within this region, involved in brain development and function, but also body growth.
Finally, this report raises the question of the diffusion of micro-arrays technology in prenatal diagnosis, not only for polymalformative fetuses, but also for diagnostic strategy of isolated IUGR.

P19.30
First case of prenatal inv dup del 11q in a fetus presented with isolated growth retardation.

S. Bacrot, *C. Bauman, C. Dupont, I. Batout, A. Verloes, B. Benzacken, A. Tabet;*
Hopital Robert Debré, Paris, France.

Interstitial inverted duplication associated with terminal deletion (inv dup del), have been identified on an increasing number of chromosomes arms. We report on the first prenatal case of inv dup del involving the long arm of chromosome 11 in a fetus presenting isolated intra uterine growth retardation (IUGR).
An amniotic fluid exam was performed at 33 SA because of an IUGR. The fetal karyotype combined with FISH studies showed a subtelomeric 11q deletion associated with additional material on the long arm of chromosome 11 derived from the chromosome 11. After reserved genetic counselling, a termination of pregnancy was proposed. Nevertheless, the mother gave birth prematurely at 36 weeks to a boy presenting growth retardation, microcephaly and joint contractures. At the age of six months, we also noted developmental delay and minor dysmorphic features. To map the chromosomal rearrangement, a SNP-array (HumanCytoSNP-12, Illumina) analysis on post natal sample was performed. It revealed a 1.45 Mb telomeric deletion associated with an adjacent 11q24.1q25 duplication of 10.26 Mb.
Distal 11q deletions are involved in Jacobsen Syndrome, a well known contiguous gene syndrome.
Regarding the duplication, only ten cases of isolated 11q duplication have been reported, six overlapped with the duplication of our patient. Common findings among these patients include developmental delay, growth retardation, microcephaly, abnormal ears, microretrognathia, and congenital heart defect.
We compare the clinical features of our patient with abnormalities previously described in overlapping 11q rearrangements to better determine the correlation genotype-phenotype.

P19.31
X chromosome related heterotaxy in a family with two consecutive Ivemark syndrome pregnancy

J. Schönléber[1], *A. Nemes*[2], *J. Hajdú*[1], *J. Rigó Jr*[1], *B. Nagy*[1], ***L. Lázár***[1];
[1]*Semmelweis University, Budapest, Hungary,* [2]*County Hospital, Kecskemét, Hungary.*

Objective: Familiar heterotaxy is a genetically heterogeneous condition and could be inherited on autosomal dominant, autosomal recessive, or an X-linked trait. Heterotaxy is defined as any deviation from the normal situs solitus. A family with two consecutive pregnancies with male fetus having signs of heterotaxy on ultrasound examination visited our department.
Materials and methods: During the second trimester ultrasound screening (20week of gestation) fetal heterotaxy was revealed in two consecutive pregnancies of the same couple. Fetal echocardiography was also performed, where severe cardiac malformation was found. Both pregnancy was terminated and fetopathological examination was performed. DNA was iso-

lated from the fetus. Protein coding exons and immediate flanking intronic regions og the ZIC3 gene where sequenced.
Results: In both pregnancies the ultrasound anatomy of the fetus showed signs of heterotaxy: the fetal heart on right side of the chest, fetal stomac on the right side of abdomen etc. Fetal echocardiography showed malposition of great arteries, atrioventricular septal deffect. During fetopathological investigation all this conditions where prooven. By sequencing of ZIC3gene c.869delC was detected in the exon 1 of the gene, the c.869delC.
Conclusion: The hemizygous mutation in the ZIC3 gene could be behind the heterotaxy observed in the family. Prenatal diagnosis from the CVS sample at 12th gestational week could be used in the next pregnancy to detect the observed genetic alteration.

Identification of a human fertility gene required for normal sperm number in semen

M. J. Mitchell[1], *E. Streichemberger*[1], *N. Eudes*[1], *G. Longepied*[1], *C. Metzler-Guillemain*[1,2], *N. Lévy*[1], *V. Delague*[1], *A. Megarbané*[3];
[1]*Inserm - Aix Marseille Université UMR_S 910, Marseille, France,* [2]*Hôpital de la Conception, Marseille, France,* [3]*Université Saint Joseph, Beirut, Lebanon.*

It is estimated that 10% of couples are unable to conceive a child without medical intervention, and that in almost half of these cases a sign of male factor infertility is present. Despite its high prevalence, few of the genes involved in male infertility have been identified, and consequently, in most cases, the risks associated with medically assisted reproduction cannot be fully assessed. We have studied a consanguineous family from the Lebanon in which five of the six sons have severe oligozoospermia, 50 000 sperm per ml (normal = > 20 million sperm per ml). Genotyping at the French National Genotyping Centre (CNG) identified a critical region of homozygosity on chromosome 15, containing 134 genes (LOD score is Z=3.1 at θ=0.01). Sequencing the entire region revealed a single coding variant that was homozygous in the five oligozoospermic sons, heterozygous in the father and absent from public databases or 190 Lebanese controls. This variant introduces a stop codon that is predicted to ablate expression of the protein. We have named this gene OZF1 (Oligozoospermia Factor 1. Preliminary expression analysis reveals that OZF1 is expressed predominately in the testis, and in the mouse its transcription increases as meiotic stages populate the post-natal testis. We conclude that loss of OZF1 expression during human spermatogenesis results in oligozoospermia, possibly through an effect on meiotic germ cell progression.

Genetic screening in Tunisian globozoospermic men: chromosomal abnormalities, Y chromosomal deletions and screening for mutations of DPY19L2. globozoospermic Tunisian men: chromosomal abnormalities, Y chromosomal deletions and screening for mutations of DPY19L2.

A. Amouri[1], *M. Ben Khelifa*[1], *W. Hammami*[1], *O. Kilani*[1], *W. Ayed*[1], *H. Elloumi*[2], *S. Abdelhak*[3], *A. Zhioua*[2];
[1]*Cytogenetics Department and Laboratory of Biomedical Genomics and Oncogenetics, Institut Pasteur de Tunis, Tunis, Tunisia,* [2]*Centre de Biologie de la Reproduction, Hôpital Aziza-Othmana, La Kasba, Tunis, Tunisia,* [3]*Laboratory of Biomedical Genomics and Oncogenetics, Institut Pasteur de Tunis, Tunis, Tunisia.*

Infertility is an important health problem affecting 10-15% of couples. The contribution of male factors to infertility is about 30-50%. Recent studies have indicated that both environmental and genetic factors are involved in the decline of reproductivity in males. The main genetic factors playing a role in male infertility are constitutional chromosomal abnormalities and Y chromosomal microdeletions. Among the male factors, globozoospermia is a rare type of teratozoospermia accounting for <0.1% of male infertility. Mutations or deletions in three genes, SPATA16, PICK1 and DPY19L2, have been shown to be responsible for globozoospermia.
In this cohort study, ten globozoospermic patients from 20 independent families were recruited during routine infertility treatment in a Tunisiain fertility center. The semen samples from these were analyzed according to the WHO criteria. Their constitutional blood karyotype was performed on cultured lymphocytes, according to standard techniques. Microdeletion analysis of the Y chromosomes used a sequence tagged site-polymerase chain reaction technique. DPY19L2 is the third gene identified as being associated with globozoospermia and the most frequently mutated in this phenotype. In order to better estimate its contribution, we performed PCR and found that four of them were homozygous for the DPY19L2 deletion.
A molecular diagnosis can now be proposed to affected men; the presence of the deletion confirms the diagnosis of globozoospermia and assigns a poor prognosis for the success of in vitro fertilization. The realization of a molecular diagnosis for globozoospermic men would permit providers to adopt the best course of treatment for these patients.

P19.34
A retrospective study of outcomes of 223 cases of prenatally detected micrognathia at two tertiary obstetric centres in London.

H. E. Grote[1], *M. Koopmans*[1,2], *L. C. Poon*[3], *B. Thilaganathan*[4], *S. Mansour*[1], *T. Homfray*[1];
[1]*South West Thames Regional Genetics Service. St. George's University of London., London, United Kingdom,* [2]*Department of Clinical Genetics. Leiden University Medical Centre, Leiden., Netherlands,* [3]*Maternal and Fetal Medicine Unit. King's College Hospital., London, United Kingdom,* [4]*Fetal Medicine Unit. St. George's Hospital., London, United Kingdom.*

Micrognathia is a feature common to a number of congenital syndromes but it can also occur in isolation. Although associated defects are correlated with a poorer outcome, accurately predicting outcomes of fetuses with isolated micrognathia on prenatal scans is challenging, owing to the paucity of literature on this subject. We undertook a retrospective analysis of 223 cases of micrognathia detected on antenatal scans at two tertiary obstetric units. This represents the largest reported case series of prenatally detected micrognathia.
21 cases (9%) had isolated micrognathia, of which there were 12 live births, 3 terminations and 6 cases with unknown outcome. Karyotyping was undertaken in 9 cases; 8 were normal. Of the 12 live births 7 were found to have Pierre-Robin sequence postnatally, but no additional anomalies.
The remaining 201 (90%) cases of micrognathia occurred in conjunction with other anomalies. 130 cases were terminated, and another 22 ended in intrauterine death. There were 29 live births, of which 13 died at less than one week of age. Summary results of karyotyping are tabulated below.

Karyotype result of fetuses with multiple anomalies	Number
Trisomy 18	36
Trisomy 13	6
Trisomy 9	2
Trisomy 22	2
Trisomy 15	1
Trisomy 21	1
Triploidy	5
Tetrasomy	1
Other chromosomal deletions/ duplications	14
Normal	79
Not done	54

These findings indicate that prenatally detected micrognathia is an ominous finding, which warrants careful examination of the fetus and growth parameters. However, in cases of isolated micrognathia, with a normal karyotype, a positive prognosis can be offered.

Introduction: Studies of eutopic and ectopic endometria have suggested microRNAs (miRNAs) are involved in endometriosis development, but the full miRNome of eutopic and ectopic endometria is a field that needs to be explored. In this study we used high-throughput sequencing to characterize miRNA expression in endometriosis foci by comparing adjacent healthy tissue to ectopic endometrium of the same patient. Also, our study aimed to reveal in what extent the miRNA expression profile in endometriosis foci differs from eutopic endometrium.

Material and methods: Deep sequencing technology was used to obtain miRNome data of five peritoneal endometriotic foci, five adjacent healthy tissues and two eutopic endometrial samples of two women with moderate-severe endometriosis. To test for differential miRNA expression between endometriosis foci, healthy tissue and eutopic endometrium, the edgeR package for R was used. miRNAs with adjusted p-value ($p < 0.05$) and false discovery rate (FDR) < 0.1 were considered statistically significant. Differentially expressed miRNAs were further validated using qRT- PCR.
Results: Endometriotic foci and adjacent healthy tissue had similar miRNA expression patterns that differed largely from eutopic endometrium. Two miRNAs (both p-values< 0.001, FDR 0.004) were significantly up-regulated in endometriotic foci compared to adjacent healthy tissues. Validation analysis confirmed differential expression of these miRNAs in endometriotic foci.
Conclusions: The comparision between endometriotic foci and healthy tissues revealed two miRNAs that could play an important role in the pathogenesis of endometriosis. miRNA expression profile of endometriosis foci and adjacent healthy tissue is more similar compared to endometrial miRNA profile.

The expression of miR-200 family in the endometrium of women with and without endometriosis

K. Vaidla[1,2], *M. Saare*[1,2,3], *A. Roost*[2], *A. Salumets*[1,2,3], *M. Peters*[1,2];
[1]*University of Tartu, Department of Obstetrics and Gynecology, Tartu, Estonia,* [2]*Competence Centre on Reproductive Medicine and Biology, Tartu, Estonia,* [3]*University of Tartu, Institute of Biomedicine, Tartu, Estonia.*

A number of studies have shown that miRNAs, including the miR-200 family, are aberrantly expressed in endometriosis and are therefore believed to play a role in the pathogenesis of the disease. Our study aimed to determine the expression levels of miRNAs from miR-200 family in the endometrium of women with endometriosis compared to healthy controls. The expression levels of miR-200a, miR-200b and miR-141 in the endometrial biopsies from patients with endometriosis and healthy women were determined by real time PCR using TaqMan microRNA assays. Endometrial biopsies were matched by menstrual cycle day. Our results indicated that the endometrial expression of studied miRNAs varied greatly between the individuals. No statistically significant differences in miRNA expression levels between the endometria from women with and without endometriosis were observed. Based on our results, we suggest that endometrial expression of miR-200 family members does not play a crucial role in the pathogenesis of endometriosis.

P19.37
Screening for and functional assessment of miscarriage CNVs

J. Wen[1], *C. Hanna*[1], *S. Martell*[1], *P. Leung*[1], *W. Robinson*[1], *M. Stephenson*[2], ***E. Rajcan-Separovic***[1];
[1]*University of British Columbia, Vancouver, BC, Canada,* [2]*University of Chicago, Chicago, IL, United States.*

Detection of unique DNA copy number variations (CNVs) in miscarriages suggests that their integral genes have a role in maintaining early pregnancy. Previously, we identified 11 unique miscarriage CNVs in ~30% of studied miscarriages, which were predominantly familial in origin. Using qPCR, we have now screened for copy number changes of 13 genes from these miscarriage CNVs in 250 couples with recurrent miscarriage (RM). RM couples showed more frequent copy number changes in *PNPLA4* (Xp22.31) (0.6% vs 0.3%) and *STX6* (1q25.3) (0.2% vs 0%) compared to controls. For three genes (*TIMP2*, *OFD1* and *TRAPP2C*) the RNA and protein expression was altered in miscarriages that had CNVs, in keeping with their genomic copy number changes. In depth analysis of a maternal duplication disrupting the *TIMP2* gene was performed in four miscarriages from one female with RM, due to the involvement of *TIMP2* in placental remodeling and embryo development, and the previous suggestion that it is maternally expressed in placenta. Methylation of upstream promoter sites in the miscarriages and control early pregnancy tissues, as well allelic expression levels, are consistent with preferential maternal expression of the *TIMP2* gene in early pregnancy; however, the regulation of its expression and imprinting appears complex. Further functional studies of miscarriage CNVs may elucidate their role in causing miscarriage.

A monozygotic twin with TRAP sequence and an incomplete mitotic trisomy rescue.

M. J. V. Hoffer[1], *A. C. J. Gijsbers*[1], *H. A. Zondervan*[2], *S. Chitoe-Ramawadhdoebe*[1], *L. Groenewegen*[1], *K. Theunissen*[3], *E. de Wilt*[1], *P. van Bunderen*[1], *E. Boon*[1], *N. S. den Hollander*[1], *F. J. Klumper*[3];
[1]*Dept. of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [2]*Dept. of Gynaecology and Obstetrics, Rijnstate Hospital, Arnhem, Netherlands,* [3]*Dept. of Obstetrics, Leiden University Medical Center, Leiden, Netherlands.*

Here we report a case where two rare events occurred almost simultaneously during the first 2 weeks of pregnancy.
A 38 old woman with a monozygotic twin pregnancy was referred because structural ultrasound analysis at 12 weeks of gestation revealed a twin reversed arterial perfusion (TRAP). In addition, large transsonic spaces without any flow were present in the placenta and the fetus showed intra-uterine growth retardation without any additional structural abnormalities. The QF-PCR revealed an additional, relatively lower peaks for the chromosome 18 markers, suggestive for low mosaicism for trisomy 18. Fluorescence in situ hybridization with uncultured amniocytes revealed trisomy 18 in 14% of the cells. In addition, QF-PCR analysis of both parents showed maternal uniparental disomy for chromosome 18 in the cell line with disomy 18. With karyotyping we could not confirm the trisomy 18 in 28 colonies. The pregnancy was terminated and follow-up studies were performed. QF-PCR analysis revealed a trisomy 18 in the placenta, a high mosaicism for trisomy 18 in the acardiacus and confirmed low mosaicism for trisomy 18 in several tissues of the pump twin.
We describe a complex case where in the first 2 weeks after conception two separate events occurred. The combined results from different diagnostic tests strongly suggest that first a trisomy rescue occurred in an early post-zygotic mitotic division followed by a division of the zygote which lead to the formation of a monochorionic, diamniotic twin with trisomy 18 mosaicism.

Reproductive options for women with affected offspring due to an mtDNA mutation

S. C. E. H. Sallevelt[1], *D. M. E. I. Hellebrekers*[1], *J. C. F. M. Dreesen*[1,2], *M. Drüsedau*[1], *S. Spierts*[1], *A. T. M. Hendrickx*[1], *C. M. H. Calis*[1], *I. F. M. de Coo*[3], *J. P. M. Geraedts*[1,2], *C. E. M. de Die-Smulders*[1,2], *H. J. M. Smeets*[1,2];
[1]*Department of Clinical Genetics, Maastricht University Medical Centre+, Maastricht, Netherlands,* [2]*School for Developmental Biology, GROW, Maastricht University, Maastricht, Netherlands,* [3]*Department of Neurology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands.*

Mitochondrial diseases are among the most common inborn errors of metabolism, in at least 15% caused by maternally transmitted mitochondrial DNA (mtDNA) mutations. Severe mtDNA mutations are often heteroplasmic. Because of the clinical severity and the lack of treatment, couples with a previous child with an mtDNA disorder may request prevention of transmission to a subsequent child. PND is technically possible, but due to limitations in predicting the phenotype, only suitable if a high likelihood exists of offspring with either no mutation or a mutation load below the threshold of expression. This is the case for *de novo* mtDNA disease, based on the absence of the mutation in multiple tissues of the mother. Correct counselling is critical, as often wrong estimates for recurrence are given, based on the high mutation load in the affected child and not on the absence of the mutation in the mother. PND could be offered for reassurance. We present some illustrating cases. PND is also an option for carriers with a low mutation load, in case these mutations demonstrate skewing. Preimplantation Genetic Diagnosis (PGD) can be offered to carriers of heteroplasmic mutations with a high recurrence risk, followed by transfer of an embryo below a mutation-specific or general threshold of expression. A 95% or higher chance of being unaffected was found at mutant level of 18% or less, irrespective of the mutation. PGD was applied for the m.3243A>G, m.8993T>G and m.8344A>G mutations. All carriers tested produced oocytes below the threshold.

Copy number variations and their role in the etiology of Müllerian aplasia

M. Sandbacka[1,2], *É. Freitas*[3], *M. Halttunen*[4], *H. Laivuori*[5], *C. Rosenberg*[3], *K. Aittomäki*[1,4];
[1]*Folkhälsan Institute of Genetics, Helsinki, Finland,* [2]*Department of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland,* [3]*Department of Genetics and Evolutionary Biology, Institute of Bioscience, University of São Paulo, Sao Paulo, Brazil,* [4]*Department of Obstetrics and Gynecology, Helsinki University Central Hospital, Helsinki, Finland,* [5]*Women´s Health, Research Programs Unit, University of Helsinki, Helsinki, Finland.*

Müllerian aplasia (MA) is a reproductive disorder characterized by congenital loss of uterus and vagina. Without treatment, intercourse is difficult and reproduction is only possible through surrogacy. Only a few MA patients have been reported with mutations in the *WNT4* and *LHX1*, but for the majority, the cause is still unknown.
We investigated copy number variations (CNVs) that could contribute to the etiology of MA using aCGH (180 kb) in 50 Finnish MA patients, whose diagnoses have been confirmed by laparoscopy. We identified nine CNVs, not commonly found in the control population, in eight (16%) patients. Seven of the CNVs were deletions and two were duplications, both detected in the same patient. Five of the observed deletions (5p14.3, 9q21.13, 11q13.4, 15q26.1, 16p13.3) and the duplications (19q13.11, 19q13.12) were novel, whereas two deletions (16p11.2 and 17q12, including the *LHX1* gene) have been previously described in MA patients. We confirmed the sizes of the CNVs by SNP genotyping (HumanOmni2.5-8). Subsequently, we could confirm the same 16p11.2 deletion in four other MA patients. The deletion expands ~0.53 Mb and includes at least 26 genes.
To date, altogether 12/112 Finnish patients (10.7%) were found to carry CNVs. Our results lend support to complex genetic etiology of MA. Further studies are needed to identify the cause in the majority of patients.

Myotonic dystrophy (MD), Huntington disease (HD) Fragile X syndrome (FXS), spinocerebellar ataxia (SCA1, SCA2, SCA3, SCA6, SCA7, SCA17), Friedreich ataxia, Oculopharyngeal Muscular Dystrophy and Kennedy disease are caused by the expansion of unstable polymorphic trinucleotide repeats. For couples at risk of transmitting one of these diseases, preimplantation genetic diagnosis (PGD) has become a reproductive option. According to the European Society of Human Reproduction and Embryology (ESHRE) PGD consortium, MD, HD and FXS are three of the most common indications for PGD for monogenic disorders. In order to define the basis for an international harmonization of technological protocols for PGD of triplet repeat disorders, EuroGentest2 granted a workshop that was held in February 2013 in Montpellier, France : experts from 9 PGD centers in Europe (Athens, Brussels, London, Maastricht, Madrid, Montpellier, Paris, Rome and Strasbourg) as well as the scheme director of EQA (UK NEQAS) for monogenic disease PGD attended the meeting, producing a first draft of guidelines.
Here we report the data discussed for the three most studied diseases for PGD : MD, HD and FXS. Several general points were addressed including :
-Strategies to use (direct or indirect analysis);
-Definition of « informative » microsatellite markers;
-Localization and genetic map of the markers used;
-Inclusion criteria depending on the number of informative markers;
-Strategies to use in the case of a lack of informativity.
Finally, depending on the triplet repeat disorder, specific recommendations were also reported.

Objectives: To review clinical and epidemiologic data of neural tube defects (NTDs) and to evaluate the efficiency of prenatal diagnosis in Alsace (northeast of France).
Material and Methods: A population-based retrospective study from data of the Registry of Congenital Malformations of Alsace between 1995 and 2009.
Results: 272 NTDs were recorded (prevalence: 1.4 per 1000), divided in 95 cases of anencephaly-exencephaly (35 % of all cases), 18 cases of craniorachioschisis (7 %), 35 cases of meningo(encephalo)cele (13 %) and 124 cases of (myelo)meningocele/spina bifida (45 %). The prevalence has been quite stable throughout the period. The following data are presented concerning each NTD malformations: isolated or associated case, associated syndromes or sequence, prenatal diagnosis, outcome of pregnancy. The rate of prenatal diagnosis was 99 % in
anencephaly, 100 % in craniorachischisis, 77 % in meningoencephalecele and 79 % in myelomeningocele and the rate of termination of pregnancy after prenatal diagnosis was respectively 98 %, 100 %, 96 % and 97 %.
Concerning myelomeningocele, our study emphasized the circumstances of prenatal diagnosis, and especially the impact of evolution of Down's syndrome prenatal screening. If the increased alphafetoprotein (AFP) used in the second trimester screening constituted a NTD indicator, is there a risk of misdiagnosis with the diffusion of first-trimester (without AFP) screening ?

Introduction of cfDNA based screening of common trisomies in Spain

V. Cirigliano, *L. Rueda, E. Ordoñez, M. Cañadas;*
Labco General Lab, Barcelona, Spain.

Objective: To evaluate the suitability of introducing cfDNA based screening for common autosomal trisomies in Spain.
Methods: A pilot study was designed to evaluate the implementation of the Harmony prenatal test (Ariosa Diagnostics) within the largest network of private hospitals in Spain. Women at both high and low risk of aneuploidies were included and 232 consecutive clinical samples were retrieved from singleton pregnancies of at least 10 weeks of gestation, egg donor patients were excluded. A total of 213 more samples were then collected also including egg donation pregnancies. Patients received genetic counselling before and after the test, results were evaluated with all available clinical information to decide if further invasive genetic tests were necessary.
Results: Results were obtained in 429 cases (96.4%), in 2.7% of samples final report was delayed to 3 weeks. A total of 425 cases were reported as low risk (<0,01%) for fetal trisomies 13, 18 and 21. In 4 cases risk score >99% for Trisomy 21 were reported, these results were confirmed by QF-PCR analysis of fetal cells obtained by invasive procedures.
Conclusions: cfDNA based screening for common trisomies using the Harmony test proved efficient and reliable, in this preliminary study we did not observe false positive results. Although follow up on all cases is still in progress, the test revealed to be a powerful alternative to conventional trisomy risk assessment, providing prompt relief of maternal anxiety and potentially reducing unnecessary invasive procedures

P19.44

Non Invasive Prenatal Diagnosis

P. C. Patsalis;
Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

For more than 40 years, prenatal diagnosis of Down syndrome is performed using invasive procedures which are associated with a significant risk of fetal loss (~1%). Many attempts have been made in the last two decades towards the development of a non-invasive prenatal diagnostic (NIPD) test. One of the most promising is the application of the Methylated DNA Immunoprecipitation (MeDIP) real time qPCR based approach. The MeDIP methodology combined with high-resolution tiling arrays revealed thousands of Differentially Methylated Regions (DMRs) between maternal and fetal DNA across chromosomes 13, 18, 21, X and Y. The best 12 DMRs were used for the development of a novel NIPD test for trisomy 21 ($NIPD^{21}$). The method was validated using 80 maternal blood samples including 34 Down syndrome pregnancies and 46 normal pregnancies demonstrating 100% specificity and 100% sensitivity. The $NIPD^{21}$ method was further improved and validated using 175 new cases, demonstrating 99.2% sensitivity and 100% specificity. The improved $NIPD^{21}$ was created using old and new DMRs and taking into account their genomic position. An additional advantage is that it consists of only seven DMRs which simplifies the diagnostic assay and reduces the cost even further. In conclusion, the MeDIP real time qPCR based approach is an accurate, reliable NIPD test for Down syndrome. It is simple, fast and easy to perform in every genetic diagnostic lab worldwide as it does not require expensive equipment, software or special infrastructure. Additional research highlighted the potential use of the novel approach for other genetic disorders.

P19.45

Targeted sequencing of SNPs results in highly accurate non-invasive detection of fetal aneuploidy of chromosomes 13, 18, 21, X, and Y: a validation study

A. Ryan[1], *B. Levy*[2], *M. Banjevic*[1], *M. Hill*[1], *B. Zimmermann*[1], *S. Sigurjonsson*[1], *N. Wayham*[1], *P. Lacroute*[1], *M. Dodd*[1], *B. Hoang*[1], *J. Tong*[1], *P. Vu*[1], *M. Hall*[1], *Z. Demko*[1], *M. Rabinowitz*[1];
[1]*Research and Development, Natera Inc., San Carlos, CA, United States,* [2]*Department of Pathology and Cell Biology, Columbia University, New York, NY, United States.*

No available non-invasive fetal aneuploidy test leverages the increased information offered by single-nucleotide polymorphisms (SNPs) and parental genotypes, which identify fetal ploidy state and parental origin. Here, we detect fetal aneuploidy at chromosomes 13, 18, 21, X, and Y via analysis of fetal cell-free DNA (cfDNA) from maternal blood by targeting 19,488 SNPs covering chromosomes 13, 18, 21, X, and Y in a single multiplex PCR reaction. Maternal plasma samples (673 euploid; 52 trisomy 21; 17 trisomy 18; 8 trisomy 13; 13 45,X) were collected at ≥9 weeks gestation under an institutional review board-approved protocol. 351 samples were externally blinded. Isolated cfDNA was amplified using 19,488-plex PCR. Sequencing data was analyzed using the NATUS algorithm, which employs Bayesian statistics to analyze multiple copy number hypotheses, determine the Maximum Likelihood hypothesis, and calculate sample-specific accuracies without a reference chromosome. In samples that passed stringent quality control metrics (94.1%), NATUS detected trisomy 13 (n=7; sensitivity: 100% [CI: 59.0-100%]), trisomy 18 (n=15; sensitivity: 100% [CI: 78.2-100%]), trisomy 21 (n=47; sensitivity: 100% [CI: 92.5-100%]), and 45,X (n=11; sensitivity: 91.7% [CI: 61.5-99.8%]), with average calculated accuracies of >99%. Fetal ploidy state was determined as low as 3.9% fetal fraction and as early as 9 weeks gestation. This is the first large-scale study, including blinded sample analysis, of the NATUS algorithm, which non-invasively detected fetal ploidy state at chromosomes 13, 18, 21, X, and Y with high accuracy. SNP- and NATUS-based cfDNA analysis thus offers a clinically viable, highly accurate, non-invasive approach to identifying fetal aneuploidies.

P19.46

Validation study of non-invasive procedures for fetal sex and RHD status determination

C. Giachini*, F. Gerundino, S. Frusconi, C. Pescucci, G. Marseglia, E. Pelo, F. Torricelli;*
Genetic Diagnostic Unit, Careggi University Hospital, Florence, Italy.

Cell-free fetal DNA (cffDNA) in maternal plasma provides the basis for non-invasive prenatal diagnosis. The diagnosis of fetal sex is indicated in X-linked genetic conditions, while fetal RhD determination is useful in RhD- women to identify pregnancies at risk of haemolytic disease of the fetus and newborn. The methods consist in multiplex qRT-PCR targeting Y chromosome-specific sequences (SRY-DYS14) and RHD gene for fetal sex and RHD determination, respectively. Since both methods are based on presence/absence of amplification signals, the simultaneous analysis of fetal DNA-specific (epigenetic) markers is compulsory to attest the presence of cffDNA.
We aim to validate these procedures on a large cohort of pregnant women (n= 2000) at different gestational period (8-11 weeks). To date 500 maternal plasma samples have been collected and a first set of 50 samples (with known fetal sex) have been already analysed for fetal gender (table 1).
Results will be compared with QF-PCR/karyotype results and/or with follow up data to establish the sensibility/specificity of the methods, and therefore whether this test could be suitable for routine clinical settings. The introduction of these procedures will allow to: i) avoid unnecessary invasive testing for carriers of X-linked diseases in case of female fetus that would be, at worst, carrier of the disease; ii) reduce the administration of anti-D prophylaxis by avoiding the treatment in women with RhD- fetus.

Plasma Samples (n=500)					**Sex Determination Results (n=50)**			
Maternal age (mean ± SD)	Weeks" gestation (mean ± SD)	Invasive PD outcome (n=50)			Female (n)	Male (n)	Sensibility	Specificity
		46,XX (n)	46,XY (n)	Other (n)				
34±5	9±1	23	26	1 (47,XX,+21)	24	26	100%	100%

P19.47

No association of free fetal DNA levels in maternal plasma with the correct classification of trisomy 21 using the MeDIP-qPCR methodology.

E. A. Papageorgiou[1,2], *S. Kyriakou*[2], *E. Kypri*[1], *C. Spyrou*[1], *E. Tsaliki*[1], *G. Koumbaris*[1,2], *V. Velissariou*[3], *P. C. Patsalis*[2];
[1]*NIPD Genetics Ltd, Nicosia, Cyprus,* [2]*The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,* [3]*Mitera Hospital, Athens, Greece.*

Non-invasive prenatal diagnosis (NIPD) of chromosomal aneuploidies has been challenging. Nevertheless, experts in the field have overcome the limitations of previous methodologies through the implementation of novel alternative approaches. We have successfully implemented the MeDIP-qPCR methodology and have demonstrated 99.2% specificity and 100% sensitivity. We hereby present a study in which we aim to evaluate whether the amount of ffDNA, total DNA and "fetal fraction" found in maternal plasma influences the enrichment ratios of Differentially Methylated Regions (DMRs) and the correct classification of trisomy 21 using the MeDIP-qPCR methodology.
Absolute quantification of ffDNA using DYS14 and total DNA using β-globin was applied in 83 maternal plasma samples. The quantification values for all 83 samples were correlated with the enrichment ratios of all seven DMRs and D-values that were obtained from the diagnostic formula of MeDIP-qPCR method.
Our analysis concluded that trisomy 21 samples had significantly higher ffDNA and total DNA levels compared to normal samples. Enrichment ratios of the majority of DMRs studied exhibited no association with ffDNA, total DNA and "fetal fraction" and only a small portion of DMRs exhibited moderate association. Correlation studies of ffDNA, total DNA and "fetal fraction" with the diagnostic D-value showed weak to no association but without affecting the classification of trisomy 21. Therefore, he hereby demonstrated that the MeDIP-qPCR is the only methodology describes so far in which the variability in the amount of ffDNA and total DNA among maternal samples does not affect the correct non-invasive prenatal diagnosis of trisomy 21.

Cell free fetal DNA (cffDNA) in maternal blood is a valuable source of fetal material for non-invasive prenatal diagnosis (NIPD). The major clinical use of cffDNA genotyping has been for the NIPD of fetal RHD status and fetal sex in the pregnancies at risk of haemolytic disease of the fetus and newborn (HDFN) or X-linked disorders, respectively. The aim of our study was to evaluate the specificity and sensitivity of the real-time quantitative PCR method for NIPD of RHD status and fetal sex determination in a clinical diagnostic setting. A total of 71 pregnancies at risk of HDFN were enrolled in the study (66%-T3, 26%-T2 and 8%-T1). RHD genotyping was done using real-time PCR amplification of exon 5 and 7 of RHD gene while fetal sex was determined by amplification of multi-copy DYS14 marker on Y-chromosome. In addition a multiplex PCR amplifying the 10 exons of RHD gene was performed on maternal and fetal DNA to exclude partial/weak RHD phenotypes. CffDNA results were compared to the results from DNA from amniocentesis/chorionic villi sampling. NIPD showed that 34% (24/71) of the fetuses were RHD negative and 35/71 (49.3%) were males. NIPD results were fully concordant with those of invasive tests, giving a 100% sensitivity and specificity of the test. We didn't detect any RHD variants in our study group. In conclusion, this method can be used in clinical practice for targeted anti-RhD prophylaxis and improvement of management of RHD fetomaternal incompatibility and in pregnancies at risk for X-linked disorders.

Noninvasive detection of fetal trisomy 21: systematic review and report of quality and outcomes of diagnostic accuracy studies performed between 1997 and 2012

E. Mersy[1,2], *L. J. M. Smits*[3], *L. A. A. P. van Winden*[4], *C. E. M. de Die-Smulders*[1,2], *S. E. Netherlands NIPT consortium*[5], *A. D. C. Paulussen*[1,2], *M. V. E. Macville*[1,2], *A. B. C. Coumans*[2,4], ***S. G. M. Frints***[1,2];
[1]*Department of Clinical Genetics, Reproductive Genetics, Maastricht University Medical Center+, Maastricht, Netherlands,* [2]*GROW School for Oncology and Developmental Biology, Maastricht University Medical Center+, Maastricht, Netherlands,* [3]*Department of Epidemiology, Maastricht University, Faculty of Health, Medicine and Life Sciences, Maastricht, Netherlands,* [4]*Department of Obstetrics & Gynaecology, Prenatal Diagnosis, Screening and Therapy, Maastricht University Medical Center+, Maastricht, Netherlands,* [5]*South-East Netherlands NIPT consortium, Maastricht University Medical Center+, Maastricht, Netherlands.*

Background: Research on noninvasive prenatal testing (NIPT) of fetal trisomy 21 detection is developing fast. Commercial tests have become available. To provide an up-to-date overview, an evaluation of the methodological quality and outcomes of diagnostic accuracy studies published between 1997 and 2012, was made.
Methods: Of 79 abstracts, 16 studies were included as they evaluated the diagnostic accuracy of a molecular technique for NIPT of trisomy 21, and test sensitivity and specificity were reported. Diagnostic parameters were analyzed and possible bias and applicability were evaluated utilising the QUADAS-2 tool.
Results: Recently published large cohort studies (7/16) examined massively parallel sequencing (MPS) with or without pre-selection of chromosomes, and reported sensitivities between 98.58% (95% CI 95.9-99.5%) and 100% (95% CI 96-100%), and specificities between 97.95% (95% CI 94.1-99.3%) and 100% (95% CI 99.1-100%). None of the studies had overall low risk of bias and low concerns regarding applicability. MPS with and without preselection of chromosomes exhibits an excellent negative predictive values (100%) in conditions with disease odds from 1:1500 to 1:200. However, positive predictive values were lower, even in high-risk pregnancies (19.7%-100%).
Conclusion: NIPT of trisomy 21 by MPS is promising and likely to replace the prenatal serum screening test that is currently combined with nuchal translucency measurement. Before NIPT can be introduced in a social insurance health care system, more evidence is needed from large prospective diagnostic accuracy studies and further assessment, of whether NIPT can be provided in a cost-effective, timely, and equitable manner, is required.

R72P p53 single nucleotide polymorphism in patients with repeated implantation failure and pregnancy loss: influence in the outcome of IVF cycle.

B. Lledo[1], *A. Turienzo*[1], ***J. A. Ortiz***[1], *R. Morales*[1], *J. Ten*[2], *J. Llacer*[2], *R. Bernabeu*[2];
[1]*INSTITUTO BERNABEU BIOTECH, Alicante, Spain,* [2]*INSTITUTO BERNABEU, Alicante, Spain.*

INTRODUCTION: Significant differences in the codon 72 polymorphic form p53 might affect its activity, R72 is markedly better than P72. Previous studies shown R72P polymorphism is a risk factor for implantation failure. The aim of this work was investigate whether R72P p53 polymorphism has a higher prevalence among women with recurrent implantation failure (RIF) and pregnancy loss (RPL) and its influence in their IVF cycle outcome.
MATERIAL AND METHODS: p53 polymorphism P72 has been studied in 181 women. The control group included 83 oocyte donors. In the study group 98 women were included: 44 with RIF and 54 with RPL. From the study group, 70 patients underwent IVF-cycles (43 RPL and 27 RIF) at Instituto Bernabeu.
RESULTS: The frequency of P72/P72 genotypes on p53 gene among women experiencing RIF was 11.4% vs 18.5% for those with RPL and 6% in controls ($p<0.01$). Significant differences were reported in pregnancy rate (73.3% for RR, 67.6% for RP and 33.3% for PP; $p<0.05$), embryo implantation rate (36.6% for RR, 43.3% for RP and 19.6% for PP; $p<0.05$) and ongoing pregnancy rate (46.7% for RR, 52.9% for RP and 14.3% for PP; $p<0.05$) among women suffering RIF and RPL.
DISCUSSION: Genotyping p53 gene is an important factor for determining the prognosis of IVF cycles on RIF and RPL women because P72 on p53 gene is more prevalent in RIF and RPL patients than fertile population. Moreover, patients carrying a PP genotype on p53 codon 72 will have less chance to achieve an ongoing pregnancy.

Evaluation of prenatal samples analyzed with the AmplideX FMR1 PCR assay

K. Storm[1], *N. Peeters*[1], *E. Reyniers*[1], *I. De Clercq*[2], *K. Claes*[2], *G. Mortier*[1], *W. Wuyts*[1];
[1]*Center for Medical Genetics, Antwerp, Belgium,* [2]*Center for Medical Genetics, Ghent, Belgium.*

Abnormal expansion of the CGG repeat in the 5' UTR of the FMR1 gene causes Fragile X syndrome. The CGG repeat lengths can be divided in four diagnostic categories: normal, grey zone, premutation and full (methylated) mutation alleles. In our lab, Fragile X testing is performed by sizing the CGG repeat with a commercially available assay, the AmplideX FMR1 PCR Kit (Asuragen), comprising primers for a sizing PCR and a CGG triplet-repeat primed PCR. Validation experiments confirmed Asuragen's results with detection of all FMR1 expansion types, with an analytical sensitivity of 100%, a detection limit of 10% for a full mutation and an accurate repeat sizing. The validation experiments were performed on different matrices, including previously analyzed prenatal samples. In routine, additional prenatal samples were analyzed. The results of these prenatal samples will be presented in more detail. Four CV samples showed an unexpectedly number of gene-specific sizing peaks: including one triploidy, one sample mosaic for a premutation/full mutation as a result of both contraction and expansion of the maternal repeat, and two samples with a low percentage of maternal contamination. In conclusion, the Asuragen assay was found very reliable and sensitive for detection of Fragile X (expanded) alleles in different matrices, including prenatal samples, with the additional advantages of a fast turnaround time and need for only a small amount of DNA. Moreover, implementation of the TP-PCR assay significantly reduces the need for Southern analysis or other methylation-sensitive assays.

P19.52

A pilot study for prenatal and preconceptional Fragile-X Syndrome screening in the Balearic Islands

*R. Alfaro, J. Rosell, **D. Heine-Suñer**;*
Hospital Universitari Son Espases, Palma de Mallorca, Spain.

The Fragile X-syndrome (FXS) is caused by the expansion of a CGG triplet located in the 5'UTR region of the *FMR1* gene and is one of the most frequent causes of hereditary intellectual disability. The estimated incidence of FXS in males in the Spanish population is 1 in 2500 for full mutation and about 1 in 250 for premutation (Fernandez-Carvajal et al. 2009). Although the prevalence of premutation in Spanish women has not been established, estimates in other western countries range from approximately 1 in 150 to 1 in 250. Given the severity of the disease, its high incidence in the general population, the exclusively maternal expansion, the familial and social impact of the FXS, and the high level of detection of current techniques (99%), we think that screening for FXS in women of reproductive age is a reliable and desirable option. Therefore, we have initiated a pilot study in the Balearic Islands to determine the feasibility and acceptability of prenatal and/or preconceptional screening in women of childbearing age. The results obtained so far, in a total of 422 women (117 preconceptional and 305 prenatal) indicate a high acceptability of FX screening in women that are referred for prenatal or preconceptional consultation. Surprisingly, the incidence of carriers of a premutation (55-200 repeats) is (to date) very high: 1 in 60, which may indicate a higher prevalence than previously thought. We will present updated results based on a total of approximately 2000 women.

P19.53

Improving Preimplantation Genetic Diagnosis for Fragile X Syndrome: a new powerful single-round multiplex test.

*E. KIEFFER[1], J. C. NICOD[1], N. GARDES[1], C. KASTNER[1], N. BECKER[1], C. CELEBI[1], O. PIRRELLO[1], C. RONGIERES[1], I. KOSCINSKI[1,2], P. GOSSET[1], **C. MOUTOU**[1,2];*
[1]Hopitaux Universitaires de Strasbourg - CMCO, 67303 SCHILTIGHEIM CEDEX, France, [2]Université de STRASBOURG, Strasbourg, France.

Fragile X (FraX) syndrome is the most common cause of inherited mental retardation, affecting around one out of 2500 individuals. FraX is caused by expansion of an unstable CGG repeat located in the FMR1 gene on Xq27.3. Preimplantation Genetic Diagnosis (PGD) can be proposed to couples at risk of transmitting the disease, i.e. when the female carries a premutation or a full mutation.
Technical conditions for FraX PGD are not trivial for many reasons: i) single-cell CGG-amplification is obtained for normal alleles only, limiting the use of a direct test to couples informative for this locus; ii) GC-rich DNA content of the repeats perturbs the amplification of other loci (i.e. microsatellites sequences) by single cell multiplex-PCR; iii) currently used polymorphic markers show limited to no informativity for a non-negligible part of the couples asking for PGD. Moreover, premature ovarian failure occurring in some premutated women often leads to poor oocyte retrieval and only few embryos analysed during PGD. Thus, a powerful PGD test is of fundamental importance to minimize the rate of non-diagnosed embryos.
We describe a new single-cell, indirect multiplex PCR using unpublished, highly heterozygous polymorphic markers. Globally increased informativity improves robustness of this test. Futhermore, it allows PGD feasibility for some couples for which previous strategies were not applicable. It was applied alone (on 2 cells) or concurrently with CGG repeats amplification (on one cell per test) for 4 PGD cycles: 10 embryos were analysed, all were successfully diagnosed, 6 were transferred, and 2 pregnancies are ongoing.

P19.54

Attitudes toward preimplantation genetic diagnosis (PGD) procedure among couples performing PGD for autosomal dominant disorders

***S. Zuckerman**[1,2], S. Gooldin[3], E. Levy Lahad[1,2], G. Altarescu[1,2];*
[1]Medical Genetics Institute - Shaare Zedek Medical Center, Jerusalem, Israel, [2]Hebrew University - Hadassah Medical School, Jerusalem, Israel, [3]Hebrew University - The Department of Sociology and Anthropology, Jerusalem, Israel.

PGD technology provides an alternative to prenatal diagnosis (PND), and since PGD obviates the need for pregnancy termination (TOP), some argue that the moral justification for using it should be less strict than for PND. Others claim that the ethical and social implications of using PGD resemble ‚eugenic' ideas and thus advocate minimizing or banning its practice.
PGD has been widely used in Israel, by many sectors of the population, for a broad range of conditions. While any couple at risk for genetic disease in their offspring face dilemmas regarding their reproductive future, one of the unique groups of PGD consumers are individuals living with a medical condition which they choose to prevent in their future offspring. As a part of a larger project on the attitudes of PGD users in Israel, semi-structured in-depth interviews were carried out with 13 PGD users with autosomal dominant disorders (Achondroplasia, Myotonic Dystrophy, Neurofibromatosis etc). The interviews explored decisions, experiences, concerns, and attitudes toward PGD. Issues concerning medical, ethical and sociological aspects of PGD were also analyzed.
Preliminary findings show that the main reason for using PGD was to prevent difficult lifetime experiences related to the genetic condition. However, more than half of the interviewees thought their condition does not justify TOP. For them, PGD is the only acceptable preventive procedure.
Understanding the experiences and attitudes of PGD consumers will contribute to the development of counseling programs for future PGD users and will assist in fostering a public debate concerning various aspects of PGD.

Reproductive life after preimplantation genetic diagnosis; the decisions couples make and why.

***A. Lashwood**[1], C. Patch[2], Y. Khalaf[1], C. Williams[3];*
[1]Centre for Preimplantation Genetic Diagnosis, Guy's Hospital, London, United Kingdom, [2]Clinical Genetics, Guy's Hospital, London, United Kingdom, [3]Brunel University, London, United Kingdom.

Success rates for PGD are well documented, but little evidence exists about the impact on reproductive decisions. An understanding of the decisions couples make and why after PGD provides valuable information in counselling potential PGD couples.
Questionnaires were sent to 251 eligible couples who had PGD between 1999-2007 at Guys Hospital; 113/251 (45%) were returned. Of these 68/113 (60.2%) couples were successful and 45/113 (39.8%) were unsuccessful.
The main reasons for PGD were; avoidance of termination of pregnancy, recurrent miscarriages and fertility problems with genetic risk. Successful couples had 105 babies and 9 of the unsuccessful couples had miscarriages following positive pregnancy tests. There were 53 unaffected non PGD children across both groups, at least 12 of whom were born after PGD. The unsuccessful couples had 5 affected children after PGD.
The reasons behind post PGD reproductive decisions were complex. Irrespective of prior success: emotional and physical stress, cost, impact of treatment and success rates were given as reasons not to proceed with further PGD. Successful PGD gave couples the confidence to try naturally. Lack of alternative choices balanced against a strong desire for children lead to options chosen by unsuccessful couples. After treatment couples in both groups reviewed their perception of the underlying genetic risk.
The findings provide insight into the value of PGD as a reproductive option and the impact it has on couples. Evidence of the reproductive decisions made after PGD should contribute to the discussions clinicians have with couples opting for PGD treatment.

Molecular techniques as an alternative to FISH (fluorescence in situ hybridization) in preimplantation genetic diagnosis (PGD) of reciprocal translocation

***T. Frumkin**[1], V. Gold[1], S. Peleg[1], T. Schwartz[1], A. Carmon[1], B. Almog[1], D. Ben-Yosef[1], A. Amit[1], Y. Yaron[1,2], M. Malcov[1];*
[1]Racine IVF Unit, Department of Ob/Gyn, Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, Tel Aviv, Israel, [2]Prenatal Diagnosis Unit, Genetic Institute,Sourasky Medical Center, Tel Aviv, Israel.

Objective: The standard method for PGD of reciprocal translocations is FISH using commercial probes. This associates with 5-7% misdiagnoses due to non-specific hybridization, overlapping or split signals. We sought to evalu-

ate whether accuracy may be improved by polymorphic marker analysis and array comparative genomic hybridization (CGH).
Methods: Balanced carrier of t(14;21)(q11.2;q22.1) has opted for PGD. Since commercial fluorescence probes were not available we designed a multiplex PCR protocol using polymorphic markers in 3 different regions along the relevant chromosomes and applied to PGD. For reanalysis, affected embryos were subjected to array CGH.
Results: Haplotype analysis of parental genomic DNA revealed that of 30 polymorphic markers tested, only 12 were informative (4 in each region). Ten embryos were biopsied for PGD and only one was diagnosed with balanced chromosomal constitution. Five embryos were unbalanced and since parental alleles were excessively overlapping in four embryos, diagnosis was inconclusive. These embryos were reevaluated by array CGH with 40 probes on average in each locus that confirmed the suspected chromosomal aberration.
Conclusion: CGH array may be the most accurate and reliable method for detection of chromosomal imbalances in PGD, but is relatively expensive. Polymorphic marker analysis is an accurate technique when there are at least 4 fully informative markers around the translocation sites. However, dozens of primers that must be tested make it time consuming and not cost effective approach. FISH is rapid, economical, relatively reliable, but, when no commercial probes are available, array CGH is favored over markers analysis for PGD of translocation.

Introduction: Preimplantation genetic diagnosis (PGD) is a technique that enables the prevention of affected embryo transfer for couples at risk of transmitting a genetic disorder to offspring. Due to its relative invasiveness it is essential to identify any adverse effects on the long term development of children born as a result of PGD.
Aim: The aim of this study was to measure and evaluate developmental neuropsychological profiles of 4-5-year-old children born after PGD relative to norms representing the general population.
Materials and methods: Twenty seven, 4-5 year old, PGD children were recruited. Participants were subjected to a battery of neuropsychological assessments including: WPPSI-III(cognitive development), PLS-4(language development), WRAVMA(visual motor abilities), CARS2(screening test for autistic spectrum disorders) and the Miles ABC Test(ocular dominance). Parental questionnaires regarding executive function and demographics were performed as well. Each subject's tests results were compared to each test's norms as provided by the test authors. When available, Israeli norms were used for comparison.
Results: Children born after PGD showed scores within the normal or above-normal ranges for all developmental outcomes. The mean WPPSI Full Scale Intelligence Quotient and Verbal Intelligence Quotient were significantly higher than the general population(P=0.013), although not clinically significant(100±15). All other tests performed within normal test ranges.
Conclusions: This pilot study shows that children conceived after PGD display normal developmental neuropsychological outcomes at age 4-5 years when compared to age-matched normal children in the general population. A larger controlled study is needed to confirm the validity of this conclusion.

Overcoming limitations of single cell analysis in duplicated genomic regions using multiple displacement amplification for Preimplantation Genetic Diagnosis (PGD)

D. A. Zeevi[1], *P. Renbaum*[1], *R. Ron-El*[2], *T. Eldar-Geva*[1,3], *A. Raziel*[2], *B. Brooks*[1], *D. Strassburger*[2], *E. J. Margalioth*[1], *E. Levy-Lahad*[1,3], *G. Altarescu*[1,3];
[1]*Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*Assaf Harofeh Medical Center, Tel Aviv, Israel,* [3]*Henrew University Medical School, Jerusalem, Israel.*

PGD on single cells requires concurrent analysis of a mutation together with multiple linked polymorphic markers from closely related family members in order to prevent misdiagnosis. In PGD cases involving childless *de novo* mutation carriers, linkage cannot be performed based on family members but rather must first be identified in single gametes. This is an especially difficult task if the mutation to be assayed lies in a duplicated genomic region because gene-specific long-range PCR must be coupled with short-range PCR analysis of genetic markers on single cells. Here we describe a novel method by which accurate PGD of pseudogene-homologous mutations can be achieved. Essentially, we performed multiple displacement amplification on single sperm or blastomeres followed by haplotype construction and long range PCR-based mutation analysis. This original and universal strategy was used to establish allelic association for two different mutations in genes with one or more pseudogene copies (*IKBKG* and *PKD1*). For *IKBKG*, the method was implemented during a PGD cycle which resulted in the birth of a healthy child. Regarding *PKD1*, our method detected unexpected germline mosaicism in single sperm from the mutation carrier. These results indicate that the methodology overcomes pseudogene masking while still facilitating the detection of single copy targets with high accuracy.

P19.59

Introducing Preimplantation Genetic Screening (PGS) by array comparative genomic hybridization in Hungary: improving outcome of *in vitro* fertilization

D. Debreceni[1], *Z. Kósa*[2], *S. Sávay*[2], *M. Csenki*[2], *L. Nánássy*[2], *B. Dudás*[2], *Z. Dömötör*[1], ***A. Vereczkey***[2];
[1]*Reprogenex Gene Diagnostic Laboratory, Budapest, Hungary,* [2]*Versys Clinics, Human Reproduction Institute, Budapest, Hungary.*

The aim of our study was to assess the aneuploidy patterns of embryos from Hungarian patients undergoing *in vitro* fertilization (IVF). Day three embryos had one cell removed as a biopsy specimen before DNA amplification and microarray comparative genomic hybridization (aCGH) analysis were performed.
Our retrospective study was performed on 421 human embryos from 107 Hungarian patients (ave. age: 36.69). Out of them 28.98% were normal, 34.44% had complex aneuploidy (embryos with >2 chromosome abnormalities), 11.88% were double aneuploidies, 13.78% monosomies and 10.93% trisomies. The number of complex abnormal embryos significantly increased with advancing maternal age while the occurance of normal embryos decreased, from 37.23% and 39.89% in patients ≤35 to 69,51% and 10.97% in patients 41 and older, respectively. Out of 107 patients, 73 had normal embryos. 16 of these patients have ongoing pregnancies and four of them delivered children already.
The results show similar tendencies with previous observations at numerous points; most importantly, the higher the maternal age, lower the euploid/aneuploid ratio is. The occurrences of the monosomy and trisomy events in the examined embryos decreased, while complex aneuploidies increased with elevated maternal age. Despite the finding of previous studies, which described chromosome X as a chromosome with the highest frequency of aneuploidy, in our study the aneuploidy of sex chromosomes were extremely rare. The most common aneuploidies were for chromosomes 15, 5, 16, 10, 20 and 1. The rarest aneuploidies were for chromosome Y, 4, 12, 3, 11 and 2.

P19.60

Preimplantation genetic screening with used 24sure microarrays, our results and the success of in vitro fertilization cycles

I. Slamova[1,2], *V. Horinova*[1], *K. Okenkova*[3], *K. Texlova*[1], *L. Pracharova*[3], *S. Kloudova*[4], *E. Matejickova*[3], *P. Texl*[5];
[1]*Sanatorium Helios ltd., Laboratory of Medical Genetics, Brno, Czech Republic,* [2]*Department of Genetics and Molecular Biology, Institute of Experimental Biology, Faculty of Science,, Brno, Czech Republic,* [3]*Sanatorium Helios ltd., Laboratory of Embryology, Brno, Czech Republic,* [4]*Sanatorium Helios ltd., Laboratory of Andrology, Brno, Czech Republic,* [5]*Sanatorium Helios ltd., Brno, Czech Republic.*

Chromosomal abnormalities are a major cause of the failure of embryos implantation and of miscarriages, also their number increases in oocytes with

age. Preimplantation genetic screening (PGS) is a principally new approach for the prevention of genetic disorders, which allows the selection of unaffected embryos in in vitro fertilization (IVF) cycles. PGS can be applied for chromozomal abnormalities such as aneuploidies using diagnostic protocols based on the Fluorescence in situ hybridization (FISH) or Array comparative genomic hybridization (aCGH).
In our work we studied cells of trophectoderm in 185 embryos. We analysed DNA of cells of trophectoderm with the use of 24sure microarrays BlueGnome. We obtained DNA from the few cells by the whole genome amplification. We found 30 % of abnormal embryos in group of women younger than 35 years and 49 % of abnormal embryos in group of women older than 35 years. Then the total 36 % in all analysed embryos was abnormal. Major part of abnormalities represented partial or total gains and losses of chromosomes 1, 7, 15, 16, 18 and 21.
The results of genetic analyses of embryos should serve as a supporting tool for the determination of chromosomal aberrations in embryos. Probability of pregnancy and birth of a healthy child improves the selection of embryos without aberrations. The succes rate of an IVF cycle is in our centre 68% with the use of PGS and strictly one embryo transfer. Cooperation is very important between embryology and andrology. Obtaining good-quality embryos is crucial for PGS.

The field of diagnosis of embryos for chromosome abnormalities, i.e. preimplantation genetic screening (PGS), has been recently re-energized by the introduction of microarray-based technologies allowing analysis of all 24 chromosomes in one test and thus providing much more information than approaches used in the past. There are two microarray platforms (BAC and oligonucleotide based) developed for use in PGS.
We describe preclinical validation of the oligonucleotide based arrays used for PGS performed on blastocyst biopsy. The validation was done in several steps: 1) validation of whole genome amplification (WGA) protocol; 2) validation of array platform on appropriate cell samples; and 3) determination of PGS array resolution.
The WGA and array platform validation was done by testing of 5-10 cells from lymphocytes of normal control samples and sample with a Down syndrome to ensure the consistent results on the array. In the second step, samples from blastocysts with known aneuploidies were tested. WGA method based on GenomePlex adjusted for single cell amplification (PicoPlex, Rubicon) was selected as the satisfactory amplification method and the Single Cell Aneuploidy Array 15K from Oxford Gene Technologie as the optimal array platform.
Array CGH resolution was tested using diluted DNA from samples with known chromosomal aberrations. Using our optimized protocol, we were able to detect multiple chromosome abnormalities including aneuploidies but also smaller structural abnormalities as, e.g. 2 Mb deletion.
Our results indicate that this oligonucleotide array platform can be reliably used for PGS in patients undergoing IVF.

Placental growth factor in prenatal diagnosis

M. Macek sr.[1], *M. Pešková*[1], *M. Turnovec*[1], *D. Springer*[2], *R. Vlk*[1], *G. Stránská*[1], *I. Špálová*[1], *R. Krejčí*[1], *A. Kestlerová*[3], *V. Novotná*[3], *L. Krofta*[3], *M. Macek jr.*[1];
[1]*University Hospital Motol, Prague, Czech Republic,* [2]*General Teaching Hospital, Prague, Czech Republic,* [3]*Institute for the Care of Mother and Child, Prague, Czech Republic.*

Placental Growth Factor (PlGF) improves 1st trimester trisomy 21 screening, detects risk of early preeclampsia (PE) and allows low-dose aspirin prevention before 16th week. The aim was to ascertain control levels within 9th-18th weeks in Czech women.
PlGF was examined in 315 sera within 8th-13th and 155 within 14th-18th weeks by Delfia Xpress. The aneuploidy and PE risk were ascertained by LifeCycle/Elipse and Preeclampsia Predictor (usable only for 1st trimester). Levels for 3rd, 5th, 25th, 50th, 75th and 95th precentiles within 9th-18th weeks correspond to the Perkin Elmer's percentiles published for 9th-13th week only. PlGF linearity increase within 9th-18th week was identical with published data. The cut-off levels for 9th-18th weeks were calculated for the PE/aneuploidy risks. PE 1st trimester risk was found in 2 women (<5th percentile). Decreased levels were found in 2 pregnancies with gestational hypertension. The levels in 16 pregnancies with severe PE referred for Caesarean section within 30th-40th weeks corresponded to medians for 9th-20th weeks. Beneficial consequence of PlGF in trisomy 21 1st trimester was confirmed by isolated PlGF decrease (<3rd percentile, 1 case) and isolated increase (>75th percentile, 2 cases). PlGF decrease (<5th percentile) was observed in 2/3 triploidies. In one trisomy 21 PAPP-A, βhCG and PlGF were normal in 11+6 week, increased βhCG and PlGF <3rd percentile in 15+1.
The results support the inclusion of the PlGF to the 1st trimester screening of aneuploidies and early PE treatment.

P19.63
CASK gene Deletion in a Female Presenting with Cystic Hygroma, Echogenic Bowel and IUGR - Expanding the Fetal *CASK* phenotype

A. Guerin[1], *N. Martin*[2], *D. Chitayat*[1,2];
[1]*The Hospital for Sick Children, Toronto, ON, Canada,* [2]*Mount Sinai Hospital, Toronto, ON, Canada.*

CASK is a calcium/calmodulin dependent serine protein kinase that belongs to the membrane associated guanylate kinase (MAGUK) protein family. Located on the X chromosome, heterozygous mutations in the *CASK* gene have previously been described in females with severe intellectual disability, microcephaly and pontocerebellar hypoplasia (MICPCH)(MIM 300749) and FG syndrome 4 (MIM 300422).
To date, there has been no prenatal description of mutations or whole gene deletions encompassing this critical region. We report a female fetus with cystic hygroma, IUGR, cardiac malformation and echogenic bowel. Investigation done to delineate the etiology of the abnormalities included Noonan syndrome gene panel, chromosome analysis and parental DNA analysis for the 39 most common mutations in CFTR gene and TORCH analysis failed to identify an abnormality. Array CGH showed a *de novo* 5 Mb deletion at Xp11.4p11.3, encompassing: *CASK, NYX, MAOA, NDP* and *KDM6A*. Deletions of the genes in this region have been described with a phenotype that is clinically indistinguishable from loss of function mutations in *CASK*, suggesting that it is the main contributor to the clinical picture. Limited autopsy results from our patient showed facial features previously described in *CASK* gene mutations including faint philtrum, thin upper lip and retro-micrognathia.
Loss of function mutations of *CASK* and large chromosome deletions of this region described previously have been associated with MICPCH. In the prenatal setting many of these key features of *CASK* mutation cannot be readily assessed. The findings in our case expand the phenotype associated with *CASK* gene mutation/deletion to the prenatal setting.

The importance of offering targeted preconception carrier testing: First results in a small fishermens' village in the Netherlands

M. C. Maarle, van[1], *P. Lakeman*[1], *L. Henneman*[2], *I. B. Mathijssen*[1], *W. Ottenhof*[3], *M. M. Weiss*[4], *H. R. Waterham*[1], *F. Baas*[5], *G. Pals*[4], *M. M. A. M. Mannens*[1], *E. J. Meijers-Heijboer*[1,4];
[1]*Academic Medical Center, dept. of Clinical Genetics, Amsterdam, Netherlands,* [2]*VU Universtity, Dept. of Communituy Genetics, Amsterdam, Netherlands,* [3]*Waterland Oost Midwifery Practice, Volendam, Netherlands,* [4]*VU University Medical Center, dept. of Clinical Genetics, Amsterdam, Netherlands,* [5]*Academic Medical Center, dept. of neurogenetics, Amsterdam, Netherlands.*

Autosomal recessive disorders in general are rare, but may be high prevalent in subpopulations. Within a small community in the Netherlands relatively many children are born with a severe autosomal recessive disease (approximately 2-4 children of 220 live births a year). Founder mutations were identified for the four following diseases: pontocerebellar hypoplasia type 2 (PCH2), foetal akinenesia syndrome (FAS), rhizomelic chondrodys-

plasia punctata type 1 (RCDP1), and osteogenesis imperfecta type II/III (OI). Children with these disorders suffer significant morbidity and have a reduced lifespan. This warranted the start of a preconception outpatients' clinic in collaboration with the local midwifery practice, aimed at couples planning a pregnancy. Standard preconceptional advice is given, combined with genetic counseling.
From September 2012 till January 2013, 63 individuals (related to 32 couples) were counseled in this clinic and carrier testing for the above disorders was performed.
In total 19/63 individuals (30%) were identified as carrier: nine were carriers of FAS, eight of PCH2, three of RCDP1 and one of OI. One carrier couple at high risk (25%) was identified. Two persons were carrier of two diseases, thus 19 individuals were carrier. In 73% (n= 46) individuals no positive family history of carriers/affected persons within the family was known. Nine of these 46 (20%) individuals were carrier of at least one disease.
These first results stress the importance of offering preconception carrier screening within populations with high prevalence of specific genetic disorders, and can be used as a test case for other community-based carrier screening programmes.

Comparative gene expression profiling of placentas from patients with moderate and severe preeclampsia

E. Trifonova[1], *T. Gabidulina*[2], *N. Ershov*[3], *A. Vorozhishcheva*[1], *V. Stepanov*[1];
[1]*Institute for Medical Genetics, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation,* [2]*The Institute for Obstetrics and Gynecology, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation,* [3]*The Institute of Cytology and Genetics, The Siberian Branch of the Russian Academy of Sciences, Tomsk, Russian Federation.*

Preeclampsia is a pregnancy related disease associated with hypertension, proteinuria and increased maternal and perinatal morbidity and mortality, without known underlying mechanism and preventive treatment. To investigate how the expression of maternal genes contributes to the mechanisms underlying the progression of the disease, we investigate global placental gene expression in preeclampsia using microarray technology. Genome-wide transcriptional profiling was performed on placental tissue from moderate preeclamptic (n=5), severe preeclamptic (n=5) and normal (n=11) pregnancies. Among the 47000 transcripts that were screened, 63 were found to be differentially expressed between normal and pre-eclamptic tissues (Fold Change>1.5, FDR<0.1). Among these candidates, 53 were up-regulated and 13 were down-regulated. These differentially expressed genes were associated with such biological processes as response to stress, immune system process, regulation of cell communication, intracellular signaling cascade etc. Comparison between moderate and severe preeclampsia showed 8 differentially expressed genes. Two genes - BAG3, encoding Bcl-2-binding protein, whose main function is the inhibition of chaperone HSP70/HSC70, and HSPA1A, whose product is heat shock protein 70 (HSP70) are the most interesting for further study. These genes may therefore prove to be novel biological markers by which the severity of this condition could be predicted. This finding may provide insight into the pathophysiology of the disorder and lead to new therapeutic possibilities for this disease. This work was supported by the Russian Foundation for Basic Research.

Background: Pregnancy-induced hypertension (PIH) affects almost 10% of pregnant women and represents a major cause of morbidity worldwide for both mother and child. The major mechanisms currently associated with PIH are metabolic and immune processes, cell communications, and angiogenesis. We have further explored the molecular basis of PIH considering both the maternal and the fetal components.
Methods: Gene expression analysis (HumanHT-12 v4-Expression BeadChip; Illumina) was performed in placental tissue, comparing expression profiles between cases (pregnant women with PIH; n=23) and controls (pregnant women without PIH; n=49). Both maternal and fetal sides of the placenta were investigated. "Genome studio" software (Illumina) was used for the data analysis. A fold change ≥1.5 and a false discovery rate (FDR)-based multiple testing correction were applied in evaluating differential gene expression.
Results: Expression data demonstrated a significant dysregulation of extracellular matrix genes involved in cell migration and focal/cell adhesion (up-regulated in fetal, down-regulated in the maternal placenta side; $p=10^{-11}$) and secreted molecules of immune adaptation (up-regulated in maternal, down-regulated in fetal placenta side; $p=10^{-3}$). For each subset we focused on specific genes: inflammation (*AIF1,APLN,VCAM1*) and hormone (*CGB5*) genes in the maternal side; apoptotic genes (*IL33,CASP1,CADM1*) and degradation molecules (*HTRA4,RNASE4*) in the fetal side of placenta.
Conclusions: The concomitant identification of differential expression of genes across the placental wall strongly highlights the molecular crosstalk between mother and fetus. These data are consistent with a model where trophoblast invasion is defective as a consequence of an immune-associated mechanism affecting cell migration, invasion and survival.

Sex determination, in 46,XY individuals, primarily occurs through the action of *SRY* gene. Whereas sex development in 46,XX individuals was thought to be merely a default pathway, several cases of XX female-to-male sex reversal have been described without presence of *SRY* gene. Further, loss of function mutations in some genes, such as *WNT4*, *RSPO1* e *FOXL2* have been considered to be ovarian promoting or anti-testis genes. Recently, *NR5A1* gene was associated with patients with abnormalities in ovarian development and function, like in premature ovarian failure (POF). Transcription of a large set of genes associated to reproduction and sex determination and differentiation is regulated by SF-1, a nuclear receptor encoded by *NR5A1* gene. The direct sequencing of the seven exons of *NR5A1*, including the promoter region, intron/exon boundaries and 3'UTR was performed in 50 patients (n=100 alleles) with POF. The study revealed 9 polymorphisms (SNPs): rs113048364 within 5'UTR (n=1), rs115601896 within intron 2 (n=3), rs138805488 within exon 3 (n=1), rs1110062 and rs1110061 within intron 4 (n=4), rs2297605 within intron 5 (n=14), rs7037254 within intron 7 (n=32) and rs5900617 and rs10120967 within 3'UTR (n=35 and n=26). The mutation p.Gly146Ala, considered a SNP (rs1110061), has now been associated with POF patients and in the present screening it was identified in 4 alleles. Considering the several interactions that *NR5A1* play and the fact that p.Gly146Ala leads to a decrease in the transactivation capability upon some gene promoters, this research can be important to elucidate the role of *NR5A1* in ovarian development and maintenance.

Repeat Primed PCR (RP-PCR) method for detection of FMR1 gene premutation in Primary ovarian insufficiency

A. Beke[1], *H. Piko*[2], *V. Karcagi*[2], *B. Nagy*[1], *M. J. Molnar*[3], *J. J. Rigo*[1];
[1]Semmelweis University, 1st Department of Obstetrics and Gynecology, Budapest, Hungary, [2]National Institute of Environmental Health, Department of Molecular Genetics and Diagnostics, Budapest, Hungary, [3]Semmelweis University, Genomic Medicine and Institute of Rare Disorders, Budapest, Hungary.

The primary ovarian insufficiency/premature ovarian failure (POI/POF) in women in fertile age can significantly influence the reproductive chances.
Objective: Introduction of a molecular genetic test method diagnostics of the POI/POF patients by which accurate and reliable results can be predicted concerned about the disease. The main research targets in patients of premature ovarian failure are the detection of the increase in the number of (CGG)n repeats in the FMR1 gene promoter region. **Patients and methods:** There was molecular genetic testing in 78 patients examined with suspected POI. Early ovarian depletion criteria were consistent with international protocols: secondary amenorrhea, ovarian failure up to the age of 40 years, levels of FSH≥ 40 IU/L, and low estrogen levels. As a first step the patients were tested by Southern blot analysis and we subsequently investigated the CGG trinucleotide repeats in the FMR1 promoter region by hybridization with radiolabeled DNA probes. In all cases, which confirmed the pre-mutation status by the Southern blot, we completed the so-called Repeat Primed PCR (RP-PCR) method used to determine the exact number of CGG repeats.
Results: In 8 cases out of 78 patients we could verify the increase of the CGG repeat number, it is 10.1% of the cases. In one cases we found mosaic form.
Conclusions: The genetic examination of the premature ovarian failure is very important for the patient and her family also, because the genetic results have serious influence on the reproductive possibilities and family planning of the premutation carriers.

Retrospective evaluation of prenatal diagnosis records in a reference genetics center: 18 years experience, 7935 samples

B. Durmaz[1], *E. A. Ates*[1], *T. Atik*[2], *B. Erturk*[1], *H. Taslidere*[1], *N. Aliyeva*[1], *A. Durmaz*[1], *E. Karaca*[1], *A. Aykut*[1], *A. Rashnonejad*[3], *C. Gunduz*[4], *H. Onay*[1], *H. Akin*[1], *O. Cogulu*[1,2], *F. Ozkinay*[1,2];
[1]Department of Medical Genetics, Ege University, Faculty of Medicine, Izmir, Turkey, [2]Department of Pediatrics, Division of Genetics, Ege University, Faculty of Medicine, Izmir, Turkey, [3]Department of Biotechnology, Ege University, Faculty of Science, Izmir, Turkey, [4]Department of Medical Biology, Ege University, Faculty of Medicine, Izmir, Turkey.

The aim of this study is to review and evaluate the prenatal diagnosis records in terms of demographic data, distributions throughout the years, indications, cytogenetic results and discuss the results in different aspects. A total of 7148 amniocentesis (ASI), 505 chorionic villus sampling (CVS) and 282 cordocentesis (CRD) results were retrospectively evaluated between the period 1995 to 2012. The mean age of the study group was 33.2±5.88. The mean gestational week for ASI, CVS and CRD was 17.74±1.65, 12.16±1.13 and 22.69±2.59 respectively. The number of referrals significantly increased throughout the years. The most common indications were advanced maternal age (49.5%), abnormal maternal screening tests (26.0%) and abnormal fetal ultrasound findings (%10.2) which were increased throughout the years. The demand for the prenatal testing of single gene disorders such as beta thalassemia (4.1%) and spinal muscular atrophy (0.7%) has increased. Normal karyotype was observed in 93% of all samples. Autosomal trisomies were detected in 2.2%. Numerical sex chromosomal anomalies including 45,X; 47,XXY and others constituted 1.1%. Balanced and unbalanced structural anomalies comprised 0.8% and 0.1% of all samples respectively. Risk of having trisomy 21 significantly increased with advanced maternal age, particularly after the age of 40. Abnormal maternal serum screening tests over 1/200 were positively correlated with trisomy 21. Cystic hygroma and intrauterine growth retardation were the most significant ultrasound findings resulted with abnormal karyotype. In conclusion, our results have contributed to our knowledge of prenatal testing and genetic counseling which may provide to develop long term and effective strategies.

Offering pregnant couples at increased risk for Down syndrome a choice between 5-10 Mb and 0,5 Mb array analysis: a first impression of what pregnant couples really want

S. Riedijk, *N. Boor, K. Diderich, D. van Opstal, G. Srebniak, M. Knapen, A. Tibben, A. Tibben, R. Galjaard;*
Erasmus Medical Center, Rotterdam, Netherlands.

Whole genome SNP array testing with a resolution of 0.5Mb is now available in our university hospital for patients with increased risk for aneuploidy and normal ultrasound examination results, referred mainly due to advanced maternal age or abnormal first trimester screening results. Thanks to higher testing resolution array technique reveals not only pathogenic abnormalities, but also so called risk factors or susceptibility loci for intellectual disability/developmental delay/autism spectrum disorders or epilepsy. Thus, more information about the (future) health of the unborn child can be obtained with this technique. We offered pregnant couples the choice between array results obtained by analysis at a 0,5 Mb or a 5 Mb resolution, the latter similar to that of karyotyping. The preliminary results of our pilot (n=30) are that 18% chose the 5 Mb resolution, 33% opted for 0.5 Mb resolution excluding risk factors and 47% opted for 0.5 Mb resolution including risk factors. Refusal to learn about risk factors was out of fear of becoming needlessly worried. Over 74% of couples indicated the wish to decide how much information they desired about the (future) health of their unborn child.
So far, our results indicate that pregnant couples differed regarding their preferences. In addition all couples appreciated being offered the choice. It seems that with the broadening of techniques for prenatal diagnosis, reproductive autonomy may only be accomplished by offering pregnant couples a choice regarding what they wish to learn about the (future) health of their unborn child.

[1]UF de Cytogenetique-Hopital Robert Debre, AP HP, Paris, France, [2]Service de Biologie du Développement- Hôpital Robert Debré- AP-HP, Paris, France, [3]Université Paris 7 Diderot, Paris, France, [4]Service de Gynécologie Obstétrique-Hôpital Robert Debré- AP-HP, Paris, France, [5]Laboratoire de Cytogénétique- Hôpital Jean Verdier- AP-HP, Bondy, France, [6]Université Paris 13, Sorbonne Cité Paris, Paris, France.

Karyotyping is the gold standard method for detecting chromosome imbalances in products of conception (POCs) but this method based upon cell culture gives a high failure rate. The KaryoLite™ BACs-on-Beads™ (KL-BoBs™) assay is a new molecular cytogenetic test using a multiplex microsphere-based suspension array technology. KL-BoBs™ quantifies proximal and terminal regions of each chromosome arms.
We prospectively tested with KL-BoBs™ each POC sample (n=175) that we received at our laboratory for chromosome analysis. It was mainly polymalformed fetus but also in utero fetal deaths and terminations of pregnancy not previously characterized by karyotype. For each sample, a cell culture was done in parallel, in order to verify by FISH and/or karyotyping, any abnormality suspected on BoBs.
We found 11.5% (20/175) chromosomal imbalances in our cohort. The failure rate was 4.6%. BoBs profile showed visible maternal cell contamination in 2.3% of the male samples. Aneuploidies account for 60% of abnormalities detected, structural chromosome imbalances for 20%, triploidy (69,XXY) for 10%, and sex chromosome abnormalities for 10%.
Our results are concordant with those found in the literature. The technical performance and feasibility of this assay for rapid detection of chromosomal abnormalities in POCs are rather good. Our data showed best results concerning detection of structural abnormalities than those reported before. However, KL-BoBs™ had also limitations as the inability to well detect polyploidy or low mosaicism. But a good management of this assay, helped by FISH or microarray, makes this test a useful tool for chromosome analysis of POCs.

Prenatal screening for Noonan syndrome mutations: high frequencies of PTPN11 mutations in fetuses with elevated nuchal translucency

A. Baumer[1], *J. Wisser*[2], *E. Wey*[1], *B. Oneda*[1], *K. Steindl*[1], *R. C. Mueller*[3], *R. Zimmermann*[2], *A. Rauch*[1];
[1]*Institute of Medical Genetics, Schwerzenbach, Switzerland,* [2]*Women's Hospital Zurich, Zurich, Switzerland,* [3]*Private Practice, Winterthur, Switzerland.*

Noonan syndrome is a common autosomal dominant disorder characterized by cardiovascular anomalies, short stature, broad neck, characteristic facial features, lymphatic dysplasia and variable degrees of intellectual disability in about 1/3 of patients. Ultrasonographic abnormalities for the prenatal diagnosis of Noonan syndrome are rather nonspecific: e.g. elevated nuchal translucency (NT), cystic hygroma, hydrops fetalis.
Pergament et al. (2011) reported the detection of Noonan syndrome mutations in the PTPN11, SOS1 and RAF1 genes in a total of 6.6% (n=120) of fetuses with elevated NT by array mutational sequencing after exclusion of a chromosomal imbalance.
Croonen et al (2012) report a higher detection of Noonan syndrome mutations (17.3%) by sequencing of all coding regions of the PTPN11, SOS1, KRAS and RAF1 genes. In these two publications PTPN11 mutations were detected in 4.1% and 12% of cases, respectively.
We performed PTPN11 sequencing of the whole coding region and array mutational sequencing of further known mutations after normal karyotyping and microarray testing in fetuses with NT >3mm. Although the number of cases we have screened so far is much lower (20 cases) the percentage of PTPN11 mutations of 25% is much higher. NT varied from 3 to 8 mm (mean: 6.04 mm). The PTPN11 mutations in our collective were all de novo and had already been described as being associated with Noonan syndrome. The aims of our study are to further collect phenotypic and genotypic data in prenatal cases and to investigate possible correlations between the NT measurements and the gene mutations.

Complex Fetoplacental chromosomal discrepancy detected by QF-PCR

E. Stathaki[1], *F. Simon*[1], *J. Matute*[2], *P. Extermann*[3], *S. Dahoun*[1], ***F. Sloan-Béna***[1];
[1]*Geneva University Hospitals, Geneva, Switzerland,* [2]*Bd Georges Favon, Geneva, Switzerland,* [3]*Dianecho, Geneva, Switzerland.*

Quantitative fluorescent PCR (QF-PCR) have been introduced to perform rapid prenatal diagnosis of common chromosome aneuploidies that allows 24 hr diagnosis of the most prevalent trisomies (13, 18, 21) thus providing rapid reassurance for women and early reflexion on pregnancy management for abnormal foetuses.
Foetoplacental discrepancy occurs in 1-2% of cases with majority of chromosomal abnormality confined to the placenta while in rare instances, the placental karyotype may be normal and fetal cells show an abnormal karyotype.
We report the situation of a 35-year-old gravida referred at 15 weeks of gestation with an increased 1st trimester serum screening risk 1/80.
The QF-PCR testing showed triallelic profile for 4/5 informative microsatellites D21S1435, D21S226, D21S1411 and D21S1270 with unusual peak area ratios of 2:1:1. The most proximal D21S11 indicated a normal diploid allele with peak area ratio of 1:1. Based on the semi-quantitative approach of QF-PCR, we determined that all the triallelic microsatellite one peak area ratio value was twice of the others two and analysis of parental samples showed in the fetus sample, one paternal allele (peak area ratio 1) and two maternal alleles (peak area ratios 0,5:0,5). Cytogenetic analysis identified a normal karyotype 46,XY [15]. No ultrasound abnormality was seen and the pregnancy was carried on. After delivery, placental analysis revealed a trisomy 21 mosaicism in 56% of the cells with isochromosome 21: 46,XY,der(21;21)(q10;q10)[30]/46,XY[23]. We describe the potential mechanisms by which this uncommon situation of trisomy rescue occurred and underline the complexity to interpretate of QF-PCR electrophoresis profiles

Expanded prenatal genetic screening: Simultaneous detection of chromosome aneuploidies and mutations for monogenetic diseases

A. Erjavec Skerget, T. Bukovnik, Š. Stangler Herodež, B. Zagradišnik, ***N. Kokalj Vokač****;*
University Medical Centre Maribor, Maribor, Slovenia.

Chromosomal aberrations are the main cause of severe developmental abnormalities during pregnancy. Quantitative fluorescent polymerase chain reaction (QFPCR) has established itself in recent years as an alternative detection method for prenatal chromosomal abnormalities which complements cytogenetic analysis . QFPCR offers a cheap and quick detection of the most common prenatal chromosomal aneuploidies which affect chromosomes 13, 18, 21, X and Y.
In this paper we present an improved QFPCR method, which allows the simultaneous detection of chromosome aneuploidies and common mutations for monogenetic diseases: cystic fibrosis, spinal muscular atrophy and congenital adrenal hyperplasia.
Allele specific PCR primers detecting following mutations for most common monogenetic diseases were incorporated into QFPCR oligonucleotide mixtures; the delta F508 mutation in CFTR gene (cystic fibrosis), the exon 7 mutation in SMN1 gene (spinal muscular atrophy), the I172N and IVS2-12A/C>G mutations and the deletion or gene conversion of the CYP21A2 gene (congenital adrenal hyperplasia). In addition, the presence of the RhD gene and Kell blood group T193M was detected as well.
A 100% concordance was obtained when 48 samples of genomic DNA with known genotypes were reanalyzed in a blind experiment. The quantitative nature of QFPCR for aneuploidy detection was not compromised. All mutations were correctly detected and non-specific signals indicating non-specific allele amplification were also absent,
We conclude that QFPCR can be amended for prenatal screening of frequent mutations which are characteristic for certain monogenetic diseases. Further mutations/genetic conditions may be added to the presented setting.

RASSF1A in maternal plasma as a molecular marker of preeclampsia

A. Kolialexi[1], *K. Agiannitopoulos*[1], *G. Tounta*[1], *A. Destouni*[1], ***E. Kanavakis***[1], *N. Papantoniou*[2], *A. Mavrou*[1];
[1]*Department of Medical Genetics, Athens University, Athens, Greece,* [2]*1st Department of Obstetrics & Gynecology, Athens University, Athens, Greece.*

Objectives: To quantitate cell free (cf) and cell free fetal (cff) DNA in maternal plasma by determining *RASSF1A* levels before and after enzyme digestion in women who subsequently developed preeclampsia (PE) and compare them to uncomplicated pregnancies.
Methods: 24 samples from pregnant women who developed PE and 48 samples from women with uncomplicated pregnancies were analysed. Blood samples were obtained at 11-13 weeks (mean 12.1±0.6). cfDNA was determined by quantifying *RASSF1A* using qRT-PCR. A second qRT-PCR was performed following methylation-sensitive enzyme digestion by *BstUI,* in order to quantitate hypermethylated *RASSF1A* sequences of fetal origin. *ACTB* gene was used as control to confirm complete enzyme digestion.
Results: cfDNA and cffDNA levels were significantly increased in women who developed PE as compared to uncomplicated pregnancies (median cfDNA: 9402 vs 2698, median cffDNA: 934.5 vs 62 respectively). Following ROC curve analysis a cut-off value of 7486Eq/mL for cfDNA and 512Eq/mL for cffDNA were chosen which provided a sensitivity of 75% and 100% and specificity of 98% and 100% respectively, to identify women at risk for PE.
Conclusions: The study demonstrates potential use of cffDNA and cffDNA in maternal plasma as markers for the early prediction of women at risk for PE. Early prediction during the first trimester of pregnancy could enable planning of an appropriate management and close surveillance of pregnant women at risk.
Acknowledgment. The study was funded by « Aristeia», through the operation program «Education and lifelong learning» co-financed by EU and the Greek state.

Genotype-Phenotype Analysis of Recombinant Chromosome 4 Syndrome: An Array-CGH Study and Literature Review

M. Hemmat*;*
Quest Diagnostics, Nichols institute, san Juan Capistrano, CA, United States.

Recombinant chromosome 4 is a rare constitutional rearrangement arising from pericentric inversion and consisting of a duplicated segment of 4p13/p15→4pter and a deleted segment of 4q35→4qter. The clinical spectrum commonly includes growth retardation, microcephaly, broad nose with anteverted nares, thin upper lips, abnormal ears, pointed chin, short neck, broad chest, and cardiac and genitourinary defects. We describe the second

case in which array-CGH was used in a 1-year-old boy patient with consistent clinical features. Conventional cytogenetics and FISH documented a recombinant chromosome 4, derived from a paternal pericentric inversion, leading to partial trisomy 4p and partial monosomy 4q. Array-CGH, performed to further characterize the rearranged chromosome 4 and delineate the breakpoints, documented a small (4.36 Mb) 4q35.1 terminal deletion and a large (23.81) Mb 4p15.1 terminal duplication. Genotype-phenotype analysis of the 10 reported cases and the present case indicated relatively consistent clinical features and breakpoints. This consistency was more evident in the two cases characterized by array-CGH, where both showed the common breakpoints of p15.1 and q35.1. A genotype-phenotype correlation study between rec (4), dup (4p), and del (4q) syndromes revealed that urogenital and cardiac defects are likely due to the deletion of 4q; other clinical features are likely due to 4p duplication. Our findings suggest that recombinant 4 syndrome is a discrete entity with relatively consistent phenotype that can be suspected on the basis of clinical features. Cytogenomic and molecular studies of patients with rec (4) may yield additional information on specific gene contributions to the phenotype.

P19.77

Recurrent pregnancy loss - karyotyping products of conception should be of the first line of investigation

M. Goldstein, *A. Reches, K. Markus-Bustani, Y. Yaron;*
Prenatal Genetic Diagnosis Unit & Genetic Institute, Tel Aviv Sourasky Medical Center. Tel Aviv University, Tel Aviv, Israel.

Recurrent pregnancy loss (RPL) affects ~1% of couples. Determining the cause and recurrence risk of miscarriages impacts family planning and may alleviate feelings of guilt or inadequacy. Aneuploidy accounts for up to 60% of early spontaneous abortions in general. The purpose of this study was to evaluate the benefit of chromosomal analysis of products of conception (POC) in RPL.
A total of 131 POCs from women with RPL were referred for karyotyping to the Genetic Institute, Tel Aviv Sourasky Medical Center, Israel.
Cytogenetic results were compiled along with demographic and clinical data. Cultures were successfully obtained in 92.4% of samples (121/131). Maternal cell growth could not be ruled out in 10 non-chorion samples with a female karyotype. Of the 111 conclusive cases, abnormal karyotype was detected in 65 (58.6%). Numerical changes were found in 43 (38.7%) and structural abnormalities in 5 (4.5%): 3 inherited and unbalanced translocations, and 2 were de novo, one of each was accompanied by trisomy. Seven cases (6.3%) revealed triploidy. Sex chromosome aberrations were detected in 10 cases (9%). The remaining 46 samples displayed a normal karyotype. Interestingly, the incidence of abnormal karyotype (~60%) was similar regardless of the number of previous pregnancies or miscarriages.
Our study demonstrates that the majority of RPLs are due to sporadic chromosomal imbalances which will readily be detected by conventional cytogenetic analysis, making other causes for RPL (such as uterine anomalies or thrombophilia) far less frequent. We suggest that karyotyping of POC be the first line in evaluating RPL.

Improvement of the non-invasive fetal *RHD* detection method and application in the first trimester of pregnancy

Z. Lasabová[1], *I. Švecová*[2], *A. Mendelová*[2], *M. Haško*[2], *I. Hudecova*[2], *V. Janušicová*[2], *M. Telková*[1], *K. Gemzová*[1], *J. Danko*[2];
[1]*Comenius University, Jessenius Faculty of Medicine, Dept. of Molecular Biology, Martin, Slovakia,* [2]*Comenius University, Jessenius Faculty of Medicine, Dept. of Obstetrics and Gynecology, Martin, Slovakia.*

The detection of *RHD* genotype of the fetus in plasma of RhD-negative women is based on *RHD* gene deletion. However, in some cases the *RHD* deletion is not complete. Here, we use an upstream step including the maternal DNA testing for exons 7 and 10 of the *RHD* gene. Then after, the plasma genotyping was performed with primers for exons 7 and 10. We compared the Ct results of method I and II using extracted DNA concentrated from 1/7 plasma volume in 25 µl PCR volume and ¼ of the plasma volume in 30 µl PCR, respectively. The real-time PCR was performed in triplicates and used *HBB* for total and *SRY* for fetal DNA as controls. The *RHD* genotype was compared to the immunologically assessed phenotype of the newborn. Student *t*- test was used for statistical evaluation. The methods I and II were applied on plasma samples obtained from 37 and 20 pregnant RhD- women in II. trimester, respectively. All 33 were *RHD* positive newborns were confirmed immunologically. From 24 immunologically RhD negative newborns were 23 negative and one false positive. The mean Ct values for exon 7 were 39.98 and 36.35 ($P < 0.0001$). The mean Ct values for exon 10 were 38.99 and 38.47 ($P=0.32$). Testing in 19 samples from I. trimester showed 100% specificity and sensitivity. Here, we describe an upstream step of maternal DNA testing and improve the Ct values to enable the I. trimester
testing. Using more samples, we will perform ROC evaluation.

P19.79

Quality of life of 19 patients with Mayer-Rokitansky-Kuster-Hauser Syndrome.

S. Turyk, *M. Sakurai, M. Notaris, S. Bonsergent, S. Pradier;*
Hospital Britanico de Buenos Aires, Buenos Aires, Argentina.

Mayer-Rokitansky-Kuster-Hauser Syndrome (MRKH) is a congenital anomaly of the female genital tract, estimated to occur in approximately 1 in every 4500 females. Phenotype features include upper vaginal atresia and uterine abnormalities that range from an absent to small uterus. Affected females have functioning ovaries, normal external genitalia and normal female karyotype. It is often found associated to renal agenesis or adysplasia as well as skeletal malformations. MRKH Syndrome is the second cause of amenorrhea and is often discovered in adolescence due to primary amenorrhea. In this study, 19 MRKH patients from 18 non consanguineous families were identified through phenotype, hormonal, chromosome, echography, laparoscopic / laparotomy studies carried out between 1989 and 2009. The participants visit the Hospital annually. A semi-structured interview was held in order to obtain information about life progress and the following specific content areas were addressed: educational progress, relationships, employment, leisure activity and sexual identity. The condition of MRKH affects a woman's quality of living by narrowing some of life's possibilities such as intercourse and childbearing. However, almost all patients reported on marriage or cohabitation. Women who had had surgery did not experience better sexual wellness or sexual function than those who were untreated. The majority were well-educated, held full-time employment, involved in optimal and diverse recreation, were financially independent and all reported to have heterosexual identity.

SOX9 duplication in 46,XX infertile males SRY negative: a case report

L. Kraoua[1], *M. Chaabouni*[1], *H. Dridi*[1], *M. Trabelsi*[1], *M. Basli*[2], *F. Maazoul*[1], *R. M'Rad*[1], *O. Zuffardi*[3], *H. Chaabouni*[1];
[1]*Department of genetics, Charles Nicolle Hospital, Tunis, Tunisia,* [2]*Department of obstetrics and gynecology, Military Hospital, Tunis, Tunisia,* [3]*Department of Molecular Medicine, Pavia, Italy.*

Male development is normally triggered by the transient expression of the SRY gene, which initiates a cascade of gene interactions orchestrated by SOX9, leading to the formation of testes from bipotential gonads. SOX9 is considered to be the direct target gene of the protein encoded by SRY and its overexpression in an XX murine gonad can lead to male development in the absence of Sry. Recently, two families were reported with respectively a 178 kb duplication and 96 kb triplication 500 kb upstream of SOX9 in the gene desert region ending in which 46,XY duplicated persons were completely normal and fertile whereas the 46,XX ones were infertile males. Here, we report a new case of 46,XX infertile male, SRY negative, and with SOX9 duplication. The patient, aged of 30 years, was referred to our department for genetic investigation of his azoospermia. Examination showed normal male secondary sexual characteristics and bilateral gynecomastia. The patient had low serum testosterone concentrations and increased follicle stimulating hormone and luteinising hormone. The scrotal sonography was normal. The karyotype revealed 46,XX chromosome constitution and SRY was negative. Array-CGH analysis showed a duplication of about 220-250 kb of the long arm of chromosome 17 [dup(17)(q24.3)]. The duplication maps about 400 kb upstream of SOX9 gene. Our results confirm the previously reports supporting that even in absence of SRY, complete male differentiation may occur, possibly driven by overexpression of SOX9 in the gonadal ridge, as a consequence of the amplification of a gene desert region.

Utility of sperm FISH analysis in patients with structural chromosomal abnormalities before pre-implantation genetic diagnosis.

*N. Le Foll[1], M. Le Lorc'h[2], L. Hester[3], F. Lamazou[3], **S. Romana**[2], N. Frydman[3];*
[1]Histologie-Embryologie-Biologie de la Reproduction, hôpital Cochin, Paris, France, [2]Histologie-Embryologie-Cytogénétique, hôpital Necker, Paris, France, [3]Unité fonctionnelle de Biologie de la Reproduction, hôpital Antoine-Béclère, Paris, France.

Objective: To optimize orientation of couples towards PGD due to paternal structural chromosomal abnormalities or towards the alternative ART with donor sperm.
Methods and Materials: 10 patients were included in this prospective study. 9 harbored a reciprocal translocation and 1 insertion. Sperm FISH was carried out on semen samples collected on the day of oocyte retrieval. Three subtelomeric probes were used, allowing distinction of meiotic segregation. For each semen sample, 250 spermatozoa nuclei were analyzed by an automated capture system. A retrospective study of 133 cycles and 108 ovarian punctures due to paternal reciprocal translocations was conducted in parallel.
Results: No correlation was found between chromosome segregation profiles in spermatozoa and embryos, except for the adjacent 2 segregation type. The rate of embryos with balanced or normal chromosomal profiles was less than that in spermatozoa in 8 out of 10 cases. The retrospective evaluation showed that it is not the age, but the number of oocytes injected that was positively correlated with the number of chromosomally balanced embryos obtained.
Conclusions: Combined sperm FISH and ovarian response to controlled hyperstimulation could be used as predictive criteria for PDG outcome which would allow orientation of couples towards the most adapted ART offering them the best chance of becoming parents.

P19.82

Cryptic familial submicroscopic translocation t(9;17)(q34.3;p13.3) associated with multiple malformation pregnancies and an affected child.

*P. C. Evangelidou, **N. Salameh**, C. Ioannidou, E. Panayiotou, E. Constantinou, A. Alexandrou, M. Moutafi, G. Tanteles, V. Anastasiadou, P. C. Patsalis, C. Sismani;*
The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

We present here the study of a familial submicroscopic reciprocal two-way translocation, discovered fortuitously through prenatal diagnosis.

A 12-week pregnancy was referred for chromosomal analysis and array-CGH due to increased nuchal translucency. Chromosomal analysis was normal but array -CGH (105K) revealed a double segmental imbalance; a terminal deletion on chromosome 9q (1.35Mb) and a terminal duplication of chromosome 17p (1.95Mb). Both imbalances fall within known syndromic regions; Miller-Dieker (includes YWHAE gene but not PAFAH1B1 gene) and 9q subtelomeric deletion syndrome. Parental subtelomeric FISH testing revealed the presence of a submicroscopic apparently balanced translocation between chromosomes 9 and 17 in the mother. Subsequent normal FISH analysis of the maternal grandparents revealed that the translocation occurred *de novo* in the mother. Following genetic counselling the couple elected to terminate the pregnancy. Family history revealed an affected son with mild intellectual disability, short stature, dysmorphic features and hypoplastic corpus callosum (no lissencephaly) and a previous pregnancy terminated based on multiple severe ultrasound findings including tetralogy of Fallot. The parents consented to perform array-CGH on stored genetic material from their previous pregnancy and their affected child which revealed the same unbalanced products of the translocation on both (a duplication on chromosome 9q and a deletion of chromosome 17p). Possibly both aberrations have an effect on the affected child's phenotype and the ultrasound findings from the terminated pregnancy. This case demonstrates that prenatal diagnosis by array-CGH is essential in cases with ultrasound findings and that obtaining detailed family history is of paramount importance.

Mosaic tetrasomy 21 in a female fetus with isolated complex heart malformation at second-trimester ultrasound screening.

***M. Perez**[1], C. Corsini[1], C. Ragon[2], E. Mousty[3], Y. Musizzano[4], A. Chaze[5], N. Bigi[1], G. Lefort[5], M. Girard[5], M. Tournaire[5], E. Haquet[1], A. Schneider[5], S. Taviaux[5], F. Pellestor[5], P. Blanchet[1], P. Callier[2], J. Chiesa[6], P. Sarda[1], D. Geneviève[1], J. Puechberty[1];*
[1]Département de Génétique Médicale, Hôpital Arnaud de Villeneuve, Montpellier, France, [2]Laboratoire de Cytogénétique, Hôpital du Bocage, Dijon, France, [3]Département de Gynécologie-Obstétrique, Hôpital Carémeau, Nîmes, France, [4]Laboratoire d'Anatomie et Cytologie Pathologique, Hôpital Gui-de-Chauliac, Montpellier, France, [5]Laboratoire de Génétique Chromosomique, Hôpital Arnaud de Villeneuve, Montpellier, France, [6]Laboratoire de Cytogénétique, Hôpital Carémeau, Nîmes, France.

Tetrasomy 21 is a rare cytogenetic aneuploidy at birth, but is often reported in acute leukemias. Fewer than 10 cases have been published in the literature and tetrasomy 21 was frequently initially confused with tetrasomy 12p (Pallister-Killian syndrome). The phenotype largely resembles that of trisomy 21. We report a mosaic tetrasomy 21 diagnosed in a female fetus born to healthy unrelated parents (maternal age 39 years). First-trimester ultrasound showed no structural anomalies (nuchal translucency 2 mm and crown-rump length 77 mm), and maternal serum markers were at low risk for trisomy 21 (1/2500). Second-trimester ultrasound at 22.5 weeks' gestation (WG) revealed isolated complete atrioventricular septal defect (AVSD). Interphase FISH for trisomy 21 and fetal karyotype on amniotic fluid were normal (46,XX). Because of the severity of the heart malformation, termination of pregnancy was discussed with the parents and performed at 30 WG. Pathology showed facial dysmorphism (moon face, flat profile, upslanting palpebral fissures, hypertelorism, marked suborbital folds, lingual interposition, dysmorphic ears), short arms, broad hands, confirmation of the complexe heart malformation (AVSD), normal bone radiographies, features strongly suggestive of trisomy 21. Microarray analysis on lung DNA showed trisomy of all chromosome 21 markers. FISH on touch-preparation slides on lung, liver, and thymus showed mosaic tetrasomy 21/trisomy 21 (74.5%/4,5%), 4% tetrasomy 21, and no aneuploidy, respectively. The phenotype of low-grade tetrasomy 21 is very suggestive of trisomy 21. Consequently, when prenatal diagnosis for trisomy 21 is negative in the light of a characteristic phenotype, mosaicism for tetrasomy 21 should be considered.

When a triploid pregnancy is diagnosed prenatally, the diagnosis of hydatidiform mole relies on the histopathological examination of the tissue from the terminated pregnancy. However, reproducibility is poor and variability is high when histopatologically diagnosing hydatidiform moles.
Triploid pregnancies can have either the chromosomal constitution of two maternal and one paternal sets or two paternal and one maternal sets, but only the conceptuses with two paternal sets has the potential to develop into hydatidiform moles. Therefore, it would be beneficial to introduce a method that reveals the parental origin of the genome of the triploid conceptus as early as possible, at best even before termination.
DNA marker analysis can been used to distinguish the two types of triploid pregnancy but has the disadvantage of requiring a sample from both parents in order to be fully informative, delaying the full diagnosis of the abnormal pregnancy.
Here we present a method, analysing imprinting-patterns, capable of determining the parental origin of the genome of triploid conceptuses within 24 hours; it is inexpensive, simple, and easy to use and parental samples are not needed.

Prenatal detection of fetal aneuploidy using bench top sequencing

T. Zwiefelhofer[1], *P. Whitley*[1], *K. Roy*[1], *R. Jean-Jacques*[1], *M. Ehrich*[2];
[1]*Sequenom Center for Molecular Medicine, San Diego, CA, United States,* [2]*Sequenom Inc, San Diego, CA, United States.*

The clinical implementation of noninvasive prenatal testing (NIPT) for fetal aneuploidy detection via massively parallel sequencing has significantly increased the sensitivity and specificity with which these anomalies are detected prenatally. Despite the many benefits of this approach, one aspect which could be improved upon is the total time required for sample processing. Sample collection to clinical result takes approximately seven days, which can be problematic in special, time critical, situations or when repeat testing is required.

Technical advances have recently produced several low-throughput but fast bench top sequencers which may prove valuable for time sensitive applications. Here, we examine the performance of an NIPT fetal aneuploidy test using the MiSeq® sequencer (Illumina®, San Diego California) and Ion Torrent™ Personal Genome Machine (PGM™) (Life Technologies™, San Diego California). Ten patient samples, eight from women carrying a known euploid fetus and two from women carrying a known trisomy 21 fetus, as determined by fetal karyotyping, were analyzed using these DNA sequencers.

The total number of aligned reads and uniformity of genome coverage was sufficient in both cases to generate the necessary discriminatory power to indicate aneuploidy status. All ten patient samples processed on both sequencing platforms were correctly identified according to their karyotype results. In terms of the required labor, total time, and hands-on time, the MiSeq platform was significantly more efficient than the PGM, though the sequencing itself was faster on the PGM. These instruments may be attractive candidates in a deployable version of the aneuploidy detection assay.

Gestational Age and Maternal Weight Effects on Fetal cfDNA in Maternal Plasma.

E. Wang, *A. Batey, C. Struble, T. Musci, K. Song, A. Oliphant;*
Ariosa Diagnostics, San Jose, CA, United States.

Objective: To determine the effects of gestational age and maternal weight on fraction of fetal cell-free DNA (cfDNA) in maternal plasma and the change in fetal cfDNA amounts within the same patient over time.

Methods: cfDNA was extracted from maternal plasma from 22,384 singleton pregnancies of at least 10 weeks gestation undergoing the Harmony™ Prenatal Test. The Harmony Prenatal Test determined fetal fraction via directed analysis of cfDNA.

Results: At 10 weeks 0 days to 10 weeks 6 days gestation, the median fetal fraction was 10.2%. Between 10 and 21 weeks gestation, fetal fraction increased 0.1% per week ($p < 0.0001$) and 2% of pregnancies were below 4% fetal fraction. Beyond 21 weeks gestation, fetal fraction increased 1% per week (p<0.0001). Fetal fraction was proportional to gestational age and inversely proportional to maternal weight (p=0.0016). Of 135 samples that were redrawn due to insufficient fetal fraction of the initial sample, 76 (56%) had greater than 4% fetal fraction in the sample from the second draw.

Conclusion: Fetal cfDNA increases with gestation, decreases with increasing maternal weight and generally improves upon a blood redraw when the first attempt has insufficient fetal cfDNA.

Short repeat tandem assay refines the diagnosis of molar trophoblastic diseases.

f. marguet[1], *a. lamy*[1], *p. bolze*[2], *j. sabourin*[1], *e. colasse*[1], *m. parésy*[1], *s. patrier*[1];
[1]*Rouen Universitary Hospital, ROUEN, France,* [2]*Lyon Sud Universitary Hospital, Pierre Benite, France.*

Introduction: Complete hydatidiform moles (CHM) and partial hydatidiform moles (PHM) are gestational trophoblastic diseases. CHM are diploid and androgenetic, PHM are triploid with an extra set of paternal chromosomes. Molecular genotyping, which determines the parental origin of alleles, refines the diagnosis.

Materials and Methods: DNA genotyping analysis was performed using the kit AmpFLSTR ® SGM Plus ® PCR Amplification (Life Technologies, Foster City, CA). Genomic DNA of maternal decidua and conceptus was extracted from paraffin embedded tissue sections after macrodissection. 10 short tandem repeat sequences loci and the amelogenin locus (Sex chromosome marker) were amplified in multiplex for each extract. The amplification products were separated by capillary electrophoresis and DNA amplification profiles obtained for conceptus and maternal tissue were compared.

Results and Discussion: 43 cases were analyzed : 11 PHM, 14 CHM, 15 non molar specimens and 3 unclassified diploid molar specimens. In 38 cases molecular genotyping confirmed morphological and immunohistochemical diagnosis : 14 diploid CHM showed exclusively paternal alleles, 10 PMH displayed diandric triploidy and 14 nonmolar specimens were biparental diploid. One unclassified case was a mosaic or chimera. Genotyping was non contributive in 2 cases (due to DNA alteration).

Conclusion: Molecular genotyping allows a more accurate diagnosis of different subtypes of molar gestational trophoblastic diseases.

Reduced fertility of *TSPY* transgenic mice on a FVB/N genetic background

S. Schubert[1], *P. Grzmil*[2], *J. Schmidtke*[1];
[1]*Hannover Medical School, Institute for Human Genetics, Hannover, Germany,* [2]*Jagiellonian University, Department of Genetics and Evolution, Institute of Zoology, Kraków, Poland.*

The *TSPY* gene is conserved in placental mammals and encodes the **t**estis-**s**pecific **p**rotein, **Y** encoded. It is assumed that TSPY plays a role in proliferation and/or meiotic differentiation of testicular germ cells. Recently, *TSPY* copy number variations and mutations within the first exon have been identified as modifiers of spermatogenesis and risk factors for male infertility. Because the laboratory mouse is carrying only a single-copy Y-chromosomal *Tspy* pseudogene (*Tspy-ps*), we generated a *TSPY* transgenic mouse line on a NMRI-outbred strain genetic background (NMRI-Tg(TSPY)9Jshm) that carries a human *TSPY* gene in approximately 50 copies on the mouse Y chromosome. *TSPY* transgenic B6;NMRI-Kit^{Wv}/Kit^{Wv} mice on a mixed NMRI/C57BL/6J genetic background are able to partially rescue spermatogenesis and fertility of homozygous Kit^{Wv}-mutant males. In order to bring the human *TSPY* transgene on FVB/N and C57BL/6J inbred genetic backgrounds we backcrossed for over 10 generations *TSPY* transgenic males with FVB/N-females and C57BL/6J-females, respectively. While fertility and spermatogenesis of *TSPY* transgenic males on a C57BL/6J genetic background were normal, impaired spermatogenesis and fertility were observed in FVB/N-Tg(TSPY)9Jshm mice. *TSPY* transgenic FVB/N males older than 5 months are showing an increased vacuolation of the seminiferous germinal epithelium in comparison to age-matched FVB/N controls. Interestingly, sperm motility parameters such as velocities (VCL, VSL, VAP) and lateral head amplitude (ALH), and mean number of epididymal sperm of FVB/N-Tg(TSPY)9Jshm males were significantly decreased in comparison to FVB/N males, thereby leading to decreased fertility of *TSPY* transgenic FVB/N males.

[1]*CHU, Caen, France,* [2]*CHI, Poissy, France,* [3]*EFS Normandie, Bois-Guillaume, France,* [4]*Hospices civils, Lyon, France,* [5]*Laboratoire Biolille, Lille, France,* [6]*CHU, Toulouse, France,* [7]*APHP, Cochin-St Vincent de Paul, France,* [8]*Centre Hospitalier, Chambéry, France,* [9]*CHU, Grenoble, France,* [10]*CHU, Tours, France,* [11]*Laboratoire cytogénétique, Fort de France, France,* [12]*CHU, Reims, France,* [13]*CHU, Strasbourg, France,* [14]*CHU, Dijon, France,* [15]*CHU, Nancy, France,* [16]*CHU, Rennes, France,* [17]*CHU, Limoges, France,* [18]*CHU, Poitiers, France,* [19]*CHU, Besançon, France,* [20]*CHU, Clermont-Ferrand, France.*

Background: Turner syndrome (TS) is a common sex chromosome aneuploidy (45,X) diagnosed prenatally with an incidence of 0.18%. It is mainly detected due to presence of abnormalities on ultrasound (US) (84%) but it

may be a fortuitous diagnosis. The associated genetic counseling is difficult and the parents' decision to continue or terminate the pregnancy depends on information provided which is different as to presence of US abnormalities, mosaicism with a normal cell line and diagnosis term. We sought to assess the pregnancy outcomes and the influence of multidisciplinary centers for prenatal diagnosis (MCPD) in France on parental decisions in cases of TS.

Methods : a cohort of 1079 french prenatal TS diagnoses between 1980 and 2012 was reported. 20 french laboratories participated to this study. In each case, the karyotype indication, maternal age, year of prenatal testing, sampling procedure, karyotype, associated US findings and outcome were recorded. We statistically (Student test) compared data before and after 1997, the year of application of MCPD.

Results and conclusions : The pregnancy termination rate fell significantly ($p<0.002$) from 90% before 1998 to 80% thereafter. This decline is significant in case of mosaicism (from 69% to 24%, $p<0.05$)), fortuitous diagnosis (from 78% to 26%, $p<0.05$) and especially along pregnancy period (93% on first trimester, 58% and 22% at second and third trimester respectively $p<0.05$), which underlines evolution in way of thinking thanks to MPCD. Nevertheless, due to an early diagnosis, mainly on first trimester, TOP rate remains high in case of lack of mosaicism.

Chromosomes involved in a reciprocal translocation form a quadrivalent at meiosis. These chromosomes segregate by alternate, adjacent-1, adjacent-2, or 3 : 1 modes to give gametes with various balanced or unbalanced chromosome complements. We report the prenatal diagnosis of an unusual segregation of a maternal reciprocal translocation. Ultrasound examination performed on a 24-year old woman at 22 weeks' gestation showed the presence of bilateral ventriculomegaly, short long bones and unusual aspect of the corpus callosum. Subsequently, a microarray performed on uncultured amniocytes showed a gain of 1q42.13q44 in combination with a gain of full 9p and a gain of 9q13q22.32. Karyotype and FISH studies revealed the presence of 47 chromosomes with an abnormal chromosome 1 and two abnormal chromosomes 9 derived from a reciprocal translocation between the long arm of chromosome 1 and the long arm of chromosome 9. After genetic counselling, the pregnancy was terminated at 24 weeks' gestation. Parental karyotypes allowed the detection of a balanced reciprocal translocation in the mother 46,XX,t(1;9)(q42.13;q22.32). Combination of two events is necessary to explain the observed chromosomal imbalances : an alternate segregation during maternal meiosis I in which the two translocated chromosomes are transmitted and the segregation of both sister chromatids of the derived chromosome 9 in a same cell. This segregation of both chromatids may result either from a premature separation of chromatids at meiosis I, or from a nondisjunction at meiosis II. To our knowledge, this unusual pattern of segregation of a common balanced reciprocal translocation has never been reported.

Two cases of large DHCR7 gene deletion in Smith-Lemli-Opitz syndrome

M. Witsch-Baumgartner[1], *K. Hinderhofer*[2], *B. Maas*[2], *D. Haas*[3], *K. Carter*[4], *M. Suri*[4], *J. Zschocke*[1], *H. Sawyer*[5];

[1]*Medical University Innsbruck, Innsbruck, Austria,* [2]*Institute of Human Genetics, Heidelberg University, Heidelberg, Germany,* [3]*Division of Inborn Metabolic Diseases, University Children´s Hospital, Heidelberg, Germany,* [4]*City Hospital Campus, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom,* [5]*Bristol Genetics Laboratory, North Bristol NHS Trust, Bristol, United Kingdom.*

Smith-Lemli-Opitz Syndrome (SLOS, MIM 270400) is an autosomal recessive metabolic malformation syndrome with variable clinical severity. SLOS is caused by mutations in the delta7sterol-reductase gene (DHCR7), resulting in impairment of endogenous cholesterol biosynthesis. More than 100 mutations have been identified and about 380 SLOS patients are documented in the DHCR7 database (http://lovd.i-med.ac.at/home.php), but a second mutation remains unidentified in 4% of patients.

Patient 1 showed growth retardation at birth, short proximal limbs, 2, 3 toe syndactyly, typical heart, and renal defect and facial features. Plasma sterol analysis showed elevated 7- and 8- dehydrocholesterol.

Patient 2 showed also highly elevated 7DHC and typical clinical features of SLOS.

The patients´ and parental DNAs have been analyzed by genomic sequencing of DHCR7 and a self-designed multiplex ligation-dependent probe amplification (MLPA) of exons 2 to 8 of the DHCR7 gene.

In patient 1 a heterozygous deletion of exons 3 to 6, in addition to the heterozygous common mutation p.Arg352Trp (c.1054C>T) has been detected.

Patient 2 carries a heterozygous deletion of exons 1 and 2 inherited from his mother, confirmed by SNP analysis. The paternal mutation was p.Thr93Met (c.278C>T).

The pathogenicity of the two deletions (one involving the 5´UTR/promoter sequences) will be demonstrated. MLPA is recommended in SLOS cases with only one mutation and elevated 7DHC. These cases highlight the importance of including all SLOS individuals (with two, one or no detected mutation) in the locus database.

P20.02

Identification of allelic imbalance in retinal expressed (disease) genes

S. Balendran, *B. Wissinger, S. Schimpf-Linzenbold;*
Institute of Ophthalmic Research, Tuebingen, Germany.

Reduced penetrance and variability in disease expression with respect to onset, course, and severity is a well-documented phenomenon in retinal diseases making reliable genotype/phenotype correlations as well as individual disease prognosis difficult.

Understanding the mechanisms behind such phenotypic variation is a key aim in human genetics.

We hypothesize that cis-acting variants regulating gene expression levels play an essential role in phenotypic variation and disease penetrance in hereditary retinal disorders.

To date the extent and mechanisms by which cis-acting polymorphisms influence the human phenotype are barely understood although they are common.

The aim of this project is the identification of such cis-acting gene variants and the determination of their impact on retinal disease expression. Individuals heterozygous for cis-acting polymorphisms that affect gene expression will show an allelic imbalance (AI).

Up to now more than 50 retinal genes were screened for heterozygous cSNPs applying PCR and sequencing in five different inbred mouse strains as a proof-of-principle experiment. Pyrosequencing assays were applied on RT-PCR amplified cDNAs generated from retinal RNA to assess AI based on the identified cSNPs.

Our results demonstrate an AI in ten retinal disease genes. However, in two genes the AI can already be seen on DNA level indicating a copy number variation. Screening of the Pde6c gene revealed a 116-bp insertion on cDNA level resulting in a premature termination codon leading, due to the nonsense mediated mRNA decay, to a downregulation of the mutant transcript. For the remaining genes the cause of the AI has to be clarified.

Nine new cases of de novo constitutional complex chromosome rearrangements (CCR) involving a single chromosome detected by aCGH: is there a unifying mechanistic model?

[1]HCL, BRON Cedex, France, [2]CRNL, CNRS UMR 5292, INSERM U1028, Université Claude Bernard Lyon I, Lyon, France, [3]AP-HP, La Pitié Salpetrière, Paris, France, [4]AP-HP, Hôpital Trousseau, Paris, France, [5]CHU Rennes, Rennes, France, [6]CHU Dijon, Dijon, France, [7]Equipe GAD EA 4271, IFR Santé STIC, Université de Bourgogne, Dijon, France, [8]AP-HP, Hôpital Henri Mondor, Paris, France, [9]CHU Toulouse, Toulouse, France, [10]CHU Montpellier, Montpellier, France, [11]AP-HP, CHU Clamart, Paris, France.

Recently, next generation sequencing data shed light on complex chromosome rearrangements involving one or few chromosomal loci that may be due to shattering of chromosomes in a single catastrophic event, called chromothripsis and identified in 2-3% of cancers.
In the present work, we reviewed the array-CGH results from 7 centers among the French array-CGH network between 2009 and 2012. Among 7774 aCGH performed in constitutional setting, we identified 9 cases of constitutional CCR involving more than 4 CNV in a single chromosome (0,01 %). These 9 cases included were referred for intellectual disability and/or malformations in pre-natal (2/9) or post-natal (7/9) context. Eight different chromosomes were involved namely chromosome 1p, 5q, 6p, 11p, 11q, 13q, 19p/q, 21q, 22q. Number of CNV per chromosome varied from 5 to 12 and chromosomal imbalances from 6.91 to 37.95 Mb. All these CNV were confirmed by FISH or R/G-banded karyotype and were de novo. Multiple rearrangement patterns were observed including various combinations of deletion, duplication, triplication and normal segments. Interestingly, in six cases, chromosome abnormality was identified on conventional R/G banding (homogeneous ring, mosaic ring, apparently balanced translocation, dicentric chromosome, insertion, karyotype disparities between cytotrophoblast and fetus).
Our study point out that constitutional CCR on a single chromosome is a rare and heterogeneous event. Recently, the mechanism of chromothripsis has been suggested to explain also constitutional CCR. Nevertheless, alternative hypotheses, such as chromoanasynthesis involving replication-based mechanisms, have been proposed. Systematic identification and breakpoint characterization of these CCR will be necessary to understand the mechanism.

P20.04
Four-break complex genomic rearrangement uncovered by FISH follow-up of an apparently de novo aCGH imbalance

***S. M. Bint[1]**, J. Ahn[2], A. F. Davies[1], C. Mackie Ogilvie[2];*
[1]Guy's & St. Thomas' Hospital NHS Foundation Trust & GSTS Pathology, London, United Kingdom, [2]Guy's & St. Thomas' Hospital NHS Foundation Trust, London, United Kingdom.

Array CGH testing is now in place in most cytogenetic laboratories, in many centres replacing traditional G-banded chromosome analysis. Follow-up of abnormal array findings is often carried out by parental array testing; when neither parent carries the proband's imbalance, this may represent a truly de novo event, or may have arisen due to a balanced parental chromosome rearrangement. FISH analysis in these cases can uncover the chromosomal status of the parents and establish reproductive risks.
To date we have carried out parental FISH studies for eleven cases where the proband had imbalance detected by array CGH that was beyond the resolution of karyotype analysis. FISH was first carried out on the proband alone, to confirm that the FISH probes were informative for the imbalance. In two of these eleven cases (18%) one parent carried a chromosome rearrangement which resulted in the imbalance seen in the proband. One case was a reciprocal translocation, with submicroscopic translocated segments. In the second case, array CGH analysis detected a 1.474Mb duplication of material from the long arm of chromosome 4 in a three year old boy. Array CGH analysis carried out on DNA from both parents showed normal copy number of this region; however, the father was found to carry a deletion of material adjacent to the region duplicated in the proband. FISH studies showed a four-break chromosome rearrangement in the father.
We will describe this latter case and speculate on possible mechanisms for these findings, and their significance for this family.

P20.05
New technologies permitted rectification of a diagnosis 14 years later

***A. Mosca-Boidron[1,2]**, A. Masurel-Paulet[3], N. Marle[1,2], S. Chancenotte[3], C. Ragon[1], M. Payet[1], S. El Chehadeh[3,2], C. Thauvin-Robinet[3,2], P. Callier[1,2], L. Faivre[3,2], F. Mugneret[1];*
[1]Laboratoire de Cytogénétique, Dijon, France, [2]Equipe GAD EA 4271, IFR Santé STIC, Université de Bourgogne, Dijon, France, [3]Centre de Génétique, Dijon, France.

Putatively benign copy number variants (bCNVs) can be broadly defined as DNA copy number gains or losses that do not lead to a recognizable clinical phenotype. The interpretation of these CNVs has presented challenges, especially in determining whether or not they are pathogenic when analyzing patients with abnormal phenotypes. Our patient was first evaluated at 2 months old for dysmorphic features and axial hypotonia with moderate distal hypertonia. A standard karyotype showed a direct 14q31 duplication inherited from his phenotypically normal mother. This duplication was also detected in five relatives with a normal phenotype and maternal inheritance through three generations. At this time, three hypotheses were suggested to explain abnormal phenotype of the proband: a variable expression of this duplication, the role of imprinting genes, or a coincidental event. Follow-up at the age of 14 years revealed slight dysmorphism, slight overgrowth (+2 SD) and developmental delay with a greater impact in the verbal sphere. The use of high resolution technologies allowed us to pursue our investigations. Array-CGH confirmed the 8.5 Mb duplication in the 14q31.1q31.3 region but also revealed a 22q11.21 duplication (DiGeorge syndrome region) of at least 3.1 Mb. This duplication was confirmed by q-PCR studies and was shown to be *de novo*. This second anomaly provided the explanation of the phenotype while we could now conclude that the 14q31 duplication was a bCNVs. The contribution of new technologies such as array-CGH and NGS will allow us to revise diagnosis initially based on karyotype anomalies.

P20.06
Inherited Cat-Eye Syndrome due to an unusual dicentric monosatellited derivative chromosome 22

***S. Dimassi[1,2]**, A. Labalme[1], M. Cordier[3], A. Rafat[1], M. Till[1], P. Edery[3,2], D. Sanlaville[1,2], C. Schluth-Bolard[1,2];*
[1]Laboratoire de Cytogénétique Constitutionnelle, Centre de Biologie et de Pathologie Est, Hospices Civils de Lyon, BRON Cedex, France, [2]INSERM, U1028 ; CNRS, UMR5292 ; TIGER Team, Lyon, France, [3]Unité de Génétique Clinique, Hôpital Femme-Mère-Enfant, Hospices Civils de Lyon, BRON Cedex, France.

Cat eye syndrome (CES) is characterized by ocular coloboma, preauricular pits and/or tags, anal atresia, heart defect and renal malformations. It is due to tetrasomy for 22q11 region, secondary to the presence of a dicentric and bisatellited supernumerary marker chromosome in most of cases.
We report here a 2 months old boy with facial dysmorphism, total anomalous pulmonary venous return, anal atresia and renal malformation. He is the first child of a 26 years old woman with bilateral coloboma, atrial septal defect and renal malformation. Standard blood karyotype of both proband and his mother showed short arm asymmetry of chromosome 22. Array CGH displayed four copies of the proximal 22q11 region (chr22: 16,133,474-18,651,673, hg19) in the child. The derivative 22 was finally characterized by FISH using 14/22 centromeric and NORs probes and BAC clone CTD-3144O3 (22q11.1) showing a dicentric monosatelited chromosome 22 with one signal CTD-3144O3 on the long arm in 22q11.1 and two signals CTD-3144O3 on the short arm between both centromeres.
Although atypical cytogenetic presentation of CES have already been described including interstitial duplication and triplication, this is the first case of maternally inherited dicentric derivative 22 presenting two additional copies of 22q11 region on its short arm. This rearrangement resulted in tetrasomy for the CES I region, consistent with patients phenotype. Mechanism of formation of such derivative chromosome will be discussed.

P20.07
CFTR interacts with metabotropic glutamate receptor and modulates IL-8 production in cystic fibrosis T-Lymphocytes

***E. Kvaratskhelia[1]**, N. Dabrundashvili[1], T. Barbakadze[2], E. Maisuradze[1], E. Zhuravliova[2], N. Natsvlishvili[2], L. Shanshiashvlili[2], T. Topuria[1], D. Mikeladze[2];*
[1]Tbilisi State Medical University, Tbilisi, Georgia, [2]Ilia State University, Tbilisi, Georgia.

The action of glutamate on the secretion of IL-8 by lymphocytes derived from healthy subjects and cystic fibrosis patients, as well as the expressi-

on of glutamate receptor and glutamate receptors binding partners in the membrane fractions of lymphocytes were investigated. The content of cystic fibrosis transmembrane conductance regulator-associated ligand, Na+/H+ exchanger 3 regulatory factor 1, as well as PDZ-binding proteins: metabotropic glutamate receptor subtype 1, ionotropic glutamate AMPA and NMDA receptor subtypes were analysed after immunoprecipitation of CFTR. Western blotting of co-immunoprecipitated proteins revealed that normal, non-mutated CFTR, as well as mutated forms of CFTR (F508CFTR mutation) were associated with NHERF-1 and CAL in the plasma membrane fractions. In the macromolecular complex of mutated, as well as of non-mutated forms of CFTR, NMDA NR2A type of glutamate receptors were found, whereas metabotropic mGluR1 in the supramolecular complex containing CFTR was detected only in the normal T-cells. Besides, in lymphocytes with DF508-CFTR mutation the amount of cell-surface expressed CFTR-CAL complex greatly decreased. Furthermore, our results have shown that CF-derived T-cells in the presence of IL-2 produce more IL-8, than T-cell from healthy control. However, only in normal lymphocytes was detected a significant increase (144%) in the IL-8 secretion during exposure to high concentration of glutamate (10-4 M). We have concluded that CFTR and mGluR1a compete for binding to CAL, which in turn can regulate levels of these two proteins. Reduced expression of surface exposed mGluR1a in lymphocytes can disarrange appropriate T-cell phenotype polarization and lead to aberrant immune responses in CF.

P20.08
Study of long-range regulatory mechanisms of the CFTR gene

S. Moisan;
Inserm U1078, BREST, France.

The cystic fibrosis transmembrane conductance regulator (CFTR) gene was identified in 1989. Twenty years later, the regulatory mechanisms controlling its complex expression are still not fully understood. Although, more than 1930 mutations have been identified, many cases of cystic fibrosis or CFTR Related Disorders remain still of unknown origin.
The promoter which binds transcription factors and drives some aspects of CFTR gene expression, cannot alone account for tissue specific control. This implicates other distal cis- or trans-acting elements in cell-type-specific regulation of CFTR expression.
The aim of our project is to study long-range regulatory mechanisms of the CFTR gene.
Our first approach consisted to map potentials regulatory elements located within conserved non-coding sequences, which could interact specifically with the CFTR gene by tri-dimentional folding mechanism. These interactions have been detected by Chromosome Conformation Captures (3C).
Subsequently, we enhanced our analyses with a high-throughput adaptation of 3C: the 3C-Carbon Copy (5C) technology. This approach allows the analysis of millions chromatin interactions.
Thanks to 3C and 3C-derived studies, we could identify new possible mutations far from the gene, which may lead to its dysfunction by modifying the chromatin conformation.
These analyses will be pursued on patients affected by cystic fibrosis in whom either a single mutation or none was found in the CFTR locus.

P20.09
DCTN4 as a modifier of *Pseudomonas aeruginosa* bronchial chronic infection in cystic fibrosis

M. Viel[1], D. Hubert[2], P. Burgel[2], I. Honoré[2], J. Chapron[2], N. Gaitch[1], R. Kanaan[2], D. Dusser[2], ***T. Bienvenu***[3];
[1]Laboratoire de Biochimie et Génétique Moléculaire, Hôpital Cochin, Paris, France, [2]Service de Pneumologie, Hôpital Cochin, AP-HP, Paris, France, [3]Université Paris Descartes, Institut Cochin, CNRS (UMR8103), Paris, France.

In Cystic Fibrosis (CF), *Pseudomonas aeruginosa* (PA) chronic airway infection is associated with faster rate of lung function decline, increased number of exacerbations and shorter survival. Recently, using exome sequencing and extreme phenotype design, it has been shown that isoforms of dynactin 4 may influence PA infection by reducing PA autophagic clearance in the airway of individuals with CF or by altering macroautophagic clearance of class II mutant *CFTR*, leading to more severe airway disease. The purpose of this study was to investigate the role of missense variants in DCTN4 on PA infection incidence, on age at first PA colonization, and chronic PA infection prevalence. PCR and direct sequencing were used to screen DNA samples for *DCTN4* variants. 109 adult CF patients from the CF Centre at Cochin Hospital have been included (patients with lung transplantation were excluded): 60 patients had chronic PA infection (CPA) and 49 had no CPA. *DCTN4* variants were identified in 22 CF patients with CPA (22/60, 37%), and in only 6 CF patients with no CPA (12%). *DCTN4* variants were predominantly observed in individuals with early age at first PA colonization (before 15 years-old). In this study, we confirm the association between chronic PA infection and *DCTN4* missense variants. The *DCTN4* genotype distribution differed significantly between the two groups (p=0.004). In conclusion, our observations suggest that p.Phe349Leu of DCTN4 may be involved in the pathogenesis of PA infection in CF.

P20.10
Telomerase mutations in families with idiopathic pulmonary fibrosis : 23 new mutations of TERT and TERC

C. Kannengiesser-Decuyper[1,2], *P. Revy[2], R. Borie[1,2], C. Ménard[1], H. Nunes[1,3], J. Naccache[1], A. Tazi[1,4], S. Marchand-Adam[5,6], G. Prévot[7], P. Delaval[8], V. Cottin[9,10], B. Crestani[1,2,4], B. Grandchamp[1,2];*
[1]AP-HP, Paris, France, [2]INSERM, Paris, France, [3]Université Paris 13, Paris, France, [4]Université Paris 7, Paris, France, [5]CHRU, Tours, France, [6]INSERM, Tours, France, [7]CHU, Toulouse, France, [8]CHU, Rennes, France, [9]Hospices Civils de Lyon, Bron, France, [10]Université Claude Bernard Lyon I, Lyon, France.

Germline telomerase mutations have been reported in approximately 10% of familial idiopathic pulmonary fibrosis (IPF). The T allele of the rs35705950 in MUC5B promoter has been associated with idiopathic pulmonary fibrosis (IPF) in American and European cohorts.
We report here our French experience until 2008 in molecular exploration of TERT and TERC in familial cases of IPF and sporadic case of IPF with associated bone marrow disease or unexplained liver disease suggestive of a telomerase disease. We identified 22 heterozygous TERT mutations in 24 patients including 20 mutations never reported. We also found 4 heterozygous variations of TERC in 6 patients. Assessing pathogenicity of TERT and TERC mutations is critical to evaluate risk of telomerase disease in carriers. By considering -the co segregation study when possible, -the presence of the variant in databases, -the predicted impact on the protein structure or splicing step and -the telomere length of mutation carriers, we conclude that most of the variants can be classed as loss of function mutations, whereas the results for new TERC variants remain of unknown significance. Discriminating between mutant and neutral variants not only provides information that can be used for genetic counselling but also adds to our understanding of the functionally critical residues or nucleotides in TERT. Moreover, we found that MUC5B promoter snp genotype of IPF patients carrier of TERT or TERC mutations (excess of G allele of the rs) is significantly different than MUC5B genotype of IPF patients from the COFI French cohort of IPF patient.

P20.11
Telomeres are normally elongated and maintained in ICF syndrome derived iPSCs

S. Sagie, *R. Shaked, M. Tzukerman, K. Skorecki, S. Selig;*
Laboratory of Molecular Medicine, Rambam Health Care Campus and Rappaport Faculty of Medicine and Research Institute, Technion, Haifa, Israel.

Human telomeric regions are packed as constitutive heterochromatin, characterized by extensive subtelomeric DNA methylation and specific histone modifications. In somatic cells, telomerase is inactive and telomeres shorten during proliferation. When human induced pluripotent stem cells (hiPSCs) are generated, telomerase is activated and telomeres elongate. In addition, subtelomeres are hypermethylated in hiPSCs and levels of TERRA, an RNA transcript emanating from telomeric regions, are elevated.
ICF (Immunodeficiency, Centromeric instability, Facial anomalies) type I patients, carry mutations in DNMT3B encoding an enzyme that de novo methylates repetitive sequences. ICF cells display hypomethylated subtelomeric regions associated with short telomeres, advanced telomere replication time and abnormally high levels of TERRA.
We study the role of de novo subtelomeric methylation during development. We used hiPSCs as a model for the developmental stage at which de novo methylation occurs and ICF syndrome cells as a natural model of almost ab-

sent subtelomeric DNA methylation.
We have generated iPSCs from ICF-fibroblasts and observed the potential capacity for elongation and maintenance of telomeres in the pluripotent state. Following differentiation, very rapid telomere shortening occurs, leading to early senescence in fibroblast-like cells derived from these ICF syndrome-derived iPSCs, similar to the pre-iPSC fibroblasts. In addition, the subtelomeres of the ICF-iPSCs remain significantly hypomethylated. Ongoing experiments, including DNA and RNA analyses are aimed to elucidate the mechanism whereby hypomethylation is linked to telomeric abnormalities in ICF syndrome.

P20.12
Positions of HSA6, HSA12, HSA18 and HSAX in interphase nuclei of human MSC depend on cultivation time and differentiation

Y. Voldgorn[1], *A. Lavrov*[1], *E. Adilgereeva*[1], *E. Nekrasov*[2];
[1]*Federal State Budgetary Institution «Research Centre for Medical Genetics» of the Russian Academy of, Moscow, Russian Federation,* [2]*Vavilov Institute of General Genetics Russian Academy of Sciences, Moscow, Russian Federation.*

Chromosome territories' (CT) positioning is not random and seems to be an important mechanism of epigenetic regulation. Study of CT is of particular interest in stem cells such as mesenchymal stem cells (MSC) because they are widely used in regenerative medicine and are of great value as a biological model capable of differentiation in different cell-lineages. The aim of the research was to identify the differences in the positions of chromosomes 6, 12, 18 and X in MSC. Cells in early (up to 4) and late (6-10) passages were analyzed as well as cells after differentiation in osteogenic and adipogenic directions. Over 4000 nuclei from 19 cell cultures were analyzed using FISH with centromere probes. Radial distances (RD) were measured for each chromosome centromer. At late passages the median RD values of the distal HSA6 homologue changed its position from 0,78 to 0,81 while centromere of HSAX in male cultures moved centrally (median values are 0,7 and 0,61 for early and later passages respectively). After adipogenic differentiation proximal homologues of both HSA18 and HSA12 moved to the periphery (median values are 0,34 and 0,39 for HSA18, 0,45 and 0,5 for HSA12 before and after differentiation respectively). In addition centromeres of HSAX showed statistically different position in male and female cultures which might be explained by different levels of activity of HSAX in male and female cells. The detected changes in the structure of the nucleus are new karyological characteristics of human MSC.

Family-based genome wide association study in Patagonia, a region with high prevalence of oral clefts: preliminary results

F. M. Carvalho[1], *D. Montaner*[2], *F. Poletta*[3], *R. F. Fonseca*[1], *J. C. Mereb*[4], *A. R. Vieira*[5], *E. E. Castilla*[6], ***I. M. Orioli***[1];
[1]*ECLAMC (Latin American Collaborative Study of Congenital Malformations) and INAGEMP (National Institute of Populational Medical Genetics) at Department of Genetics, Institute of Biology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*Bioinformatic Department, Research Center Principe Felipe, Valencia, Spain,* [3]*ECLAMC and INAGEMP at Center for Medical Education and Clinical Research, Buenos Aires, Argentina,* [4]*ECLAMC and INAGEMP at Hospital Zonal El Bolsón, El Bolsón, Argentina,* [5]*Departments of Oral Biology and Pediatric Dentistry and Center for Craniofacial and Dental Genetics, School of Dental Medicine, University of Pittsburgh, Pittsburgh, PA, United States,* [6]*ECLAMC and INAGEMP at Congenital Malformations Epidemiology Laboratory, Oswaldo Cruz Institute, FIOCRUZ, Rio de Janeiro, Brazil.*

The etiology of cleft lip and/or palate (CL±P) is complex and several SNPs and chromosomal regions had been associated with this condition. We hypothesized that in a CL±P high prevalence region, as the Patagonia, one of these associated factors may be prevalent over the others. We aim the identification of polymorphic markers that may contribute to CL±P in our population with a family-based design for genome-wide association (GWA) analysis. The CL±P high prevalence population in Patagonia was identified by the ECLAMC and 150 families were until now ascertained and studied. SNPs from Genome-Wide 6.0 array from Affymetrix were tested (TDT) for association with isolated CL±P in 11 trios, 2 duos, and 10 sibs using PLINK. We found statistical evidence of association between polymorphic markers on chromosome 1, 4, 5, 7, 10, 12, 13, 17 and 18 with CL±P ($p < 0.0009$). None of these SNPs were previously described as associated with CL±P. The STRING 9.0, a tool used to know and predicted protein-protein interactions, shows that the *MACF1* gene protein (1p34.3) appears directly related to the *IRF6* product. These preliminary results suggest some *loci* on chromosomes 1, 4, 5, 7, 10, 12, 13, 17 and 18 as candidate regions for CL±P. Although a relation between one of those SNPs (on MACF1 gene) and IRF6 could be of interest to CL±P etiology in this population, more families must be analyzed in order to confirm our preliminary results.

P20.14
Somatic mosaicism for DNA Copy Number Variations: a rare phenomenon in human genome

M. Koltšina[1], *A. Metspalu*[1,2], *N. Tõnisson*[1,3], *A. Salumets*[4,5,6];
[1]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [2]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [3]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [4]*Competence Centre on Reproductive Medicine and Biology, Tartu, Estonia,* [5]*Department of Obstetrics and Gynaecology, University of Tartu, Tartu, Estonia,* [6]*Institute of Biomedicine, University of Tartu, Tartu, Estonia.*

Somatic mosaicism is defined by the presence of genetically distinct populations of somatic cells in a single organism. Mosaicism can be caused by DNA mutations, epigenetic alterations, chromosomal abnormalities and spontaneous reversion of inherited mutations. DNA copy number variations (CNVs) ranging from kilobases to megabases are a well-known type of genetic variation in human. However, the somatic mosaicism for CNVs in humans is not well studied. It is unknown whether CNVs arise in somatic cells, but it is, however, generally assumed that normal cells are genetically identical. It is suggested, that mosaicism may result from a mutation during postzygotic development which is propagated to only a subset of the adult cells.
The aim of the present study was to test the hypothesis that cells from different fully differentiated tissues could carry different CNV patterns. We tested 48 tissue samples from four subjects, 12 different tissues from each subject, applying Illumina HumanOmniExpress-12 BeadChip (Illumina, Inc; San Diego, USA) for copy number variation detection and observed at least three CNVs, affecting more than one tissue in one of the four individuals studied.
Our results suggest that somatic mosaicism for CNVs is not very common in normal human cells. The data also indicates that further examination of samples derived from a larger cohort may be needed to reveal the frequency of CNV mosaicism. CNVs occurring in a substantial fraction of normal cells might predispose certain types of cells or a tissue to a specific disease-related phenotype.

P20.15
A complex chromosome rearrangement involving four chromosomes, nine breakpoints and a cryptic 0.6 Mb deletion in a boy with hypoplasia cerebellar and defects in skull ossification

R. S. Guilherme[1], *M. C. P. Cenarch*[1], *T. E. Sfakianakis*[1], *S. S. Takeno*[1], *L. M. M. Nardozza*[1], *C. Rossi*[1], *S. S. Bhatt*[2], *T. Liehr*[2], ***M. I. Melaragno***[1];
[1]*Universidade Federal de São Paulo, São Paulo, Brazil,* [2]*Friedrich Schiller University, Jena, Germany.*

Complex chromosomal rearrangements (CCRs) are considered rare cytogenetic events. Most apparently balanced CCRs are de novo and are usually found in patients with abnormal phenotypes. In these cases, high-resolution techniques are unveiling genomic imbalances in a great percentage of cases. In this paper, we report a patient with growth and developmental delays, dysmorphic features, nervous system anomalies (pachygyria, hypoplasia of the corpus callosum and cerebellum), a marked reduction in the ossification of the cranial vault, skull base sclerosis and cardiopathy who presents a CCR with nine breakpoints involving four chromosomes (3, 6, 8 and 14) and a 0.6 Mb deletion of 14q24.1. Although the only genomic imbalance revealed by the array technique was a deletion, the clinical phenotype of the patient most likely cannot be attributed exclusively to haploinsufficiency. Other events must also be considered, including the disruption of critical genes and position effects. A combination of several different investigative approaches (G-banding, FISH using different probes and SNP-array techniques) was required to describe this CCR in full, suggesting that CCRs may be more frequent than initially thought. Additionally, we propose that a chain chromosome breakage mechanism may have occurred as a single rearrangement event resulting in this CCR. This study demonstrates the importance of applying different cytogenetic and molecular techniques to detect subtle rearrangements and to delineate the rearrangements at a more accurate le-

vel, providing a better understanding of the mechanism involved in CCR formation and a better correlation with phenotype. (Financial support: FAPESP and CAPES, Brazil; Else Kröner-Fresenius-Stiftung).

Background: Congenital erythrocytosis results from 1) inherited intrinsic defects in red blood cell precursors that cause increased responsiveness to EPO due to a mutation in EPO receptor gene (*EPOR*); 2) inherited defects in hypoxia sensing pathway due to mutation in the Von Hippel-Lindau gene (*VHL*), in the prolyl hydroxylase domain 2 gene (*PHD2*) or in the hypoxia-inducible factors gene (*HIF2α*); 3) high affinity hemoglobin variants (HBB and HBA); 4) 2,3-bifosfogliceratomutase (*BPGM*) enzyme deficiency. The inheritance is autosomic dominant for Congenital erythrocytosis associated to *HBB*, *HBA*, *EPOR*, *PHD2* and *HIF2α* mutations and recessive for *BPGM* and *VHL* gene mutations. Conversely, in a great number of congenital erythrocytosis the underlying defect remains unknown.
Material and Methods: With the main objective of describing the aetiology and molecular basis of congenital erythrocytosis, we studied 70 unrelated patients.
According to a proper algorithm, we have sequenced the genes described as associated with congenital erythrocytosis.
Results and discussion: Erythrocytosis molecular aetiology was identify in 27 (39%) of the 70 subjects. High-affinity Hb variants were the most common causes, present in 20% of the cases. New mutations were identified in the *EPOR* (c.1310G>A, p.Arg437His; c.1311_1312delTC, p.Pro438Metfs*6; c.1235C>A, p.Ser412*), *VHL* (c.586A>G, p.Lys196Glu) and *PHD2* (c.1000 T>C, p.Trp334Arg) genes. None of the subjects showed mutations in *BPGM* or *HIF2α* genes.
Conclusion: We were able to identify the congenital erythrocytosis molecular aetiology in 27/70 unrelated subjects. In spite of the genes already known to be involved in congenital erythrocytosis, the majority of the cases still has unknown etiology.

P20.17

Co-occurrence of 4p16.3 microdeletion and 11p15 microduplication in a boy carrying a der(4)t(4;11)(p16.3;p15.4)mat

A. Bonaldi[1], *A. C. S. Fonseca*[1], *D. R. Bertola*[2], *A. M. Vianna-Morgante*[1];
[1]*Department of Genetics and Evolutionary Biology, University of São Paulo, São Paulo, Brazil,* [2]*Genetics Unit, Children's Institute, Clinics Hospital, University of São Paulo, São Paulo, Brazil.*

We report on a boy carrying an unbalanced translocation der(4)t(4;11)(p16.3;p15.4)mat. He was referred for genetic evaluation at 1 year of age because of severe prenatal and post-natal growth retardation (<3rd centile), developmental delay, seizures, and facial dysmorphisms. MS-MLPA was initially carried out due to the diagnostic possibility of Silver-Russell syndrome (SRS), and revealed an 11p15 microduplication on the maternal chromosome, including both imprinting centers. When refining the microduplication limits by a-CGH (180K whole-genome platform; Agilent), in addition to a 3.3 - 3.5 Mb 11p15.4-pter microduplication, we detected a terminal microdeletion of the short arm of chromosome 4, spanning about ~3.85 Mb. Subsequent FISH analysis confirmed the array findings, and revealed a balanced translocation t(4;11)(p16.3;p15.4) in the patient's mother. Clinical re-evaluation of the patient indicated features of both Wolf-Hirschhorn syndrome and SRS, but most of them could be attributed to the 4p16.3 microdeletion. Two previously described patients carrying similar chromosomal imbalances due to maternally inherited der(4)t(4;11) presented a similar phenotype (South et al. Am J Med Genet A. 2008;146A:2691; Ou et al. Genome Res. 2011;21:33). Both breakpoints in the translocation here described fall within segments rich of segmental duplications sharing high sequence identity between chromosomes 4 and 11, pointing to a rearrangement originated through non-allelic homologous recombination, as previously demonstrated for other t(4;11) (Ou et al. 2011). Financial support: FAPESP (CEPID 98/14254-2; Student fellowship 2011/12486-0)

P20.18

Application of array comparative genomic hybridization (array-CGH) for detection of chromosomal imbalances in children with Developmental Delay/congenital malformations in Saudi Arabia

I. M. R. Hussein[1,2], *A. G. Chaudhary*[1], *H. J. Schulten*[1], *R. Bassyouni*[3], *S. Sogati*[4], *J. Manikandan*[1], *M. M. Al-Quaiti*[1], *M. H. Al-Qahtani*[1];
[1]*King Abdulaziz University, Jeddah, Saudi Arabia,* [2]*National Research Centre, Cairo, Egypt,* [3]*Ministry of Health, Al-Taif, Saudi Arabia,* [4]*Maternity and Child Hospital, Jeddah, Saudi Arabia.*

Microarray - based Comparative Genomic Hybridization (a-CGH) has enabled wide investigation of the genome at high resolution and has been implemented in different centers as a clinical diagnostic tool. Chromosomal imbalances are implicated in the etiology of Developmental Delay (DD)/Intellectual disability (ID)/ congenital malformations. However, most of these cases could not be diagnosed by conventional cytogenetic techniques. We aimed to establish (a-CGH) technique and assess its potential as a diagnostic tool of chromosomal imbalances and to detect known and novel chromosomal aberrations in patients with DD/ ID. Subjects & Methods: A total of 72 patients presented with DD/ ID with or without congenital malformations were referred to the CEGMR for cytogenetic analyses. We used both conventional cytogenetic G-banding and Fluorescent in-situ hybridization techniques, besides we applied (array-CGH) high resolution Agilent scanner with 1X244 K array format. Chromosomal aberrations could be detected in 10/72 (13.8%) patients by G-banding technique and 4/50 (8%) by FISH technique, however, 17/72 (23.6%) were diagnosed by a-CGH technique. All microdeletion syndromes and partial duplications were detected by the chromosomal microarray technique. However, one patient with unbalanced translocation and another with mosaicism could not be detected by this technique. We noticed the increased number of CNVs detected by a-CGH which need further investigation for contribution to phenotypes. Our results indicated the strength of high resolution genomic arrays in diagnosing cases of unknown etiology and in detection of contiguous genomic alterations in the wide spectrum of cases with DD/ID/congenital malformations.

Down Syndrome (DS) is the most common aneuploïd genetic disorder caused most frequently by trisomy of whole chromosome 21. Thus, correction of trisomy 21 and autologous cell-replacement therapies would be a promising therapeutic strategy. We explored this hypothesis by using induced pluripotent cells (iPS) technology to model DS and follow the ploïdy of the iPS during extended culture. Amniotic fluid cells (AFC) harboring a complete trisomy 21 from three donors were reprogrammed into iPS and DS-iPS lines (polyclonal and clonal iPS). The pluripotency was tested in vitro and in vivo and the trisomy 21 confirmed by karyotype. We observed that upon iterative manual passage, one polyclonal iPS has completely lost the supernumerary chromosome 21 during extended culture. Correction was reproducible (n=3) and due to chromosome mis-segregation and pronuclei formation mechanisms. We eliminate the hypothesis of a normal unrela-

ted iPS contamination using microsatellite assay. In addition, we showed by ch21p polymorphism both parental contributions of the two remaining chromosome 21. CGH-array (135K Roche-Nimblegen) did not reveal major genomic instability. We reported minor alterations with a dup12q24.33 of 277.55Kb (including the genes POLE, PXMP2, PGAM5, ANKLE2, GOLGA3, CHFR, ZNF605) and a qupYp11.32 of 167.11Kb (SHOX gene).This is the first demonstration that iPS can reproduce in vitro a spontaneous mis-segregation procedure resulting in a trisomy 21 correction. The generation of related isogenic disomic iPS should rescue the phenotype of disease and will allow evaluating consequences of phenotypic reversion in DS by a potential autologous normal substitution cell therapy.

P20.20

Altered expression of immune-related genes in children with Down syndrome

*B. L. Zampieri[1], J. M. Biselli[1], D. B. Victorino[1], C. R. S. Silva[1], J. E. S. Souza[2], M. C. Bürger[3], W. A. Silva Junior[4], E. M. Goloni-Bertollo[5], **E. C. Pavarino**[1];*
[1]Faculdade de Medicina de São José do Rio Preto- FAMERP, São José do Rio Preto, Brazil, [2]Fundação Hemocentro de Ribeirão Preto, Ribeirão Preto, Brazil, [3]Faculdade de Medicina de Ribeirão Preto - FMRP, Ribeirão Preto, Brazil, [4]Faculdade de Medicina de Ribeirão Preto- FMRP, Ribeirão Preto, Brazil, [5]Faculdade de Medicina de São José do Rio Preto - FAMERP, São José do Rio Preto, Brazil.

Down syndrome (DS) individuals have high incidence of immunological alterations with increased susceptibility to bacterial and viral infections besides high frequency of hematologic malignancies and autoimmune disorders. In this study, we investigated the expression pattern of 92 immune-related genes in DS children aiming to identify candidate genes that might be involved on the immunological alterations frequently associated to DS. Peripheral blood mononuclear cells (PBMC) samples were obtained from six healthy individuals with full trisomy 21 and six healthy control individuals (ages 2-6 years). Gene expression was profiled in duplicate according to the manufacturer's instructions provided by commercially available TaqMan® Human Immune Array representing 92 immune function genes and 4 housekeeping genes on a 96-plex gene card (Applied Biosystems, Carlsbad, CA). Of the 92 genes, 15 did not meet criteria for statistical analysis. Thus, 77 genes were subjected to statistical analysis and the comparison between children with DS and controls resulted in 16 differentially expressed genes after correction for multiple tests. Four of them (*CCR2*, *BCL2L1*, *IL10* and *CCR5*) were up-regulated (adjusted *P*-values: < 0.001, 0.006, 0.008 and 0.047; respectively), while twelve genes (*BCL2*, *CCL3*, *IL6*, *EDN1*, *CD40LG*, *CD80*, *CCR7*, *IKBKB*, *CD28*, *CD19, SKI* and *CD40*) were down-regulated (adjusted *P*-values: 0.001, 0.001, 0.001, 0.003, 0.007, 0.008, 0.010, 0.019, 0.026, 0.046, 0.05 and 0.05; respectively). This study identified a modest dysregulation in the expression of some genes that may be related to the immunological alterations seen in DS and indicates candidate genes for further investigation into the molecular mechanism underlying DS pathology.

Alterations in gene expression microarray in oesophageal atresia tissues - the role of SHH and Wnt pathway signalling

***R. Smigiel**[1], A. Lebioda[2], M. Blaszczyński[3], K. Korecka[4], P. Czauderna[5], W. Korlacki[4], A. Jakubiak[1], D. Bednarczyk[1], H. Maciejewski[6], M. M. Sasiadek[1], D. Patkowski[7];*
[1]Genetic Department Wroclaw Medical University, Wroclaw, Poland, [2]Institute of Molecular Techniques Wroclaw Medical University, Wroclaw, Poland, [3]Department of Pediatric Surgery, Traumatology and Urology, Poznan University of Medical Sciences, Poznan, Poland, [4]Department of Surgery of Congenital Defects in Children and Traumatology, Silesian Medical University, Zabrze, Poland, [5]Department of Surgery and Urology for Children and Adolescents, Medical University of Gdansk, Gdansk, Poland, [6]Institute of Computer Engineering, Control and Robotics, Wroclaw University of Technology, Wroclaw, Poland, [7]Department of Pediatric Surgery and Urology, Wroclaw Medical University, Wroclaw, Poland.

Introduction: Esophageal atresia (EA) may occur as an isolated (IEA) or syndromic anomaly (SEA). It is supposed that combination of multigenic factors and epigenetic modification of genes can play a role in its aetiology. The aim of work was to assess the gene expression in microarray study in esophageal tissue samples.
Material and methods: RNA was extracted from 26 esophageal tissue collected during thoracoscopic EA repair in neonates with IEA and SEA. Lower pouch of esophageal tissues were analysed. Control esophageal tissues were taken during autopsy from aborted fetuses and stillborn neonates without macroscopic defects. We used Agilent Human Gene Expression Microarrays to determine gene expression profiling. Quality analysis and scale normalization for results were performed. Analysis of differential expression (DE) was done (R limma package) and functional pathway analysis were performed (globaltest method, KEGG and DAVID database).
Results: We identified 787 down- and 841 up-regulated transcripts between SEA and controls, and about 817 down- and 765 up-regulated probes between IEA and controls. 50% of these genes showed DE specific for either IEA or SEA. Functional pathways analysis revealed substantial enrichment for Wnt and SHH as well as cytokine and chemokine signaling pathways. We performed reverse transcription PCR study in a group of SHH and Wnt genes with DE in microarray profiling to confirm the microarray results. We verified the altered expression in SFRP2 gene (Wnt) as well as SHH, GLI1, GLI2 and GLI3 (SHH).
Conclusion: The results suggest a important role of SHH and Wnt pathways for EA etiology.

P20.22

Luciferase assays of 5' untranslated region polymorphisms of the alpha-galactosidase gene

***S. Ferreira**, C. Reguenga, J. P. Oliveira;*
Faculty of Medicine, Porto, Portugal.

INTRODUCTION:
Lysosomal alfa-galactosidase (α-Gal) is the enzyme deficient in Fabry disease. The 5' untranslated region (5'UTR) of the GLA gene shows a remarkable degree of polymorphic variation, with single nucleotide polymorphisms (SNPs) described at nucleotide positions 44 (g.1136C>T), 30 (g.1150G>A), 12 (g.1168G>A) and 10 (g.1170C>T) relative to the AUG start codon. In vivo studies in hemizygotes have shown that SNP 30AUG is associated with high plasma α-Gal activity and that SNP 10AUG is associated with moderately decreased α-Gal enzyme activity in leucocytes, whereas SNP 12AUG does not seem to affect enzyme activity. Limited data suggest that the rarer SNP 44AUG might be associated with increased α-Gal plasma activity. We used a luciferase reporter system to assess the relative transcription efficiencies of the different GLA 5'UTR variant isoforms in vitro, as compared to the wild-type sequence.
METHODS:
The wild type 134bp GLA 5'UTR and the four variant isoforms were amplified from genomic DNA and inserted into pGL3 Luciferase Reporter Vector. All five plasmids were cloned into recombinant Escherichia coli and transfected into HeLa and ND7 cells with luciferase and β galactosidase reporter vectors, and their relative expressions were measured.
CONCLUSIONS:
SNPs 12AUG and 44AUG significantly raised luciferase activity in both cell types, while the activities observed with the 10AUG and the 30AUG SNPs were within the wild type range of variation. These results are in contrast with the in vivo findings in hemizygotes and do not support the explanation that these are due to 5'UTR related differences in GLA gene transcription.

P20.23

Study of ACVR1 gene expression regulation: a way to discover a „druggable" target toward Fibrodysplasia Ossificans Progressiva (FOP) treatment.

***S. Cappato**[1], F. Giacopelli[1], L. Tonachini[1], R. Ravazzolo[1,2], R. Bocciardi[1,2];*
[1]DINOGMI, University of Genova and CEBR, Genova, Italy, [2]Medical Genetics Unit, G. Gaslini Institute, Genova, Italy.

The ACVR1/ALK2 gene encodes a type I receptor for Bone Morphogenetics

Proteins (BMPs). ACVR1 gain of function mutations are associated with FOP (OMIM 135100), a rare disease characterized by congenital malformation of great toes and progressive heterotopic ossification in soft tissues leading to severe disability. No treatment is available for FOP and much interest is devoted to find targets for novel therapies.
Given our interest in understanding the poorly investigated molecular mechanisms regulating ACVR1 gene expression, we have characterized its promoter region. We identified a Transcription Start Site for ACVR1, and focused on the 2.9 kb genomic region upstream of it. We analyzed the sequence by bioinformatic means and performed a transfection-based functional study.
We found that the region is able to drive a strong transcriptional activity in different cell lines. We characterized the contribution of different parts of this region to the transcriptional control of the gene and defined a GC-rich core promoter. Finally, we used this functional region as target for High-throughput screening (HTS) of chemical compounds with potential pharmacological effect on the ACVR1 mediated pathway, by targeting its expression at the transcriptional level. Thus, we generated a cellular system in ATDC5 cells stably expressing Luciferase reporter gene under the control of the identified ACVR1 promoter and we adapted cell culture conditions to the 96-well format useful for HTS.
We report here the results of the functional characterization of the ACVR1 promoter and the results obtained by testing our cellular system with a small library of chromatin-modifier compounds.

Two novel variants affecting splicing of *FLNA* exon 18 cause a severe PVNH phenotype

N. Houcinat[1], *I. Coupry*[2], *S. Moutton*[1], *J. Deforges*[1], *J. Amiel*[3], *A. Dieux*[4], *D. Lacombe*[1,2], *B. Arveiler*[1,2], *C. Goizet*[1,2], *P. Fergelot*[1];
[1]*Génétique médicale,Hôpital Pellegrin, Bordeaux, France,* [2]*Université Bordeaux Segalen, Laboratoire Maladies Rares: Génétique et Métabolisme (MRGM), Bordeaux, France,* [3]*Département de génétique clinique, Hôpital Necker-Enfants-Malades, Paris, France,* [4]*Génétique médicale, Hôpital Jeanne-de-Flandre, CHRU, Lille, France.*

Loss of function mutations of *FLNA* are responsible for X-linked periventricular nodular heterotopia (PVNH) which generally leads to prenatal lethality in affected males.
We report 2 novel *FLNA* mutations identified in exon 18 by direct DNA sequencing, a synonymous variant in one female (P1) and a missense substitution of the last nucleotide in one male (P2), displaying a severe PVNH phenotype. *In silico* analysis predicted a splicing effect: activation of a cryptic donor site in P1 and abolition of the canonic donor site in P2.
FLNA transcripts were studied using RT-PCR of total RNA extracted from lymphocytes and agarose gel electrophoresis. Amplicons were then cloned and sequenced.
In both cases, at least two transcripts were visualised. The sequencing of the clones confirmed the presence of the same aberrant transcript lacking 34 bp, in both patients, due to the preferential utilization of the predicted cryptic donor splice site in exon 18. A longer transcript was also detected in P2 resulting from the use of a cryptic splice site in intron 18.
The detection of these aberrant transcripts, containing a premature stop codon is consistent with a partial NMD. Unlike in P1, the canonic donor splice site was functional in P2 maintaining a full length mutated transcript. Male patient survival could be explained by the production of a mutated full length FLNA protein.
These results point to a sensitive regulation of exon 18 splicing and stress the relevance of mRNA studies in filaminopathy A molecular diagnosis especially in case of synonymous variants.

FOXL2 and its coregulators in ovarian function

A. Georges[1,2], *D. L'Hôte*[1,2], *A. Todeschini*[1,2], *J. Kim*[3], *R. A. Veitia*[1,2], *J. Bae*[3];
[1]*Institut Jacques Monod, PARIS, France,* [2]*Université Paris Diderot-Paris VII, Paris, France,* [3]*CHA University, Seongnam, Korea, Republic of.*

FOXL2 is a forkhead transcription factor and a major determinant of ovarian development and function. FOXL2 germline mutations are responsible of the BPES syndrome, a genetic condition involving facial malformations and premature ovarian failure. Recently, a unique FOXL2 mutation (p.C134W) was discovered in more than 95% of adult-type granulosa cell tumors, suggesting a role for FOXL2 in cancer.
FOXL2 regulates a wide variety of cellular processes in the granulosa cells of the ovary, including steroidogenesis, cell cycle, apoptosis and oxidative stress response. To better understand how FOXL2 integrates extra and intracellular signals, we used a yeast two-hybrid screening approach that led us to the discovery ten new protein partners of FOXL2. We next characterized their effect on FOXL2 activity using an array of target genes. Importantly, we found that FOXL2 pro-oncogenic mutant may be impaired in its ability to integrate pro-apoptotic signals from its partners. In parallel, we have used mass spectrometry to identify eight sites of post-translational modification on FOXL2 protein, suggesting that FOXL2 modification affects its stability and activity.
Many transcription factors of the nuclear receptor family are FOXL2 partners and are of major relevance in ovarian biology. We therefore started to characterize how FOXL2 regulates the cellular response to the sex steroids through nuclear receptors. Our findings suggest that FOXL2 is a major regulator of estrogen and androgen responses in granulosa cells of the ovary. This multifaceted approach will bring new insights into the role of FOXL2 both normal and pathological conditions.

Hirschsprung´s disease (HSCR, OMIM 142623) is a developmental disorder characterized by the absence of the enteric ganglia in variable lengths of the hindgut, resulting in severe intestinal dysfunction. HSCR is attributed to cell proliferation, migration and/or differentiation failure of the enteric neural precursors along the gut during normal embryonic development. Although some genes involved in this pathology are known, many aspects remain poorly understood. In this study we have characterized the precursors of human Enteric Nervous System (ENS) and have identified a group of genes with differential expression patterns between ENS precursors from HSCR patients and controls, being worth of mention the DNMT3B gene, which encodes a a DNA methyltransferase that performs *de novo* DNA methylation during the embryonic development, and that is involved in the expression of crucial genes for the proper human tissue growth. Through the experiments designed to study the role of *DNMT3B* in HSCR disease, we have observed a decrease of DNA methylation in enteric precursors from HSCR patients resulting in lower pluripotency. Taken together, our results demonstrate that in the context of HSCR, ENS precursors seem to have a limited capacity to response to stimuli implicated in neuronal differentiation. We show, for the first time, that DNMT3B could be involved in the ENS development, and therefore would play a role in the onset of HSCR. Moreover, DNMT3B may be regulating the expression of known genes implicated in this pathology through DNA methylation.

Chromosomal analysis of induced pluripotent stem cells (iPSCs) derived from senescent cells of elderly persons

F. Pellestor[1], *L. Lapasset*[2], *F. Becker*[3], *J. Puechberty*[1], *P. Sarda*[1], *J. Lemaitre*[2], *G. Lefort*[1]; *[1]Chromosomal Genetics, Hospital Arnaud de Villeneuve, Montpellier, France, [2]Equipe INSERM, Montpellier, France, [3]IRB, Hopital St Eloi, Montpellier, France.*

Reprogramming of adult somatic cells into induced pluripotent stem cells (iPSCs) provide a unique opportunity to generate patient-specific stem cells with potential application in regenerative therapies and without the ethical concerns of human embryonic stem cells (hESCs). However, important question persist about the safety of iPSCs and their chromosomal stability.

In order to assess the chromosomal consequences of reprogramming process, we performed classical and molecular cytogenetic analysis on 4 iPSC lines generated from 74- and 96-years-old men's fibroblasts. Cytogenetic analysis was carried out using standard methods. FISH assays with both centromeric and painting probes were used for chromosomal detection on interphase nuclei. A minimum of 20 metaphase spreads and 100 interphase nuclei per cell line were analyzed. The 4 cell lines exhibited normal karyotypes. In three iPSC lines, these investigations were completed by an analysis of the telomere sizes since senescence is characterized by telomere shortening. We measured in situ the length of telomere repeat domains using PNA pantelomeric probes and Metasystems image analyzer software Isis for quantifying the fluorescence intensity of telomeres from metaphases and nuclei from each cell line. In the 3 iPSC lines, we observed a significant increase in telomere length, when compared with their parental fibroblasts and control hESCs. These data were confirmed by telomere restriction fragments analysis.

The perspective of using iPSCs in regenerative medicine is of particular interest in the context of age-associated disorders, but cytogenetic and genetic screening of iPSCs need to become standard practice before these cells might be used clinically.

P20.29

Characterization of unbalanced chromosomal abnormalities in three Jacobsen syndrome using array-CGH and FISH-BACs

C. Fuster[1], *M. Sola*[1], *C. Hernando*[1], *A. Meneses*[2], *C. Templado*[1]; *[1]Universitat Autonoma de Barcelona, Bellaterra (Barcelona), Spain, [2]Hospital Virgen del Rocío, Sevilla, Spain.*

Context: Jacobsen syndrome occurs in approximately 1 out of every 100,000 births and the majority of cases are *de novo.* Classic phenotypes of this syndrome includes mental retardation, characteristic facial trait and thrombocytopenia. Its karyotype shows a terminal 11q deletion, which can vary from 7 to 20 Mb, with phenotypic expression related to the lost size.

Objective: Characterization of the 11q deletion using array CGH (aCGH) and FISH with BACs in three patients with Jacobsen syndrome have been carried out in order to establish a more accurate genotype-phenotype association. These 11q deletions had been previously identified by G-banding and high resolution CGH (HR-CGH).

Results: The aCGH analysis confirms the terminal 11q deletion in three patients and redefined the size deleted in each patient (15Mb, 14.6Mb and 11.53Mb). Additionally, the aCGH revealed the presence of one microduplication (dup 16p13.11 of 784 Kb) in a patient and one microdeletion (4p15.33 of ~ 244 Kb) in another patient. Moreover, the observation of BACs in interphasic nuclei demonstrates that the duplication 16p13.11 presents a direct orientation. So far it is the smallest duplication in which their orientation has been identified.

Conclusion: The 11q deletions identified in all three patients are within the range of the size associated with the syndrome. These are the first two Jacobsen syndrome cases showing other structural chromosome alterations in addition to the 11q deletion. These findings suggest that a more complex genetic disorder could be involved in heterogeneity of clinical features associate to Jacobsen syndrome.

P20.30

Reactivation of Foetal Haemoglobin by Chemical Inducers

L. Grech[1], *G. Grech*[2], *R. Galdies*[1], *W. Cassar*[1], *C. A. Scerri*[1], *A. E. Felice*[1], *J. Borg*[1,3]; *[1]Laboratory of Molecular Genetics, University of Malta and Thalassaemia Clinic, Mater Dei Hospital, Msida, Malta, [2]Department of Pathology, University of Malta, Msida, Malta, [3]Department of Applied Biomedical Science, Faculty of Health Sciences, University of Malta, Msida, Malta.*

Pharmacogenomic studies aimed at understanding how particular compounds are able to induce foetal haemoglobin (HbF) may help to elucidate the molecular control of globin gene switching. In this study, a collection of Maltese healthy adults (n=5), β-thalassaemia homozygotes and compound heterozygotes (n=5), and KLF1-haploinsufficient adults (n=3) from two families were explored. The effects of hydroxyurea (HU), thalidomide (Thal) and 5-Aza-2'-deoxycytidine (Aza), all well-known HbF inducing agents, were explored to quantify the HbF effect. HbF augmentation was minimal across the groups (< 1.5 FC) with the exception of one healthy adult that was hyper responsive to all three drugs after 24hrs (for Thal 1μM FC 2.26, Thal 10μM FC 2.34, Thal 100μM FC 2.50, with Aza 1μM FC 2.16, Aza 10μM FC 3.47, Aza 100μM FC 2.28) and maintained with two drugs even after 72hrs. The HbF of β-thalassaemia homozygotes and compound heterozygotes was inducted late after 72 hours in culture with thalidomide. Western blot assays for KLF1 showed an attenuation of the protein by the drugs (In cultured cells without drugs phosphoimager intensity 1,176 while in some cultured cells with drugs decreased to 880) hence suggesting a role of inhibition by drugs in culture (in vitro) in human haematopoiesis. The KLF1 gene may be an important pharmacogenomic marker to predict efficacy of HU, thalidomide or 5-Aza-2'-deoxycytidine treatment. HU, thalidomide and 5-Aza-2'-deoxycytidine mechanisms might be acting on HbF control by down regulation of KLF1 but the effect on Hb F may be inhibited by "Foes of KLF1".

Prelamin accumulation in primary endothelial cells induces premature senescence and activation

N. Bonello-Palot[1,2], *S. Simoncini*[3], *S. Robert*[3], *N. Lévy*[1,2], *F. Dignat-George*[3], *C. Badens*[1]; *[1]Laboratoire de Génétique Moléculaire, Hôpital Timone enfants, Marseille, France, [2]UMR_S910, Faculté de Médecine, Aix-Marseille Université,, Marseille, France, [3]UMR_S1076, Faculté de Pharmacie, Aix-Marseille Université, Marseille, France.*

Defects in lamin A maturation result in premature aging syndromes and severe atherosclerosis as observed in Hutchinson-Gilford Progeria Syndrome. In age-related atherosclerosis, several features of cell senescence have been characterized in endothelial cells including telomere shortening and increased oxidative stress, but lamin A alterations have been little investigated. To study lamin A-related senescence in primary endothelial cells and consequences in the activation status of cells, normal primary endothelial cells from human umbilical vein (HUVEC) or cord blood (ECFC) were used. Lamin A defects were induced by treatment with the protease inhibitor Atazanavir during 48h.We showed that PI treatment led to the accumulation of farnesylated prelamin A and induced nuclear shape abnormalities and premature senescence in both HUVEC and ECFC. ICAM-1-dependent activation was present and monocyte adhesion was increased in HUVEC whereas ability to generate a microvascular network in matrigel was decreased for ECFC. The effects of PI treatment were reversed when cells were PI-treated in combination with Pravastatin and Zoledronate in both mature and progenitor endothelial cells. Reversion was also demonstrated with 2 antisense oligonucleotides targeted toward lamin A specific splice sites.This study showed that PI treatment reproduces premature senescence due to lamin A defects in primary endothelial cells after a 2 day exposure. The cells used were extracted

from neonates, allowing considering that other senescence pathways were not activated and that the observed alterations were specific of prelamin A accumulation. This constitutes a valuable model to test different approaches aimed at reversing specifically lamin A-related cellular senescence.

Premature ageing syndromes, and especially Hutchinson-Gilford progeria syndrome, which is associated with mutations in LMNA, are rare genetic disorders mimicking some clinical and molecular features of ageing. They are associated with numerous alterations of cell homeostasis. LMNA pre-mRNAs physiologically undergo an alternative splicing event leading to the production of Prelamin A (the Lamin A precursor) and Lamin C. Several deleted Prelamin A transcripts (prelamin AΔ50, Δ35 and Δ90) have been implicated in the physiopathology of lamin-related diseases (Navarro et al 2004, Hishima et al 2011, Fukushi et al 2004). Most patients affected with typical HGPS carry an heterozygous de novo mutation located in exon 11 (c.1824 C>T; p.Gly608Gly) which leads to an in-frame deletion of the last 150 base pairs of the exon, and the production of prelaminAΔ50, a truncated and permanently farnesylated precursor. The purpose of this work was to study the presence and the effect of Prelamin A truncated transcripts, including prelaminAΔ90, which lack the entire exon 11, on clinical phenotypes in a cohort of patients affected with progeria-like syndromes. PrelaminAΔ90 was exclusively identified in patients carrying mutations close from the donor splice site of exon 11. In these patients we attempted to correlate the clinical phenotypes with either: the presence of the rs4641 polymorphism (p.His566His), the impact of the ratio between all the deleted prelamin A isoforms and wild type lamins A and C or the level and the severity of cellular abnormalities observed. Finally, we try to demonstrate the existence of prelaminAΔ90 at the protein level.

P20.33

Functional characterization of genetic variations in *MATE* promoter in Koreans

J. Kim*, T. Kim, J. Choi;*
Ewha womans university school of medicine, Seoul, Korea, Republic of.

BACKGROUND: Multidrug and toxin extrusion transporters (*MATE1* and *MATE2-K*) play important roles for the elimination of many cationic drugs and their metabolites from the body. To date, a few genetic variants have been described in *MATE1* and *MATE2-K*. The goal of this study was to identify and functionally characterize novel genetic variations of *MATE1* and *MATE2-K* promoters in Koreans.
METHODS: DNA samples from 48 healthy Korean subjects were screened for variants in the promoter regions of *MATE1* and *MATE2-K*. To measure promoter activities of *MATE1* and *MATE2-K* haplotypes, reporter assays were performed. Potential transcription factors that regulate the transcription of *MATE1* and *MATE2-K* were identified using TFSearch and confirmed by electrophoretic mobility shift assays.
RESULTS: There were five variants in the *MATE1* and nine variants in the *MATE2-K* promoter regions. Two of the *MATE1* and seven of the *MATE2-K* variants were polymorphic. In the case of *MATE1,* haplotype 3 containing a variant, V1 showed a 72% increase in reporter gene expression, compared to that of the reference. Results from electrophoretic mobility shift assays showed that three transcriptional factors are involved in the regulation of *MATE1* transcriptional activity. Two haplotypes of *MATE2-K*, H1 and H2 also showed a significant increase in reporter activity.
CONCLUSION: Our studies revealed that novel promoter genetic variations of *MATE1* and *MATE2-K* result in changes in transcriptional activity of these genes. These variants can potentially affect the pharmacokinetics or drug response of many drugs that are substrates of MATE1 or MATE2-K.

Gene expression modifications in Wharton's Jelly mesenchymal stem cells promoted by prolonged in vitro culturing

V. Gatta*, M. D'Aurora, S. Sperduti, S. Franchi, L. D'Onofrio, P. Lanuti, L. Pierdomenico, M. Marchisio, S. Miscia, G. Palka, L. Stuppia;*
University, Chieti, Italy.

The umbilical cord matrix, represented by the Wharton's Jelly (WJ), contains a great number of mesenchymal stem cells (MSCs), which have been characterized as expressing the best suited MSCs markers, shared by both human and animal models. The abundant amount of WJ makes it an attractive source of MSCs for cell-based therapies. However, as in other stem cells models, a deeper investigation about the biological properties of WJ-MSCs related to their long expansion and fast growth abilities is required before their use in a clinical setting. In this context, in order to analyze the gene expression modifications occurring in WJ-MSC promoted by the prolongation of culture, we investigated the transcriptomic profile of WJ-MSCs cultures at 4th and 12th passage in vitro expansion by microarray analysis Hierarchical clustering analysis of the data set originated from a total of 6 experiments revealed that 12 passages in vitro expansion of WJ-MSCs promote the selective over-expression of 157 genes, while 440 genes were down-regulated as compared to 4 passages . Ingenuity Pathway Analysis was carried out to investigate the main functions played by the selected genes disclosing that several transcripts are related to inflammatory and cell stress response, cell proliferation and maturation, and apoptosis. Taken together, these modifications may lead to an impairment of the cell expansion ability and resistance to apoptosis, two hallmarks of aging cells. In conclusion, the results provided by this study suggest the necessity of novel culture protocols able to preserve the stem cells plasticity.

P20.35

Expression of a linear reporter construct in isolated human mitochondria

C. B. Jackson, S. Gallati, ***A. Schaller****;*
Division of Human Genetics, Bern, Switzerland.

Transfection of reporter genes is a standard method to study nuclear gene expression. For mammalian mitochondrial DNA, such a genetic manipulation has so far been elusive. Thus, disease causing mutations in the mitochondrial DNA cannot be functionally characterised and basic genetic mechanisms of the mitochondria still remain unknown. Isolated mammalian mitochondria possess the ability to import DNA from their environment. We used this ability to study reporter constructs. After isolation of active mitochondria from cultured rat Zajdela hepatoma cells and human HepG2 cells, we monitored DNA import using quantitative PCR and confocal microscopy. Import of linear double-stranded DNA from 100 bp up to 3.3 kbp revealed time-dependent uptake. After DNA import, mitochondria were then sustained in respiration buffer for expression of imported constructs. Expression of human reporter genes in isolated rat hepatoma mitochondria was successfully achieved. Using a circular RNA (CR)-RT-PCR assay, accurate maturation, i.e. adding of the CCA trinucleotide post-transcriptionally to the heterologues expressed human tRNAArg was demonstrated. By generation of constructs containing all regulatory elements adapted to the human expression system, we could show that a rat-specific tRNALeu(UUR) is fully processed at its 3`end with CCA trinucleotide addition, but aberrantly processed at its 5`end. Furthermore, mRNA expression of an imported GFP reporter could be demonstrated. Establishing such a system for human cells not only allows the characterisation of mitochondrial gene expression (e.g. maturation, cis-acting elements, polyadenylation, turnover of mRNAs, regulation), but also the elucidation of the systemic impact of mitochondrial DNA mutations at a functional level.

Mechanisms of rearrangements at 1p36

M. Gajecka[1,2];
[1]*Institute of Human Genetics PAS, Poznan, Poland,* [2]*Department of Genetics and Pharmaceutical Microbiology, Poznan University of Medical Sciences, Poznan, Poland.*

Deletions of 1p36 occur in approximately 1 in 5,000 newborns. To date, we have ascertained more than 150 cases with monosomy 1p36, representing four possible classes of rearrangements: pure terminal deletions, interstitial deletions, unbalanced translocations, and complex rearrangements (involving duplications in monosomy 1p36). For each individual, deletion and duplication sizes, and parental origin of the rearrangements were determined using array CGH and genotyping. To further understand the mechanisms of 1p36 aberrations the rearrangements breakpoints were investigated using molecular cytogenetics and molecular biology methods. Deletion sizes as well the breakpoints locations were different in each patient. Our results show higher than accepted complexity of the studied rearrangements and indicate involvement of multiple mechanisms in the DNA breakage and repair process during rearrangement formation. Although the causes of the chromosomal breaks that initiate the rearrangement formation are unknown, the joining mechanisms were consistent with features of the non-homologous end-joining pathway. Examples of the rearrangements and the mechanisms will be discussed.
Supported, in part, by Polish Ministry of Science and Higher Education, Grant NN301238836.

P20.37

Detection of splicing-affecting mutations in the primary-immunodeficiencies related genes.

P. Lockerová[1], *B. Ravcuková*[1], *T. Freiberger*[1,2], *L. Grodecká*[1,2];
[1]*Molecular Genetics Laboratory, CKTCH, Brno, Czech Republic,* [2]*Molecular Immunology and Microbiology, Central European Institute of Technology, Masaryk university,, Brno, Czech Republic.*

Mutations that influence splicing of precursor mRNA are conservatively estimated to cause 15 % of Mendelian disorders. They generally have severe impact on gene expression. However, their detection is not always elementary.
In order to test the incidence of splicing-affecting mutations in our patients, we took 92 point mutations we found in the genes BTK, SerpinG1, STAT3, IL2RG, WAS and CD40LG. At first, we analysed these mutations using in silico prediction tool NNSplice. Accordingly, we selected 16 mutations most probable to disrupt splicing (including 13 mutations affecting authentic splice sites) and we tested them in vitro by splicing minigene analysis. Minimal score change between these wild type and mutant sequences was 7 %.
Effect of all 13 mutations predicted to disrupt splice sites was confirmed by in vitro analyses. Two of these mutations simultaneously created de novo splice sites that were utilized in vitro. Of three other mutations predicted to create de novo splice sites, only one disrupted splicing in vitro. Surprisingly, this novel site was predicted with lower score than the authentic splice site, as opposed to the other two de novo splice sites.
Overall, we found out that 14 of the 92 originally tested mutations (15 %) disrupted splicing of pre-mRNA. RT-PCR from RNA of seven mutations carriers (all of the available) confirmed results of minigene analysis, showing no false positive or negative results. When assessing the predictions, generally recommended 10 % cut-off limit of score difference would lead to omission of one of the splicing affecting mutation.

P20.38

NPHS2 mutations in Brazilian children with nephrotic syndrome

M. S. Guaragna[1], *A. C. Lutaif*[2], *S. Z. P. Rigatto*[2], *L. C. Prates*[2], *V. M. S. Belangero*[2], *G. Guerra-Jr.*[3], *M. P. de Mello*[1];
[1]*Centro de Biologia Molecular e Engenharia Genética (CBMEG) - UNICAMP, Campinas, Brazil,* [2]*Ambulatório de Nefropediatria (APA) do Centro Integrado de Nefrologia (CIN) - UNICAMP, Campinas, Brazil,* [3]*Centro Integrado de Pediatria (CIPED) - UNICAMP, Campinas, Brazil.*

Nephrotic syndrome (NS) is defined by heavy proteinuria, hypoalbuminemia, edema and hyperlipidemia. It is divided into two categories based on the response to steroid therapy: steroid-sensitive (SSNS) and steroid-resistant (SRNS). *NPHS2* gene mutations cause autosomal-recessive NS. In this study we report the molecular evaluation of the *NPHS2* gene of 111 Brazilian patients (n=222 alleles) with infantile NS. The eight coding exons, promoter region and intron/exon boundaries of *NPHS2* were direct sequenced. A total of 11 nucleotide variations (11/222, 4.95%) had been identified. Five out of 11 were located in the promoter region in the heterozygous or homozygous state. Three of them (c.-51G>T, c.-116C>T and c.-535TTTTTT$_2$/TTTTTT$_3$) were described as determining downregulation of the reporter gene expression when transfected in podocytes. Two others (c.-196C>G and c.-267C>G) had been identified here for the first time. Six already described heterozygous missenses were identified: p.P20L, p.R229Q, p.A242V, p.E264Q, p.A284V and p.E310K. We analyzed the possible impact of the amino acids substitutions based on *in silico* prediction sites and all of them returned in a damaging outcome. This is the first study in a Brazilian cohort and emphasizes the relevance of the molecular analysis of NS in childhood since it is a clinically heterogeneous disease in which informations on the genotype may guide further treatment. Additionally, living related donor transplantation might be considered promptly since SRNS patients with homozygous or compound heterozygous mutations in *NPHS2* have reduced risks of recurrence of focal segmental glomerular sclerosis after renal transplant compared with children without mutations.

Neurofibromatosis type 1 (NF1) affects about one in 3,500 people in all ethnic groups. Most NF1 patients have private loss-of-function mutations scattered along the *NF1* gene. Here, we present an original *NF1* investigation strategy and report a comprehensive mutation analysis of 565 unrelated patients from the NF-France Network. A *NF1* mutation was identified in 546 of the 565 patients, giving a mutation detection rate of 97% never reached before. The combined cDNA/DNA approach showed that a significant proportion of *NF1* missense mutations (30%) were deleterious by affecting pre-mRNA splicing. Multiplex ligation-dependent probe amplification and/or custom array-*comparative* genomic hybridization allowed the identification of restricted rearrangements that would have been missed if only sequencing or microsatellite analysis had been performed. In four unrelated families, we identified two distinct *NF1* mutations within the same family. This fortuitous association points out the need to perform an exhaustive *NF1* screening in the case of molecular discordant related patients. A genotype-phenotype study was performed in patients harboring a truncating (N=265), splicing (N=145), or missense (N=41) mutation. The association analysis of these mutation types with 12 common NF1 clinical features confirmed a weak contribution of the allelic heterogeneity of the *NF1* mutation to the NF1 variable expressivity.

Neurofibromatosis type 1 (NF1) is one of the most frequent autosomal dominant genetic disease. NF1 is caused by loss of function mutations of the tumour suppressor gene *NF1*. A large spectrum of *NF1* molecular abnormalities is found: large locus deletions, missense or nonsense mutations, splice mutations, and intragenic deletions/insertions. In our laboratory, *NF1* molecular investigation is performed by intragenic microsatellite pre-screening study, quantitative PCR, and a combined approach of cDNA/DNA sequencing. Here, we have evaluated the usefulness of the multiplex ligation-dependent probe amplification (MLPA) approach, which allows a simultaneous gene dosage of nearly all *NF1* exons. Among 564 NF1 index

cases of the French NF1 cohort, thirty patients were identified as „negative" patients with no molecular abnormality found using the molecular strategy of our laboratory. These „negative" patients were subsequently tested by MLPA. Quantitative abnormality of one or more exons was identified in 12 of them (40% of "negative" patients). This MLPA approach also allowed the confirmation of nine deletions and one tandem duplication that were previously identified by the cDNA/DNA analysis. In total, MLPA identified a *NF1* molecular defect in nearly 4% of the 564 patients clinically affected by NF1. The abnormalities found were single exon deletions (eight cases including four affecting the *NF1* promoter and exon 1), multiple exons deletions (11 cases including one mosaic deletion), one double deletion, and two duplications. All results were confirmed using a custom array-CGH which allowed characterisation of the duplication/deletion boundaries and identification of recurrent breakpoints.

Partial monosomy 22qter resulting from a paternal chromosome 22 inversion: a cytogenetic pitfall

A. Paubel[1,2], *A. Ardalan*[3], *M. Jimenez-Pocquet*[1], *C. Le Caignec*[4], *A. Chailloux*[1], *E. Jagut*[1], *V. Ract*[5], *A. Barthez*[6], *A. Toutain*[1,2];

[1]*Service de Génétique, Hôpital Bretonneau, CHRU de Tours, TOURS, France,* [2]*INSERM U930, Université François-Rabelais, Tours, France,* [3]*Laboratoire BIOMNIS, PARIS, France,* [4]*CHU Nantes, Service de Genetique Medicale, NANTES, France,* [5]*Service de Médecine et Biologie de la Reproduction, Hôpital Bretonneau, CHRU de Tours, TOURS, France,* [6]*Service de Neuropédiatrie, Hôpital Clocheville, CHRU de Tours, TOURS, France.*

Pericentric inversions are rare chromosomal rearrangements leading to a variable risk of aneusomic recombination depending on the chromosome involved and the inversion size.

We report the case of a child affected with 22q13 deletion syndrome resulting from a paternal pericentric inversion of chromosome 22 which was first missed by using solely molecular and FISH analyses.

In the proband, R banding prenatal chromosome analysis was normal but telomere screening by MLPA revealed a 22q13 deletion which was confirmed by FISH analysis. FISH analysis of both parents was interpreted as normal leading to the diagnosis of de novo 22q13 deletion. The proband's phenotype was in keeping with the Phelan-McDermid syndrome. A favourable genetic counselling for a next pregnancy was given.

Subsequently, investigation of both parents for infertility by high resolution R and G banding chromosome analysis on peripheral blood lymphocytes revealed in the father a pericentric inversion of chromosome 22 [46, XY, inv(22)(p11.2q13.3)]. This was confirmed by Ag-NOR staining in the proband and his father. As expected, Agilent® human genome 60K CGH microarray analysis showed in the proband a terminal 7.8 Mb deletion from 22q13.2 to 22qter with no other genomic imbalance, particularly no duplication.

This observation confirms that, in the absence of a previously known familial chromosome anomaly, conventional cytogenetic analysis remains the only method able to diagnose balanced chromosomal rearrangements which cannot be detected by the powerful and modern molecular techniques currently considered as the first-rate strategy in MCA/ID syndrome investigation.

Mitochondrial helicases such as Twinkle and DNA2, play a crucial role in replication and repair of the mitochondrial genome (mtDNA) and are involved in late-onset mitochondrial myopathies with mtDNA instability. Here, we show that inactivation of mPif1, a third member of this family, causes a similar phenotype in mouse. Pif1-/- animals develop a mitochondrial myopathy after 1 year of age with accumulation of mtDNA deletions. Muscle weakness is objectified by a decreased exercise capacity in Pif1-/- mice with a daily running distance significantly lower compared to wild-type animals. The mouse PIF1 mitochondrial isoform, that occurs via downstream alternative translation initiation (dATI), is present inside mitochondria and binds to mtDNA. Furthermore, we show that mPif1 inactivation is responsible for a deficiency to repair oxidative stress-induced mitochondrial DNA damage, thus confirming the role of this helicase in mtDNA maintenance. These results open new perspectives for the exploration of patients with mtDNA instability disorders and for the study of mitochondrial helicases that play a critical role in the maintenance of mtDNA stability, possibly preventing age-associated accumulation of mtDNA mutations.

Prader Willi : a typical case with a 118 kb paternally inherited microdeletion of the snoRNA SNORD116 cluster

E. Bieth[1], *A. Buffet*[2], *V. Gaston*[1], *D. Cailley*[3], *J. Plaisancie*[1], *S. Eddiry*[4], *C. Molinas*[5], *F. Lorenzini*[2], *J. Cavaille*[6], *J. Salles*[5], *B. Arveiler*[3], *M. Tauber*[5];

Prader Willi syndrome (PWS) is a neurobehavioral disorder caused by the loss of expression of the paternal allele of several imprinted genes including snoRNA within 15q11-q13. Large interstitial deletions encompassing the SNRPN gene of paternal origin, chromosome 15 maternal uniparental disomy and rare imprinting defects are the classical mechanisms reported in almost all cases of PWS. Because these etiologies result in the lack of the unmethylated allele at the SNRPN locus, methylation analysis is the first genetic test used for the diagnosis of PWS. However, three individuals with features of PWS were recently reported as having a normal SNRPN methylation status. Remarkably, these patients displayed a micro-deletion overlapping the paternally expressed SNORD116 gene cluster. Here, we describe the smallest paternally inherited microdeletion of the SNORD116 in a patient with typical features of PWS, including, notably, severe neonatal hypotonia. Our study strengthens the notion that the lack of SNORD116 expression genes contributes to the pathogenesis of PWS.

Breakpoints of non allelic homologous recombination (NAHR) events at the *DPY19L2* locus are centered around a *PRDM9* recognition sequence

C. COUTTON;

CHU Grenoble, Grenoble, France.

We demonstrated previously that 75% of infertile men with round, acrosomeless spermatozoa (globozoospermia) had a homozygous 200 Kb deletion removing the totality of *DPY19L2*. We showed that this deletion occurred by Non Allelic Homologous Recombination (NAHR) between two homologous 28 Kb Low Copy Repeats (LCRs) located on each side of the gene.

NAHRs are believed to occur during meiotic prophase, induced by the crossing-over machinery on misaligned homologous sequences. Recent work showed that PRDM9 apposed post-translational histone modifications preferentially in the vicinity of a 13 nucleotide consensus sequence, which has been found to be associated with recombination hotspots. These epigenetic marks likely contribute to the recruitment of the recombination initiation complex, thus favouring the occurrence of recombinations at these loci.

Here, we developed two PCR assays that allowed us to detect approximately 90% of the recombined alleles (deletions and duplications) occurring at the *DPY19L2* locus. We amplified and sequenced a total of 46 recombined alleles from globozoospermia patients and heterozygous individuals and 139 *de novo* recombined alleles from control sperm DNA. We identified 5 distinct breakpoints and showed that they all cluster within a 1153 bp region roughly located in the middle of the 28 Kb LCR. We found a *PRDM9* consensus site at the epicentre of all identified breakpoints. Our work therefore reinforces the theory indicating that the *PRDM9* recognition sequences represent a strong signal for the occurrence of double strand break and recombination.

Comparison of conventional cytogenetic techniques with molecular cytogenetic techniques in analysis of chromosomal imbalances in spontaneous abortion and fetal demise

R. Kariminejad[1], *K. Najafi*[1,2], *K. Najafi*[1,2], *N. Sadatian*[1], *A. Moshtagh*[1], *P. Rostami*[1], *S. Valizadeh*[1], *M. Ghalandari*[1], *F. Azimi*[1], *N. Nabavinia*[1], *H. Najmabadi*[1], *M. Kariminejad*[1];
[1]Kariminejad-Najmabadi Pathology and Genetics Center, 14665/154, Tehran, Islamic Republic of Iran, [2]Tehran University of Medical Science, Tehran, Islamic Republic of Iran.

Traditionally, chromosomal study of product of conception (POC) has been conducted on specimens received following spontaneous abortion. It is also possible to perform chromosomal study on tissue obtained following IUFD and perinatal fetal death. There are major limitations in successful chromosomal analysis as it requires viable cells for culture.

In 15 years, we have performed chromosomal analysis on 2053 samples obtained from chorionic villi, placental tissue and/ or muscle biopsy following abortion or fetal demise. Tissue culture failed in 384 of these samples and in the remainder, approximately 23% show chromosomal abnormalities.

For the past 3 years, as an alternative to chromosomal study we have started to use molecular cytogenetic techniques for analysis of these samples. Following DNA extraction, we have performed QF-PCR for common 5 chromosome aneuploidy (13. 18. 21. X and Y). Thereafter in those cases where a chromosome abnormality has not been detected we have performed array comparative genomic hybridization, initially on BAC array and more recently on oligoarray platforms. Of the more than 400 samples thus studied, only 15 have failed to label and of the successfully studied cases, approximately 30% have shown chromosomal abnormalities.

The techniques are compared and the age related ratios of chromosomal aberrations are further discussed in detail. Overall, it appears that the application of the molecular cytogenetic techniques is much more efficient in detecting chromosomal aberrations, specially in later gestational age fetuses.

Lamin A expression is downregulated by miR-9 in the brain of a progeria mouse model, a mechanism that protects HGPS patients from cognitive impairment

R. Fayek*[1,2], *C. Navarro*[*1,2], *C. Bartoli*[1,2], *N. Da Silva*[1,2], *F. Merono*[1,2], *P. Cau*[1,3,2], *P. Roubertoux*[1,2], *A. De Sandre-Giovannoli*[1,2,4], *N. Lévy*[1,4,2];
[1]Inserm UMR_S910, Marseille, France, [2]AMU (Aix-Marseille University), Marseille, France, [3]Departement of cellular Biology, La Timone Children's hospital, Marseille, France, [4]Departement of Medical Genetics, La Timone Children's hospital, Marseille, France.

Hutchinson-Gilford Progeria syndrome (HGPS) is an extremely rare disease characterized by segmental premature aging leading to premature death at the mean age of 13.5 years. Clinical features are severe dermal and bone abnormalities, a general lipoatrophy, sarcopenia, as well as major cardiovascular defects. HGPS is typically caused by a *de novo* transition (c.1824C>T) in *LMNA*, encoding major components of the nuclear lamina and matrix, lamins A and C. This mutation activates a cryptic splicing site which delete 150 base pair, leading to accumulation a truncated and aberrantly farnesylated form of lamin A, called progerin. Nonetheless, despite a wide spectrum of affected tissues, no cognitive defect was never reported in HGPS patients. Recent studies proposed a brain protective role of mir-9, a brain specific microRNA targeting Lamin A. To better characterize *in vivo* relation between mir-9 and low levels of lamin A and progerin in brain tissues, we studied KI $Lmna^{G609G}$ Progeria mouse model which closely reproduces the human pathology both at the molecular and phenotypic level. First, we monitored cognitive processes. Then we performed MRI and volumetric analyses on a panel of cerebral structures. Altogether these explorations evidenced absence of cognitive impairment in mice $Lmna^{G609G}$. In parallel we analyzed Lamin A/C and progerin expression by western blot and immunofluorescence in several cerebral regions and showed reduced lamin A and progerin levels correlated with an overexpression of miR-9 in the same regions. This developmental and biological study confirmed the protective role of mir9 identified in neuronal cells derived from HGPS iPS.

P20.47

Submicroscopic deletions at GNAS locus and their putative underlying causative mechanisms

I. Garin[1], *F. M. Elli*[2], *J. Clarke*[3], *G. Mantovani*[2], ***G. Perez de Nanclares***[1];
[1]Molecular (Epi)Genetics Laboratory, Vitoria-Gasteiz, Spain, [2]Endocrinology Unit, Department of Clinical Sciences and Community Health, University of Milan, Fondazione IRCCS Ca' Granda Policlinico, Milan, Italy, [3]Professeur d'enseignement clinique, Université de Sherbrooke, Quebec, QC, Canada.

Introduction: Different genetic/epigenetic defects within *GNAS* locus result in a human disorder called Pseudohypoparathyrodisim type 1 (PHP-I), characterized by hypocalcemia and hyperphospatemia due to resistance to parathyroid hormone (PTH). Heterozygous mutations within the *GNAS* locus lead to pseudohypoparathyroidism type Ia (PHP-Ia), which is caused by maternally inherited inactivating mutations affecting the exons encoding Gsα. In very few cases, submicroscopic deletions including part or the whole gene have been reported. The MS-MLPA technique is a powerful tool for evaluating genetic deletions that cannot be detected using PCR based sequencing techniques, in addition to detect aberrant methylation patterns.

Objective: In this study, we aimed to establish the subjacent genetic mechanisms of large deletion(s) identified by MS-MLPA in patients with PHP-Ia.

Design: First, dosage and methylation analyses of *GNAS* locus were carried out by MS-MLPA using SALSA ME031 kit. An Illumina Human660W-Quad BeadChip was run for patients with whole gene deletions. Finally, breakpoints delimitations at nucleotide level of the different deletions were performed by Semiquantitative multiplex PCR of short fluorescent fragments and confirmation was done by large PCR and posterior direct sequencing.

Results and Conclusion: Two patients presented large deletions at *GNAS* locus. The breakpoints at nucleotide level of these deletions show that they are located inside non-long terminal repeat (Non-LTR) retroposons. Several consequences of activation of these non-LTRs have been described, including DNA's breaks. So, the breakpoints location around GNAS locus in our patients could be associated with the presence of this kind of elements.

P20.48

ROR-Alpha Target Genes in Monocyte and Endothelium

N. Erginel-Unaltuna, *C. Gulec, N. Coban, B. Ozsait, S. Sirma-Ekmekci;
Istanbul University, Institute for Experimental Medicine, Dep. of Genetics, Istanbul, Turkey.*

Aim: ROR-alpha is a member of nuclear receptor family of transcription factors, and therefore has ligand-dependent activity. Natural ligands of ROR-alpha include cholesterol and melatonin. Due to importance of ROR-alpha ligands in atherosclerosis, we aimed to identify ROR-alpha target genes in monocyte and endothelium.

Methods: After administration of THP-1 and HUVEC cells with ROR-alpha specific ligand, chromatin immunoprecipitation (ChIP) was performed. Following fixation and fragmentation, chromatins were precipitated with anti-ROR-alpha antibody to perform enrichment of DNA fragments bound by ROR-alpha. Enriched DNA fragments were then amplified using whole genome amplification kit. Identification of DNA fragments was performed with whole-genome tiling array (NimbleGen).

Results: Whole-genome tiling array analysis of enriched ChIP DNA gave 11,600 and 13,000 peaks for THP1 and HUVEC cells, respectively. Considering the FDR score, p value and genomic location of these peaks ($p<0,05$, FDR<0,01), we found 3,790 genes for THP1 and 4,290 genes for HUVEC which had ROR-alpha peaks between -5000 bp and +2000 bp accordance with TSS. Of these genes, 1,330 were found to be common to both cell types. Annotation clusters with highest enrichment score were glycoprotein and cell/plasma membrane (4.26 for HUVEC and 4.02 for THP1). Other common annotation clusters were cell motion, motality, migration, adhesion and actin-binding, actin cytoskeleton.

Conclusion: Our results showed that ROR-alpha peak freaquency tends to increase at -1500 and +1500, while decreasing around TSS. Functional annotation of target genes suggests that ROR-alpha may involve in cell-cell and cell-matrix interactions through regulating membrane glycoproteins, cell cytoskeleton, cell movement and cell migration.

P20.49

Inhibitory Effect of SR1001 on ROR-Alpha Activity Requires Intracellular Cholesterol

C. Gulec, N. Coban, B. Ozsait, S. Sirma-Ekmekci, N. Erginel-Unaltuna;
Istanbul University, Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey.

Aim: ROR-alpha is a member of nuclear receptor family of transcription factors. In addition to natural ligands, like cholesterol and melatonin, some synthetic compounds have also been shown to bind ROR-alpha as a ligand. One of these synthetic ligands is SR1001 which was demonstrated to inhibit ROR-alpha activity. We aimed to investigate the involvement of cholesterol in the antagonistic effect of SR1001 on ROR-alpha activity.
Methods: Target gene identification was performed by ChIP-PCR. ROR-alpha activity was inhibited by administration of SR1001 in the culture medium. Cholesterol synthesis was inhibited at various steps by the administration of zaragozic acid (ZA), neridronate or simvastatin. RNA levels of *SPP1* were measured using UPL probe in LC480 device.
Results: Both ChIP-PCR and expression analyses showed that *SPP1* is a target gene of ROR-alpha in THP1 monocyte. In cultured THP1, SR1001 suppressed *SPP1* expression in concentration-dependent manner. In the presence of distal cholesterol synthesis inhibitors, antagonistic effect of SR1001 on *SPP1* expression decreased or disappeared. This effect was more obvious in ZA than neridronate. In simvastatin, however, antagonistic effect of SR1001 was independent of inhibition of cholesterol synthesis. Absence of LDL-derived cholesterol enhanced the disappearance of antagonistic effect of SR1001 in the presence of neridronate. In the presence of ZA, however, absence of LDL-derived cholesterol converted the antagonist effect of SR1001 to agonistic.
Conclusion: Our results suggest that the cholesterol is not only a ligand for the ROR-alpha, but also it may be a component which arranges the relationship of ROR-alpha with other synthetic/natural ligands.

New point mutations and exon deletions of the EP300 gene in patients with Rubinstein-Taybi syndrome

*G. Negri[1], P. Colapietro[1], F. Forzano[2], D. Rusconi[1], D. Milani[3], L. Consonni[4], L. Caffi[5], F. Faravelli[2], S. Spena[1], A. Selicorni[6], L. Larizza[1], **C. Gervasini**[1];*
[1]Medical Genetics, Dept. Health Sciences, Università degli Studi di Milano, Milano, Italy, [2]Medical Genetics, Ospedali Galliera, Genova, Italy, [3]UOC Pediatry, Fondazione IRCCS Ca' Granda, Ospedale Maggiore, Policlinico, Milano, Italy, [4]Infantile Neuropsychiatry Medical School, Università degli Studi di Milano, Milano, Italy, [5]Infantile Neuropsychiatry, A.O. Papa Giovanni XXIII, Bergamo, Italy, [6]Dept. Pediatry, Università Milano Bicocca, Fondazione MBBM, Osp. S. Gerardo, Monza, Italy.

Rubinstein-Taybi syndrome (RSTS, #180849, #613684) is a congenital neurodevelopmental disorder characterized by postnatal growth deficiency, characteristic skeletal abnormalities, dysmorphic features and cognitive deficit. Mutations in two genes, CREBBP (16p13.3) and EP300 (22q13.2), have been identified in ~50% and ~3% affected individuals, respectively.
CREBBP and EP300 are ubiquitously expressed homologous proteins acting as transcriptional co-activators with intrinsic histone and non histone acetyltransferase activity.
So far, only seven EP300-mutated RSTS patients have been described and other 13 mutations including four exon deletions are reported in the LOVD database.
EP300 analysis by DHPLC/direct sequencing and MLPA of 25 CREBBP-negative cases showed four new germline EP300 alterations including two early inactivating point mutations, an indel in exon 1 (c.41_51delinsT) and a duplication in exon 2 (c.668dupT) both leading to a frameshift and premature stop codon (p.K14Ifs*31 and p.Q223Sfs*19) and two novel exonic deletions involving exon 12 and both exons 17-18. The transcripts analysis of patient carrying the exon-2point mutation revealed the presence of the aberrant one, but at reduced level, suggesting its possible instability.
According to the limited literature about all the four EP300-mutated patients show a convincing RSTS phenotype, but at the mild level with minor skeletal anomalies, a slight cognitive impairment and absence of major malformations. Beyond expanding the RSTS EP300 mutations repertoire, our study points to a contribution of the "minor" gene EP300 less negligible than predicted. Results, implemented by extending the study to our accumulated 52 CREBBP-negative patients, will also help the clinical practice in genotype-phenotype correlation doing.

Xq chromosome duplication, including SOX3 gene, in a male: clinical and molecular characterization

*A. Zagorac[1], **A. Blatnik**[1], E. Zemljič[1], N. Kokalj Vokač[1,2];*
[1]University Medical Centre Maribor, Maribor, Slovenia, [2]Medical Faculty, University of Maribor, Maribor, Slovenia.

Duplications of the distal long arm of the chromosome X are rare events. Clinical manifestations widely vary depending on the gender of the patient and on the gene content of the duplicated segment. In XY males, structural X disomy always results in functional disomy.
We report on a 39-year old male with hypogonadotropic hypogonadism associated with short stature and obesity. In childhood, he was diagnosed with growth hormone deficiency. On re-evaluation, he was found to have panhipopituitarism, low levels of TSH and gonadotropins as well as an abnormal adrenal response after ACTH stimulation test. He was of normal intelligence and his brain MRI was unremarkable.
Chromosome analysis on peripheral blood lymphocytes showed a male karyotype with pericentric inversion of chromosome 10: inv(10)(p11.2q21.1) and additional material on the long arm of the X chromosome. Fluorescence in situ hybridization using whole chromosome painting probes showed that additional material is derived from chromosome X.
To define the exact duplicated region on chromosome X an array-CGH was performed, indicated two copies of Xq27.1q28, 12,4 Mb in range. After aCGH, the karyotype was re-written: 46,Y,dup(X)(q27.1q28)inv(10)(p11.2q21.1).arr Xq27.1q28(139412100-151852048)x2.
The duplicated region contains 53 genes, among them SOX3. In males both under and overdosage of SOX3 are associated with similar phenotypes, ranging from isolated growth hormone deficiency to panhipopituitarism, and sometimes also with mental retardation. We have compared the clinical, cytogenetic and molecular findings of our patients with those previously reported. According to the literature reported pericentric inversion of chromosome 10 is a normal chromosome variant.

P20.52

First report of a small supernumerary marker chromosome derivative from chromosomes 8 and 14

*R. S. Guilherme[1], **S. Bragagnolo**[1], A. R. N. Dutra[1], A. B. A. Perez[1], S. S. Takeno[1], M. M. Oliveira[1], L. D. Kulikowski[2], E. Klein[3], A. B. Hamid[3], T. Liehr[3], M. I. Melaragno[1];*
[1]EPM-UNIFESP, São Paulo, Brazil, [2]USP, São Paulo, Brazil, [3]Jena University, Jena, Germany.

/>Small supernumerary marker chromosomes (sSMC) are usually detected unexpectedly in routine cytogenetics with no correlation with a specific clinical outcome. We present the first report of a patient with a *de novo* complex sSMC derived from chromosomes 8 and 14. G-banding, SNP-based array and FISH revealed: 47,XY,+der(14)t(8;14)(p23.2;q22.1)dn.arr 8p23.3p23.2(46,385-4,301,995)×3,14q11.2q22.1(19,002,111-51,106,110)×3 resulting in a 4.3 Mb 8p duplication and a 51 Mb 14q duplication. Our propositus, born at preterm with 2550 g, 47 cm and Apgar 4/7/9, mother 44 years-old. At age 21 months, presented common characteristics of partial duplication and triplication 14q: intellectual disability, seizures, neuropsychomotor development delay, brachycephaly, low set ears, high palate, macrostomia, tongue protusion and cryptorchidism. According to OMIM there are about 14 and 250 genes duplicated at 8p and 14q, respectively. The 8p22→p23.3 duplication have been reported to be clinically normal or have mild mental retardation with no dysmorphic features, suggesting a minor role in the development. We propose that the clinical features in our patient mainly result from the trisomy 14q. Most of the patients described in the literature with microduplication 14q12 including the *FOXG1* gene suffered of seizures or infantile spasms similar to our patient. The clinical phenotype of our patient may be the result of the additional genes present in the duplicated region and not only the *FOXG1* gene, which represents the most interesting candidate to explain the abnormal neurodevelopmental phenotype. The sSMC originated from maternal chromosomes 8 and 14 probably from errors in meiosis that could be related to mother's advanced age.<br FAPESP, Brazil.

P20.53

The genetic basis of TAR syndrome: Compound inheritance of a low-frequency regulatory SNP and a rare null mutation /deletion. A model for microdeletion syndromes.

R. A. Newbury-Ecob[1], *C. Albers*[2], *J. Stephens*[3], *D. Paul*[3], *H. Schulze*[4], *K. Freson*[5], *L. Greenhalgh*[6], *K. Shah*[1], *A. Guyatt*[1], *K. Smith*[7], *M. Williams*[7], *W. Ouwehand*[8], *C. Ghevaert*[8];
[1]University Hospitals, Bristol, United Kingdom, [2]Welcome Trust Sanger Centre, Hinxton, United Kingdom, [3]Welcome Trust Sanger Institute, Hinxton, United Kingdom, [4]Institute for Transfusion Medicine, Berlin, Germany, [5]Centre for Molecular and Vascular Biology, Leuven, Belgium, [6]Alder Hey Hospital, Liverpool, United Kingdom, [7]Bristol Genetics Laboratory, Bristol, United Kingdom, [8]Department of Haematology, Cambridge, United Kingdom.

Thrombocytopenia -Absent radius syndrome (TAR) is characterised by bilateral radial ray defects, thrombocytopenia and other congenital abnormalities. Previously shown to be associated with a chromosome 1q21.1 deletion, this was also found in 50% of unaffected first degree relatives, suggesting that this was not sufficient alone to cause TAR. Exome sequencing identified a SNP in either the 5'UTR or intron 1 of the RBM8A gene from the deleted TAR 1q21.1 region in the majority of TAR cases. The SNP were inherited from different parents. Sequencing of RBM8A in two TAR cases without the TAR 1q21.1 deletion but with the 5'UTR SNP, identified null mutations. We also showed that TAR 1q21.1 deleted cases ascertained by array CGH with non-TAR phenotypes lack the RBM8A SNP. Genotype-phenotype correlation has been assessed in 60 cases including one sib pair each witha different SNP/deletion combination and marked phenotypic differences
The RBM8A gene encodes Y14 one of the four exon-junction complex (EJC) units which performs essential RNA processing tasks. The SNPs result in reduction of transcription and Y14 expression is reduced in platelets from TAR cases.
We conclude that compound inheritance of a rare null allele and one of two low-frequency non-coding SNPs in RBM8A causes TAR syndrome. This novel bi-allelic inheritance may be a mechanism which explains the variable penetrance and expression in other microdeletion syndromes which currently hinders accurate genetic counselling..
Recurrence risks for TAR affecting siblings and offspring can now be predicted based on family testing for the 1q21.1 deletion and RBM8A SNP.

P20.54

Towards the identification of novel palindrome-mediated translocations

H. KURAHASHI[1], *H. Inagaki*[1], *T. Ohye*[1], *M. Tsutsumi*[1], *T. Kato*[1], *N. Okamoto*[2];
[1]Division of Molecular Genetics, ICMS, Fujita Health University, Toyoake, Aichi, Japan, [2]Division of Medical Genetics, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Osaka, Japan.

Constitutional t(11;22)(q23;q11.2) is the most frequent recurrent non-Robertsonian translocation in humans. The breakpoints on both 11q23 and 22q11.2 are located at the center of palindromic AT-rich repeats (PATRR). To date all the palindrome-mediated translocations involve the PATRR22. To identify novel PATRR on translocation partner chromosome, we analyzed breakpoints of four translocations from patients with multiple congenital anomaly with mental retardation; 45,XX, der(14)t(14;22)(q32.3;q11.2),-22, 45,XY,der(2),t(2;22)(q37.3;q11.2),-22, 45,X,der(X)t(X;22)(p22.1;q11.2),-22, and 47,XX,+der(22)t(15;22)(q26.1;q11.2). All were unbalanced translocations via 3:1 malsegregation in meiosis I. Cytogenetic array revealed that each translocation had a breakpoint at the different location on 22q11. Only the t(14;22) was found to have a 22q11 breakpoint at the same interval with that of the recurrent t(11;22). The breakpoint on chromosome 14 was narrowed down within 7kb region. However, no PATRR-like sequence was identified within the 7kb region according to the reference human genome sequence. However, it is well documented that PATRR is often deleted from the genome database due to unclonability or inability to sequence. Further, PATRR often manifests deletion polymorphism due to the genomic instability. We are now looking for missing gap within the 7kb region to find a novel PATRR that induced the t(14;22) translocation.

Involvement of the same TNFR1 residue in Mendelian and multifactorial inflammatory disorders

I. Jéru[1,2,3], *S. Charmion*[4], *E. Cochet*[3], *B. Copin*[1], *G. Le Borgne*[1,2], *P. Cathebras*[4], *J. Gaillat*[5], *P. Duquesnoy*[1], *S. Karabina*[1,2], *V. Hentgen*[6], ***S. Amselem***[1,2,3];
[1]INSERM U.933, Paris, France, [2]Université Pierre et Marie Curie-Paris6, UMR_S933, Paris, France, [3]Assistance Publique Hôpitaux de Paris, Hôpital Trousseau, Paris, France, [4]Centre Hospitalier Universitaire Saint-Etienne, Saint-Etienne, France, [5]Centre Hospitalier de la Région d'Annecy, Pringy, France, [6]Centre Hospitalier de Versailles, French Reference Centre for Auto-Inflammatory Diseases, Le Chesnay, France.

Objectives. TNFRSF1A is involved in a Mendelian autosomal dominant auto-inflammatory disorder called TNFR-associated periodic syndrome (TRAPS). Most TNFRSF1A mutations are missense changes and, apart from those affecting conserved cysteines, their deleterious effect remains often questionable. This is especially true for the frequent R92Q mutation, which might not be responsible for TRAPS per se but represents a susceptibility factor to multifactorial inflammatory disorders. This study investigates TRAPS pathophysiology in a family exceptional by its size (13 members).
Methods. TNFRSF1A screening was performed by PCR-sequencing. Comparison of the 3-dimensional structure and electrostatic properties of wild-type and mutated TNFR1 proteins was performed by in silico homology modeling. TNFR1 expression was assessed by western blotting and ELISA in lysates and supernatants of HEK293T cells transfected with plasmids encoding wild-type and mutated TNFR1.
Results. A TNFRSF1A heterozygous missense mutation, R92W (c.361C>T) perfectly segregated with typical TRAPS manifestations within the family ($p<5.10^{-4}$), and was associated with very high disease penetrance (0.9). Prediction of its impact on protein structure revealed local conformational changes and alterations of electrostatic properties. In addition, R92W leads to abrogation of the receptor shedding, whereas TNFR1-R92Q behaves like the wild-type receptor.
Conclusions. These data demonstrate the pathogenicity of a mutation affecting arginine 92, a residue whose involvement in inflammatory disorders is deeply debated. Combined with previous data on arginine 92 mutations, this study discloses an unusual situation in which different amino acid substitutions at the same position in the protein are associated with a clinical spectrum bridging Mendelian to multifactorial conditions.

Hamartin and Tuberin expression studies: Further insights into *TSC1* and *TSC2* genes in a cohort of patients with well define Tuberous Sclerosis phenotype

N. LANNOY[1], *J. F. Durant*[2], *T. Corbisier*[1], *M. Nellist*[3], *A. Jansen*[4], *K. Pelc*[5], *M. Nassogne*[6], *K. Keymolen*[7], *J. L. Gala*[2], *B. Delle Chiaie*[8], *S. Gaillez*[9], *N. Van Der Aa*[10], *D. Lederer*[11], *M. Vikkula*[1], *Y. Sznajer*[1];
[1]Center of Human Genetics, Cliniques Universitaires St Luc, U.C.L, Brussels, Belgium, [2]Centre de Technologies Moléculaires Appliquées, Brussels, Belgium, [3]Department of Clinical Genetics, Rotterdam, Netherlands, [4]Pediatric Neurology-UZ Brussel, Brussels, Belgium, [5]Pediatric Neurology-ULB, Brussels, Belgium, [6]Pediatric Neurology-UCL, Brussels, Belgium, [7]Centrum for Medische Genetica, UZ Brussel, Brussels, Belgium, [8]Centrum for Medische Genetica, UZ Gent, Gent, Belgium, [9]Center of Human Genetics -ULG, Liège, Belgium, [10]Center of Human Genetics, Antwerp, Belgium, [11]Center of Human Genetics-IPG, Charleroi, Belgium.

Tuberous sclerosis complex (TSC) represents an autosomal dominant genodermatosis with multisystemic involvement. In 20% of patients with a definite diagnosis, no point mutation, deletion or duplication in TSC1 or TSC2 gene could be identified. No other mechanism or anomaly in another gene has so far been identified as contributing to the cause of TSC. To further evaluate the implications of the TSC1and TSC2 genes, we conducted expression studies among a cohort of 132 index patients referred with definite, possible or probable TSC diagnosis. 25 did not carry a deletion/duplication or a mutation. Among these 25 patients, two were familial. RT-PCR was used to quantify TSC1/TSC2 mRNA (DNA and RNA from blood samples and from 5 normal and/or abnormal fibroblast cultures). Gene expression was assessed after normalization with the β-actin housekeeping gene and with the DU145 cell line as a qPCR calibrator using the 2-ΔΔCt method. Sequencing of TSC1/TSC2 promoters and flanking 5'/3'UTR regions was performed in 8 patients with a definite diagnosis. In one familial presentation, segregation was associated with the TSC2 locus. After validation with healthy controls expression studies identified either elevated or decreased hamartin or tuberin level (in one only or both TSC alleles): this was recorded in all patients with a 'definite diagnosis' and in 50 % with 'possible' or 'probable' diagnosis. Any sequence distortion was found both in promoters and in the 5'/3'UTR regions

of TSC1/TSC2 genes. The present results allow to postulate on additional heterogeneity or epigenetic mechanism as causative for TSC.

Variant ataxia telangiectasia (A-T) may be an underdiagnosed entity, as it is associated with milder neurological impairment and fewer systemic symptoms compared to the classic form. We have investigated a patient with generalized mild dystonia, moderately dysarthric speech, increased serum α-fetoprotein but no ataxia nor telangiectasias, no nystagmus or oculomotor dyspraxia. She has a severe IgA deficiency, which is unusual in atypical A-T patients, but does not suffer from recurrent infections or other immune-related diseases.
Molecular analysis showed that the patient is compound heterozygote for *ATM* c.8122G>A (p.Asp2708Asn) and c.8851-1G>T, leading to *in frame* loss of 63 nucleotides at the cDNA level. In the patient ATM protein expression is strongly reduced, but a trace amount of protein is translated from both alleles. Residual kinase activity is derived only from the p.Asp2708Asn allele.
The conventional G0 micronucleus test, based on irradiation of resting lymphocytes, revealed a radiosensitive phenotype for the patient, but not for the heterozygous relatives. As ATM is involved in homologous recombination and in the G2/M cell cycle checkpoint, we developed a novel test, evaluating micronuclei in lymphocytes irradiated in the S and G2 phases. This test showed increased radiosensitivity for both the patient and heterozygous carriers. Intriguingly, heterozygous carriers of c.8851-1G>T (mutation associated with absence of kinase activity) showed a stronger radiosensitive phenotype with this assay than heterozygous carriers of p.Asp2708Asn (mutation associated with residual kinase activity). Our novel S-G2 micronucleus assay provided phenotypic insight to complement the diagnosis of this atypical A-T patient

P20.58

VariantMaster: a tool to analyze High Throughput Sequences to identify causative variants in family trees, unrelated individuals and matched tumor-to-normal design.

F. A. Santoni*, P. Makrythanasis, S. I. Nikolaev, S. E. Antonarakis;*
University of Geneva, Geneva, Switzerland.

The availability of high throughput DNA sequencing technologies has significantly advanced the discovery of the sea of genomic variants per individual. Complex pipelines can map billion of sequences up to the identification of single nucleotide variants (SNVs) and insertion and deletions (indels). In parallel, international research projects have resulted in a rich annotation of common and rare genomic variants with population frequencies, damaging potential, and association with genomic features (i.e. transcription factor binding sites, epigenetic and chromatin marks). Cancer genomics too has greatly advanced since somatic variants driving tumor initiation and progression could be identified.
VariantMaster is a novel software that apply several modes of inheritance (dominant, recessive, X-linked) and identify denovo mutations to detect putative causative variants in affected individuals. It can also extract the additional somatic or lost germline variants in tumor cells in order to estimate the recurrence of mutations in unrelated patients. VariantMaster uses as input annotated or unannotated variants, aligned reads (bam files) and/or phased haplotypes to reliably assess the presence of a mutation. Prioritization of variants with respect to allelic frequencies (1000 Genome project, dbSNP and Exome Variant Server) as well as pathogenicity scores and other features is easily customizable by the user. Additionally VariantMaster can evaluate unrelated families with similar phenotype, searching for variants in one or more mutated genes. This unique software has been successfully employed in clinical genetics to identify putative causative variants in trios, recessive diseases in consanguineous couples, X-linked disorders and to identify somatic driver mutations in tumor cells.

Expanding the Wolf-Hirschhorn syndrome critical region to a 1.5 Mb region on 4p16.3: a model for contigous gene deletion syndromes.

D. Orteschi[1], *M. Ruiter*[2], *R. Pfundt*[2], *K. Steindl*[3], *C. Cafiero*[1], *I. Contaldo*[4], *D. Chieffo*[4], *D. Ranalli*[4], *C. Acquafondata*[5], *M. Murdolo*[1], *G. Marangi*[1], *D. Battaglia*[4], *G. Neri*[1], ***M. Zollino***[1];
[1]*Istituto di Genetica Medica, Università Cattolica del Sacro Cuore, Rome, Italy,* [2]*Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [4]*Istituto di Neuropsichiatria Infantile, Università Cattolica del Sacro Cuore, Rome, Italy,* [5]*Istituto Santa Caterina, Francavilla, Italy.*

Wolf-Hirschhorn syndrome (WHS) is a contiguous gene syndrome caused by partial 4p deletion, with critically deleted region, WHSCR-2, restricted to an about 400 kb interval on 4p16.3. Great variability of the WHS phenotype exists, however there is a consensus in considering the core phenotype as defined by severe growth delay, intellectual disability, peculiar facial dysmorphisms, and seizures. Pathogenesis of the WHS phenotype was already assumed to be multigenic, with *WHSC1* being the candidate gene for the facial characteristics and growth delay, and *LETM1* as the major gene for seizures.
We report on four ID subjects with atypical 4p16.3 deletions without true clinical evidence of WHS. Deletions were interstitial and encompassed the WHSCR-2 in two. They spanned 1.2 Mb with preservation of the terminal 1.75 Mb region, and 0.81 Mb with preservation of the terminal 1.06 Mb region, respectively. Affected individuals never had seizures, nor had the peculiar WHS facial appearance. The last two subjects, brother and sister, were referred because of epilepsy and learning difficulties. They had a terminal 0.55 Mb deletion preserving the WHSCR-2, inherited from their healthy father, who suffered from febrile seizures and learning difficulties as a child.
Our observations provide evidence that *LETM1* is not the only gene for seizures and *WHSC1* not the only gene for growth delay and facial dysmorphisms. The WHSCR should be rather expanded throughout a 1.5 Mb segment. It is proposed as a model for other contigous gene syndromes, for the benefit of proper genetic diagnosis and search for candidate genes.

Incidence of large VWF gene deletions and duplications in the French cohort of 1182 patients with von Willebrand disease (VWD)

P. Boisseau[1], *M. Giraud*[1], *P. Talarmain*[1], *M. Gourlaouen*[1], *G. Landeau Trottier*[1], *C. Ternisien*[1], *C. Caron*[2], *E. Fressinaud*[3], *J. Goudemand*[2], *A. Veyradier*[3], *S. Bezieau*[1];
[1]*CHU Hotel Dieu, Nantes, France,* [2]*CHU, Lille, France,* [3]*CHU, Clamart, France.*

The French reference center for VWD (CRMW) organizes a national biologic platform for the phenotype/genotype characterization of VWD. After an exhaustive sequencing of VWF gene, at least one deleterious sequence variation was identified in 1153 patients (635 families). However, the direct sequencing failed to detect any causative mutation in 17 index cases (IC). Then we search in these patients a large VWF gene deletion/duplication using multiple ligation-dependent probe amplification (MLPA) (MRC Holland). Nine distinct large gene alterations (6 novel*) were identified at a heterozygous state in 10 IC: deletion spanning exons 1-3, exons 6-18*, exons 19-20*, exons 32-34*, exons 33-34, whole gene deletion; duplication exon 6*, exons 35-37*, exons 38-42*. VWF gene alterations occur in about 2% of our large cohort of patients, and around 5% of patients with type 3 VWD. Hypothesis concerning the deleterious process of these defects may be (1) a frame shift which abolish VWF gene expression (feature of type 3 mutations), (2) the maintenance of the frame: then the truncated or the longest translated VWF affects the structure of the multimeric VWF and provides a dominant negative effect interacting with the normal VWF allele, (3) prevent the correct dimerization or multimerization process and subsequent extracellular secretion of VWF inducing a type 1 VWD. Finally, only 7 patients out of our 1182 patients (~ 0.5%) remain without identified VWF gene abnormality. Our results demonstrate that the screening of large deletions and duplications is an essential way to explain some VWD phenotype.

Gonadal dysgenesis in a women with an unusual t(X;9) and partial trisomy of chromosome 9 centromeric region

M. M. Oliveira[1], *R. S. Guilherme*[1,2], *S. S. Takeno*[1], *M. A. Haidar*[3], *G. M. Carvalehira*[1], *N. Kosyakova*[2], *K. Mrasek*[2], *E. Klein*[2], *T. Liehr*[2], *M. I. Melaragno*[1];
[1]*Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, Brazil,* [2]*Institute of Human Genetics, Jena University Hospital, Friedrich Schiller University, Jena, Germany,* [3]*Department of Gynecology, Universidade Federal de São Paulo, São Paulo, Brazil.*

Women with balanced X-autosome translocations constitute a heterogeneous group of patients whose most frequent phenotypic alteration is premature ovarian failure. Since the long arm of X-chromosome is a critical region for ovarian function, it has been postulated that this phenotype might result from epigenetic modifications in the region involved in the translocation, as a consequence of a chromosomal position effect. A woman with gonadal dysgenesis and an apparently balanced translocation of chromosomes X and 9 was studied. The SNP-array analysis did not detect any pathogenic genomic imbalances. Reverse-FISH (Fluorescence in situ hybridization) after microdissection of the derivative chromosomes suggested pericentromeric breakpoints. FISH with whole-chromosome paint and single-sequence probes showed the breakpoints in Xq12 and 9q10. Surprisingly, FISH with centromeric probes resulted in three signals of 9-chromosome centromere: one in the normal 9-chromosome and one in each derivative chromosomes of the translocation, one of them being dicentric. Then, the patient´s katyotype was determined as 46,X,dic(X;9)(XpterXq12::9p11.19qter),der(9)(9pter9q11.1::Xq12Xqter). The SNP-array was unable to detect this trisomy. Immunostaining of centromeric proteins (CENP) B and C in the dicentric chromosome detected signals only in the X-chromosome centromere, suggesting that CENP DNA-biding domain of 9-chromosome could be subjected to an epigenetic modification. These results indicate that the presence of the chromosome 9 centromeric region in both derivative chromosomes could interfere in the expression profile by the spreading of heterochromatic characteristics to Xq, causing the gonadal dysgenesis in this patient. This hypothesis needs to be demonstrated by further investigation.

Fabry disease : skewed X inactivation leads to full-blown expression of the disease and feminine phenotype in a patient with a 16 Mb deletion in a der(X)t(X;Y)(SRY+)

D. P. GERMAIN[1,2,3], *K. BENISTAN*[2,3], *A. TOUSSAINT*[4], *S. HEIDE*[2], *C. BELDJORD*[4], *P. de MAZANCOURT*[5], *F. VIALARD*[5];

BACKGROUND: Fabry disease (FD; OMIM #301500) is an X-linked (Xq22.1) inborn error of glycosphingolipid catabolism resulting from deficient lysosomal α-galactosidase A activity due to mutations in the GLA (OMIM #300644) gene, leading to the systemic accumulation of globotriaoslyceramide (Gb3) in lysosomes. Females with FD often develop clinical manifestations. However, the disease generally follows a milder course in heterozygotes. PATIENT AND METHODS: The 27-year-old daughter of a FD male patient presented with full-blown expression of the disease. Alpha-Gal A enzymatic assay, GLA gene sequencing, karyotype, fluorescent in situ hybridization (FISH), comparative genomic hybridization (CGH) and X-chromosome inactivation (XCI) analysis using the androgen receptor (AR) methylation assay were done. RESULTS: Alpha-Gal A activity was totally absent and Gb3 urinary excretion was highly elevated. A missense mutation (c.154T>C, p.C52R) was detected in the GLA gene. Karyotype found 46,X,der(X)t(X;Y)(p22.3?;p11) formula while FISH showed der(X)t(X;Y)(p22.3?;p11).ishYp11.3(SRY+). The t(X;Y) translocation was confirmed by CGH which also identified a 16.6 Mb deletion spanning from Xp22.13 to Xp22.32 in the derivative. Using polymorphic markers at the AR locus, complete skewed X-inactivation of the der(X)t(X;Y)(p22.13;p11.2)(SRY+) was demonstrated. Maternal inheritance of the derivative was confirmed through its identification in the patient's mother. Sequencing of the translocated SRY gene revealed a normal sequence. DISCUSSION: Complete skewed inactivation of a der(X)t(X;Y)(p22.13;p11.2)(SRY+) due to the presence of a large 16.6 Mb deletion led to full-blown phenotype of the paternally inherited FD mutation in trans and to feminine external and internal genitalia despite the presence of a wild-type SRY gene in the patient.

Fabry disease (FD; OMIM 301500) is a lysosomal X-linked disorder caused by the deficiency of the lysosomal α-galactosidase A (α-GalA) enzyme. The deficient enzymatic activity leads to the progressive accumulation of globotriaosylceramide (Gb3) in the plasma and lysosomes of many cell types. Due to X-linked inheritance, heterozygous females had been traditionally described as asymptomatic carriers of the disease. Nevertheless, the phenotype in females ranges from nearly asymptomatic to the classical phenotype observed in males. The phenotypic spectrum expressed in heterozygotes has been attributed to the random inactivation of the X chromosome. However, the contribution of X-inactivation skewing to disease manifestations remains controversial. The aim of this study was to investigate whether correlations between the clinical phenotype and the X-inactivation pattern exist in heterozygous patients in an age-dependent way. In a cohort of 40 consecutive heterozygous females, the diagnosis of Fabry disease was confirmed by GLA sequencing. In all patients, clinical symptoms and phenotype were assessed using exhaustive check-up (renal, cardiac and cerebrovascular) along with two validated global severity scores (Mainz Severity Score Index (MSSI) and DS3). In all patients, methylation assays of the AR gene were carried out in 4 different tissues from different embryonic origins (skin, blood, urinary cells and buccal cells) in order to assess X-inactivation status. Results have shed insight in better understanding the expressivity of the disease in relation with X-inactivation skewing and will help to monitor enzyme replacement therapy in heterozygous female patients.

Mechanisms underlying non-recurrent microdeletions causing Incontinentia pigmenti

M. Conte[1], *S. Raimo*[1], *M. McAleer*[2], *G. Giardino*[3], *A. Irvine*[2], *C. Pignata*[3], *M. Ursini*[1], *F. Fusco*[1];

[1]*Institute of Genetics and Biophysics 'Adriano Buzzati-Traverso', IGB-CNR, Naples, Italy,* [2]*Department of Paediatric Dermatology, Our Lady's Children's Hospital, Crumlin, Dublin 12, Ireland,* [3]*Department of Pediatrics, Federico II University, Naples, Italy.*

Incontinentia Pigmenti (IP, OMIM#308300) is a genomic disorder, X-linked dominant affecting neuroectodermal tissues in females and lethal in males. IP is caused by NEMO/IKBKG gene mutations that result in alterations of NF-kB (Nuclear Factor kappaB) activation pathway. Indeed, NEMO/IKKgamma protein represents the central hub in the regulation of this signaling.

The NEMO gene partially overlaps the G6PD gene on the 5'-side and Low-Copy-Repeat (LCR1) on the 3'-side. This LCR contains an high frequency of repeated sequences, micro/macro-homologies and tandem repeats that increases the genomic instability of the locus by unusual molecular mechanisms (NAHR, NHEJ) generating de novo rearrangements. In the duplicated Low-Copy-Repeat (LCR2), closely linked to gene, lies the non-functional NEMO-pseudogene, involved in rare inversion/gene-conversion events with the LCR1 that cause the repositioning/copying of non-pathologic mutations from pseudogene to gene.

We have recently reported that such genomic instability produces about 80% of IP-causing deletions while de novo point mutations account for only the 12% of IP-causing alterations.

Here, we report a novel rearrangement (del36bp), that alters the open reading frame of NEMO protein synthesis producing a premature stop codon (p.Q145X). The breakpoint sequence analyses suggested that a DNA-replication-based mechanism, Fork-Stalling-and-Template-Switching (FoSTeS), has occurred during parental germline.

Moreover, we show 7 new mutations (2 missense, 3 splicing, 2 small deletion variants) found in IP patients.

Taken together these findings highlight how the vulnerability of the IP-locus produces novel alleles generating new sporadic IP cases. This study is supported by the Association Incontinentia Pigmenti France(http://www.incontinentiapigmenti.fr).

The italian craniosynostosis biobank: a national "hub" for the International Craniosynostosis Consortium (ICC)

W. Lattanzi[1], *C. Bernardini*[1], ***M. Barba***[1], *L. Massimi*[2], *F. Pignotti*[2], *F. Novegno*[2], *G. Tamburrini*[2], *S. A. Boyadjiev Boyd*[3], *F. Michetti*[1], *C. Di Rocco*[2];

[1]*Inst. Anatomy and Cell Biology, Università Cattolica S. Cuore, Rome, Italy,* [2]*Dept. Neurosurgery - Pediatric Neurosurgery Unit- Università Cattolica S. Cuore, Rome, Italy,* [3]*Section of Genetics, Department of Pediatrics, University of California Davis, Sacramento, CA, United States.*

Craniosynostosis (CS), the premature fusion of one or more cranial sutures, is the most common craniofacial malformation (1/2000 live births). Nonsyndromic forms (NCS, i.e., without unrelated, major birth defects or developmental delay) represent 85% cases and are heterogeneous conditions, classified according to the involved suture. Gene mutations have been reported in very few cases, thus the genetic/environmental etiopathogenesis is still largely unclear. The International Craniosynostosis Consortium (ICC) was established in 2000 to organize the efforts of physicians and researchers studying CRS worldwide, in the attempt to better characterize the phenotypes, the genetic background, the environmental factors and the biological pathogenesis of NCS.Our research group based in Rome recently joined the ICC. In 2010 we started collecting calvarial suture specimens and blood. This allowed creating a biological repository that currently includes samples from over 230 CS patients, from the whole italian territory including 195 (84%) NCS cases. For each patient, we extract

genomic DNA from blood, for mutational screening in CS-associated genes, along with total tissue RNA and calvarial cells, for expression profiling, flow citometry and in vitro assays. DNA from parents are being collected to create a significant italian sample of case/parent trios for whole exome sequencing by the

ICC. The goal of this presentation is to show in details our sample database and protocols, and to inform geneticists who are willing to send us specimens to implement the biobank and cooperate in the mission of the ICC.

Atopic dermatitis is the common chronic inflammatory cutaneous disorder that often precedes asthma and allergic diseases. Number of studies has shown an association between pattern recognition receptor, particularly toll-like receptor genes variations and allergic diseases development. We have screened 62 SNPs in TLR1, TLR2, TLR4, TLR5, TLR6, TLR9, TLR10, NOD1, NOD2, CD14 and LRRC32 genes and C11orf30 gene that was associated with AD in GWAS. The AD group consisted of 335 AD patients from Volga-Ural region of Russia (Russians, Tatars and individuals of mixed origin). The control group included 330 non-atopic individuals of the same ethnic origin. Genomic DNA was isolated by phenol-chloroform extraction. The genotyping of SNPs was performed by OpenArray SNP Genotyping System (Applied Biosystems).

In our study we have found an association of AD development with SNPs in the TLR1 (rs5743604*A, p=0.022 and rs5743571*C, p=0.0004), TLR6 (rs5743794*C, p=0.0115) and TLR10 (rs10004195*T, p=0.0325 and rs4543123*A, p=0.0426) genes map closely together on chromosome 4p14, and with SNPs of the TLR2 gene (rs1816702*C, p=0.0016 and rs4696483*C, p=0.0367). The haplotype analysis revealed statistically significant difference in frequencies of TTATACG haplotype (consists of rs11466617, rs10004195 and rs4543123 of TLR10 gene and rs4833095, rs5743604, rs5743571 and rs2101521 of TLR1 gene) between AD patients and controls (p=0.0124). The C11orf30 gene SNPs (rs2508755 and rs2508747) was also associated with AD development in this investigation (p=0.0022 and p=0.0312).

The results of our research show that TLR1, TLR2, TLR6, TLR10 and C11orf30 genes variants are important risk factors of atopic dermatitis in the Volga-Ural region of Russia.

Genomewide linkage and exome sequencing analyses of a Dowling-Degos disease pedigree

Y. Li[1], *H. Liu*[2], *H. Liany*[1], *F. Zhang*[2], *J. Liu*[1];

[1]*Genome Institute of Singapore, Singapore, Singapore,* [2]*Shandong Provincial Institute of Dermatology and Venereology, Ji Nan, China.*

Reticular pigmented anomaly of the flexures (also known as Dowling-Degos disease) is an autosomal dominant pigmentary disorder. Dowling first delineated this genodermatosis as a distinct entity in 1938. In 1954, Degos and Ossipowski described a patient with a similar case. DDD is slowly progressive, appearing in adolescence or adulthood, affecting the axillae, neck, inframammary and sternal areas, etc. Betz et al, adopting linkage scan followed by fine mapping, discovered that loss-of-function mutations in KRT5 (on chromosome 12q) caused this condition. The advance of next generation sequencing technology makes the pinpointing of causal genes for Mendelian diseases much more effective. Here we investigated the molecular genetic architecture of DDD by genomewide linkage scanning of a Chinese DDD pedigree and target sequencing 50 Mb of exomes for each of the four members from the same pedigree using Illumina GAII platform. The mean coverage depth is 102.2, and on average, 83.4% of targeted bases were covered by >=15x. 47860 high quality SNPs and 5451 short indels were discovered among the 4 persons. Assuming autosomal dominant inheritance mode, we identified four candidate genes that were supported by both the linkage signals and sequence evidence. Further validations are being carried out. These candidate genes, besides KRT5, will shed more light on the pathological mechanisms of DDD.

Molecular Genetic Investigation of a Large Iranian Pedigree Affected with Sever Multiple Synostosis Syndrome2 (Farhud Type)

D. D. Farhud[1], *M. Zarif Yeganeh*[2], *M. Sarfarazi*[3], *T. Rezaee*[3];
[1]*School of Public Health, Tehran University of Medical sciences,, Tehran, Islamic Republic of Iran,* [2]*Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid, Tehran, Islamic Republic of Iran,* [3]*Surgical Research Center, Department of Surgery, University of Connecticut Health Center, Farmington, CT,, Farmington, LA, United States.*

Background: Bone Morphogenetic Proteins and the related Growth&Differentiation Factors (GDFs) are much conserved signaling proteins. GDF5 is pivotal for skeletal development. Several skeletal dysplasias and malformation syndromes are known as a result of mutations in GDF5. Multiple Synostosis Syndrome2 (SYNS2) for the first time was identified in a large Iranian family. SYNS2 is characterized by tarsal-carpal coalition, humeroradial synostosis, brachydactyly, and proximal symphalangism.
Method: We studied a large Iranian pedigree affected with SYNS2 (Farhud Type) in five successive generations (58patients,61relatives). Genetic linkage analysis of this pedigree excluded the locus on chromosome 17q21-q22 in our previous study. Thus, we focused on GDF5. Molecular genetics investigation was performed on 25individuals from the last generation that 16 members of them affected with SYNS2. Also, 40healthy Iranian individuals of the age, sex, and origin matched were included.
Results: Direct DNA sequencing results showed no mutation in NOG gene, whereas a heterozygote missense mutationc.1424G>A, S475N was identified in GDF5 gene. This mutation was found in all affected members of the family but not in the unaffected individuals and controls. This substitution has located in highly conserved and active mature domain of the protein and may has unknown interaction with normal active 3rd and 4rd structure of the product. Also the S475 was conserved in all 23 different species (according to multiple alignments).
Conclusion: We concluded that our findings may elucidate some aspects of discausative nature of such a mutation. We propose further etiological considerations for GDF5 as a secondary responsible gene for Multiple Synostosis syndrome2.

Multiple osteochondromas in Russian Federation

N. Galeeva, *E. Ivanova, T. Milovidova, A. Polyakov;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

Multiple hereditary exostoses (multiple osteochondromas (MO)) is an autosomal dominant skeletal disease characterized by the presence of multiple benign cartilage-capped tumors that develop mainly from the juxtaepiphyseal regions of long tubular bones. MO is genetically heterogeneous, and is associated with mutations in Exostosin-1 (EXT1) or Exostosin-2 (EXT2) genes. To date, an EXT1 or EXT2 mutation is detected in 70-95% of affected individuals. EXT1 mutations are detected in 65% and EXT2 in 35% mutations in MO patient cohorts. We investigated 17 patients with MO and found mutations in 10 (60%) patients. To detect mutations in EXT1 and EXT2 genes have been used sequence analysis and multiple ligation-dependent probe amplification (MLPA) analysis. EXT1 mutations were detected in 9 (90%) and EXT2 -in 1 (10%) patient. In EXT1 we found three novel mutations: c.771_772insT, c.1296_1301delCAGAAT and deletion of exons 10 and 11. In EXT2 we also found novel mutation c.678C>A (Tyr226Stop). Among our patients we investigated two families in which MO combined with hereditary motor and sensory neuropathy type 1B or primary pulmonary hypertension, confirmed by mutations in MPZ gene and BMPR2 gene.

G1138A mutation in FGFR3 gene in patients with achondroplasia

S. Bucerzan[1], *R. Popp*[2], *C. Al-Khzouz*[1], *M. Crisan*[1], *D. Vlonga Pacurar*[1], *T. C. Mboh*[1], *P. Grigorescu-Sido*[1];
[1]*First Pediatric Clinic, Cluj-Napoca, Romania,* [2]*Department of Medical Genetics, Cluj-Napoca, Romania.*

Introduction. Achondroplasia is a common form of chondrodyplasia with a frequency of 1/15.000 - 40.000 new borns. It is transmitted by autosomal dominant trait with full penetrance but approximately 75-80% of the cases are caused by de novo mutations. The disease is determined by mutations in receptor-3 gene of the fibroblast growth factor (FGFR3), mapped to band 4p16.3, resulting in decreased endochondral ossficication, inhibited proliferation of chondrocytes in growth plate cartilage and decreased cartilage matrix. The most frequent mutations (up to 99%) are G1138A and G1183C. The aim of this study is to establish the prevalence of G1138A mutation in FGFR3 gene in patients with achondroplasia in our care.
Patients and method. The study group consisted of 24 patients (16 girls and 8 boys), aged between 1 year 8 months - 22 years, who were registered in the Centre of Genetic Diseases of First Pediatric Clinic Cluj in the period 2007-2012. The method consisted in: clinical assessment and radiological examinations (radiograms of the skull, upper and lower limbs, spinal column and pelvis). The DNA analasys was performed by PCR-RFLP technique.
Results. Between 2007 - 2012, 85 patients were diagnosed with bone dysplasia; 24 of them (28,23%) were diagnosed (on clinical and radiological basis) with achondroplasia. Out of this group, 16 patients (66,66%) were identified as heterozygotes for G1138A mutation in FGFR3 gene; this prevalence is very low comparatively with other studies.
Conclusions. It is the first study that reports the prevelance of this mutation in Romania.

Novel *CGI-58* mutation in an Iranian boy with ichthyosiform erythroderma, mental retardation, hearing loss and hepatomegaly

M. Mirzazadeh[1], *A. Kariminejad*[1], *N. Nabavi-Nia*[1], *A. Rajaee*[1], *R. Borojerdi*[2], *M. H. kariminejad*[1], *D. S'Aulis*[3], *W. Rizzo*[3];
[1]*Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran,* [2]*Qom Genetic Counseling Center, Qom, Islamic Republic of Iran,* [3]*Department of Pediatrics, University of Nebraska Medical Center, Omaha, NE, United States.*

Neutral lipid storage disease with ichthyosis (Chanarin-Dorfman syndrome) (OMIM 275630) is a rare disorder of lipid metabolism characterized by nonbullous congenital ichthyosiform erythroderma, hepatomegaly and other systematic manifestations that are associated with accumulation of triacylglycerol lipid droplets in many tissues. It has an autosomal recessive pattern of inheritance and is caused by mutation in the *CGI-58* gene (also known as *ABHD-5*) located on chromosome 3p21. We report a five-year-old male Iranian child with intellectual disability, ichthyosiform erythroderma, bilateral hearing loss and hepatomegaly, who was born to first cousin parents. Peripheral blood smear showed lipid vacuoles in his leukocytes. Sequencing of *CGI-58* from the proband revealed a novel homozygous mutation (c.838C>T, p.R280X) in exon 6; his parents were heterozygous for the mutation. This mutation results in truncation and loss of 69 amino acids from the carboxy-terminal region of the protein. Chanarin-Dorfman syndrome should be considered in all patients with mental retardation and ichthyosis. Checking for lipid vacuoles in peripheral leukocytes is an inexpensive and relatively easy method for a presumptive diagnosis of this disease.

A novel mutation in the coding region of OSTM1 gene in lethal infantile osteopetrosis

S. Seyedhassani[1], *S. Asadollahi*[1], *M. Neshan*[1,2], *F. Saeb*[1];
[1]*Dr. Seyedhassani Genetic Center, Yazd, Islamic Republic of Iran,* [2]*Yazd welfare organisation, Yazd, Islamic Republic of Iran.*

Introduction: Osteoporosis is a heritable disorder of the skeleton characterized by increased bone density on radiographs. The autosomal recessive osteopetrosis (ARO) has an incidence of 1 in 250000 births. Osteopetrosis is caused by failure of osteoclast differentiation or function and mutations in at least 10 genes have been identified as causative in humans. In severe neonatal and infantile forms, TCIRG1, CLCN7, OSTM1, RANKL and RANK genes could be considered.
Case report: There were two cases of osteopetrosis in investigated family. This couple had first cousin marriage; and there were 4 similar cases in the their familial pedigree. The first pregnancy lead to a female neonate with birth weight 2800 gr. Clinical manifestations were: poor feeding, debilitation from first month, disturbed swallow from sixth month, urinary infections , hepatomegaly, hydrocephaly and finally death in 1 years old. *Osteosclerosis was seen in radiographic aspects. The second neonate had* almost similar signs and symptoms too.
We analyzed the second infant for promoter, splicing site and coding regions of TCIRG1gene by sequencing method. No mutation was found. The next candidate gene was OSTM1. There was a small two nucleotide deletion (CT)

at c. 231 (ACAAAACT^ 231 GAGTAGT) of exon 6. This mutation was novel.

J01.10
Molecular-genetic diagnostic thrombocytopenia-absent radius (TAR) syndrome.

A. Stepanova[1], *T. Fedotova*[2], *V. Fedotov*[2], *A. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Regional Clinical Hospital, Voronezh, Russian Federation.*

Thrombocytopenia-absent radius (TAR) syndrome is a congenital malformation syndrome characterized by bilateral radial hypoplasia or aplasia with preservation of thumbs and congenital thrombocytopenia. TAR syndrome affected fewer than 1 in 100,000 newborns. TAR - syndrome caused by submicroscopic deletion of 1q21.1 combined with one of two low-frequency SNPs in the regulatory regions of RBM8A gene, encoding the Y14 subunit of EJC.

We have studied three unrelated patients with TAR syndrome and both parents of one dead patient with TAR syndrome. All patients presented with bilateral radial aplasia/hypoplasia with preserved thumbs and thrombocytopenia.

The rs 201779890 was found in homozygous/hemizygous state for two patients with TAR syndrome and father of dead patient with TAR syndrome in heterozygous state, the rs 139428292 was found in homozygous/hemizygous state for one patient with TAR syndrome using Sanger sequencing of the RBM8A gene.

For registry deletion at the RBM8A locus we created the multiplex system for MLPA PCR-analysis. Multiplex probemix contains MLPA probes for exons 1, 4 and 6 of the RBM8A gene and fragments of the TBP, USP3 and SIRT genes, as controls.

Now we carry out deletion in the RBM8A locus for all patients with TAR syndrome and parents of one dead patient with TAR syndrome.

Common polymorphisms in glutathione-S-transferases are not major determinants of psoriasis in the Central-European population

S. Rybecka[1], *J. A. Bienertova Vasku*[1], *F. Zlámal*[1], *D. Ambrozkova*[1], *J. Vinklárek*[1], *J. Novák*[1], *I. Nečesánek*[1], *V. Vasku*[2], *A. Vasku*[1];
[1]*Faculty of Medicine, Masaryk University, Department of Pathological Physiology, Brno, Czech Republic,* [2]*University affiliated Hospital, Clinic of Dermatovenerology, Brno, Czech Republic.*

Introduction: It is generally known that there is large interindividual variability in response to psoralen-ultraviolet A (PUVA) photochemotherapy that is routinely used for treatment of psoriasis. The glutathione S-transferases (GSTs) are detoxifying enzymes capable of inducing cutaneous defence against UV radiation-induced oxidative stress and as such represent elegant candidate biomarkers of UV sensitivity. Human GSTs, e.g. GSTM1, GSTT1 and GSTP1, are known to be polymorphic, and specific variants have been associated with increased UVB erythemal sensitivity and skin cancer risk. The aim of the study was to investigate possible association of common polymorphisms in GSTs (GSTM1, GSTT1 and GSTP1) with psoriasis and its severity.

Materials and methods: We investigated common polymorphisms in GSTs (deletion variants in GSTM1, GSTT1 and an Ile105Val substitution in GSTP1) in a cohort of 692 Central-European patients (402F/297M, 52.47+-15.53y) with psoriasis vulgaris chronica diagnosed according to criteria defined by AAD and compared them with those of a population sample of 749 control non-psoriatic individuals (193M/556F, 47.89+-13.90y). Staging of psoriasis was based on PASI score.

Results: No significant differences of the investigated polymorphisms were observed between the cases and the control cohort, moreover, we observed no associations of the investigated polymorphisms with psoriasis severity, neither in the univariate or multivariate modelling.

Discussion: Based on our observations, the investigated polymorphisms in the GSTs do not serve as major determinants of the psoriasis in the Central-European population.

Association of Catalase gene polymorphism to Vitiligo susceptibility in Gujarat, India Population.

S. S. Chettiar[1,2], *K. Mistry*[1], *P. Agarwal*[1], *M. Adhvaryu*[1], *A. Patel*[3], *D. Jhala*[2], *D. Umarigar*[4], *R. Uppala*[5];
[1]*Shree Ramkrishna Institute of Computer Education and Applied Sciences, Surat, India,* [2]*Department of Zoology, Gujarat Unviersity, Ahmedabad, India,* [3]*GeneExplore Diagnostics Research Laboratory, Ahmedabad, India,* [4]*Department of Dermatology, Civil Hospital, Surat, India,* [5]*Department of surgery-Transplant, University of Nebraska Medical center, Omaha, NE, United States.*

Vitiligo is a skin condition characterized by development of white patches on the skin resulting from the loss of functional melanocytes and melanin from the skin and mucous. Its incidence ranges from 1 in 100 to 1 in 400 with the onset of disease is usually ~20 years old, and it affect men and women equally. In India; more Gujaraties and Rajastanies are affected (8.8%) than other parts of the country (0.5-2.5%). The etiology of vitiligo remains unknown; both genetic and environmental factors have been identified as potential causative causes.Oxidative stress plays a vital role in etiology of depigmentation in skin by cellular loss, while catalase (CAT) is proven enzymatic defense system, catalyzing break down of hydrogen peroxide. Altered activity of the enzyme and increased stress markers have been reported in vitiligo patients of different geographic locations. We have analyzed the single nucleotide polymorphisms (SNPs) of CAT gene including one in the promoter region rs7943316 (T/C) and the other in the exon 9 rs769217 (A/T) with recognition site of BstXI and Hinf I respectively, in 54 vitiligo patients from Gujarat, India and 45 normal controls from the same geographic region. The genotype distribution and allele frequency of promoter region were not significantly different between vitiligo patients and normal controls. However, exon 9 showed significant correlation between affecteds and normal controls. While the haplotypesof these two polymorphisms also showed association with vitiligo. The present study suggests possible association between the CAT gene and the vitiligo susceptibility.

Congenitally missing upper lateral incisors and their orthodontic approach. Cases Reports

S. I. Pop[1], *B. D. Cristina*[2], *P. V. Radu*[2];
[1]*UMF TG MURES, TIRGU MURES, Romania,* [2]*UMF Victor Babes, Timisoara, Romania.*

Hypodontia is defined as the developmental absence of one or more teeth. It is one of the most common dental anomalies in permanent dentition. Heredity is recognized to be one of the possible factors associated with congenitally missing upper incisors. Several studies have shown that MSX1 and PAX9 genes play a role in early teeth development. PAX 9 is a paired domain transcription factor that plays a critical role in odontogenesis. The mutation of the gene MSX1 on chromosome 4p was identified, on a large family with several teeth agenesis.

Hypodontia creates significant challenges to the clinicians in both diagnosis and management. Comprehensive management often requires a multidisciplinary approach.

Three cases-a mother's (42 years) and two sons' (10 years and 8 years), with upper lateral incisor agenesis, are presented. Diagnosis was based upon clinical examination, study model examination, panoramic and retroalveolar radiographs and cephalometric analysis.

Different treatment modalities have been used to treat the malocclusions. Fixed orthodontic therapy was used for space opening and implant supported restoration inserted in the case of the mother. For both sons mesial eruption of the maxillary canines was facilited in order to obtain space closure.

These cases reports illustrate the need for a multidisciplinary team approach, not only at the treatment planning stage, but also throughout the entire course of treatment.

J01.14
Clinical and neuroimaging management of children with achondroplasia

S. Dumitriu[1], *A. Chirita-Emandi*[1], *C. Haivas*[1], *S. Arghirescu*[1], *C. Gurban*[2], *M. Puiu*[1];
[1]*University of Medicine &Pharmacy, Timisoara, Roumania, Timisoara, Romania,* [2]*University of Medicine &Pharmacy Victor Babes, Timisoara, Romania.*

Aims: Children with achondroplasia may develop a broad panel of symptoms from subtle central apnea, respiratory distress, motor impairment, to quadriplegia and sudden infant death secondary to cervicomedullary

compression.
Methods: We evaluated, 6 children with clinical genetic and radiologic confirmed achondroplasia, for 18 months, quarterly. The average age was 11 months (range 1-36). The follow-up protocol included neuromotor developmental exam - evaluation with Peabody Developmental motor scale (0-6years) 2nd ed. and sleep studies. Imagistic evaluation was made by cranial ultrasound for infants under 18 months. Additionally, all patients (except the newborn) had cranio-cervical magnetic resonance imaging (MRI).
Results: Benign hydrocephalus and moderate ventriculomegaly has been present in all children since the moment of enrolling. The sleep study showed obstructive apnea in 66.7% of the children, showing a negative correlation with the developmental and neurologic status. Cerebral and cervical MRI revealed, in all children, symptoms of spinal cord compression, a hypoplastic cranial base with a narrowing of the foramen magnum, compression on the cervical cord and a combination of abnormal cord signal intensity myelomalacia and trunkal edema. Conclusion: Our study showed that complex evaluation including is needed to define disease status and indicate if more complex neuroimaging is necessary. Cranio-cervical MRI offered mandatory information directing the therapeutic attitude to neurosurgical decompression of the cord.

A rare skeletal dysplasia Acromesomelic Dysplasia, type Maroteaux

***E. KOPARIR**;*
Istanbul university cerrahpasa medical school, Istanbul, Turkey.

Acromesomelic Dysplasia, type Maroteaux (AMDM) is characterized by disproportionate shortening of skeletal elements, predominantly affecting the middle segments (forearms and forelegs) and distal segments (hands and feet) of appendicular skeleton. In addition, axial skeletal involvement occurs characterized by wedging of vertebral bodies, with dorsal margins being shorter than the ventral margins. Mode of inheritance of AMDM (MIM 602875) is an autosomal recessive with a prevalence of 1/1,000,000. Acromesomelic dysplasia was mapped on chromosome 9p13-q12 identified mutations in gene NPR2, encoding natriuretic peptide receptor B.
We here report a 4-year-old girl and 16-year-old boy, both products of consanguineous marriages, from different families with classical features such as short stature, disproportionate, acromesomelia, wedging of vertebral bodies, short broad fingers, normal intelligence. Clinical diagnosis of both patients will be confirmed by molecular analysis of the *NPR2.*

J01.16

Influence of VKORC1 c.-1639G>A, CYP2C9*2 and CYP2C9*3 variant alleles on the acenocoumarol dosage requirements in the group of patients under anticoagulation therapy in Serbian population

***D. Radojkovic**[1], L. Rakicevic[1], J. Kusic-Tisma[1], M. Kovac[2,3];*
[1]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, [2]Blood Transfusion Institute of Serbia, Hemostasis Department, Belgrade, Serbia, [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

During the last decade genetic factors affecting coumarin therapy have been extensively investigated. Among genetic determinants that have been studied, so far, variant alleles of the *VKORC1* and the *CYP2C9* genes have made the greatest impact on coumarin dose variability. Numerous studies have proved the impact of the *VKORC1* c.-1639G>A, *CYP2C9*2* and *CYP2C9*3* variant alleles on coumarin therapy, and benefits of genotyping before the start of the therapy. The frequency of *VKORC1* c.-1639G>A, *CYP2C9*2* and *CYP2C9*3* alleles differs considerably between ethnic groups and populations - consequently, the benefit of genotyping these alleles is expected to depend on the investigated population.
We set the goal to investigate influence of *VKORC1* c.-1639G>A, *CYP2C9*2* and *CYP2C9*3* variant alleles on the acenocoumarol dosage requirements in a group of 197 patients under stable anticoagulation therapy.
Our results showed that patients with AA genotype required 2.6 times lower dose, than carriers of GG genotype. Relative to the homozygous wild-type genotypes, individuals with *CYP2C9*2* or *CYP2C9*3* variant alleles required significantly lower (25- 59%) doses of acenocoumarol. Simultaneous presence of variant alleles of the both genes, represent a strong predictive factor for extreme response during the initiation of anticoagulation therapy associated with bleeding complications, especially in elderly patients.
In the studied group, 83% patients were carriers of the least one of variant alleles associated with low dose requirements of coumarin derivates, suggesting high percentage of subjects predisposed to low doses requirements of coumarins in our populations.

Atherosclerosis is associated with reduced peroxisome proliferator-activated receptor gamma and liver X receptor beta gene expression

***E. Demina**[1], V. Miroshnikova[1], N. Mayorov[2], V. Davydenko[2], A. Denisenko[3], A. Schwarzman[1];*
[1]National Research Centre „Kurchatov Institute" B.P.Konstantinov Petersburg Nuclear Physics Institute, Gatchina, Russian Federation, [2]Saint-Petersburg Pavlov State Medical University, Saint-Petersburg, Russian Federation, [3]3Saint-Petersburg Institute of Experimental Medicine Russian Academy of Medical Sciences, Saint-Petersburg, Russian Federation.

Peroxisome proliferator-activated receptor (PPAR) gamma and liver X receptors (LXR) alpha/beta regulate genes involved in the control of cholesterol homeostasis and reverse cholesterol transport and are expressed in all major cell types of atherosclerotic lesions. Lipid-loaded macrophages are important during the early development of atherosclerotic plaques. The characteristic component of the atherosclerotic plaque is the differentiation of monocytes to macrophages that accumulate lipoprotein-derived cholesterol to form foam cells within the arterial wall.
Our aim was to study correlation between *PPAR gamma* and *LXR alpha* and *beta* gene expression and its possible contribution to atherosclerotic lesion development.
M-CSF–differentiated human macrophages was used for measure expression *PPAR gamma* and *LXR alpha* and *beta* in a group of patients with angiographically determined atherosclerosis (N=11) and in a control group (N=11).
Macrophage *PPAR gamma* expression was reduced in patients with atherosclerosis comparing with controls 0.27±0.11 and 1.42±0.48 ($p<0.001$), respectively and it was paralleled by a significant decrease in *LXR beta* expression in the same groups 0.38±0.11 and 0.65±0.16 ($p<0.001$), respectively. LXR alpha mRNA levels in macrophages did not differ in studied groups (0.53±0.27 0.79±0.44 ($p=0.17$)).
Our results suggest that the PPAR gamma and LXR beta mRNA levels may serve as a novel molecular target in the treatment of atherosclerosis since it can promote cholesterol efflux from macrophages and prevent foam cell formation.

Factor VIII gene inversions in Serbian patients with Hemophilia A

***N. S. Ilic**[1], A. Krstic[1], M. Kuzmanovic[1], D. Micic[1], N. Konstantinidis[2], M. Guc-Scekic[3,1];*
[1]Mother and Child Health Care Institute, Belgrade, Serbia, [2]Institute for Child and Youth Health Care of Vojvodina, Novi Sad, Serbia, [3]University of Belgrade, Faculty of Biology, Belgrade, Serbia.

Hemophilia A (HA) is an X-linked recessive bleeding disorder caused by heterogeneous mutations in FVIII gene. The recurrent inversions which cause 50% of severe HA cases are inversion of intron 1 (inv1) and intron 22 (inv22) with reported frequency of 2-5% for inv1 and 45% of severe HA patients for inv 22. The goal of the present study was to assess the presence of inv22 and inv1 inversions in the F8 gene in Serbian severe HA patients and to compare these frequencies with published data from other populations. This study describes the first HA mutation series from Serbia. Since May 2009, we started at our Laboratory for Medical Genetics, Mother and Child Health Care Institute of Serbia "Dr Vukan Cupic" (IMD) with analyses for the presence of inv1 and inv22 using Inverse Shifting PCR (IS-PCR). The cohort of 50 patients has been analyzed and inv1 was detected in 6% of patients while inv22 in 42% of them (inv22 type I in 34% of and inv22type II in 8%). These frequencies were not statistically different from other populations. Analyses for carrier status of mentioned inversions were also performed for 65 of family members of HA patients and according to that the *de novo* inversion of intron 22 were found in one family. Genetic counseling unit of IMD provide the adequate genetic advice to all HA affected patients and their family members.

Connective tissue disorders: mutation screening of genes associated with Marfan and marfan-like syndromes in patients from different regions of Russian Federation

R. Valiev, *R. Khusainova, R. Valiev, E. Khusnutdinova;*
Bashkir State University, Ufa, Russian Federation.

Marfan syndrome (MFS) is an inherited autosomal dominant connective tissue disorder. Abnormalities appear in skeletal, ocular and cardiovascular systems. Marfan-like syndromes (MFLS) combines a group of diseases with symptoms that resembles Marfan syndrome but doesn't quite fulfill all the criteria. The main cause of MFS and MFLS are mutations in the several genes - fibrillin1 gene (FBN1) and the transforming growth factor beta receptor 1 and 2 gene (TGFBR1, TGFBR2) Currently we analyzed some regions of FBN1 and TGFBR2 genes in 106 patients with MS and marfan-like syndromes from different areas of Russia by several methods: SSCP, TTGE, Heteroduplex Analysis on the BioRad DCODE Universal Mutation Detection System and HRM-method on Bio-Rad CFX96 system; and sequencing on MegaBace 1000. Several mutations have been detected in FBN1 gene in patients with Marfan syndrome (G1176Y, C2489Y), which affects cbEGF-like motifs of fibrillin-1 protein in two patients with classical MFS symptoms and mutation c.1455 G>A in patient with MFLS. Also 14 polymorphisms have been found throughout FBN1 gene, which 4 are not described. One novel mutation (670C>T; T223M) has been found in TGFBR2 gene in two unrelated patients with marfan-like syndrome who did not fulfill Ghent nosology and who did not have mutations in FBN1 gene. Mutation T223M affects highly conserved serine/threonine protein kinases catalytic domain that leads to change phospho transferring status of TGFBR2 protein. In addition two novel polymorphisms have been found in intronic regions of TGFBR2 gene.

Noonan-like syndrome with loose anagen hair in 2 cases: clinical history and investigation results

E. Obersztyn;
National Institute of Mother and Child, Warsaw, Poland.

Noonan-like syndrome with loose anagen hair (NS/LAH; OMIM 607721) is the autosomal dominant disorder related to the SHOC2 missense mutation predicting p.Ser2Gly. Phenotype of this syndrome is reminiscent of Noonan syndrome but specific ectodermal features are characteristic. We present two patients with molecularly confirmed NS/LAH diagnosis, and comparison of clinical history since 3to 29 years of their life. Both patients manifested severe growth retardation and short stature, delayed psychomotor development, mitral valve stenosis ASD, feeding difficulties in the infancy, relative macrocephaly, short and webbed neck, pectus excavatum, hoarse voice and Noonan like dysmorphic features (high forehead, hypertelorism, posteriorly rotated ears, palpebral ptosis). Characteristic skin involvement with sparse, thin, very slow growing silver-blond hair, sparse eyebrows, dry skin and dystrophic /thin nails were also observed. Tendency to darkly skin pigmentation was present only in older girl in whom neonatal lymphatic edema, coagulation abnormalities with thrombocytopenia, and respiratory distress following premature birth in 28 week of gestation were documented. Her intellectual development was assessed as a mild degree of impairment but specific attention deficit and hyperactivity disorder was diagnosed. In both patients pathogenic, heterozygous c.4A>G (p.Ser2Gly) mutation in exon 1 of the *SHOC2* (10q25.2) gene was identified by NGS and confirmed by sequencing analysis. Detailed clinical, anthropometric and molecular studies will be discussed with natural history of the disorder in each of the cases.

E. Obersztyn: None.

Novel splice site mutation in LEPRE1 gene cause severe recessive OI in patient from Russia

D. Nadyrshina, *R. Khusaiova, E. Khusnutdinova;*
Bashkir State University, Ufa, Russian Federation.

Osteogenesis imperfecta (OI) is a clinically and genetically heterogeneous disorder characterized by susceptibility to fracture. Most OI cases are inherited in an autosomal-dominant manner and are caused by mutations in COL1A1 and COL1A2 genes, these 2 genes encode for the 2 α chains of collagen type I the predominant protein component of the bone matrix. For OI patients, an autosomal-recessive inheritance is described as including underlying mutations in CRTAP, LERPE1, PPIB, SERPINH1, SERPINF1, FKBP10, SP7 and BMP1 genes. Mutations in COL1A1 or COL1A2 genes result in primary structural or quantitative defects of collagen I molecules, whereas genetic mutations cause for recessive forms, which mainly lead to defects in collagen I modifications. Earlier we analyzed COL1A1 and COL1A2 genes in OI patients from Russia and only in 20% of cases mutations in COL1A1 gene were found.
The aim of our study was to identify mutations in LEPRE1 gene in OI patients from Russian populations.
We investigated 41 patients with OI from 33 families and 50 healthy control individuals. The LEPRE1 gene was sequenced including all coding and flanking intron regions.
Previously unreported splice site mutation c.1724+4G>A in LEPRE1 gene was identified in heterozygous state in one patient with recessive OI type 8. All family members were screened for this mutation by Sau96I restriction digestion. Mutation was confirmed in heterozygous configuration in proband's mother.
The present study revealed one novel mutation in LEPRE1 gene in OI patient from Russia, which hasn't been reported before.

Interleukin 1 Gene Polymorphisms Positively Influence NFκB Expression In Psoriasis

N. Moorchung[1], *B. Vasudevan*[1], *B. R. Achyut*[1], *B. Mittal*[2];
[1]*Department of Pathology, Armed Forces Medical College, Pune, India,* [2]*Department of Medical Genetics, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Psoriasis is a chronic inflammatory disease which is thought to be driven by an exaggerated production of pro-inflammatory cytokines, such as tumour necrosis factor (TNF-α, Interferon-γ, interleukin IL-1β, IL8, and IL-12. This disorder has a heterogeneous genetic background genetic polymorphisms are believed to be associated with the disease. NFκB regulates the expression of an exceptionally large number of genes and is believed to be involved in the pathogenesis of psoriasis. Methods: 112 cases of psoriatic skin biopsies were studied. Histology was done on the sections and genotyping was done for the IL-1β and IL-1RA genetic polymorphisms. In addition, NFκB immunostain was performed on 89 sections and the intensity of staining was evaluated in the epidermis, basal cells and the lymphocytes. Results: There was a strong association of IL-1β-511C/T polymorphism with psoriasis with both genotypes and alleles. There was a strong correlation between the IL-1β genotype and the grade of NFκB immunostaining (p - 0.012). The grade of lymphocyte staining showed a strong correlation with the IL-1RA genotype (p - 0.025) but not with the IL-1β genotype (p - 0.226). The genetic polymorphisms did not show any correlation with the histological features. Conclusions: Our study suggests that the Interleukin-1 genetic polymorphisms are not critical in the pathogenesis of psoriasis. However, NFκB appears to be activated more in cases that show pro inflammatory genetic polymorphisms. NFκB then influences the severity of psoriasis. The study underlies the central role played by NFκB and interleukin 1 genetic polymorphisms in the pathogenesis of psoriasis.

Gene Variants of the Catalase, Gutathione Peroxidase 1, Endothelial Nitric Oxide Synthase in Vitiligo

K. Turhan[1], *S. Pehlivan*[2], *S. Inaloz*[1], *S. Oguzkan Balci*[2], *M. Pehlivan*[3];
[1]*University of Gaziantep, Faculty of Medicine, Department of Dermatology, Gaziantep, Turkey,* [2]*University of Gaziantep, Faculty of Medicine, Department of Medical Biology and Genetics, Gaziantep, Turkey,* [3]*University of Gaziantep, Faculty of Medicine, Department of Hematology, Gaziantep, Turkey.*

Vitiligo is a relatively common skin disease characterized by development of patchy depigmented macules and the cause is still unknown. Previous studies of vitiliginous melanocytes showed that an imbalance between oxidative and antioxidative patterns. For this reason, we aim to investigate the variants of detoxification genes, including catalase (CAT), glutathione peroxidase 1 (GPX 1), endothelial nitric oxide synthase (eNOS) in patients with vitiligo and healty controls groups by PCR and/or PCR-RFLP method. One hundred twenty-five patients with vitiligo and 100 healthy volunteers with no personal and family history of vitiligo were enrolled in the study. There were no significant differences in the two variants of eNOS, between vitiligo patients and healthy controls. TT genotype in CAT A/T promotor region are significantly increased in patients with vitiligo in comparison with controls.

However, there were no significant differences in the variants of CAT T/C codon 389 in exon 9 gen, between vitiligo and controls. TT genotypes in GPX 1 codon 200 are significantly increased in patients with vitiligo in comparison with controls (p=0.027). When all gene variants were analyzed also according to the clinical types and family history of vitiligo there were no significant differences between these parameters. In conclusion, TT genotype of catalase A/T promotor region and GPX 1 codon 200 may be associated with vitiligo susceptibility.

Clinical aspects and treatment options in a case of hemifacial microsomia

C. D. Bratu[1], *D. Belengeanu*[1], *B. Raluca*[1], *P. I. Silvia*[2];
[1]*UMF Victor Babes, Timisoara, Romania,* [2]*UMF Tg Mures, Tirgu Mures, Romania.*

Hemifacial microsomia (HFM) is the most frequently encountered form of isolated facial asymmetry and the second most common facial anomaly. It is a syndrome of the first branchial arch, involving underdevelopment of the temporomandibular joint, mandibular ramus, mastication muscles and the ear. The exact etiology of HFM is not fully understood, but teratogenic and genetic components have been examined by many investigators. However, a few cases have had a positive family history suggesting autosomal dominant, autosomal recessive, or multifactorial etiolgy.
A case of 13 year old patient with right hemifacial microsomia is reported by us. Also, the management steps to improve facial and oclussal aspects are described. The orthodontic diagnostic was class II division 1 malloclusion, with frontal open bite, narrowed maxilla on the involved side, decreased palatal width and unilateral crossbite. Three-dimensional CT reconstruction showed hypoplastic, malformed right mandibular body, underdevelopment of the condyle, incomplete zygomatic arch, small maxilla and squamous temporal bone.
Treatment of the anomaly included orthodontic therapy and facial reconstruction (face contouring plasty with silicon grafts). Esthetic appearance and social integration of the patient were improved.
In our case the financial situation of the patient did not allow other complex reconstructions (ear reconstruction,distraction osteotomy of the mandible,etc).
The treatment of patients with HFM always requires an interdisciplinary approach including at least maxillofacial surgery, plastic surgery and orthodontics. Co-operation not only within the team, but also with the patients and their family is essential in order to achieve the best results.

Polymorphisms P53 gene in children with juvenile idiopathic arthritis.

A. N. Kozhevnikov[1], *M. M. Nikitin*[2], *N. A. Pozdeeva*[1], *V. I. Larionova*[1], *G. A. Novik*[3], *S. V. Vissarionov*[1], *M. N. Slyadnev*[2];
[1]*The Turner Scientific and Research Institute for Children´s Orthopedics, Saint-Petersburg, Pushkin, Russian Federation,* [2]*Lumex Ltd, Saint-Petersburg, Russian Federation,* [3]*Pediatric Medical University, Saint-Petersburg, Russian Federation.*

Background: reduced capacity (sensitivity) of cells to apoptosis is one the possible mechanisms maintaining synovial inflammation in juvenile idiopathic arthritis (JIA). Polymorphisms *Arg72Pro 4ex*, *ins/del16bp 3in*, *G/C 6in* can determine activity of the *P53* protein - the key protein of intrinsic apoptosis pathway. (P.Dumont et al 2003; Sallivan A. et al, Ghosh A et al 2004)
Objective: we evaluated role of *P53* gene polymorphism in JIA pathogenesis.
Methods: clinical, serological and x-ray manifestations were analyzed in 125 JIA children. 60 healthy children without family history of any autoimmune disease were controls. The *P53* gene polymorphisms was detected by PCR-RFLP.
Results: we haven't revealed significant differences in genotypes distributions of *Arg72Pro ex4*, *ins/del16bp in3* and *G/C in6* between JIA children and controls. We identified significant difference of exon genotype Arg72Pro in girls who still persistently in «active» arthritis more 2 years compared with girls who achived clinical remission (AA - 36,7% и 83,3%, AP – 51,1% и 16,7%, PP – 12,2% и 0%). Boys havn´t any difference of exon polymorphism. We received no information about influence of intronic polymorphisms on the JIA course. Gaplotypes AA*dGG и AAddG* were significantly higher in girls with «inactive» oligoarthicular (OA) and polyarthicular (PA) disease course. Girls who still «active» OA and PA course had gaplotypes AP*dG*, PPi*GC и PPiiCC.
CONCLUSION: presence of AA genotype of Arg72Pro was associated with achieving clinical remission in JIA girls with OA and PA course.

J01.26
Vitamin D receptor gene polymorphism influences on bone mineralization and metabolism in juvenile idiopathic arthritis.

M. M. Kostik[1], *A. M. Smirmov*[2], *G. Demin*[3], *L. A. Scheplyagina*[4], *V. I. Larionova*[5];
[1]*State Pediatric Medical University, Saint-Petersburg, Russian Federation,* [2]*Department of molecular diagnostics, Gene, Ltd,, Saint-Petersburg, Russian Federation,* [3]*Department of molecular diagnostics, Genetic Systems, Ltd, Saint-Petersburg, Russian Federation,* [4]*Moscow scientific and research clinical institute named M.F. Vladimirskiy, Moscow, Russian Federation,* [5]*Department of molecular diagnostics, Turner's Scientific and Research Institute for Children's Orthopedics, Saint-Petersburg, Russian Federation.*

Objectives: We evaluated bone mineralization and metabolism changes related to vitamin D receptor (VDR) polymorphic genotypes in children with juvenile idiopathic arthritis (JIA).
Methods: 198 children (82 boys and 116 girls) were included in our study. Bone mineral density (BMD) was measured by lumbar spine DXA. Osteocalcin, CTX, parathyroid hormone, total and ionized calcium, inorganic phosphate, total alkaline phosphatase activity was utilized for assessment of bone metabolism. Molecular testing: TaqI (rs731236) and Cdx2 (rs11568820) polymorphisms of VDR were detected by RFLP.
Results: no differences in TaqI and Cdx2 haplotypes, genotypes and alleles distribution related with normal and low BMD (<-2SD) were found. Girls with TT TaqI VDR, who never been treated by glucocrticoides had lower BMD-Zscore than C allele carriers (TT =-0.94SD [IQR:-2.1;-0.5], TC+CC =-0.62SD [IQR:-1.26;0.39], p=0.03). Girls with Tanner I with TT had higher total and ionized Ca level than carriers of C allele (Ca: TT = 2.43±0.15 mmol/l, TC+CC = 2.28±0.2 mmol/l, p=0.024; Ca2+: TT = 1.15±0.08 mmol/l, TC+CC = 1.06±0.13 mmol/l, p=0.026). Presence of TT genotype negatively correlated with BMD-Zscore (r=-0.28, p=0.04), and positively with frequency of LBMD (r= 0.3, p=0.037).
Boy with GG Cdx2 genotype had lower total Ca (GG = 2.3±0.17 mmol/l, GA+AA = 2.43±0.17 mmol/l, p=0.004) compare with carriers of A allele. Pubertal boys (Tanner IV-V) with GG had higher CTX (GG = 1.75±0.11 ng/ml, GA+AA = 1.06±0.07 ng/ml, p=0.04.
Conclusion: TT genotype of TaqI and GG genotype of Cdx2 could be possible negative factor impact bone mineralization and metabolism in JIA children.

J01.27
Management and genetic profile in an Apert syndrome case

A. Belengeanu[1], *M. Stoian*[2,3], *S. Farcas*[2], *D. Belengeanu*[4], *D. Misceo*[5];
[1]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Department of Morphologic Microscopy, Discipline of Molecular and Cellular Biology, Timisoara, Romania,* [2]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Department of Morphologic Microscopy, Discipline of Genetics, Timisoara, Romania,* [3]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [4]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Department 1, Discipline of Oral Rehabilitation, College of Dental Technique, Timisoara, Romania,* [5]*Olso University Hospital and University of Oslo, Department of Medical Genetics, Oslo, Norway.*

Apert syndrome is a type of acrocephalosyndactylia that belongs to the group of craniofacial synostoses.
It is characterized by craniofacial dysmorphism and syndactyly of hands and feet.
We present a six years old boy referred for genetic analysis for Apert syndrome. Family history revealed that he is the first child of a young couple. At birth, he presented the specific signs that emphasized the clinical diagnosis, craniosynostosis and symmetric syndactyly of all digits of the hands and feet. For craniosynostosis, a surgical intervention was performed at the age of one year old, and repeated surgical interventions for syndactyly were performed since. On the examination date, syndactyly was present in the left hand between the fingers II-IV and between the fingers II and III in the right hand. In lower limbs the syndactyly is present in all the fingers where correction was not performed.
A prominent metopic suture, middle facial floor hypoplasia, extended palpebral slants down oriented, less significant exophthalmia, palpebral ptosis, half-open mouth and low inserted ears were observed from a craniofacial point of view. The oral examination emphasized the absence of teeth erupti-

on in the central part of the upper maxillary, with open occlusion.
The genetic evaluation revealed a p.P253R mutation in fibroblast growth factor receptor type 2 consisting in a c.758C>G. This mutation is responsible for 26 % of cases.
According to literature data, the patients with Apert syndrome and p.Pro253Arg mutation have a more improved craniofacial appearance after a craniofacial surgery, fact confirmed also in our case.

Detection and characterisation of Molecular biomarkers associated with low bone mass in Thalassemia major patients.

k. singh, *s. agarwal;*
SGPGI-MS, lucknow, India.

Background: Osteoporosis represents an important cause of morbidity in β-thalassemia major (TM) and its pathogenesis has not been completely understood. Genetic factors play an important role in the pathogenesis of osteoporosis and several candidate gene polymorphisms have been implicated in the regulation of this process. A G→T polymorphism in the regulatory region of the collagen type I alpha 1 (COLIAI) gene and Parathyroid hormone (PTH) is well known to play an important role in calcium and bone metabolism.
Aim: To find out the distribution of COLIAI polymorphism and BST B1, RFLP of the PTH gene and its relationship with bone mineral density (BMD) in TM patients.
Material and Methods: G→T polymorphism and BST B1, RFLP of the PTH gene was detected in 150 TM patients and their BMD was measured in by Dual Energy X ray Densitometry (DEXA). Biochemical levels were estimated by ELISA.
Result : A total of 19.8% of the β -thalassemia patients were homozygous for G/G (SS) 35.8% were heterozygous for G/T (Ss) polymorphism and homozygous mutant (ss) 43.4% .There was significant difference between Z-score of patients hip (p=0.047) and at lumbar spine (p=0.001) region. We have observed frequency of each genotype_BB, Bb, and bb_was 43.1 %, 39.7%, and 17.2%, respectively and significant association was found with BMI (P=0.026) , PTH level (P=0.032) ,Vitamin D level (P= 0.02) and Z score at spine (P=0.001).
Conclusion: Our results raise the possibility that genotyping could be of clinical value in identifying chances of low bone density.

Ankyloblepharon-Ectodermal Defects-Cleft Lip/Palate Syndrome due to a new heterozygous missense mutation in the SAM domain of P63

M. TAJIR[1,2], *J. LYAHYAI*[1,2], *S. GUAOUA*[1,2], *M. EL ALLOUSSI*[3], *A. SEFIANI*[1,2];
[1]*Centre de Génomique Humaine, Faculté de Médecine et de Pharmacie, Université Mohamed V Souissi, Rabat, Morocco,* [2]*Département de génétique médicale, Institut National d'Hygiène, Rabat, Morocco,* [3]*Service d'odontologie pédiatrique-Prévention, Faculté de Médecine Dentaire, Université Mohamed V Souissi, Rabat, Morocco.*

Ankyloblepharon-ectodermal defects-cleft lip/palate (AEC) syndrome is a rare autosomal dominant disorder with multiple congenital anomalies. Clinical manifestations include ankyloblepharon filiforme adnatum, ectodermal defects (sparse frizzy hair; skin defects; nail alterations; dental changes; decrease in transpiration capacity) and cleft lip/palate. The diagnosis is based on clinical criteria and molecular genetic testing of *P63* gene, the only gene known to be associated with AEC syndrome. All mutations result in an amino acid substitution in the Sterile Alpha Motif (SAM) domain, and are predicted to alter protein-protein interactions. Here, we report a case of Moroccan girl aged 2 years with clinical diagnosis of AEC syndrome. The molecular studies and bioinformatics tools showed a novel heterozygous mutation c.1798G>C (p.Gly600Arg) in *P63* gene. The molecular analysis and the early diagnosis of this syndrome are important to implement appropriate genetic counseling for parents, as well as clinical and dermatological treatment of the patient.

Mutational analysis of NF1 gene on Greek patients with Neurofibromatosis Type I.

M. Tsipi[1], *M. Tzetis*[1], *S. T. Kitsiou*[1], *K. Kosma*[1,2], *E. Kanavakis*[1];
[1]*University of Athens, Department of Medical Genetics, School of Medicine, Athens, Greece,* [2]*"Aghia Sophia" Children's Hospital, Athens, Greece.*

Neurofibromatosis Type I is a genetic disorder that affects 1 in 3,000 individuals worldwide and is characterized by cafe-au-lait spots, Lisch nodules in the eye, multiple cutaneous neurofibromas and increased susceptibility to the development of benign and malignant tumors. It is inherited in a autosomal dominant fashion and is caused by mutations at NF1 gene located at chromosome 17q11.2. While penetrance is 100%, expressivity of the disease is extremely variable. The gene is large and codes for at least three alternatively spliced transcripts. NF1 pseudogenes also occur in various genomic locations complicating the design of molecular assays for NF1 mutations.
In our study we focused on the elucidation of the genetic causes underlying the disease. A multi step protocol based on genomic DNA has been established for molecular diagnosis in Greek patients fulfilling the diagnostic criteria for Neurofibromatosis Type I. This protocol included multi-step PCR, sequencing of all NF1 gene exons and multiplex ligation-dependent probe amplification (MLPA) for deletions/ duplications.
We found a great number of genetic variants in coding and non-coding regions, the majority already reported in databases. However we have also found novel variants in coding and non-coding regions of NF1, stop codon mutations and variants which may affect the splicing process. All were analyzed with the use of bioinformatic tools. Different mutations were found in patients within the same family, indicating the genetic complexity of the disease. We have also attempted possible phenotype/genotype correlations.

J01.31

Novel mutations in FBN1 causing Marfan syndrome in Portuguese patients

A. R. Marques[1], *A. F. Brandão*[1], *I. Ayhan*[1], *P. Brandão*[2], *A. Barros*[2], *J. Pinto-Basto*[1,3,4], *J. Sequeiros*[1,3,4], *I. Alonso*[1,3,4];
[1]*CGPP, IBMC, Porto, Portugal,* [2]*Centro Hospitalar do Alto Minho, Viana do Castelo, Portugal,* [3]*UnIGENe, IBMC, Porto, Portugal,* [4]*ICBAS, University of Porto, Porto, Portugal.*

Marfan syndrome (MFS) is an autosomal dominant connective tissue disorder, generally caused by a pathogenic mutation on the *FBN1* gene, encoding fibrillin-1, an extracellular glycoprotein essential for connective tissue structure. Its major manifestations include tall stature, long thin limbs and arachnodactyly, *pectus excavatum/carinatum*, myopia, mitral valve prolapse and regurgitation, and dilation of the aortic root (occasionally leading to dissecting aneurysm and death). Symptoms can appear at any age and vary greatly between patients, even within the same family.
We have screened 6 patients, with a clinical phenotype suggestive of MFS, for mutations in the *FBN1* gene. All exons and flanking intronic regions were amplified by PCR followed by bidirectional sequencing. MLPA was also performed to detect large gene rearrangements.
Mutation screening revealed the presence of three novel mutations in three of our patients: one indel mutation, c.2422delinsCTGTTT, leading to a frameshift and a premature stop codon (p.Ile808LeufsX41); one missense mutation, p.Tyr2149Asn (c.6445T>A); and another missense mutation, p.Met1? (c.3G>A), probably resulting in the loss of the protein start codon. Until now, we did not find any large gene rearrangements.
Our results suggest that *FBN1* mutations may also be the main cause of MFS in Portuguese patients. *FBN1* testing is useful to confirm the clinical diagnosis and to allow proper genetic counselling to patients and families. Regarding the three patients in whom no mutations were found, clinical information must be reviewed, in order to evaluate the need to pursue with mutation screening in other genes.

Relationship between vitamin D receptor and collagen type I alpha-1 chain gene polymorphism with bone metabolic markers in children with congenital scoliosis

I. Kazarian[1], *M. Kostik*[2], *S. Vissarionov*[1], *A. Voitovich*[2], *M. Mnuskina*[3], *I. Nichunaeva*[3], *V. Larionova*[1];
[1]*The Turner Scientific and Research Institute for Children's Orthopedics, Saint-Petersburg, Russian Federation,* [2]*Saint-Petersburg State Pediatric Medical University,*

Saint-Petersburg, Russian Federation, [3]Saint-Petersburg Medical Diagnostic Center №1, Saint-Petersburg, Russian Federation.

Background: genetic polymorphisms of gene which operated in bone remodeling can influence on levels of bone metabolic markers.
Objectives: we evaluated changes of bone metabolic markers in children with congenital scoliosis due to TaqI and -3731A/G vitamin D receptor (VDR); SpI and -1997G/T collagen type I alpha-1 chain (COL1A1) gene polymorphic genotypes.
Materials and methods: 154 children (63 boys and 91 girls) with congenital scoliosis aged 6 moths to 17 years were included. Molecular testing: detecting TaqI and -3731A/G VDR; SpI and -1997G/T COL1A1 polymorphism were performed by polymerase chain reaction with restriction fragment length polymorphism. We evaluated serum biomarkers of bone formation: osteocalcin, amino pro-peptide of type I collagen (P1NP), serum biomarkers of bone resorption - C-terminal telopeptides (CTT), and hydroxyvitamin D 25(OH)D3.
Results: in children with TaqI VDR polymorphic genotypes we have revealed differences in osteocalcin levels (p=0.006) and levels of 25(OH)D3 (p=0.003). We detected increased osteocalcin levels (p=0.012) in carriers of GG genotype -1997G/T COL1A1 compare with T allele carriers (TT+GT). No differences in markers of bone turnover related to -3731A/G VDR and SpI COL1A1 polymorphic genotypes were found.
Conclusions: we found differences in levels of bone metabolic markers, associated with polymorphic VDR and COL1A1genotypes.

Marfan syndrome combined with balanced translocation

A. Klímová[1], *M. Soukupova*[1], *J. Lastuvkova*[1], *P. Cibulkova*[2], *M. Wilimska*[1];
[1]Department of Medical Genetics, Ústí nad Labem, Czech Republic, [2]The Institute of Molecular Genetics, Novy Jicin, Czech Republic.

Our case is a family, where Marfan syndrome was diagnosed during genetic counseling in pregnancy. Marfan syndrome is a systemic disease of connective tissue characterized by a variable combination of cardiovascular, musculo-skeletal, ophthalmic and pulmonary manifestations. The incidence of Marfan syndrome is approximately 1 in 5,000 worldwide and there is no difference between men and women. It is associated with autosomal dominant inheritance - child has 50% risk of inheriting the disorder.
We saw our family because of genetic and drug risk in pregnancy for the first time. The father had clinical signs of Marfan syndrome.The father´s height was 208cm, he had arachnodactyly, he was observed because of mitral valve prolapse, an ectopia lentis, an abnormal joint flexibility, a high palate and he had osteoporosis. The risk for the children was 50%.
In the father we found normal karyotype 46,XY. In the mother we found balanced translocation 46,XX,t(3;10). Molecular genetic testing of Marfan syndrome started in the father. First tests did not find any causal mutation in the TGFBR1,2, FBN1genes by the single strand conformation polymorphism and multiplex ligation-dependent probe amplification. Examination was supplemented by next generation sequencing and mutation in the FBN1, c.5578T>C(p.Cys1860Arg) was found. Daughter of the pair was four years old and had some features of Marfan syndrome - arachnodactyly, high palate, mitral valve prolapse, ascending aorta dilatation. Molecular genetic testing was performed and the same mutation as in the father was found and balanced translocation 46,XX,t(3;10) inherited from the mother was found simultaneously.

Comparative study of allele frequencies of MTHFR, F2 and F5 gene polymorphisms in children with primary systemic vasculitis, vasculitis associated with autoimmune diseases and in healthy children.

N. Shirinbekova[1], *M. Nikitin*[2], *G. Novik*[1], *M. Slyadnev*[2], *V. Larionava*[3];
[1]St. Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation, [2]Lumex-Marketing Ltd., Saint-Petersburg, Russian Federation, [3]North-Western State Medical University named after I.I.Mechnikov. Saint Petersburg State University. The Turher Scientific and Research Institute for Childrens Orthopedics., Saint-Petersburg, Russian Federation.

Objectives: Comparative analysis of alleles and genotypes distribution of methylenetetrahydrofolate reductase (MTHFR) 677C/T polymorphism, prothrombin (F2) A20210 G/A polymorphism and blood coagulation factor V (F5) 1691G/A polymorphism in children with primary systemic vasculitis (1), vasculitis associated with autoimmune diseases (2) and healthy children (controls).
Patients and methods. 1st- group consisted of 27 patients (8 boys and 19 girls), 2nd- group - 34 patients (13 boys and 21 girls). Control group - 31 apparently healthy children (20 boys and 11 girls). MTHFR 677C/T, F2 and F5 1691G/A polymorphisms were analysed by real-time PCR using microchips containing lyophilized PCR mixture method. Statistical significance of differences between groups was assessed using $\chi 2$ tests.
Results. There was no difference($p>0.05$) in allele and genotype distribution of analyzed polymorphisms between groups. The genotype distribution was in accordance with Hardy-Weinberg equilibrium for all variants. Genotype F5 1691GA was found in 3,6% (n=1) in 1st group and in 2,9% (n=1) in 2nd group.
Conclusion. Despite the lack of statistically significant differences in the groups studied polymorphisms, we should continue to study more patients.

Prothrombotic Gene Polymorphisms in Young Patients with Cerebrovascular Accident

K. Hekimler Öztürk[1], ***A. Özgöz***[2], *F. Mutlu İçduygu*[1], *Y. Soysal*[1], *Ö. Yılmaz Küsbeci*[3], *N. İmirzalıoğlu*[4];
[1]Department of Medical Genetics, Faculty of Medicine, Afyon Kocatepe University, Afyonkarahisar, Turkey, [2]Department of Nutrition and Dietetics, Fazıl Boyner School of Health, Kastamonu University, Kastamonu, Turkey, [3]Department of Neurology, Faculty of Medicine, Afyon Kocatepe University, Afyonkarahisar, Turkey, [4]Genetic Diagnosis Center, HRS Ankara Women Hospital, Ankara, Turkey.

Cerebrovascular diseases which are affected by genetic and environmental factors are complex multifactorial disorders. Their incidence increases with age and these are the most frequently encountered ones among neurological diseases. The objective of this study was to investigate thrombotic gene polymorphisms that may take place in formation of cerebrovascular diseases in young adults. In our study in 43 patients with CVA (cerebrovascular accident) below age of 51, thrombotic gene polymorphisms were evaluated. Anamnesis of the patients (including CVA story and risk factors in the family) were taken. DNA was obtained from peripheral blood samples and the related gene regions were amplified by multiplex PCR method. Of the patient samples, twenty were studied by CVD strip assay, five were studied by FV-PTH-MTHFR strip assay, eighteen were studied by real time PCR method and the common polymorphisms were evaluated. Twenty six of 43 cases with CVA were women (mean age:35.12±9.2) and 17 were men (mean age:34.56±10.07). Most of the etiologic reasons were idiopathic and the most important ones were smoking and hypertension. MTHFR C677T polymorphism heterozygous frequency was 46.1%, homozygous frequency was 9.3 %; MTHFR A1298C polymorphism heterozygous frequency was 39.47%, homozygous frequency was 26.31%; prothrombin polymorphism heterozygous and homozygous frequency was 2.3%; Factor V Leiden polymorphism heterozygous frequency was 9.3% in our patient group. It is thought that MTHFR gene C677T and A1298C polymorphisms might be risk facors in CVAs. We observed that together with these polymorphisms smoking hypertension and existence of family story increased the available risk.

Polymorphism gene angiotensinogen M235T with clinical, structural and functional indexes of the heart in patients with chronic heart failure (CHF)

O. Krasnova[1], *V. Larionova*[2], *M. Sitniciva*[1], *B. Smirnov*[3];
[1]Federal centre heart blood and endocrinology, Saint-Petersburg, Russian Federation, [2]Scintific researcher orthipedic institusion aftre by G.I. Turner, Saint-Petersburg, Russian Federation, [3]Saint Petersburg Electrotechnical University, Saint-Petersburg, Russian Federation.

Purpose: To detect the association of polymorphism gene AGT with clinical features, structural and functional indexes of the heart in patients with CHF of ischemic etiology. **Methods:** 105 men with left ventricle ejection fraction ≤45 % (Simpson). Mean age 59,4±8 y.o **Results:** 25 patients were homozygous for the M-allele, 60 had the MT polymorphism and 20 patients were homozygous for the T-allele. All patients did not differ by CHF f.c. The incidence of MI in group of patients with T-allele had significantly earlier than in group of patients with M-allele (58.0±9.0 vs 51.9±9.1 y.o correspondently;

p<0,05). 18% of patients with T-allele had history of stroke and group of patients with MM-genotype didn't have stroke at all. Patients with M-allele had more significantly increased left ventricular end-diastolic and end-systolic diameters (LVDD/LVSD), significantly elevated pulmonary artery pressure (PAP) than patients with TT-genotype (LVDD/LVSD 59.1 ±10.0/60.4±10,0 mm vs 54.7±10.1/55.7±10.0 mm correspondently; p=0.03; PAP 41.6 ±18.1 vs 28.3 ±11.0 mmHg correspondently; p=0.02). Group with M-allele gene AGT had 12% events of paroxysmal atrial fibrillation and group with TT-genotype had no paroxysms. There was no difference in prevalence and onset of hypertension, presence of hypercholesterolemia and obesity. **Conclusion:** There was association of the TT-genotype with earlier cases of myocardial infarction and significantly more events of stroke than in patients with M-allele. Patients with ischemic CHF and M-allele had significantly higher sizes of left ventricle, degree of pulmonary hypertension in spite of equal duration of CHF and f.c. of CHF.

Clinical study of C677T polymorphisms of methylentetrahydrofolatreductase gene in children with Juvenile Idiopatic Arthritis

I. Romankevych;
P.L.Shupik National Medical Academy of Post-Graduate Education, Kyiv, Ukraine.

The children with juvenile idiopatic arthritis (JIA) have an increase risk of early atherosclerosis development under the influence of systemic inflammation, endothelial dysfunction and homocisteine. Low activity of methylentetrahydrofolatreductase (MTHFR) can cause the elevation of homocysteine level. MTHFR activity changes due to mononucleotide polymorphisms (SNP) of its gene.
The aim of study was the determination of SNP of MTHFR.
Materials: 13 children with polyarthritis, 11 oligoarthritis, 3 systemic JRA were examined. High activity was observed in 4, moderate in 9, low in 14 patients. χ2-criterion was used for comparison and odds ratio was calculated.
Results: polymorphic variant C677C MTHFR was observed in 32%, C677T in 68% patients, T677T was absent.
Allele C677T was determined in11 children with polyarthritis (85.7%) (p = 0.0322; OR = 7.2, 95% CI:1.07- 48.64). In children with oligoarthritis with almost equal frequency C667T and C677C were observed. Only C677T genotype was observed in all cases of systemic form of JIA. It was determined in all causes of III degree and in 75% cases of II degree activity of JIA.
In our study observed protective influence of C677C polymorphism on development of polyarthritis (OR= 0.14, 95% CI: 0.02-0.94) and 7 time higher risk of polyarthritis in cases of C677T genotype.
Didn`t found statistical correlation between SNP and homocisteine level. Its level in children with C677T genotype was 13 ± 4.3 mmol/l vs 12.01 ± 3.62 mmol/l in C667Cgenotype.
Conclusion: determination of C677T polymorphisms of MTHFR is important genetic test for early diagnostic process in children with JIA.

Mutation in ST6GALNAC5 identified in family with coronary artery disease

K. Inanloo Rahatloo[1,2]*, A. F. Zand Parsa*[3]*, K. Huse*[4]*, P. Rasooli*[1]*, S. Davaran*[5]*, M. Platzer*[4]*, M. Kramer*[6,4]*, J. Fan*[7]*, E. Elahi*[1,8]*;*
[1]School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, [2]Genome Analysis, Fritz Lipmann Institute, Jena, Germany, [3]Department of Interventional Cardiology, Imam Khomeini Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran, [4]Genome Analysis, Leibniz Institute for Age Research–Fritz Lipmann Institute, Jena, Germany, [5]Department of Interventional Cardiology, Imam Khomeini Hospital, Tehran, Islamic Republic of Iran, [6]Integrated Research and Treatment Center, Center for Sepsis Control and Care (CSCC), Jena University Hospital, Jena, Germany, [7]Illumina, San Diego, CA, United States, [8]Dept. of Biotechnology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran.

Coronary artery disease (CAD) is a leading cause of death worldwide and atherosclerosis which results in decreased supply of blood to the heart is its major cause. Myocardial infarction is the most severe outcome of CAD. Despite extensive efforts, the genetics of CAD is poorly understood. We aimed to identify the genetic cause of CAD in a pedigree containing several affected individuals. Genetic analysis including linkage analysis and exome sequencing was performed on the pedigree. Functional analysis was done to access the effect of the identified causative mutation on protein localization and enzyme activity. The identified gene was screened in 100 additional unrelated patients. A missense mutation in ST6GALNAC5 that encodes Sialyltransferase 7e was identified as the cause of CAD in the pedigree. Changed intracellular localization of the mutated enzyme was not observed, however the mutation was shown to cause increased sialyltransferase activity. Another mutation in ST6GALNAC5 was found in two unrelated CAD patients while screening only 100 additional cases. In conclusion mutations in ST6GALNAC5 can cause CAD. Mutations in the gene may contribute to CAD in not an insignificant fraction of patients. Although sialyltransferase and sialic acid levels are not among the commonly recognized risk factors for CAD, there is substantial literature that suggests a relation between these molecules and coronary disease. Our findings provide strong evidence for the existence of this relation. There are implications of our findings for diagnosis and prevention of CAD.

Identification of FBN1 gene mutation in Ukrainian patients with Marfan syndrome

R. Zhuraev;
Institute of Clinical Pathology Lviv National Medical University after Danylo Halytski, Lviv, Ukraine.

Background. Marfan syndrome (MFS) is an autosomal dominant disorder of the connective tissue characterized by early development of thoracic aortic aneurysms/dissections together with symptoms of the ocular and skeletal systems. The main pathogenesis of MFS is currently thought to be driven by mechanisms due to haploinsufficiency of wild-type fibrillin-1
Purpose. To identify a mutation in the fibrillin-1 (FBN1) gene in Ukrainian patients with Marfan syndrome.
Methods. We examined 36 patients (24 male and 12 female) with MFS after aortic valve-replacing root operations. We have used an Haloplex (Agilent) assay for enrichment of 12 TAA genes and sequenced the samples with next generation sequencing on a Miseq (Illumina). After that we have confirmed the putative mutations with Sanger sequencing on an ABI sequencer (Life Technologies).
Results. We detected FBN1 mutation in 24 patients (66.7%). Patients with FBN1 mutation had heavier clinical indicators than patients without mutations. The average age in patients with FBN1 mutation during the surgery was 35.2±11.8 year, and in patients without FBN1 mutation - 47.4±13.3 year. The average Z-score in patients with FBN1 mutation was 8.2±2.9, and in patients without FBN1 mutation - 7.4±4.6. Ectopia lentis was present in 6 MFS patients with FBN1 mutation and has not been in any patient without FBN1 mutation.
Conclusions. This is a first report of FBN1 mutation in Ukrainian MFS patients. We found that patients with FBN1 have younger age at diagnosis and a higher probability of developing ectopia lentis, ascending aortic dilatation, aortic surgery, mitral valve abnormalities, scoliosis.

Ofd1 controls dorso-ventral patterning and axoneme elongation during embryonic brain development

B. Franco[1,2]*, A. D'Angelo*[1]*, A. De Angelis*[1]*, B. Avallone*[3]*, I. Piscopo*[1]*, R. Tammaro*[1]*, M. Studer*[1]*;*
[1]Telethon Institute of Genetics and Medicine-TIGEM, Naples, Italy, [2]Department of Translational Medicine, Federico II University of Naples, Naples, Italy, [3]Department of Biological Science, University of Naples, Naples, Italy.

Oral-facial-digital type I syndrome (OFDI) is a human X-linked dominant-male-lethal developmental disorder caused by mutations in the OFD1 gene. Similar to other inherited disorders associated to ciliary dysfunction OFD type I patients display neurological abnormalities. We characterized the neuronal phenotype that results from Ofd1 inactivation in early phases of mouse embryonic development and at post-natal stages. We determined that Ofd1 plays a crucial role in forebrain development, and in particular, in the control of dorso-ventral patterning and early corticogenesis. We observed abnormal activation of Sonic hedgehog (Shh), a major pathway modulating brain development. Ultrastructural studies demonstrated that early Ofd1 inactivation results in the absence of ciliary axonemes despite the presence of mature basal bodies that are correctly orientated and docked. Ofd1 inducible-mediated inactivation at birth does not affect ciliogenesis in the cortex, suggesting a developmental stage-dependent role for a basal body protein in ciliogenesis. Moreover, we showed defects in cytoskeletal

organization and apical-basal polarity in Ofd1 mutant embryos, most likely due to lack of ciliary axonemes. Thus, the present study identifies Ofd1 as a developmental disease gene that is critical for forebrain development and ciliogenesis in embryonic life, and indicates that Ofd1 functions after docking and before elaboration of the axoneme in vivo.

Genomic Variation in Congenital Heart Disease

L. D. Kulikowski[1,2], *E. A. Zanardo*[1,2], *R. L. Dutra*[1,2], *F. B. Piazzon*[1], *A. T. Dias*[1], *M. M. Montenegro*[1], *G. M. Novo-Filho*[2], *M. M. Basso*[2], *T. V. M. M. Costa*[1], *A. M. Nascimento*[1], *M. S. Grassi*[2], *M. M. S. Carneiro-Sampaio*[2], *C. A. Kim*[2];
[1]*Departament of Pathology, Cytogenomics Laboratory, LIM 03, University of São Paulo, São Paulo, Brazil, São Paulo, Brazil,* [2]*Department of Pediatrics, The Children's Institute, University of São Paulo, São Paulo, Brazil.*

Congenital heart disease (CHD) constitutes by far the major cause of infant morbidity and mortality. Most CHD cases present concomitant non-cardiac anomalies such as facial dysmorphisms and/or developmental delay. And most of patients with conotruncal defects carry a hemizygous microdeletion of chromosome 22q11 justifying the use of cytogenomic analysis. In this sense, we prospectively studied a cohort of 107 patients with CHD with or without dysmorphic features or additional congenital abnormalities. We use distinct MLPA (Holland) kits (P064, P036, P070, P250, P356, P095, P029) and arrays (HumanCytoSNP-12, Illumina). Unexpected our analysis identified duplications (8,4%) as well as deletions (17,8%) associated with 22q11.2 region, and smaller atypical CNVs (19,6%) that implicated IL17-RA, CECR1, PEX26, PRODH, CLDN5, SHANK3, ACR deletions. We also found genomic changes involving 1p36, 4p16.3, 4q35.2, 5q35.3, 7p21.3, 7q36.3, 8p23.3, 9q34, 10p12.3, 11q13, 11q24, 15q11.2, 16p13.3, 17p11, 19p13.3 and 20q13.3 regions. All of these alterations were already reported in patients with multiple congenital anomalies suggesting that these CNVs are pathogenic and consistent with a model where imbalance of multiple genes associated with contributes to congenital heart disease.

A rare case of a complete 9p trisomy without autistic features and resulting from a de novo unbalanced t(9;15) translocation

F. Abdelhedi[1], *A. Lebbar*[2], *I. Ben Ayed*[2], *H. Ben Othmen*[3], *L. Dardour*[4], *B. Ben Rhouma*[1], *C. Triki*[3], *N. Belguith*[4], *H. Kamoun*[4], *J. M. Dupont*[2];
[1]*Faculté de Médecine, Sfax, Tunisia,* [2]*Laboratoire de Cytogénétique, APHP, Hôpitaux universitaires Paris Centre, Paris, France,* [3]*Service de Neuro-Pédiatrie, CHU Hedi Chaker, Sfax, Tunisia,* [4]*Service de Génétique, CHU Hedi Chaker, Sfax, Tunisia.*

Trisomy 9p is one of the most frequent autosomal anomalies compatible with long survival rate. The phenotype of the 9 p duplication syndrome is clinically recognizable, and phenotype/genotype correlations suggested that the critical region is located on 9p22. We report on a rare case of a trisomy for the whole short arm of chromosome 9 resulting from a de novo unbalanced t(9;15) translocation. A 3-year-old girl was referred to genetic counselling because of facial dysmorphism, seizures, and moderate mental retardation. MRI (Magnetic resonance imaging) was interpreted as normal. Chromosome analysis revealed a 46,XX,der(15)add(15)(p11) karyotype. Parental karyotypes were normal. Thus, we conclude that this chromosomal rearrangement occurred de novo. In order to identify this additional material on chromosome 15, we performed array CGH (Nimbelgen Whole genome tiling135K HG18) that showed a duplication of the whole short arm of chromosome 9. No other imbalances were found elsewhere in the genome. FISH studies performed with whole chromosome 15 and chromosome 9 painting probes confirmed that the chromosomal material added on chromosome 15 derived from 9p. Our observation is unique because the duplication of the whole short arm of chromosome 9 without monosomy of another chromosome and resulting from a de novo unbalanced translocation was never reported. Our patient had the most common clinical findings of the trisomy 9p syndrome but neither visceral anomalies, nor autistic features. Our report doesn't strengthen the hypothesis that a critical region for autism or autism spectrum disorders (ASD) may be located on the area of 9p23-24.3.

J02.04

Novel mutations involved in Bardet-Biedl syndrome

S. Castro-Sánchez[1], *M. Álvarez-Satta*[1], *D. Valverde*[2];
[1]*University of Vigo (equal contribution), Vigo, Spain,* [2]*University of Vigo, Vigo, Spain.*

Bardet-Biedl syndrome (BBS, #209900) is a rare, human genetic disorder with an estimated prevalence in Europe of 1:160 000 live births. This syndrome shows early-onset retinitis pigmentosa, obesity, polydactyly, hypogonadism, intellectual disabilities and renal abnormalities as primary features. BBS is inherited in an autosomic recessive manner, although some authors suggest that triallelic inheritance could explain some family pedigrees. To date 17 BBS genes (BBS1-17) are involved in the development of BBS phenotype. Pathogenic mutations in these genes are responsible for 70-80% of the cases. Therefore, strong efforts are needed to find new genes and mutations related with BBS.
The purpose of this work was to analyse two BBS genes with a high prevalence, BBS1 and BBS12, to identify pathogenic mutations.
We chose patients with a negative result for BBS/AS Asper Ophthalmics genotyping microarray (Asper Biotech), among a set of 90 Spanish, Indian and Arab affected families. We studied the coding region of BBS1 and BBS12 genes, 27 and 39 patients respectively, by direct sequencing and analysis with specific software.
We found two pathogenic mutations in coding region of 10 patients, confirming their clinical diagnosis. Four of these pathogenic changes are novel mutations: c.68G>A / p.W23X (BBS1) in an Indian patient and c.1510_1520delCACCTGCAGAA / p.H504fsX552 (BBS1), c.1082delG / p.G361fsX382 (BBS12) and c.1140delA / p.T380fsX382 (BBS12) in Spanish families.
Classical molecular approach by direct sequencing remains a good strategy to discover new pathogenic changes in clinically diagnosed BBS patients.

[1]*Genetics Department Wroclaw Medical University, Wroclaw, Poland,* [2]*Department of Medical Genetics, Institute of Mother and Child, Warsaw, Poland,* [3]*Genetic Clinic Medgen,, Warsaw, Poland,* [4]*Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland,* [5]*Department of Child and Adolescent Psychiatry, The Medical University of Warsaw, Warsaw, Poland,* [6]*Pediatrics and Neurology of Children, Silesian Medical University, Katowice, Poland,* [7]*nstitute of Medical Genetics, University of Zurich, Zurich, Switzerland.*

Introduction:
Mowat-Wilson syndrome (MWS, OMIM #235730) is a rare congenital disorder characterized by distinctive facial features, intellectual disability and characteristic congenital anomalies. Estimated birth incidence is 50000-100000 life births. The only known causes of MWS are mutations in ZFHX1B gene or rarely micoredeletions in region 2q22-23.
The aim of the work was to evaluate the phenotype of patients with MWS confirmed by molecular analysis of ZFHX1B gene and to assess the differences between them and in whom any genetic alterations were detected.
Material and Methods:
Clinical diagnosis of MWS based on distinctive facial dysmorphy, developmental delay or intellectual disability and at least one congenital malformation were established in 10 patients. Patients were not consanguineous. They came from various regions of Poland. All patients were performed cytogenetic and subtelomeric MLPA test, which did not reveal any abnormalities. Molecular tests of ZFHX1B gene were performed including direct bidirectional sequencing of ZFHX1B gene and MLPA reaction with P169 KIT by MRC Holland.
Results:
Diagnosis of Mowat-Wilson syndrome was confirmed in five cases - two females and three males. Patients has typical facial dysmorphy with uplifted earlobes with a central depression visible irrespective of patient's age. Among congenital malformations the most common were heart defects, agenesis of corpus callosum and kidney defects. Psychomotor or intellectual development were severely retarded in all cases. Especially verbal language abilities were impaired.
Conclusion:
Mowat-Wilson syndrome is still underestimated entity. The further examinations and analysis are needed to study the phenotype of patients with MWS and establish clinical criteria.

Position effect leading to haploinsufficiency in a ring chromosome 14 in a boy with mental retardation, epilepsy and cryptorchidism

L. Dardour[1], *F. Abdelhedi*[2], *A. Lebbar*[3], *B. Ben Rhouma*[2], *I. Ben Ayed*[3], *M. A. Ksentini*[1], *H. Ben Othmen*[4], *C. Triki*[4], *N. Belguith*[1], *H. Kamoun*[1], *J. M. Dupont*[3];
[1]*Service de Génétique, CHU Hedi Chaker, Sfax, Tunisia,* [2]*Faculté de Médecine, Sfax, Tunisia,* [3]*Laboratoire de Cytogénétique, APHP, Hôpitaux universitaires Paris Centre, Paris, France,* [4]*Service de Neuro-Pédiatrie, CHU Hedi Chaker, Sfax, Tunisia.*

Ring chromosome 14 is a rare cytogenetic disorder, associated with mental retardation, epilepsy, retinal anomalies, and cranio-facial dysmorphisms. Most of these features are also found in patients with linear terminal deletions of chromosome 14, except for seizures and retinal abnormalities. We report a patient with cryptorchidism and a ring chromosome 14 with a small terminal deletion that was characterized by array-CGH. The patient was referred to genetic counseling at 04 years because of facial dysmorphism, microcephaly, hypotonia, drug-resistant epilepsy, and cryptorchidism. MRI noted cortical atrophy, while ophthalmologic examination detected an abnormal macula. Chromosome analysis showed a ring chromosome 14 with a 46,XY,r(14) karyotype. Parental karyotypes were normal and confirmed that the structural abnormality occured de novo. FISH studies with 14 q telomeric probe demonstrated that subtelomeric region was not deleted in the ring chromosome 14. Array-CGH performed with Nimbelgen Whole genome tiling135K, showed a small terminal deletion with a size of 1.03 Mb within the 14q32.33 region, which was confirmed by FISH analysis using a BAC clone : RP11-5F6. Analysis of informative microsatellite markers on chromosome 14 showed the absence of uniparental disomy (UPD). Our report is very intersting because genital anomalies such as cryptorchidism was never reported in ring 14 patients. We could also hypothesize that a candidate gene called ADAM6 located nearly from the breakpoint on 14q, and expressed in testis, could explain cryptorchidism in our patient. Therefore, we suggest that position effects need to be taken into account, when analyzing genotype-phenotype correlations based on chromosomal imbalances.

Cytogenetic microarray in characterization of unexplained mental retardation or developmental delay with dysmorphism

I. Panigrahi[1], *R. Saxena*[2], *P. Jain*[1], *S. Das*[1], *R. K. Marwaha*[1];
[1]*PGIMER, Chandigarh, India,* [2]*Sir Gangaram Hospital, New Delhi, India.*

Mental retardation (MR) is a common problem encountered in clinical practice. Down syndrome and Fragile X syndrome are two common genetic causes. In some cases, metabolic disorders are detected especially mucopolysaccharidosis. Syndrome diagnosis in MR cases is facilitated by use of databases. In some cases, even after detailed evaluation, the underlying cause is not identified. We did chromosomal microarray analysis (CMA) in seven cases of MR with dysmorphism attending the Genetic Clinic of a tertiary care centre, after a detailed initial evaluation, including biochemical and radiological tests. An underlying chromosomal defect was identified in at least 3 cases. One child showed deletion of 9.4 megabases at cytogenetic band 7p21p15.3, including the TWIST gene. Another child showed abnormal marker on routine karyotyping and the origin of the marker was ascertained on microarray analysis. One boy showed duplication of 2p25.3. Two others showed duplication of chromosomal regions with doubtful clinical significance. Copy neutral LOH on chromosome 15q was found in one case. Prenatal diagnosis was done in one family using karyotyping, CMA and MLPA analysis, and the fetus was found to be normal. Thus, CMA can have a high yield if done in carefully selected cases of MR with dysmorphism, after initial screening tests. Limitations of CMA analysis include inability to detect balanced chromosomal rearrangements, inversions, balanced insertions, and some cases of polyploidy and mosaicism.

15 Mb tandem microduplication in chromosome 11q22.3-q24.1 associated with developmental delay, dysmorphic features and overweight. Further characterization of duplication distal 11q region.

D. Gieruszczak-Białek[1,2], *M. Kugaudo*[1,2], *M. Kucharczyk*[2], *M. Pelc*[2], *E. Ciara*[2], *A. Marczak*[2], *A. Skórka*[1,2], *M. Krajewska-Walasek*[2], *K. Chrzanowska*[2];
[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*The Children's Memorial Health Institute, Warsaw, Poland.*

Isolated duplications of the distal 11q region are rare with only a few cases reported to date in the literature. All patients presented with intellectual impairment and dysmorphic features. Hypotonia, short stature and different congenital anomalies were also described.
Here we report the molecular karyotyping and phenotypic description of a new patient with a 15.1 Mb de novo tandem microduplication of 11q22.3-q24.1 region. Our patient presents with moderate developmental delay, severe verbal impairment, dysmorphic features, cryptorchidism and overweight.
Our observation contributes to the further characterization and dissection of a distal region 11q duplication. The possible role of genes within the duplicated region is discussed. Some genes located in the critical region, e.g. SORL1 and ASAM, may play an essential role in development of intellectual impairment and obesity, respectively. A comparison with previous case reports is provided.
Description of additional patients in the future will help to refine detailed genotype-phenotype correlation associated with this chromosomal region.
The study was supported by MNiSW Grant No. 0605/B/P01/2009/37. Acquiring of the Roche NimbleGen microarray platform was co-financed by ERDF (EU Structural Funds) project POIG.02.01.00-14-059/09.

16p12.1 microdeletion and developmental delay: a case report

S. Briuglia, *I. Loddo, E. Moschella, M. I. S. Crapanzano, S. Manti, T. Alterio, C. Romano, C. D. Salpietro;*
Genetics and Pediatric Immunology, Messina, Italy.

We describe the case of a boy that was born to non consanguineous parents at 38 weeks of gestation by cesarean section performed for podalic presentation. Reported poor fetal movements. Birth weight was 2.900 kg. Perinatal history was normal. Phenotypic examination: failure to thrive, dystrophic appearance, axial hypotonia, muscolar hypotrophia, body asymmetry, microcephaly, hypotelorism, micrognatia, pectus carenatum, joint stiffness, hypertonia with difficulty to the extension of the lower limbs, kyphosis. Array-CGH showed a microdeletion in the 16p12.1 region of paternal origin, extending aproximately 651 kb. Also the father showed poor growth in infancy and psychomotor delay (walking and first words at the age of 2 years) but with actual performance within normal limits.
Specific human chromosomes are enriched for interspersed segmental duplications and multiple genomic disorders have already been assigned to these "hotspot" regions of the genome. The short arm of human chromosome 16 is enriched for large segmental duplications that have arisen specifically during human-great ape evolution. The 16p12.1 microdeletion is a risk factor for intellectual disability and developmental delay, and also acts in concert with other large copy-number variants (CNVs) to modify neuropsychiatric phenotypes, thereby supporting a "two-hit" model for the generation of severe cognitive deficits involving this region. Analysis of other microdeletions suggests that this model may help to explain the variability in expressivity of recurrent CNVs associated with neuropsychiatric phenotypes. However, variable phenotypes were associated with the 16p12.1 microdeletion, such as congenital heart defects, seizures and severe growth abnormalities.

A case of early diagnosis of 1p36 deletion in a girl with multiple congenital abnormalities including pulmonary lobulation defect, tetralogy Fallot, and early onset of focal epilepsy

A. A. Vasilishina[1,2], *M. A. Bulatnikova*[1,2], *E. A. Kotelevskaya*[1,2], *A. B. Smolyaninov*[1,2], *V. I. Larionova*[1,3];
[1]*North-Western State Medical University named after I.I. Mechnikov, St.Petersburg, Russian Federation,* [2]*Stem Cell Bank Pokrovski, Medical Center Pokrovski, St.Petersburg, Russian Federation,* [3]*The Turner Scientific and Research Institute for Children's Orthopedics, St.Petersburg, Russian Federation.*

We present a case of early diagnosis of 1p36 in a child with multiple congenital abnormalities including tetralogy of Fallot, pulmonary lobulation anomaly, and focal epilepsy. A 4-month-old girl was the product of the first pregnancy of healthy non-consanguineous parents. Prenatal ultrasound examination revealed tetralogy of Fallot and intrauterine growth retardation.

Delivery was complicated by long first period with intrauterine hypoxia. Apgar score was 5/6. There was a significant muscular hypotonia with inability to suck. In the second month of life, focal seizures of right arm or right side of the body began. Craniofacial features included microbrachycephaly with wide forehead and frontal bossing, mild bitemporal narrowing, hypoplasia of supraorbital ridges, absence of eyebrows, deep-set eyes with short palpebral fissures, wide and plant nasal root, long and fine formed philtrum, Pierre Robin sequence. Thin upper lip covered lower lip. The patient was also characterized by short neck and limbs. Karyotyping at 450 band level did not reveal any chromosome anomalies. Aminoacid, organic acid, and acylcarnitine spectrum was normal. Deletion in the 1p36.33 region was detected by SALSA MLPA kit P290. Further examination revealed pulmonary lobulation defect with two lobes in the right lung. There were hypertrophic pyloric stenosis and hypoplasia of left kidney. In the fourth month of life microphthalmia was diagnosed. Absence of eyebrows with dysplastic but long supraorbital ridges, relative or real microphthalmia, Pierre Robin anomaly were noted in publications on early diagnosis of 1p36 monosomy. We suggest these findings may be helpful for early diagnostics of 1p36 syndrome.

Haploinsufficiency of genes involved in the synaptic pathway and located on chromosome 5q33q34 leads to pharmaco-resistant epilepsy, ataxia, and severe mental retardation.

H. Karmous-Benailly[1], *F. Giuliano*[1], *N. Rabasse*[2], *C. Massol*[1], *V. Paquis-Flucklinger*[1], *M. Dayem-Quere*[1];
[1]*Service de Génétique, Archet II, Nice, France,* [2]*Service de Pédiatrie, Archet II, Nice, France.*

Deletions of the long arm of chromosome 5 could vary considerably, and involvement of all bands between 5q11 and 5q35 have been described (Royer-Pokora et al, 2006; Schoch et al, 2005). Constitutional interstitial deletions of 5q are less common, and very few cases were described in the literature. The deleted segments vary in region and size, making it difficult to delineate a typical syndrome. To our knowledge, very few cases of *de novo* 5q33q34 deletions were previously cytogenetically described (Giltay et al, 1997; Spranger et al, 2000). Due to the large number of genes involved in these deletions, and the lack of precisely defined boundaries, genotype-phenotype correlations are not easy to evidence. We describe here a young female patient involving a proximal 5q deletion, mapping to region 5q33.3-q34. The deletion appeared *de novo*. Our patient shows the following features: microcephaly, strabism, psychomotor development retardation, stereotypes, and hypotony. A pharmaco-resistant epilepsy appeared at the age of 18 months. She then displayed great ataxia when walking, and, at the age of fourteen, she was severely mentally delayed. We depict a distinct phenotype associated to this region, and delineate a minimal critical region involved in pharmaco-resistant epilepsy, ataxia and mental retardation. We further highlight the involvement of the deleted genes in the synaptic transmission network.

J02.12

Analysis of deletion size in regions 7q11.23 and 22q11.21 and their correlation to the clinical phenotype in patients with Williams-Beuren (WBS) and Di George (DGS) syndromes

N. Yaneva[1], *S. Bichev*[1], *R. Vazharova*[1], *V. Stoyanova*[2], *V. Bojinova*[3], *E. Simeonov*[4], *A. Savov*[1];
[1]*National Genetic Laboratory, University Hospital of Obstetrics and Gynecology "Maichin Dom", Medical, Sofia, Bulgaria,* [2]*Department of Pediatrics and Genetics, University Hospital, Plovdiv, Bulgaria,* [3]*USBALNP „Saint Naum", Sofia, Bulgaria,* [4]*University Hospital "Alexandrovska", Sofia, Bulgaria.*

Background: WBS is caused by hemizygous deletion (1.5-1.8 Mb) in 7q11.23. Molecular defects in DGS include 1.5-3 Mb deletion in 22q11.2. Both syndromes are relatively common in clinical practice and show wide clinical variability.
Aim: The aim of this study was to clarify differences in phenotype of patients with WBS and DGS according to affected chromosome regions.
Materials and Methods: DNAs from 150 patients, with mental retardation and/or multiple congenital abnormalities were examined. Initially patients were tested by MLPA using P245-A2 kit. Deletions/duplications have been confirmed by MLPA P064- B2 kit. ArrayCGH was used to determine breakpoints and the size of deletions. We paid special attention to patients with atypical clinical presentation and typical deletion size.
Results: We detected 7q11.23 deletion (1.413 Mb, 1.434 Mb and 1.918Mb) in three patients with clinical picture, relevant to WBS. The severe phenotype found in patients with DGS is result of haploinsufficiency of more genes than WBS. Five patients have 22q11.21 deletion (2.023 Mb, 2.438 Mb, 2.471Mb, 2.471 Mb, 2.522 Mb). The complexity of the clinical picture is likely to depend not only on the deletion size, but also to be a result of influence of molecular changes outside the causing deletion.
Conclusion: The application of high resolution molecular tests could provide more detailed insight into the relationships between the deletion size and clinical phenotype. This is important for making correct genetic diagnosis, genetic counseling and management of the affected individuals, but also from the point of view of molecular pathogenesis of the disease.

J02.13

Hypomandibular faciocranial dysostosis: Two new cases in the same family without mutations in PRRX1, PRRX2 and OTX2 genes

G. PI, ***L. PEDROLA****, M. ORTIZ, A. ZUNIGA;*
HOSPITAL DE LA RIBERA, ALZIRA (VALENCIA), Spain.

Hypomandibular faciocranial dysostosis syndrome, HFD (OMIM #241310), is a very rare condition with typical craniosynostosis, prominent eyes, deficient midface and zygomatic arches, short nose with anteverted nares, protruding lower face, minute oral aperture, persistent buccopharyngeal membrane, severe mandibular hypoplasia, and various extracephalic anomalies. The most typical features are abnormalities in the first branchial arch and derivatives.
Case report: we present genetic study of two 20 week old foetus with HFD syndrome in two consecutive and spontaneous miscarriages in a Spanish woman. Both parents were young and healthy, non-consanguineous. These two foetus were males with multiple abnormalities: malar hypoplasia, prominent eyes, short and flat nose, microstomy, protruding lips, tongue present and a skull with normal structure. In the first foetus we could appreciate in the intestinal cavity a diaphragmatic hernia, intestinal hypoplasia, duodenal stenosis, intestinal malrotation, absence of duodenum and anus atresia. In the second foetus we could appreciate esophageal atresia, intestinal hypoplasia, duodenal atresia and intestinal malrotation. Both foetus present normal karyotypes 46, XY. Mutations of PRRX1, PRRX2 and OTX2 genes have been recently associated with abnormal development of mandible, so we have performed genetic studies of DNA from foetal tissues. We screened for mutations the whole coding region of the three genes, including intron-exon junctions. First, amplification of all exons was performed followed by Sanger sequencing using ABI3100XL but we did not identify mutations in these genes. Probably another genes would be implicated in the HFD syndrome. Intestinal malformations have not been described in HFD syndrome previously.

Allgrove (triple A) syndrome with *AAAS* common Slavic mutation in Russian families

G. E. Rudenskaya*, E. Y. Zakharova;*
Medical Genetics Research Centre, Moscow, Russian Federation.

Allgrove (triple A) syndrome is a rare autosomal recessive disorder caused by mutations of *AAAS* gene. Along with "triple A" (alacrima, achalasia of cardia and addisonism) numerous neurological disorders which may appear much later are typical. We diagnosed Allgrove syndrome in three non-consanguineous Russian families. 1. A 47-year-old female had congenital asymptomatic alacrima and achalasia. After esophagocardiomyotomy in childhood she was free of symptoms up to 4th-5th decades, when dysphonia, dysphagia, ataxia, tremor, general weakness and weight loss developed; initial diagnosis was motor neuron disease. On examination bulbospinal amyotrophy, polyneuropathy with foot deformity, ataxia, autonomic disorders and mild adrenal insufficiency were found. Case is familial: patient's brother had achalasia and died in 6 yrs of unrecognized severe adrenal insufficiency which developed acutely after esophagal surgery. 2. A 17-year-old male had moderate dysphagia since 7-8 yrs and slowly progressing leg spasticity since 9-10 yrs, initial diagnosis was Strumpell's disease. On examination in 15 yrs spastic paraparesis, axonal polyneuropathy with foot deformity and severe adrenal insufficiency were found. Adrenomyeloneuropathy was excluded, and signs of achalasia were ignored. We suspected Allgrove syndrome 1.5 yrs later, and only then achalasia and alacrima were recognized. 3. A 5-year-old boy had alacrima and achalasia. In all patients

homozygosity for most common in other Slavic populations *AAAS* mutation c.787T>C (p.Ser263Pro) was detected. Ours are first findings of the mutation in Russians, an only previously reported Russian family had compound heterozygosity for novel mutations. Delayed diagnosis in cases 1 and 2 points to Allgrove syndrome underestimation in practice.

Thoracic syrinx and ventriculomegaly in a girl with alpha-thalassemia mental retardation syndrome, chromosome 16 related

A. C. Yu, *J. Richer;*
Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.

We describe a 5-year-old girl with dysmorphic features, developmental delay, alpha-thalassemia trait and hypotonia who, at 3 years old, was discovered to have ventriculomegaly and a thoracic syrinx on MRI. A genomic microarray identified a 1.819 Mb isolated monosomy of 16p13.3. Fluorescence in situ hybridization of the proband and her parents confirmed that this deletion was de novo. Alpha-thalassemia mental retardation chromosome 16 related syndrome (ATR-16) is a contiguous gene syndrome due to the deletion of α-1, α-2 and a variable number of surrounding genes. A literature review revealed only 23 reported cases of pure monosomy of 16p13.3. Although several of these cases have described neurologic abnormalities, such as hypotonia, impaired coordination or seizures, only two patients have reported radiologic imaging which were both abnormal: one patient had asymmetry of the periventricular white matter volume with thinning of the corpus callosum on CT, while the other patient had an arachnoidal cyst in the right temporal lobe on MRI. Syrinx are rare with an estimated 8.4 new cases of syrinx per year per 100 000 people. Our patient is the first reported case of a syrinx in a child with ATR-16 syndrome. It remains unclear whether a thoracic syrinx is a more frequent finding in ATR-16 than in the general population. However, based on the clinical presentation of our patient, we advocate for early imaging of the entire spine in children with ATR-16 and focal neurologic symptoms.

Anal Atresia, Coloboma, Microphthalmia, and Nasal Skin Tag in a Female Patient with 3.5 Mb Deletion of 3q26 encompassing SOX2

N. J. M. Salem[1], M. Hempel[1], K. Heiliger[1], S. Hosie[2], T. Meitinger[1], ***K. Oexle***[1]*;*
[1]Institute of Human Genetics, MRI, München, Germany, [2]Department of Pediatric Surgery, Klinikum Schwabing, München, Germany.

A full term female newborn presented with prominent forehead, bilateral microphthalmia, iris coloboma and cataract, wide intercanthal distance, large, low set and protruding ears, skin tag at the left nasal nostril, imperforate anus with rectovestibular fistula, and postnatal growth delay with brachymicrocephaly. A marker chromosome was not detectable and the copy number of 22q11 was normal. However, array CGH revealed a 3.5 Mb microdeletion of chromosome region 3q26.32-3q26.33 (chr.3:178,598,162-182,114,483; hg19) which comprised the SOX2 gene. While SOX2 haploinsufficiency is known to cause microphthalmia and coloboma, it has not been described before in patients with anal atresia. Possible relations to the Notch and sonic hedgehog pathways will be evaluated.

CNV analysis in monozygotic twin pairs discordant for uro-rectal malformations

M. Draaken[1,2]*, F. Baudisch*[3]*, E. Bartels*[1]*, E. Schmiedeke*[4]*, S. Bagci*[5]*, P. Bartmann*[5]*, M. M. Nöthen*[1,2]*, M. Ludwig*[3]*, H. Reutter*[1,5]*;*
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Department of Genomics, Life & Brain Center, Bonn, Germany, [3]Department of Clinical Chemistry and Clinical Pharmacology, University of Bonn, Bonn, Germany, [4]Department of Paediatric Surgery and Urology, Centre for Child and Adolescent Health, Hospital Bremen-Mitte, Bremen, Germany, [5]Department of Neonatology, University of Bonn, Bonn, Germany.

Monozygotic (MZ) twins are expected to be identical for their genome and phenotype. A large number of reports on discordant MZ twin pairs suggest that this phenomenon might be explained by very early post-twinning mutational events. Uro-rectal malformations, especially anorectal malformations (ARM) and the bladder-exstrophy-epispadias complex (BEEC) occur mostly sporadic and are associated with reduced reproduction. We hypothesized that early post-twinning CNVs might contribute to the discordance in MZ twin pairs with ARM or the BEEC and this may help in identifying further chromosomal regions involved in the development of these malformations.
We investigated four discordant MZ twin pairs (3 ARM, 1 BEEC) using Illuminas' HumanOmni1-Quad Chip. CNVs were predicted using the program QuantiSNP (v2.2) that used an Objective-Bayes Hidden-Marcov model for the estimation. In order to identify possible disease causing de novo CNVs we searched for CNVs present (i) only in the affected twin but not in the unaffected twin or the parents and (ii) in both twins but not in their unaffected parents (resembling incomplete penetrance). The remaining CNVs from each patient were also filtered against an internal control cohort as well as publicly available databases.
After filtering no potentially causative CNV remained. Our results suggest that post-twinning CNV events in the human coding regions have not contributed to the discordant phenotypes in the investigated MZ twin pairs. Possible causes for the discordant phenotypes include changes in regulatory elements or smaller genetic changes within coding regions, which may be detectable with whole genome sequencing.

A sporadic Tunisian Apert syndrome case resulting of Pro253Arg mutation in fibroblast growth factor receptor 2

R. Louati[1]*, N. B. ABDELMOULA*[1]*, W. Ben Romdhane*[2]*, M. Zenker*[3]*, T. Rebai*[1]*;*
[1]Medical University, Sfax, Tunisia, [2]Regional Hospital, Gabes, Tunisia, [3]Institute of Human Genetics University Hospital Magdeburg, Magdeburg, Germany.

Unregulated fibroblast growth factor 2 (FGF2) signaling caused by mutations in the fibroblast growth factor receptor (FGFR2) leads to human craniosynostosis such as the Apert syndrome.
We report on a sporadic Tunisian Apert syndrome case for who the genetic evaluation revealed heterozygous C-G transversion in exon 7 of FGFR2 gene [dbSNP:rs77543610], resulting in a pro253-to-arg (P253R) gain-of-function substitution within a highly conserved linker region between the second and third extracellular immunoglobulin domains of the protein.
A 6-month-old girl, born of healthy distant consanginous parents, was referred for our genetic consultation because of severe cranial and limbs skull malformations, facial dysmorphic features and congenital heart defect (atrial septal defect). She died few months before diagnosis confirmation of Apert syndrome which was made in the basis of dysmorphic evaluation. In fact, the patient presented cranial skull malformations with brachycephaly, high and prominent forehead and a flat posterior cranium resulting from premature fusion or synostisis of bilateral coronal sutures demonstrated by radiography. Moreover, she had short neck, a concave face due to midfacial hypoplasia, short nose, low set ears and bulging and broadly spaced eyes. She had particularly the uncommon severe form of limbs abnormalities (rosebud hands and feet) with bilateral complex syndactly of hands and feet.
Molecular investigation of hot spot mutations by direct sequencing and detection of P253R mutation was helpful in confirmation of the diagnosis. Additionally, syndactyly in both the hands and the feet which was reported as more severe in patients with the P253R mutation was elucidated.

Acute lymphocytic leukaemia in a child with Beckwith-Wiedemann syndrome

I. M. Furquim[1]*, C. E. F. Andrade*[1]*, A. C. de Paula*[2]*, R. Guedes*[3]*, S. Epelman*[3]*, E. S. Ramos*[4]*;*
[1]Unidade de Genética - Hospital Santa Marcelina, São Paulo, Brazil, [2]Unidade de Genética - Hospital Municipal da Criança e Adolescente, Guarulhos, Brazil, [3]Unidade de Oncologia Pediatrica - Hospital Santa Marcelina, São Paulo, Brazil, [4]Departamento de Genética - FMRPUSP, Ribeirao Preto, Brazil.

Beckwith-Wiedemann syndrome (BWS) is a rare overgrowth syndrome associated with cancer predisposition. BWS is phenotypically variable, but it is usually recognisable at birth based on clinical features. It may include macrosomia, macroglossia, abdominal wall defects and visceromegaly. Between 2% and 30% of BWS patients (depending of the molecular anomaly identified) develop cancer, most commonly of embryologic origin.There has been three reports of BWS patients who develop acute leukemia, but little information about the molecular analysis was available for most of the patients. Herein we report the case of a 5-year-old female patient diagnosed with BWS who developed a B-type acute lymphoblastic leukaemia (ALL).

She is the first child of non consanguineous parents diagnosed with BWS during the neonatal period, after an unenventful pregnancy. Triad of macrosomia, posterior helical ear pits and macroglossia led to the diagnosis of BWS. Follow-up of this patient was carried out as recommended. At 5, she felt fatigue and suffered from shortness of breath. Upon physical examination she exhibited pale skin and hepatosplenomegaly. Laboratory studies were performed and the diagnosis of ALL was made. Cytogenetic analysis of peripheral blood was previously normal and further molecular testing to identify epigenetic and genomic alterations of chromosome 11p15 is being performed. Different genetic disorders, such as trisomy 21 and ataxia-telangiectasia, have been associated with ALL. Further investigation is necessary, but it is conceivable that a causal relationship exists between BWS and ALL.

J02.20

First familial case of inherited 2q37.3 deletion with isolated skeletal abnormalities including brachydactyly type E and short stature.

N. Jean-Marçais[1], *V. Ribault*[2], *M. Decamp*[1], *J. Andrieux*[3], *M. Gérard*[1], *M. Kottler*[1,4], *G. Plessis*[1];
[1]*Service de Génétique, Caen, France,* [2]*Endocrinologie Pédiatrique, Caen, France,* [3]*Laboratoire de Génétique Moléculaire, Lille, France,* [4]*UFR de Médecine, Caen, France.*

Albright hereditary osteodystrophy-like syndrome is also known as Brachydactyly-mental retardation syndrome (BDMR) (OMIM 60040). This complex disorder includes hypotonia, intellectual deficiency, seizures, sleep disturbances, obesity, short stature, craniofacial abnormalities and skeletal abnormalities including brachydactyly type E in approximately half of cases. Patients with 2q37 microdeletions or HDAC4 mutations are defined as having an AHO-like phenotype with normal stimulatory G (Gs) function. We report on the first family case of 2q37.3 deletion with brachydactyly E and short stature without intellectual deficiency. The proband is a 11 year-old female, the first child of healthy unrelated parents. She first consults at age of 8 for bilateral shortening of the IVth, Vth metacarpals and of the III, IV, V metatarsals. She had mild dysmorphic features, a normal psychomotor development. At the age of 11, she measures 131 cm (-1,8DS). Her father has similar dysmorphic features. He has normal intellect. His skeletal manifestations comprised bilateral shortening of the IV, Vth metacarpals and bilateral shortening of the III, IV, V metatarsals and relative short stature. The sisters, mother and grand-mother of the father have a short stature and brachymetarcarpy /brachymetatarsy. DNA microarray analysis revealed a small deletion at 2q37.3 inherited from proband's father. This deletion includes HDAC4, interrupted in intron 2 and TWIST2, MGC16025 included in HDAC4, FLJ43879 and the 3' telomeric part of LOC151171. To conclude, we suggest that haploinsufficiency of HDAC4 causes a variety of phenotypes going from isolated brachydactylie E to brachydactyly-mental retardation syndrome.

Carpenter syndrome, also known as 'acrocephalopolysyndactyly type II', is a rare autosomal recessive disorder characterized by multiple sutures craniosynostosis, preaxial polydactyly of the feet, post-axial polydactyly of the hands and soft-tissue syndactylies. Six different mutations in the *RAB23* gene have been identified in 21 patients from 16 independent families until now.

We report here the first prenatal description of Carpenter syndrome with a *RAB23* mutation. It was the fifth pregnancy of healthy consanguineous Turkish parents. Cystic hygroma and bowed femora were seen on ultrasound scan since 14-15 weeks of gestation. In addition, at 22 weeks a complex heart defect (double outlet right ventricle of Fallot type) was detected. At 28 weeks abnormal skull shape with irregular outlines and too easily visible brain structures, associated with bowing of the femora raised the question of osteogenesis imperfecta. This was reinforced by the fetal bone CT scan which showed the same skeletal anomalies and suggested a depressed fracture of the skull. However, physical examination and skeletal X-rays of the newborn patient lead to the diagnosis of Carpenter syndrome. Direct sequencing of the *RAB23* gene identified a novel homozygous frameshift mutation c.481G>C (p.Val161Leu).

This observation illustrates the difficulty of prenatal diagnosis of Carpenter syndrome. Tetralogy of Fallot and bowing of the femora are rare postnatal findings which were reported each in only one patient among the 21 cases of Carpenter syndrome with *RAB23* mutations. Carpenter syndrome should therefore be considered in case of abnormal skull shape with bowed femora, and cardiac defect.

Introduction

Chromosome abnormalities account for 50% of all spontaneous miscarriages and are present in 0,5-1% of all newborn infants. On an individual basis, most of these are very rare, but together they make a major contribution to human morbidity and mortality.

Material and Methods

Were cytogenetically investigated a total of 927 patients between the years 2010 - 2012 using G banding technique for identifying and characterizing the chromosomes of lymphocytes.

Results

We identified a total of 121 chromosomal aberrations (13%), of which 83 were number abnormalities (8.9%) and 38 were structural abnormalities (4.1%). Of the 38 structural abnormalities, 28 were autosomal chromosomal abnormalities. Changes in chromosome structure encountered were: different translocations-11 cases, deletions-7 cases, inversions-5 cases, 3 cases chromosomal polymorphisms and 2 cases of marker chromosomes.

Conclusions

Detection of structural chromosomal abnormalities is a key element for both correct etiologic diagnosis and genetic counseling. The results are comparable to those of similar studies.

CNVs and complex rearrangements: Investigation in patients with congenital anomalies and development delay

R. L. Dutra[1,2], *E. A. Zanardo*[1,2], *F. B. Piazzon*[1,2], *A. T. Dias*[1,2], *M. M. Montenegro*[1,2], *M. M. Basso*[1,2], *G. M. Novo-Filho*[1,2], *T. V. M. M. Costa*[1], *A. M. Nascimento*[1], *C. A. Kim*[2], *L. D. Kulikowski*[1,2];
[1]*Department of Pathology, Cytogenomics Lab/ LIM 03, HC-FMUSP, Sao Paulo, Brazil,* [2]*Genetics Unit, Department of Pediatrics/ LIM 36, HC-FMUSP, São Paulo, Brazil.*

Introduction: The genomic imbalances are the most common cause of miscarriage, congenital anomalies and developmental delay, however the etiology of these imbalances are not well understood, making difficult the counseling genetics and the treatment. In recent years the improvement of cytogenomics diagnostic techniques, such as the MLPA (Multiplex Ligation-dependent Probe Amplification) and the screening by arrays showed that changes in gene copy numbers (CNVs) influence the pathogenic variability of phenotypes in different syndromes. Patients and methods: Thus, the present studied the presence of CNVs in 278 patients with congenital anomalies and developmental delay, by MLPA technique using specific kits for microdeletions syndromes (P064) and subtelomeric regions (P036 e P070). Results: We identified changes in the gene copy numbers (CNVs) in 89/ 278 patients (32%), 49 patients (17.6%) by P064 kit and 40 patients (14.4%) by P036 and P070 kits. Complex rearrangements were observed in seven patients, including three patients with normal gene copy numbers interspaced with genomic duplications and/or deletions, confirmed by oligo-array technique (CytoScan™ Affymetrix®). Conclusion: Although array is the first-tier cytogenomic test for detection of CNVs, the MLPA technique can be used like an alternative screening test, mainly in the cases with multiple congenital anomalies and developmental delay. In addition, the recognition that the

human genome contains a large number of CNVs associated with the origin of chromosomal rearrangements improved our understanding of genetic variation and the genotype-phenotype correlation.

A coalescence of two syndromes in a girl with a terminal deletion and inverted duplication of chromosome 5

D. Krgović[1], *A. Blatnik*[1], *A. Burmas*[2], *A. Zagorac*[1], *N. Kokalj-Vokač*[1,3];
[1]*Laboratory of Medical Genetics, University Medical Centre Maribor, Maribor, Slovenia,* [2]*Pediatrics Clinics, University Medical Centre Maribor, Maribor, Slovenia,* [3]*Faculty of Medicine, University of Maribor, Maribor, Slovenia.*

Rearrangements involving chromosome 5p often result in two syndromes, Cri-du-chat (CdCS) and trisomy 5p, caused by a deletion and duplication, respectively. A cat-like cry is considered to be a hallmark observed in CdC patients. The 5p15.2 has been define as critical region of CdCS, however genotype-phenotype studies allowed isolation of particular characteristics such as speech delay, cat-like cry or mental retardation, caused by distinct deletions of 5p. A varius clinical outcome was also observed in patient with trisomy 5p. A duplication of 5p10-p13.1 manifest in more severe phenotype, while trisomy of regions distal to 5p13 mainly causes mild and indistinct features. Combination of terminal deletion and inverted duplication of 5p are infrequent in literature. Consequences of these chromosomal rearrangements differ, depending on size of deletion and duplication in particular cases, although authors mainly describe deletion as causative for clinical picture observed. Here we present a newborn girl with de novo terminal deletion and inverted duplication of chromosome 5p. Our patient presents a cat-like cry, characteristic of CdCS, but features like dolichocephaly, macrocephaly and ear malformations, observed in trisomy 5p, are also present. We assume that deletion will probably have minor impact in clinical outcome, involving just a region responsible for speech delay as described in CdCS. A duplication on contrary will probably result in more severe phenotype, especially considering that some characteristics are still not fully revealed. Interestingly, a cat-like cry was noted in our patient, despite the fact that deletion is not fully consistent with previously defined critical region.

Contribution of 7q33 deletion in a portuguese family with intellectual disability and multiple dysmorphic features

A. Fortuna[1], *M. Barbosa*[1], *F. Lopes*[2], *S. Sousa*[2], *C. Gomes*[2], *P. Maciel*[2];
[1]*Centro Genética Medica Jacinto Magalhães, Porto, Portugal,* [2]*Life and Health Research Institute,University of Minho, Braga, Portugal.*

Intellectual disability (ID) is one of the most frequent/ disabling neurological impairments in adolescents. aCGH in routine diagnostic may reveal undetermined genomic imbalances and ID associated genes.
A maternally inherited 7q33 deletion is reported (19-year-old male, mild ID, IQ= 53). Clinical evaluation: short stature, dysmorphisms (frontal cowlick-two whirlwind at forehead, spiky hair, bulbous/snub nose, downslanting palpebral fissures, epicanthic folds, deep-set eyes, bushy eyebrows, thin upper lip, poor dental implantation, narrow cleft palate, dysplastic ears and prognatism, aggressiveness and hyperactivity. His sister (IQ=62, short stature, facial dysmorphisms) has the same alteration. Their mother has mild MR and similar dysmorphisms.
The deletion was determined by aCGH analysis (human genome CGH Agilent 180K custom array, mean resolution of 17Kb) (Agilent, Santa Clara-CA). Confirmation studies and inheritance analysis were done by qPCR (fragment designed inside altered region).
aCGH revealed a 2Mb deletion (15 genes: *AGBL3, AKR1B1, AKR1B10, AKR1B15, BPGM, C7orf49, CALD1, CNOT4, EXOC4, LRGUK, NUP205, SLC35B4, STRA8, TMEM140, WDR91*) in 7q33. One of the most interesting deleted genes is the *CNOT4* (CCR4-NOT transcription factor complex, subunit 4) gene: *CNOT4* protein plays both positive and negative roles in transcriptional regulation and positive role in transcriptional elongation. In yeast, the ortholog of *CNOT4* (Not4) regulates the expression of Jhd2 (the yeast ortholog of *JARID1C*, for which mutations have been described in a X-linked ID patient). aCGH was essential for detecting this imbalance and this family's diagnosis. Comparison with similar cases, expression and functional studies may help us clarify the relevance of the deleted genes for ID.

Down Syndrome and the spectrum of associated malformations

G. S. Doros[1], *A. V. Popoiu*[1], *A. But*[2], *M. Gafencu*[1];
[1]*"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [2]*"Louis Turcanu" Emergency Children Hospital, Timisoara, Romania.*

Aim: To present the spectrum of associated malformations in Down syndrome patients from our clinic, the largest in the west part of Romania.
Material and methods: Between 2010-2012, a number of 29 patients confirmed with Down Syndrome, were admitted in our clinic. The age was between 1 mo and 15 yo. Sex ratio: 52% female, 48% male. 68 % were from urban area and 32% from rural. All of them performed clinical examination, lab tests, ECG, Echocardiography, abdominal ultrasound and selective cardiopulmonary X ray and angio CT.
Results: Congenital heart defect(CHD) was present in 75% of patients. Only 5 cases presented cyanotic CHD: 75% Fallot Tetralogy, 25% double outlet right ventricle. 24 cases presented noncyantic CHD: 39% atrial septal defect(ASD), 33% complex heart malformations, 22% ventricular septal defect(VSD), 6% complete atrioventricular canal defect. Two patients with heart defect associated renal malformations: unilateral hydronephrosis and ureteral hypoplasia or stenosis, severe in one case, due to gr. III/IV of hydronephrosis. The patient with severe hydronephrosis had to perform kidney surgery, prior to heart intervention. One case associated to heart malformation, congenital ectropion and cataract.
Conclusions:
In our group, ASD was dominant. Lower than in literature was VSD and atrioventricular canal defect. Severe renal malformation was discovered late in life and was a priority to surgery. Not all parents with Down Syndrome children are directed to a pediatric screening in the first year of life. To screen for malformations of all Down syndrome patients is mandatory at discharge from the newborn unit.

Down syndrome with Type 2 Abernethy malformation, porto-systemic shunt and hepato-pulmonary hypertension

R. Stroescu[1,2], *T. Bizerea*[1], *O. Marginean*[1,2], *G. Doros*[1,2];
[1]*Louis Turcanu Emergency Hospital for Children, Timisoara, Romania,* [2]*V. Babes Medicine and Pharmacology University, Timisoara, Romania.*

Introduction: The type II Abernethy malformation is an extremely rare abnormality of the splahnic venous system, where portal venous blood is diverted away from the liver through latero-lateral shunts. Associations between Abernethey malformation and portal aneurysm are rare; few cases have been described in the literature until now.
Material and Methods: To report a one month-old male, diagnosed with Down syndrome, who was admitted in our clinic for complex investigations, to detect associated pathology.
Results: Atrial septal defect (ASD), with platypnea and increased vascular markings on X ray were found. The ASD was too small to explain the increased pulmonary circulation. No pulmonary artery hypertension was found. Pulmonary artery and inferior vena cava were dilated. Additional investigations were performed: abdominal ultrasound and angio CT scan. Type II Abernethey malformation and portal vein aneurysm, with porto-systemic shunt were the diagnose that stated to produce hepato-pulmonary hypertension. The O2 Sat vary from orto to clino position.
Conclusions: It is the first case described in the literature of Down syndrome with congenital heart defect (ASD) associated with type 2 Abernethy malformation and portal aneurysm with porto-systemic shunt. Our patient is at high risk of developing hepato-pulmonary syndrome due to angiogenic factors from spleen, that bypass the liver, hepatic encephalopathy and long term metabolic complications due to liver dysfunction. He was addressed to the hepatic surgery department, to decide the closure of the porto-systemic shunt or to wait for hepatic transplant.

Ellis-Van Creveld syndrome with preauricular sinus: report of two Turkish female patients

M. S. Yildirim, *A. G. Zamani, E. Tuncez, A. Acar;*
Necmettin Erbakan University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey.

Ellis-Van Creveld(EVC) Syndrome(OMIM 225500) is a rare chondro-ectodermal dysplasia characterized by short ribs, polydactyly, growth retardation, ectodermal and heart defects. The birth prevalence in non-Amish population is estimated as 7/1,000,000. The phenotype is variable and is inherited in an autosomal recessive pattern with parental consanguinity has been reported in about 30% of cases. Mutations in EVC and EVC2 genes, located in a head-to-head configuration on chromosome 4p16, have been associated with this syndrome. We report two Turkish female patients with EVC syndrome born to consanguineous parents.

Patient 1: A 8-year-old female patient presented with short stature, short limbs, sparse hair, blue sclera, broad base to nose, simple philtrum, high palate, hypodontia, prominent and simple ears, pectus carinatum, increased lumbar lordosis, sacral dimple, lateral deviation of the toes, dysplastic nails. She has undergone surgical correction of postaxial polydactyly of all four limbs.

Patient 2: A 2-year-old female patient presented with short stature, short limbs, prominent occiput, sparse hair, epicanthus, depressed nasal bridge, high palate, short and deep philtrum, hypodontia, preauricular sinus and skin tag behind the right ear, deep plantar creases, hemangioma located on neck(2x0.5cm), dysplastic nails. She had a history of neonatal teeth and surgical correction of bilateral postaxial polydactyly of hands.

In conclusion, we present the first report, to our knowledge, of EVC syndrome with preauricular sinus in the literature and also discuss the variable expression, management and genetic counseling.

Interstitial dup(6)(q22.3q24) characterized by cCGH resulting from familial inv ins(6)(p11.2q25.3q22.3): case report

N. Oliva-Teles[1], *M. M. Ribeiro*[1], *B. Marques*[1], *H. Correia*[1], *J. Aires-Pereira*[2], *C. Dias*[1], *A. Fortuna*[1];
[1]*Centro de Genética Médica Jacinto Magalhães, INSA I.P, Porto, Portugal,* [2]*U. L. Saúde Matosinhos, EPE, Matosinhos, Portugal.*

We report on a female child aged 2 months, referred for complex cardiac anomalies and Down-*like* facial dysmorphisms, strongly suggesting a possible chromosomal abnormality. Chromosomal studies with high-resolution GTG banding showed an abnormal chromosome 6. The parents were investigated and their karyotypes revealed a normal chromosomal constitution in the father and an inv ins(6)(p11.2q25.3q22.3) in the mother; the latter was also present in the maternal grandmother, allowing us to conclude that the child's abnormality was a recombinant of the apparently balanced familial inverted insertion. Comparative genomic hybridization (cCGH) techniques proved that the abnormal chromosome 6 found in the proband has a duplication of the segment 6q22.3→6q24, with an extension of 24 Mb, resulting in the partial trisomy of that segment. The final karyotype of the child was thus: 46,XX,rec(6)dup(6q)inv ins(6)(p11.2q25.3q22.3)mat.ish cgh dup(6)(q22.3q24).

The patient's follow-up studies were only possible until she was 5 months and her main clinical features included dysmorphic facial features with plagiocephaly, membranous auricular and ventricular septal defects and developmental delay.

This is the first presentation of a "pure" interstitial duplication of bands 6q22.3 to 6q24. The authors enhance the importance of an adequate use of molecular cytogenetic techniques such as the use of oligonucleotide-based array-CGH in a clinical diagnostic laboratory for detecting subtle chromosome imbalances and accurately define the breakpoints in patients with atypical phenotypic characteristics, while assuring a good cost-efficiency diagnostic rate. The cytogenetic and clinical findings in this newly reported duplication are also compared with previously published similar data.

A Novel *MEK1* Mutation in a Patient with LEOPARD Syndrome

E. Nishi[1,2], *S. Mizuno*[3], *Y. Aoki*[4], *Y. Saito*[4], *Y. Fukushima*[5], *Y. Matsubara*[4], *T. Kosho*[5];
[1]*Division of Medical Genetics, Nagano Children's Hospital, Azunimo city, Japan,* [2]*Department of Medical Genetics, Shinshu University Graduate School of Medicine, Matsumoto, Japan,* [3]*Department of Pediatrics, Central Hospital, Aichi Human Service Center, Kasugai city, Japan,* [4]*Department of Medical Genetics, Tohoku University School of Medicine, Sendai, Japan,* [5]*Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan.*

LEOPARD syndrome (LS) is characterized by lentigines, ECG conduction abnormalities, ocular hypertelorism, pulmonary stenosis, abnormal genitalia, growth retardation, and sensorineural deafness. *PTPN11*, *RAF1,* and *BRAF* have been reported to be causal for LS [Digilio et al. 2002, Pandit et al. 2007, Sarkozy et al. 2009]. Here, we report a patient with LS who has been found to have a novel *MEK1* mutation. The patient, a Japanese 13-years-old boy, was born at 41 weeks and 4 days of gestation with the birth weight as 4350g. He showed hypotonia and sucked poorly in the neonatal period. His psychomotor development was delayed with DQ as 55 at age 19 months. Around the age 3 years, lentigines appeared on his face and limbs. He had flexion deformity of bilateral knees. His linear growth was retarded but showed spurt from age 9 years because of precocious puberty. When seen by us at age 10 years, he weighs 22.1kg (−1.5SD), height 130cm (−1.2SD), and OFC 51.8cm (−1SD). He had multiple lentigines, ocular hypertelorism, and sensorineural hearing impairment, but showed no ECG abnormalities or hypertrophic cardiomyopathy (HCM). He was clinically diagnosed as LS according to the criteria by Voron [1976]. Molecular investigation demonstrated a *de novo* heterozygous missense mutation in *MEK1* (c.305A>G; p.E103G). To date, heterozygous missense *MEK1* mutations have been reported in four patients clinically diagnosed as cardiofacialcutaneous (CFC) syndrome without HCM in all four and with nevi in one [Dentici et al. 2009]. Heterozygous missense *MEK1* mutations could cause phenotypic spectrum including CFC and LS.

Molecular findings of three different male under- virilization cases with 47, XXY karyotype.

K. Ulucan[1], *T. Akcay*[2], *M. Boyraz*[3], *N. Taskin*[4];
[1]*Üsküdar University, Faculty of Engineering and Natural Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey,* [2]*Dr. Sadi Konuk Education and Research Hospital, Department of Pediatric Endocrinology, Istanbul, Turkey,* [3]*Fatih University, Faculty of Medicine, Department of Pediatric Endocrinology, Ankara, Turkey,* [4]*Kanuni Sultan Süleyman Education and Research Hospital, Division of Pediatrics, Istanbul, Turkey.*

Introduction: Male under virilization is a rare condition mostly due to the mutations of hormone genes that effect male reproductive tract. One of the most important gene mutations that effect that pathway is the androgen receptor gene (AR) mutations, located at Xq12 in individuals with 46, XX. In this report, we present the *AR* and *SRD5A2* gene analysis of three different under- virilized patients with 47, XXY karyotype.

Materials and Methods: Chromosome analysis of the patients were assessed by standard lymphocyte karyotype, with Giemsa staining. PCRs were carried out by amplifying all the exons of related genes, and direct sequencing protocol was applied for mutation detection.

Results: One of the patients had no mutation in *AR* and *SRD5A2* genes, but had a 23 repeat polymorphism on exon 1 of AR gene. The second had no mutation in AR gene, had a 22 and 23 repeats polymorphism, but had a homozygous p.G196S mutation in *SRD5A2* gene. The third had a heterozygous mutation in p.F891L in *AR* gene, with a 16 and 21 repeat polymorphism, and had no mutation in *SRD5A2* gene.

Discussion: 47, XXY karyotype is a very rare condition in male virilization cases. Mutations in *AR* gene, in addition with *SRD5A2* gene, are thought to be the common reasons of this condition. According to our results, we suggest that not only the *AR* gene analysis, but also *SRD5A2* gene analysis and poly-Gln polymorphism of the exon 1 of *AR* gene have important impacts for the diagnosis of male under virilization.

Diagnostic pitfalls and mosaic unbalanced translocations: a case of 18q- deletion syndrome

V. Uliana[1], *R. Biancheri*[2], *L. Doria Lambda*[2], *A. Rossi*[3], *M. Severino*[3], *M. Malacarne*[4], *C. Marciano*[1], *G. Mandrile*[1], *F. Forzano*[1], *E. Di Maria*[1,5], *F. Faravelli*[1];
[1]*Division of Medical Genetics, Galliera Hospital, Genova, Italy,* [2]*Department of Neuroscience, Istituto G. Gaslini, Genova, Italy,* [3]*Pediatric Neuroradiology, Istituto G. Gaslini, Genova, Italy,* [4]*Laboratory of Genetics, Galliera Hospital, Genova, Italy,* [5]*Department of Health Sciences, University of Genova, Genova, Italy.*

We report a male patient with intellectual disability, club feet, growth hormone deficiency and diffuse white matter hypomyelination.

The patient was first seen at 4 years. On physical examination we noticed: height 91 cm (3-10° cnt), weight 14 kg (3-10° cnt); microcephaly (head circumference 47.5 cm, <3°cnt), brachycephaly, frontal bossing, blue sclerae, sparse eyebrows, deep-set eyes, mild strabismus, tented upper lip and single palmar crease were noted. Stereotypical behaviours and bruxism were present.
Due to neuroradiological and clinical findings, a deletion of the long arm of chromosome 18 was hypothesized, but karyotype and subtelomeres FISH analysis were normal.
The follow-up evaluation at 10 years of age confirmed the clinical signs and symptoms. Array-CGH analysis was then performed and showed two rearrangements: a 26 Mb deletion of 18q21.2q23 region (52258392-77982126; UCSC hg 19) and a 37 Mb duplication of 9p24.3p13.2 region (271257-37246576; UCSC hg 19). FISH analysis demonstrated a mosaicism involving two cell lines: one showing normal karyotype and one with an unbalanced autosomal translocation involving the short arm of chromosome 9 and the long arm of chromosome 18. Parental karyotype and subtelomeres FISH analysis were normal, indicating a de novo postzygotic rearrangement in the proband.
In this case a correct clinical diagnostic hypothesis had been ruled out by citogenetic testing and lately confirmed by means of Array-CGH.

Noonan-like Syndrome with Loose Anagen Hair in a Girl Presenting with Perinatal Distress and Coarctation of Aorta

M. Zmolikova[1], *A. Puchmajerova*[1], *P. Hecht*[2], *S. Pruhova*[3], *M. Trkova*[4], *A. Krepelova*[1];
[1]*Department of Biology and Medical Genetics, 2nd Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [2]*Pediatric Cardiocentre, Motol University Hospital, Prague, Czech Republic,* [3]*Department of Pediatrics, Endocrinology, 2nd Faculty of Medicine, Charles University in Prague and Motol University, Prague, Czech Republic,* [4]*Gennet, Prague, Czech Republic.*

Noonan syndrome belongs together with cardiofaciocutaneous, Costello, LEOPARD, neurofibromatosis type I, Legius and CBL-mutation associated syndrome into a group of developmental disorders termed RASopathies. These conditions are caused by germ line mutations in genes encoding for proteins involved in the RAS/MAPK signalling cascade and share many phenotypic features (facial dysmorphism, heart defects, short stature, developmental impairment and other anomalies). Previously, Noonan-like syndrome with loose anagen hair (NS/LAH) with facial features reminiscent of NS, reduced growth, neurocognitive impairment, cardiac anomalies and easily pluckable, slow growing, thin and sparse hair was described. Recently, a missense mutation c.4A>G in SHOC2 resulting in the Ser2Gly amino acid substitution in the encoded protein was documented. We report on a patient with molecularly confirmed NS/LAH exhibiting perinatal distress and coarctation of the aorta. The girl was rapidly born at 37 weeks gestation at home, 3-minute CPR must have been performed. Increased nuchal translucency and aortic coarctation with small VSD was described prenatally, hypertrophic cardiomyopathy and tricuspidal valve dysplasia were detected after delivery. The proband presented with facial dysmorphism typical of NS with very thin, sparse, slow growing hair, relative macrocephaly, redundant skin at the back and neck and abnormal sweating. Reduced growth, considerable dystrophic appearance and failure to thrive together with hypotonia and developmental delay mainly in motor milestones occured. Endocrinological evaluation revealed very low IGF-1 levels. To our knowledge, coarctation of the aorta has not been described in this condition yet, so we extend phenotypic spectrum of NS/LAH. Supported by the research organisation project 00064203.

Looking like Oculo-auriculo-vertebral spectrum, but different diagnosis - clinical study of two cases

C. Rusu[1], *I. Miron*[1], *M. Volosciuc*[2], *E. Braha*[1], *A. Sireteanu*[1], *L. Butnariu*[1], *D. Mihaila*[2], *C. Romanescu*[3];
[1]*University of Medicine and Pharmacy, Iasi, Romania,* [2]*Children's Hospital, Iasi, Romania,* [3]*Individual Medical Unit, Iasi, Romania.*

Epibulbar dermoids and preauricular tags are clinical features very suggestive for the diagnosis of Oculo-auriculo-vertebral (OAV) spectrum. However, associated features may change the final diagnosis. We present two cases that looked like OAV at the first glance, but received a different final diagnosis due to the associated features, to illustrate two rare disorders and to discuss particularities and patient management.
Case 1: 6 years old female, 5th child of a healthy, young, unrelated couple; pregnancy and birth uneventful; normal growth and psycho-motor development; physical examination revealed scalp defects and areas of different hair, cleft upper right eyelid, marked bilateral epibulbar dermoids and inverted nipples; normal spine radiography, cardiac investigations (ECG, echocardiography) and abdominal ultrasound scan. Diagnosis: Oculo-ectodermal syndrome;
Case 2: 8 years old female, raised in an institution (no family, pregnancy or birth history); moderate/severe growth and psychomotor retardation; physical examination revealed proportionate dwarfism, marked facial asymmetry, downslanting palpebral fissures, nasal tag, mouth deviated to the right, median upper alveolar incisure, asymmetric mandible, abnormal right ear, moderate/severe intellectual disability; spine radiography: cervical vertebral block; echocardiography: ASD; normal renal ultrasound. Diagnosis: Pai syndrome.
In conclusion, we present two cases that look like Oculo-auriculo-vertebral spectrum (but have a different diagnosis) in order to discuss differential diagnosis, but in the same time to present a comprehensive literature review, to illustrate two rare disorders and to discuss patient management.

J02.35
Case report: a novel mutation in *GJA1* gene in a family with oculodentodigital syndrome

A. Stembalska[1], *A. Sowińska*[2], *A. Jamsheer*[2];
[1]*Department of Genetics, Wroclaw Medical University, Wroclaw, Poland,* [2]*Chair and Department of Medical Genetics, Poznan University of Medical Sciences, Poznan, Poland.*

Introduction: Oculodentodigital syndrome is a rare, congenital autosomal dominant disorder that is characterized by abnormalities of the face, eyes, teeth, and limbs. The most common clinical findings include a thin nose, short palpebral fissures, type III syndactyly, and dental abnormalities including generalized microdontia and enamel hypoplasia. The syndrome is caused by *GJA1* mutations (6q22-q23), which encodes the gap junction protein connexin 43.
Clinical case: A two year old girl was referred for genetic evaluation because of short stature (3-10c), craniofacial dysmorphic features (dysplastic ears, microphtalmia, microcornea, palpebral fissure hypoplasia, epicanthal folds, thin nose, hypoplastic alae nasi with small nares, prominent columella, cleft soft palate, microdontia, enamel hypoplasia, fine and sparse hair) and syndactyly of third and fourth fingers of the right foot, syndactyly with camptodactyly of fourth and fifth fingers of the hands. Neither neurological symptoms nor congenital defects of internal organs were present in the girl. The same facial features and syndactyly of the fingers of the hands in 11 year old sister of the proband was observed. The mother of the girls presented similar facial features with additional unilateral decreased visual acuity and brachydactyly but not syndactyly.
Results: In three family members (mother and two daughters) a novel mutation c.G139C (p.D47H) in *GJA1* gene was detected.
Dissusion: Oculodentodigital syndrome is characterized by intra- and interfamilial phenotypic variability. The affected family members presented striking similar facial features, but variable skeletal manifestations. In prevention and treatment of the variety of clinical manifestations of oculodentodigital syndrome an early diagnosis is important.

J02.36
Severe Pitt-Hopkins-like syndrome caused by a pericentric inversion resulting in a 6.7 Mb loss at 18q21.2q21.32 and a deletion at 2q24.2

O. S. Kurinnaia[1,2,3], *S. G. Vorsanova*[1,2,3], *M. A. Zelenova*[2,3], *A. D. Kolotii*[1,2], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[1,2];
[1]*Institute of Paediatrics and Children Surgery, Ministry of Health, Moscow, Russian Federation,* [2]*Mental Health Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [3]*Moscow State University of Psychology and Education, Moscow, Russian Federation.*

Pitt-Hopkins syndrome (PHS) is caused by mutations in TCF4. Additionally, significant proportion of PHS cases occurs due to both submicroscopic and microscopically visible chromosome imbalances. Karyotyping of a girl with severe congenital malformations (renal, ocular and neurological abnormalities; scoliosis; anal atresia; microcephaly) and intellectual disability sho-

wing facial dismorphisms similar to PHS has suggested a rearrangement of chromosome 18. Molecular cytogenetic analysis by FISH has shown that a de novo inversion of chromosome 18, i.e. inv(18)(p11.2p21.3), has occurred. To gain further insights into genomic basis of the phenotypic outcome, we performed array CGH using NimleGen 135K oligonucleotide array. We have detected a 6.7 MB loss at 18q21.2q21.32 (50,396,511-57,063,895), which has resulted in a loss of 21 OMIM genes including TCF4. Therefore, a genomic basis for PHS-like phenotype was provided. However, some phenotypic features could not be attributed to this imbalance. We also detected a de novo 2 Mb deletion at 2q24.2 (160,185,503-162,242,742), which has resulted in a loss of 9 OMIM genes. Taking into account the phenotype observed in the index case and bioinformatic analysis performed for evaluation of clinical relevance of genomic rearrangements, we concluded that a cumulative effect of detected genome rearrangements is the most likely explanation of the phenotypic outcome. To our knowledge, this is the first chromosome 18 inversion associated with PHS-like syndrome. Our report demonstrates that array CGH with bioinformatic analysis allow the identification of intrinsic causes of clinical conditions regardless of their erroneously evident phenotypic manifestations.

The craniometric evaluation on a group of patients with Prader-Willi phenotype

D. Belengeanu[1], *N. Andreescu*[2], *M. Stoian*[2,3], *C. Bratu*[4], *A. Podariu*[5];
[1]*University of Medicine and Pharmacy "Victor Babes" of Timosoara, Department 1, Discipline of Oral Rehabilitation, College of Dental Technique, Timisoara, Romania,* [2]*University of Medicine and Pharmacy "Victor Babes" of Timosoara, Department of Morphologic Microscopy, Discipline of Genetics, Timisoara, Romania,* [3]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [4]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Department 2, Discipline of Pediatric Dentistry and Orthodontics, Timisoara, Romania,* [5]*University of Medicine and Pharmacy "Victor Babes" of Timosoara, Department 1, Discipline of Medical Dental Prevention and Oral Health, Timisoara, Romania.*

Through availability, facility as technique, craniometry is an investigation that allows evaluation, monitoring and description of the subject and three-dimensional quantification of craniofacial morphology. The aim of the study was to assess dynamic changes in morphometric analysis in a well defined Romanian group of subjects (26 patients aged 4 to 33 years old) presenting clinical signs for Prader-Willi syndrome.
For the study group were registered cephalic, facial and nasal heterogeneous-types and the craniometric typologies were studied within the 2 groups defined by genetic investigations, one with Prader-Willi syndrome (18 patients) and the other (8 patients) with varied etiopathogenic substratum, integrated as Prader-like.
Within the study group, the mesocephalic-pattern was the most frequent (36,46%), then dolichocephalic (26,92%) and brachycephalic (23,08%), only three hyperbrachicephalic cases (11,54%). Regarding the patients' ages in the study group, the dolichocephalic-pattern was specific in childhood. The euryprosope-type had the greatest incidence (50%), followed by leptoprosope-type (30,77%). As nose model, the 2 Caucasian-characteristic types, leptorrhine and mesorrhine, had comparable incidences 38,46%, respectively 34,61%.
For the patients with Prader-like phenotype, heterogeneous data was observed regarding cranial-type, facial-type and nose-type.
The mesocephalic pattern was the greatest within the Prader-group (55,56%) followed by dolichocephalic (27,78%), the brachycephalic-type being the lowest (16,67%). Regarding the patients' age, dolichocephalic-type was specific in children.
For the Prader-group, the greatest incidence of facial-type was euryprosope (50%). The increased frequency of facial euryprosope-type is correlated with the cephalometric parameters which, within this casuistry presented reduced size values of inferior-anterior facial floor and mandibular plane angle.

Mutational Spectrum of Smith-Lemli-Opitz Syndrome Patients in Hungary

K. Koczok[1], *G. P Szabó*[1], *K. Hadzsiev*[2], *G. Csábi*[2], *L. Balogh*[3], *E. Dzsudzsák*[1], *É. Ajzner*[4], *L. Szabó*[5], *V. Csákváry*[5], *A. V Oláh*[1], *I. Balogh*[1];
[1]*University of Debrecen, Debrecen, Hungary,* [2]*University of Pécs, Pécs, Hungary,* [3]*Semmelweis University, Budapest, Hungary,* [4]*Jósa András Teaching Hospital, Nyíregyháza, Hungary,* [5]*Markusovszky Hospital, Szombathely, Hungary.*

Smith-Lemli-Opitz (SLO) syndrome is an autosomal recessive disorder characterized by multiple congenital abnormalities and mental retardation. The disease is caused by the deficiency of 7-dehydrocholesterol reductase (DHCR7) which catalyzes the final step in cholesterol biosynthesis. The prevalence of SLO syndrome is between 1:20,000 and 1:40,000 among Caucasians. Although the mutational spectrum of the disease is wide, approximately 10 mutations are responsible for more than 80% of the cases. These mutations show a large interethnic variability. Diagnosis of SLO is based on the measurement of 7-dehydrocholesterol (7-DHC) in the patient serum and on the mutation analysis of DHCR7 gene. In order to establish the mutation distribution data from Hungary, thirteen patients were tested with suspected SLO syndrome in our laboratory. First, serum 7-DHC and total cholesterol were measured and molecular genetic analysis of the DHCR7 gene was performed. Complete genetic background of the disease could be identified in 12 cases. In 1 case only 1 mutation was detected in a heterozygote form. One patient was homozygous for the common splice site mutation c.964-1G>C, while all other patients were compound heterozygotes. One novel missense mutation, c.374A>G (p.Tyr125Cys) was identified.

Smith-Magenis syndrome in three infants with congenital heart defects

V. Antonenko[1], *Y. Kozlova*[1], *M. Minzhenkova*[1], *E. Shestopalova*[2], *Y. Kotalevskaya*[2], *O. Kislenko*[3], *N. Shilova*[1], *T. Zolotuhina*[1];
[1]*Research Centre for Medical Genetics, RAMS, Moscow, Russian Federation,* [2]*Moscow Region Research Clinical Institute, Moscow, Russian Federation,* [3]*Municipal Clinical Hospital 67, Moscow, Russian Federation.*

We report on clinical, cytogenetic and molecular-cytogenetic findings in 3 infant girls with Smith-Magenis syndrome (SMS). Case 1. The 19-day-old girl with the ventricular septal defect had displastic, low-set ears with the thick helixes; short nose; up-slanted palpebral fissures; prominent upper lip, long philtrum; micrognathia and short neck. At the age of 2 years she had a typical neurobehavioral pattern: sleep disturbance, self-injurious and aggressive behavior. Case 2. The 28-day-old girl with Tetralogy of Fallot had low-set ears; narrow palpebral fissures; long nose; micrognathia; long, thin fingers and clubfoot. Case 3. The 12-day-old premature girl with Tetralogy of Fallot; displasia of corpus callosum and congenital hydrocephaly had low-set ears with the displastic helixes; cleft of soft palate; narrow palpebral fissures; long nose and micrognathia. She had the respiratory distress and died on the 17th day of her life. The standard cytogenetic analyses revealed the interstitial deletion of chromosome 17p11.2 in all 3 patients, which was confirmed by FISH-analyses, karyotype: 46,XX,del(17)(p11.2p11.2).ish del(17)(p11.2p11.2)(RAI1-). Many features of SMS are subtle in infancy and become more recognizable with advancing age. This report represents new data in SMS manifestations which is significant for its clinical polymorphism exploration.

Clinical Findings of Stuve-Wiedemann Syndrome from Turkey: Case Report

S. Yalcintepe[1], *E. Simsek*[2];
[1]*Canakkale On Sekiz Mart University, School of Medicine, Department of Medical Genetics, Canakkale, Turkey,* [2]*Eskisehir Osmangazi University, School of Medicine, Department of Children's Health and Diseases, Endocrinology Clinic, Eskisehir, Turkey.*

Stuve-Wiedemann syndrome is a congenital bone dysplasia characterized by small stature, congenital bowing of the long bones and other skeletal anomalies and is inherited as an autosomal recessive trait. This syndrome is caused by mutations in the leukemia inhibitory factor receptor (LIFR) gene on chromosome 5p13. Patients present with serious complications including respiratory and feeding distress and recurrent episodes of unexplained hyperthermia. Survivors have progressive scoliosis due to severe spinal deformities, prominent joints, osteoporosis, and spontaneous fractures. We confirm that survival in this syndrome is possible and that the prognosis improves after the first year of life. This should be taken into consideration when counselling parents of affected children. We describe a 5-years-old-

female patient presented with the phenotypic and the radiographic features consistent with the diagnosis of Stuve-Wiedemann syndrome. She came us for growth retardation. She had also motor-mental retardation, short stature, severe scoliosis and bilateral cataract. Her parents had consanguineous marriage (mother 27-years-old and father 35-years-old) and she was one of their four daughters, her sisters were healthy. We report what might be the first clinical report of Stuve-Wiedemann syndrome from Turkey.

A genotype-phenotype correlation of two cases with terminal 4q deletion

M. Kugaudo[1,2], *M. Kucharczyk*[2], *A. Skorka*[2,3], *D. Gieruszczak-Bialek*[2,3], *A. Cieslikowska*[2], *M. Krajewska-Walasek*[2];
[1]*Department of Child and Adolescent Psychiatry, Medical University of Warsaw, Warsaw, Poland,* [2]*Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland,* [3]*Department of Pediatrics, Medical University of Warsaw, Warsaw, Poland.*

Deletion of the terminal region of the long arm of chromosome 4 is a rare, well-recognized syndrome. The patients' clinical findings include developmental delay, craniofacial, digital, skeletal and cardiac anomalies. Distinctive phenotype of distal 4q deletion depends on size of the deletion and ranges from only minor physical findings to more severe abnormalities. The 4q31-q34 region was suggested as a critical region for most of the features of clinical phenotype.
Hereby we present molecular and clinical findings of two patients with de novo distal deletion of chromosome 4q. The sizes of the deletions were estimated by aCGH which revealed a 25.92 Mb distal deletion in 4q32.3 in the first patient, whereas in the other one, apart from 37.92 Mb distal deletion in 4q31.3, also 1.45 Mb distal duplication of 6p25.3 was found.
Both of our patients apart from characteristic facial dysmorphism had digital stigmata typical of 4q deletion syndrome. Patient 1, who died at 4 months, had a complex cardiac defect. Besides two right, three left renal arteries and inguinal hernia were noted.
Patient 2, mildly mentally retarded, presented with delayed speech development and hearing loss diagnosed at 6 years. His height at 23 years of age was 182 cm. Inguinal hernia and bicuspid aortic valve were also noted.
We would like to present detailed genotype-phenotype correlation of two cases with terminal 4q deletion with review of the literature.
The study was supported by MNiSW Grant No.0605/B/P01/2009/37. Acquiring of the Roche NimbleGen microarray platform was co-financed by ERDF project POIG.02.01.00-14-059/09.

J02.42
Clinical and molecular cytogenetic characterization of two patients with a *de novo* trisomy 9p

V. Cejnova[1], *V. Harmas*[1], *D. Novotna*[2], *M. Wilimska*[1], *M. Stara*[1], *M. Soukupova*[1], *A. Klimova*[1], *J. Lastuvkova*[1];
[1]*Regional Health Corporation, Masaryk Hospital in Usti nad Labem, Department of Medical Genetics, Usti nad Labem, Czech Republic,* [2]*2nd Faculty of Medicine and University Hospital Motol, Charles University, Department of Biology and Medical Genetics, Prague, Czech Republic.*

Trisomy 9p is the fourth most frequent chromosome anomaly in liveborns after trisomy 21, 18 and 13. A possible explanation might be that these chromosomes as well as 9p are relatively gene poor. The first case of trisomy 9p was described in 1970 by Rethore *et al*. Since then, more than 150 patients with partial or complete trisomy 9p have been reported and this kind of chromosomal imbalance was characterized as a clinically recognizable syndrome.
The phenotype of the syndrome is characterized by variable degrees of mental retardation, mild downslanting of palpebral fissures, hypertelorism, prominent or bulbous nose, downturned corners of the mouth, hand-foot anomalies, and abnormal dermatoglyphic patterns.
We present two cases of a *de novo* trisomy 9p syndrome detected using G-banding, fluorescent *in situ* hybridization, spectral karyotyping, and microarray based comparative genomic hybridization (array CGH). The first case represent a 4-year-old girl with partial trisomy 9p with trisomic segments extending from 9p22 to 9p13. In second case we present a 15-month-old girl with duplication involving the whole short arm of chromosome 9. Using array CGH analysis we estimated the size of the duplication about 38.6 Mb. Clinical findings common to both cases were craniofacial dysmorphism, developmental delay, and hand-foot anomalies. The karyotypes of the girls´ parents were normal.
The spectrum of clinical severity in trisomy 9p roughly correlates with the extent of trisomic chromosome material. Previously reported phenotype genotype correlation studies proposed that the critical region for phenotype in trisomy 9p is located in 9p22.

V. Cejnova: None. **V. Harmas:** None. **D. Novotna:** None. **M. Wilimska:** None. **M. Stara:** None. **M. Soukupova:** None. **A. Klimova:** None. **J. Lastuvkova:** None.

J02.43
A case report of mosaicism in trisomy 8-Turner syndrome (45,X/47,XX,+8) in a patient with aortic dissection

M. Lee, *K. Choi, D. Kim, S. Lee, S. Kim;*
Samsung Medical Center, Seoul, Korea, Republic of.

Chromosomal aneuploidy is quite frequent and may involve either autosomes or sex chromosomes. While double aneuploidy involving both autosomal and sex chromosomes is rare, there are dozens of reported cases of sex chromosomal aneuploidies in combination with trisomy 21, such as Down-Klinefelter and Down-Turner syndrome. In contrast, trisomy 8-Turner syndrome has been rarely described to date. Here we report a case of a 28-year-old female with mosaicism in trisomy 8-Turner syndrome. The patient was referred to our hospital for operation of aortic dissection. On physical evaluation, her phenotype, including short stature, webbed neck and cubitus valgus, suggested congenital anomalies such as Turner syndrome. Chest CT showed aortic dissection with coarctation. Cytogenetic analysis of peripheral blood by G-banding revealed mosaicism with 2 cell lines (45,X[17]/47,XX,+8[33]). FISH analysis showed that 15% of the cells had monosomy X karyotype and 85% of the cells had XX karyotype; trisomy 8 was only detected in the XX cells. While the patient showed clinical features of Turner syndrome, such somatic stigmas are not clearly distinguishable from those of trisomy 8, such as short stature, skeletal and cardiac abnormalities. Most double aneuploidy cases showed that the patient's phenotype did not have a significant correlation to the ratio of autosomal and sex chromosomal aberrations. The patient deceased from septic shock 36 days after surgery. Mosaicism in trisomy 8-Turner syndrome has rarely been documented and we believe this is the first reported case of mosaicism in trisomy 8-Turner syndrome presenting with aortic dissection and surviving into adulthood.

J02.44
Three new Omani cases of Warburg micro syndrome with two different *RAB3GAP1* novel mutations

K. S. Al-Kharusi, *Z. Bruwer, A. Al Kindy, F. Al Murshedi;*
Sultan Qaboos University Hospital, Muscat, Oman.

Warburg Micro Syndrome is a rare autosomal recessive disorder in which less than 60 cases have been reported. The condition is characterised by ocular and neurodevelopmental findings including microophthalmia, microcornea, optic nerve atrophy, congenital cataract, microcephaly, corpus callosum hypoplasia, spastic quadriparesis, hypogenitalism and intellectual disability. We hereby report three new Omani cases from families of Arab origin. Although the families came from the same village, two different novel homozygous mutations were identified in the *RAB3GAP1* gene. The first patient is a four year old girl from a family with multiple loops of consanguinity. Clinical features include: bilateral congenital cataract, microcornea, microcephaly, deep-set eyes, prominent nasal bridge, overriding toes and spastic quadriparesis. Brain MRI had been reported as normal. The second patient is a 10-month-old baby boy from a non-consanguineous family. His main features were bilateral microphthalmia, microcornea, congenital cataract, microcephaly, deep-set eyes, bilateral cryptorchidism, overriding toes, and spasticity. Brain MRI revealed thin corpus callosum with mild increase in extra axial CSF spaces. Recently we identified a third patient who is a double cousin of the first patient. Diagnosis has been confirmed by full sequencing *of RAB3GAP1* gene. Two unreported mutations were identified [p.E83100 (c.2491G>T) and IVS 13-2 A>G (c.1235-2A>G)]. *RAB3GAP1* is a regulator for synaptic vesicle exocytosis with predominant brain expression. The finding of two different novel mutations from two families that are habituating the same geographical area was unexpected. Incidence of this syndrome may be underestimated in our area and other mechanisms like carrier selective advantage may be present.

Overgrowth and intellectual deficiency in a female with an 6,8 Mb Xp21-p22 duplication

M. Miguet[1], *Y. Alembik*[1], *V. Pelletier*[1], *E. Flori*[2], *V. Kremer*[2], *F. Girard-Lemaire*[2], *H. Dollfus*[1], *N. Calmels*[3];
[1]*Service de Génétique Médicale, Strasbourg, France,* [2]*Laboratoire de Cytogénétique, Strasbourg, France,* [3]*Laboratoire de Diagnostic Génétique, Strasbourg, France.*

We report on the case of a 29 year-old woman presenting moderate intellectual disability (ID) specially affecting language and an overgrowth phenotype (over 3 S.D.), macrocephaly and increasing overweight. At the endocrinal level, hirsutism was associated with type B insulin resistance. Coarse facial features, almond shaped eyes, bowed forehead, prognathism and multiple naevi were noticed. Axial hypotonia and hand tremor were observed during childhood. Many cases of diabetes in her family (paternal and maternal branches) are reported.
A *de novo* interstitial duplication of 6.8 Mb in the chromosomal region Xp22.11p21.2 was discovered using the Affymetrix CytoScan HD SNP array. Furthermore, no skewed X chromosome inactivation was found.
This duplication, involving the *ARX* and *IL1RAPL1* genes, is well known to be associated with intellectual disability (1). Both male and female patients have been reported with a huge expression variability.
Our observation extends the clinical spectrum of the Xp21-p22 duplication syndrome to overgrowth and endocrine manifestations.

A Complex Phenotype-Patient with de novo 16q21-q24.3 Duplication and 15q11.1-q11.2 Deletion

H. Gurkan[1], ***H. Tozkır***[1], *Ü. Vatansever-Ozbek*[2], *G. Sarı*[1], *M. Yazar*[1];
[1]*Trakya University, Medical Faculty, Department of Medical Genetics, Edirne, Turkey,* [2]*Trakya University, Medical Faculty, Department of Pediatrics, Edirne, Turkey.*

Duplication of the entire long arm of chromosome 16 causes a malformation syndrome with early postnatal lethality, a phenotype resembling trisomy 18. In 18.03.2011, the boy was born with vaginal delivery at 34th weeks of gestation.Broad and flat nasal bridge, telecanthus, hypertelorism, long eyelashes, optical ocular coloboma and ptosis in the right eye, bilateral low-set ears, hearing test is negative in both ears, preauricular pit on the left ear, long philtrum, frenulum of the tongue is short, no high-arched palate, micrognathia, inguinal hernia, bilateral ureteropelvic obstruction. *Transthoracic Echocardiography*: Partial anomalous pulmonary venous turn, right ventricular dilatation, mild pulmonary hypertension. *Cranial MRI:* Hypoplasia of the corpus callosum. *Cranial BT:* Bifrontal subarachnoid benign enlargement. **Laboratory Findings:** G-banding and high-resolution chromosome analysis showed **46,XY,16q+.** Karyotypes of his parents are **46,XY and 46,XX,16qh+**. Spectral karyotyping analysis elicited that extra-chromosomal structure observed in chromosomal analysis originated from chromosome 16. 2,407,775 bp heterozygous deletion on 15q11.1-q11.2 region and 25,832,063 bp heterozygote duplication on 16q21-q24.3 region were detected and also partial trisomy of 16q21-q24.3 was showed with aCGH analysis.15q11.1-q11.2 is reported as the classic PWS / AS deletion is flanked by either of the proximal BP1-BP2 region spans approximately 500 kb and contains four evolutionarily conserved genes (NIPA1, NIPA2, CYFIP1, and TUBGCP5) that are not imprinted in previous studies. Based on the literature data, intermediate-distal 16q duplications are assosiated with growth retardation, developmental, mental and speech delay, learning difficulties, behavioral problems, dysmorphic facial features, congenital anomalies in skeletal, genitourinary, and central nervous system and epilepsy.

22q13.3 deletion syndrome in a newborn with ring chromosome 22 presenting with congenital hypotonia

D. Begovic, *S. Huljev Frković, R. Lasan Trčić, J. Stipanović Kastelić, L. Letica, M. Šalamon Janečić;*
Medical School University of Zagreb, Department of pediatrics, 10000 Zagreb, Croatia.

The 22q13.3 deletion syndrome or Phelan-McDermid syndrome is characterized by neonatal hypotonia, global developmental delay, absent to severely delayed speech, normal to accelerated growth with minor dismorphic features such as dolichocephaly, large or unusual ears, long eye lashes, bulbous nose, pointed chin, large hands and dysplastic toe nails. Most individuals have moderate to profound intellectual disability with autistic like behaviour and decreased pain perception. Frequency of the syndrome is equal in males and females while incidence is still unknown. Beside the simple deletion, loss of 22q13.3 can also result from translocation, ring chromosome formation and other less common structural changes affecting the region containing SHANK3 gene on long arm of chromosome 22. The most features of the syndrome thought to be the consequence of loss that specific gene.
We present a case of female newborn with Phelan-McDermid syndrome. The child was born on term, from first, uncomplicated pregnancy with unremarkable family history. She was initially treated in NICU because of early neonatal infection. Because of congenital hypotonia with mild facial dysmorphic features genetic analysis were performed. The karyotype revealed ring chromosome (22): 46,XX,r(22)(p12q13.3). A fluorescent in situ hybridisation analysis was performed, indicating that the deletion encompassed the critical 22q13.3 region. After good clinical evaluation, congenital hypotonia especially with dysmorphic features may be the only indication for genetic evaluation, so we suggest importance of genetic review in cases like this.

Introduction: genomic imbalances cause a significant proportion of MR/MCA syndromes; array-CGH has uncovered many rare imbalances associated with MR/MCA. We report a patient with a deletion in chromosome 2q11.2-12.2 and review patients with similar anomalies.
Clinical case: female, second child of non-consanguineous couple; mother had learning difficulties, healthy older. Neonatal asphyxia occurred with good recovery. She had global developmental delay with hypotonia, behavior problems (hyperactivity, aggression, tantrums), growth retardation, macrocephaly, facial dysmorphisms and no major malformations or other health problems.
Molecular analysis (aCGH): genomic DNA was extracted from blood using the Citogene® DNA isolation kit (Citomed, Portugal). The aCGH analysis was performed on a human genome CGH Agilent 180K custom array (AMADID: 023363) designed by Dr. Klass Kok for use in the Low Lands Consortium. Hybridization and image analysis were performed using the across-array methodology described previously (Buffart T et al, 2008). aCGH data was analyzed using Nexus Copy Number 5.0 software with FASST Segmentation algorithm and a minimum of three probes in a region required to be considered an copy number alteration.
Molecular analysis (qPCR): the qPCR fragments were designed in exon 1 for the GPR45 gene. qPCR run was carried out in a 7500 FAST equipment (Applied Biosystems) and relative quantification analysis was performed using Data Assist™ Software (Applied Biosystems).
Discussion: genomic analysis is a powerful tool to uncover imbalances associated with developmental problems; detailed description of phenotypes associated with those imbalances allows clinicians to more accurately and rapidly make diagnosis and correctly interpret results obtained with array-CGH

Novel NHS gene mutation in a Turkish family with Nance-Horan syndrome

F. E. Percin[1], *E. Tug*[1], *N. F. Dilek*[1], *S. Javadiyan*[2], *K. P. Burdon*[2];
[1]*Medical Genetics, Ankara, Turkey,* [2]*Flinders University Department of Ophthalmology, Adelaide, Australia.*

Nance-Horan syndrome (NHS) is a rare X-linked syndrome characterized by congenital cataract which leads to profound vision loss, characteristic dysmorphic features and specific dental anomalies. Microcornea, microphthalmia and mild or moderate mental retardation may accompany these features. Heterozygous females often manifest similarly but with less severe features than affected males. We describe two brothers who have the NHS phenotype and their carrier mother who had microcornea but not cataract. We identified a previously unreported frameshift mutation (c.558insA) in

exon 1 of the NHS gene in these patients and their mother which is predicted to result in the incorporation of 11 aberrant amino acids prior to a stop codon (p.E186Efs11X). We also discussed genotype phenotype correlation according to relevant literature.

Chromosome markers charazterization by Array-CGH. Case report.

***M. Perez Sanchez**, A. Mora., J. L. Barrionuevo, A. R. González.;*
Servicio Andaluz de Salud (SAS)., Granada, Spain.

Microarray-based comparative genomic hybridation (array CGH) has provide a relatively quick method to scan the genome for gains and loses of chromosomal material with significantly higher resolution and greater clinical yield than was previously possible. This new methodologies have led to identification of genomic material from chromosome marker detected by karyotyping and determine the possible pathological effect on patients.
A ten years old girl who was noticed to have growth and psicomotor delay, microcephaly and dismorfic features was referred for genetics studies. She was the third baby born to a healthy non-consanguineos couple. The examination findings were: small frontal, hypertelorism, flat nasal bridge, peripheral mild hypotonic, microcephaly and growth and psicomotor delay.
Chromosome culture and karyotyping were realized by standard thecnics. The array-CGH was performed at NimbleGen CGX Cytogenetics Microarrays Platform.
The karyotype result was 47,XX + mar (47 %); 48,XX + mar + mar (53 %) and then the array-CGX for chromosome marker genomic material detection was performed.
The array-CGX detected a pericentric duplication of 7,47 Mb with 22 genes implicated on chromosome 8.
With this results is possible to think that the second chromosome marker detected en part of the metaphases is a duplication del original marker, and the presence of this marker can be de responsible for the patient pathology. Previously a girl with similar pathology and with a chromosome marker also originated on pericentic region of chromosome 8 has been described.
As a conclusion, array CGH actually is the election method for chromosome marker genomic characterization.

J02.51
Currarino syndrome with a terminal deletion of long arm of chromosome 7 (7q)

***J. Lanneaux**, A. Lavillaureix, J. Fabre-Teste, J. Masliah-Planchon, C. Dupont, S. Passemard, S. Drunat, A. Tabet, A. Verloes;*
Department of Genetics and INSERM U676, Robert Debre hospital, PARIS, France.

We describe a 7q terminal deletion in a 15 year-old girl with partial Currarino syndrome, born to non consanguineous parents from Mali.
Fetal karyotype, prompted by detection of microcephaly and IUGR detected with second trimester echography revealed a 7q deletion. At birth at 41 GW, head circumference was 29cm (-5 SD), weight was 2500g (-2SD), length 42,5 cm (<-3SD). Pregnancy was normal (no drug nor alcohol). She stayed 2 months in neonatology and required feeding by naso-gastric tube. She was lost to follow up afterwards till 14 year-old. The anomaly was recently reassessed by SNP array.
The patient had moderate developmental delay, she started walking at 27 month-old, she is toilet trained during the day. She makes simple sentences. She has followed special schooling until 14 year-old, but remained unable to read or write.
At the last assessment, at age age 15, OFC was 46cm (-6SD), weight 31kg (-3,5SD), and length 137cm (-3,5DS). She has scoliosis, short fifth metacarpals, and no sign of puberty. She has facial dysmorphism with prognathism. Echocardiography was normal, MRI revealed a small brain with normal gyration. She had coccyx and sacral defects (S3-5), tethered spinal cord and presacral mass (13x10mm), but no anorectal malformation. Neurosurgical consultation is pending.
The malformations of this patient are explained by HLXB9 haploinsufficiency: Currarino syndrome is an autosomal dominant disorder with reduced penetrance. Mutations in a homeobox gene, HLXB9, localised in 7q36, were identified in several affected patients.DI and microcephaly are caused by deletion of other genes within 7q36 region.

A Case of dup(3q) Syndrome

***A. Koc**[1], O. Ozer[1], A. Yilmaz Ekmekci[2];*
[1]Tepecik Training and Research Hospital, Izmir, Turkey, [2]Gentest Laboratories, Izmir, Turkey.

Duplication of 3q is an extremely rare disorder characterized by "mental retardation, deficiency of growth, broad nasal root and hypertrichosis". Which had similar clinical findings with Cornelia de Lange syndrome. Although it is generally accepted that the duplication of the 3q25-qter region is sufficient to generate characteristic face, there is a debate about critical region. An interesting point of view, the dup(3q) cases also had additional chromosomal anomalies as in our presented case. The patient had copy gain at 21q22.12 (partial trisomy of Down syndrome critical region). In this report, we present the clinical and molecular findings of a case with dup(3q) syndrome.

A. Koc: None. **O. Ozer:** None. **A. Yilmaz Ekmekci:** None.

J02.53
A case report of newborn girl with interstitial deletion of chromosome 1: del(1)(p22;p31)

***S. D. Teofilova**, M. Bulatovic, T. Ostojic, O. Miljanovic;*
Clinical Center of Montenegro, Podgorica, Montenegro.

An interstitial deletion means that the chromosome had broken in two places and the broken ends fused, leaving out the deleted segment. We report a case of newborn girl with interstitial deletion of the short arm of chromosome 1. Given the newborn's dysmorphic appearance, cytogenetic analyses were indicated for the baby girl and her parents. Karyotype was analyzed from cultured peripheral blood lymphocytes, using G-banding method. Parental chromosome analysis showed a normal chromosome constitution with normal banding patterns, while karyotype of the newborn revealed "de novo" interstitial deletion of the short arm of chromosome 1, with deleted segment: p22 - p31. No pregnancy or delivery problems have been reported. A female newborn was born at term, and birth measures were within normal range. Specific dysmorfic features were present at birth: dolychocephaly, low forehead and neck hairline, prominent eyebrows, broad nasal bridge, down slant eyelids and narrow eye opening, microphtalmia, cataract, anteversion of nostrils, macrostoma, high-arched plate, micrognathia, short neck, overlapping fingers and toes. No internal system/organ major anomaly was found. Contrary to the fact that this deletion is reported with incidence approximately 1:5000 liveborns, this was the single one diagnosed in our centre, which is the only laboratory that conducted cytogenetic diagnostics in Montenegro since 2000 (approximately 8000 liveborns per year).

S.D. Teofilova: None. **M. Bulatovic:** None. **T. Ostojic:** None. **O. Miljanovic:** None.

Ring chromosome 6 in an infant with multiple congenital anomalies

***B. Burnyte**[1,2], G. Brusokiene[3], Ž. Čiuladaite[1,2], N. Drazdiene[3], A. Utkus[1,2];*
[1]Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, [2]Centre for Medical Genetics, Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania, [3]Centre of Neonatology, Childrens Hospital, Affiliate of Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania.

Ring chromosome 6 has been reported in the literature as a clinically recognizable syndrome, which occurs rarely and manifests as various phenotypes. We present clinical and cytogenetic findings on a four-week-old female infant.
The girl was born of a second pregnancy to a 23 year-old mother at 39 gestation week by vaginal delivery. The couple had previously had one first trimester spontaneous pregnancy loss. Birth weight was 3550 g (50% centile), height 50 cm (25% centile); head circumference was 31 cm (<3% centile). At the immediate neonatal period, she failed at all attempts to breastfeed and required a nasogastric feeding tube. Dysmorphic findings on clinical genetics evaluation showed ocular hypertelorism, flat nasal bridge with anteverted nares, short grooved philtrum, open triangular-shaped mouth, high arched palate, bifid tongue, retrognathia, large low-set ears, short neck, widely spaced nipples, tapering fingers, camptodactyly of the left 5th finger and overlapping toes. Hirsutism was presented on the back, upper arms and lower legs. She had ectopic vaginal anus with stenosis and congenital bilateral hip dislocation. An echocardiogram revealed a moderate patent ductus arteriosus and secondary atrial septal defect. Ophthalmologic examination

has revealed bilateral chorioretinitis. Hearing screening was negative. High resolution chromosome analysis revealed a ring chromosome 6, designated by the karyotype, 46,XX,r(6)(p23q27). Parental chromosome analyses were normal.
Comparison with the previously reported cases of ring chromosome 6 illustrates the phenotypic variability of this syndrome. To our knowledge anorectal malformations have not been previously reported. Further investigation is needed to ascertain the genes that were deleted.

Saethre-Chotzen syndrome with unusual cranial features and intrafamilial phenotypic variability.

A. Poluha[1], *A. Sobczyńska-Tomaszewska*[2], *I. Jaszczuk*[1], *D. Winnicka*[3], *M. Lejman*[3], *B. Styka*[3], *M. Babicz*[3], *J. R. Kowalczyk*[4];
[1]*Division of Medical Genetics, Childrens University Hospital, Lublin, Poland,* [2]*Medgen, Warsaw, Poland,* [3]*Cytogenetic Laboratory, Department of Pediatric Hematology, Oncology and Stem Cell Transplantation Childrens University Hospital, Lublin, Poland,* [4]*Department of Pediatric Hematology, Oncology and Stem Cell Transplantation Childrens University Hospital, Lublin, Poland.*

Saethre-Chotzen Syndrome (SCS; OMIM #101400) is a dominantly inherited disorder characterized by broad spectrum of dysmorphic features: craniosynostosis, facial asymmetry, ptosis, partial cutaneous 2 / 3 syndactyly and prominent pineal crura. Less common manifestations include short stature, ocular hypertelorism parietal foramina and hearing loss.
SCS is caused by mutation in TWIST1 gene leading to haploinsufficiency of the protein product, Twist-related protein 1. In some cases there is an underlying chromosomal aberration involving 7p21.
We report on a four generation family with 6 members affected with Saethre Chotzen syndrome presenting with significant intrafamilial phenotypic variability. Our proband, the youngest affected individual in a family, has been evaluated in neonatal period by medical geneticist because of dysmorphic features: facial asymmetry, high forehead, bilateral ptosis, symmetrical prominent ear crus, broad haluces and significantly dilated parietal foramina. Examination of the mother revealed similar dysmorphic features with additional partial cutaneous 2 and 3 syndactyly. She also reported the presence of unusual cranial feature in infancy: asymmetric "lack" of frontal bones. She has been unaware of dysmorhic features being the part of inherited disorder. Detailed family history identified 4 more individuals with similar phenotypic expression. The unusual frontal bone malformations were present in all of them with a varied degree.
The clinical diagnosis of Saethre-Chotzen syndrome has been confirmed by sequence analysis of TWIST1 leading to identification of mutation c.421dup21.
This report underlines the intrafamilial phenotypic variability and adds an unusual feature: frontal bone anomaly to the broad spectrum of phenotypic expression in Saethre-Chotzen syndrome.

A patient with SMC(22) due to the maternal translocation t(16;22)) (p13.1;q11.2)

M. Y. Alp[1,2], *T. Tos*[3], *N. Okumus*[4];
[1]*Department of Medical Genetics, Medical Faculty, Karadeniz Technical University, Trabzon, Turkey,* [2]*Department of Medical Genetics, SB Ali Osman Sönmez Oncology Hospital, Bursa, Turkey,* [3]*Department of Medical Genetics, SB Sami Ulus Women's and Children Hospital, Ankara, Turkey,* [4]*Department of Pediatrics, SB Sami Ulus Women's and Children Hospital, Ankara, Turkey.*

Partial trisomy 16p is a rare chromosomal abnormality, associated with microcephaly, distinct facial features, psychomotor and growth retardation. 22pter-q11 trsisomy or tetrasomy, cat eye syndrome, is characterised with mild mental retardation, ocular coloboma, cardiac, kidney, and skeletal malformations. Our patient, 1 months old girl, refered to the department of medical genetics because of congenital heart defects. She was born via spontaneous vaginal way at a gestational age of 36. She required neonatal intensive care for 35 days. She has microcephaly, microretrognati, dysplastic low set ears, pitosis, wide spaced nipples. Echocardiografic examination revealed ASD, VSD, and pulmoner hypertension. Cytogenetic analysis from patient's peripheral blood showed a supernumerary derivative chromosome 22. FISH analysis confirmed partial trisomy 22q11. The chromosome analyses of father was normal. Mother has balanced translocations between chromosome 16 and 22 [46,XX,t(16;22)(p13.1;q11.2)]. We decided that supernumerary der(22) is originated from mother's balanced translocation, t(16;22), due to the error in maternal meiosis and yielding partial trisomy 16p13.1-pter and partial trisomy 22pter-q11.2.

A recurrent mutation of TCOF1 gene in a Moroccan patient with Treacher-Collins syndrome: report of a new case and review

A. Lamzouri[1,2], *I. Ratbi*[1], *S. Chafai Elalaoui*[2], *C. Collet*[3], *I. Turquois*[3], *A. Sefiani*[1,2];
[1]*Centre de génomique humaine, Faculté de médecine et pharmacie, Université Mohammed V Souissi, Rabat, Morocco,* [2]*Département de génétique médicale, Institut National d'Hygiène, Rabat, Morocco,* [3]*UF de génétique moléculaire, CHU Paris-GH St Louis Lariboisière F.Widal, Hôpital Lariboisière, Paris, France.*

Treacher Collins syndrome (TCS, OMIM # 154500) also known as mandibulofacial dysostosis and Franceschetti-Zwahlen-Klein syndrome is a rare congenital disorder of craniofacial morphogenesis, its prevalence ***is*** 6 per 100000 persons. Most TCS is inherited in an autosomal dominant manner, a small portion (~1%) is inherited in an autosomal recessive manner. Typical cases of TCS are ***characterized by*** four ***major clinical manifestations,*** hypoplasia of the zygomatic bones and mandible, external ear abnormalities, lower eyelid abnormalities and family history consistent with autosomal dominant inheritance. Mutation of one of three genes is known to be causative, *TCOF1* (78%-93% of individuals with TCS) and *POLR1C* or *POLR1D* (8%). The TCOF1 gene located at ***5q32-q33.1*** encodes a nucleolar phosphoprotein known as Treacle, which is an important spatiotemporal regulator of ribosome biogenesis. More than 130 disease-causing mutations in *TCOF1* have been documented in individuals with TCS, only one mutation c. 4369_4373delAAGAA, p.Lys1457GlufsX12, has been identified as commonly recurrent; it is present in 16% of individuals with an identifiable mutation. Mutations in *TCOF1* lead to treacle haploinsufficiency which disrupts neural crest cell formation and proliferation, causing the hypoplasia characteristic of TCS craniofacial anomalies.
We report here a 7-year-old Moroccan boy with typical features of TCS. The molecular studies showed the recurrent homozygous mutation at c. 4369_4373delAAGAA of *TCOF1* gene.

A. Lamzouri: None. **I. Ratbi:** None. **S. Chafai Elalaoui:** None. **C. Collet:** None. **I. Turquois:** None. **A. Sefiani:** None.

J02.58

A unique case of intrachromosomal triplication of 2q13q21.1 and contiguous small duplication in a 13 years old boy

K. T. ABE*, M. F. Pereira, D. R. Carvalho, M. Schneider, L. L. Roese, L. M. Formigli, M. V. Oliveira, N. Sakai Jr, A. V. Coelho, I. M. P. O. Rizzo, C. Speck-Martins;*
SARAH Network of Rehabilitation Hospitals, Brasília - DF, Brazil., BRASILIA - DF, Brazil.

Cytogenetically visible intrachromosomal triplication producing partial tetrasomies are rare and have been reported for few different chromosomes. Regarding to proximal 2q intrachromosomal triplication, only three cases have previously been described. Two of them with more proximal 2q triplication did not survive. The third with a smaller triplication segment was an infertile 33-year-old female. The chromosomal breakpoints with duplication or triplication of proximal 2q are varied, as well as the clinical features. We describe a 13-year-old boy with mild intellectual disability and dysmorphic craniofacial features with a large face, deep set eyes, small nose, prominent cheeks and retracted malar region, prognathism, webbed neck and posterior low hairline. Cleft palate and bilateral cryptorchidism were surgically corrected; diabetes mellitus was diagnosed at 6-year-old and renal failure at 10-year-old. The karyotype was 46,XY,trp(2)(q13q21.1) and arrayCGH analysis (Affymetrix CytoScan HD microarray) showed a complex rearrangements consisting of triplication at 2q13q21.1 (minimum of 20,207 kbp) and duplication at 2q21.1 (minimum of 2,759 kbp). Some genes within this region as *NPH1* and *IL1* could play role to patient´s features. Mutations in the *NPH1* have been related to most patients with juvenile nephronophthisis, however our patient presenting triplication shows similar effect to loss of gene function. Polymorphisms in *IL1* were associated with diabetic nephropathy and it may play role in the patient´s deterioration of renal function. To our knowledge, the present patient has the biggest triplication 2q proximal segment, and he is alive once the triplication of this region is not as harmful to vital functions.

A case of de novo deletion 9q33

T. Tos[1], *M. Y. Alp*[2,3], *N. Andıran*[4], *E. Yağlı*[4];
[1]*Department of Medical Genetics, SB Sami Ulus Women's and Children Hospital, Ankara, Turkey,* [2]*Department of Medical Genetics, Medical Faculty, Karadeniz Technical University, Trabzon, Turkey,* [3]*Department of Medical Genetics, SB Ali Osman Sönmez Oncology Hospital, Bursa, Turkey,* [4]*Division of Pediatric Endocrinology, SB Keçiöğren Training and Research Hospital, Ankara, Turkey.*

Partial deletions of 9q are associated with mental retardation, distinct facial features, developmental delay and congenital heart defects. Common deletions involving 9q are subtelomeric deletions of 9q34. Terminal deletion 9q33 is very rare.We report a 10 years old girl with de novo partial deletion 9q33. She referred to the department of medical genetics because of mental retardation and developmental delay. She has short stature (<3th percentile), delayed developmental milestones, bushy eyebrows, thick lips, and simian variant in left hand. She is also suffering from epilepsy. MRI findings revealed cortical dysplasia localised to the left temporal lobe. Cytogenetics analysis from peripheral blood showed distal partial deletion of the long arm of chromosome 9. Parental karyotype examinations were normal.

Newborn with agenesis of right lower limb and right renal agenesis case presentation

D. Iacob, *M. Boia, A. Manea, R. Iacob;*
Timisoara University of Medicine and Pharmacy, Timisoara, Romania.

I will present the case of a female newborn from a monitored pregnancy, gestational age=41 weeks, birth weight=2600gr, Apgar score=5; her father, suffering from chronic renal failure, is enrolled in a dialysis programme. According to anamnesis no teratogen factors that could act during pregnancy are revealed.
At hospital admission she has poor health status general health status, dysmorphic skull, cardiopulmonary functions within normal limits, systolic breath grade III/VI, agenesis of right lower limb - absence of thigh and shank, abnormal foot size that is attached to the hip through a cord.
Radiography of lower limbs shows the absence of right lower limb bones, while the radiography of lumbosacral head shows no structural changes.
Ultrasonography of the heart indicates tricuspid insufficiency grade I. Abdominal ultrasonography: normal structure liver, left kidney in the renal lodge.
CT scan with contrast substance has been performed, revealing right hemiabdomen and pelvis reduced in size and hypoplastic.
Right kidney is evidenced neither in the right renal lodge, nor in other abdominal-pelvic section. Right renal artery emergent from aorta is not evidenced; left kidney of normal size; spleen of normal size; thoracolumbar scoliosis with axial rotation of vertebral bodies; right coccyx bone is hypoplastic, and the right femur cannot be evidenced.
Case particularity:
Newborn with right hemi-abdomen and pelvis hypoplasia associated with right renal agenesis and right lower limb agenesis, in which no teratogen factors that could have been act during pregnancy are revealed.

The clinical phenotype in a case with 49,XXXXY

G. C. Cozaru[1,2], *A. F. Mitroi*[1,3], *M. Aschie*[1], *I. Poinareanu*[1,3];
[1]*Constanta County Emergency Hospital, Constanta, Romania,* [2]*"Andrei Saguna" University, Constanta, Romania,* [3]*"Ovidius" University, Faculty of Medicine, Constanta, Romania.*

The 49, XXXXY syndrome is a rare sex chromosomal aneuploidy syndrome characterized by the presence of three extra X chromosomes in males and was first reported in 1960 by Fraccaro et al. It has an annual incidence of 1/85,000 to 1/100,000 male births.
We report here, a male child with mental retardation and impairment of language abilities, remarkable facial dysmorphism (microcephaly, hypertelorism, large flat nose with a depressed nasal curvature, upslanting palpebral fissures, epicanthus, prognathism, folded-over ears, short neck), important anemia and other associated congenital defects (cubitus valgus, flat feet, clinodactyly of the fifth finger, joint laxity, radio-ulnar synostosis). The cytogenetic study showed the constitution to be 49, XXXXY in all cells. The parent's of the patient has solicited genetics counseling to know the risk of having another child with a chromosome disorder.
Management needs to be handled by a multidisciplinary team and includes the treatment of skeletal defects, the monitoring of psychomotor development with physiotherapy, psychomotricity, speech therapy, orthopedic and sensory management (ophthalmological examination), neurological, hormonal (if necessary) and psychological care and regular dental follow-up. Patients have an essentially normal life expectancy but will need to attend regular medical visits.

J02.62
Additional genomic imbalance detected by arrayCGH in a prenatal case of Down syndrome

M. Stoian[1], *C. Ionescu*[1], *V. Celmare*[1], *A. F. Anca*[2], *G. Cardos*[1];
[1]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [2]*Bucharest Emergency University Hospital, Bucharest, Romania.*

Down syndrome is the most common chromosomal aneuploydy and several screening and diagnostics tests are available for prenatal diagnosis. Most cases identified have free trisomy 21, but there are reports associating other aneuploydies, usually double trisomies, involving mainly sex chromosomes. Additional structural chromosomal aberrations are very rare.
We report a prenatal case of 19 weeks of gestation, referred for cytogenetics investigations due to increased risk for Down syndrome. QF-PCR and conventional cytogenetics analysis were performed. QF-PCR detected trisomy 21 in a male fetus. Chromosomal analysis revealed three copies of chromosome 21 in all metaphases evaluated. The decision of the parents was to terminate the pregnancy, but since in our center an array comparative genomic hybridization study was going on, the parents gave concern to this analysis, as they wanted to further investigate the case. ArrayCGH was carried out on a NimbleGen ISCA Plus 3x1.4M Platform (Roche) and data was analyzed using Nexus Copy Number software (BioDiscovery). ACGH detected the 21 trisomy indentified by conventional cytogenetics, but additionally detected several duplications larger than 500 kb, on subtelomeric regions of chromosomes: 2p, 4p, 7p, 7q, 8p, 8q, 9q, 10p, 10q, 11p, 12q, 13q, 16q, 17q, 18q, 19p, 20q, 22q and on centromeric regions of chromosomes 2, 3, 6, 7, 8, 12. It is well known that 1.5-fold increase in dosage of transcripts and proteins encoded by genes in a trisomic segment, directly affects the phenotype. To evaluate a putative contribution of genomic imbalances detected, aCGH analysis for both parents should be performed.

M. Stoian: None. **C. Ionescu:** None. **V. Celmare:** None. **A.F. Anca:** None. **G. Cardos:** None.

J02.63
R3321Stop Mutation in MLL2 Gene Causes Kabuki Syndrome in a Spanish Patient

G. PI[1], *L. PEDROLA*[1], *A. SANCHIS*[2], *S. CLIMENT*[3], *A. MARTINEZ*[4], *M. ORTIZ*[1], *A. ZUÑIGA*[1];
[1]*HOSPITAL DE LA RIBERA, ALZIRA (VALENCIA), Spain,* [2]*HOSPITAL DR. PESET, VALENCIA, Spain,* [3]*HOSPITAL D'ONTINYENT, ONTINYENT (VALENCIA), Spain,* [4]*HOSPITAL DE REQUENA, REQUENA (VALENCIA), Spain.*

Kabuki syndrome, KS (OMIM# 147920) is a rare syndrome characterized by mental retardation and multiple congenital abnormalities. Mutations in *MLL2* gene have been recently identified in the majority of cases and rarely, mutations in *KDM6A* gene are causing the syndrome.
Case report: We report the molecular and phenotype studies of a Spanish patient who have typical features of KS. The patient is a 7 y.o. infant with mental retardation, a peculiar facies characterized by long palpebral fissures, a broad and depressed nasal tip, large prominent earlobes, a cleft palate, scoliosis, radiographic abnormalities of the vertebrae, hands, and hip joints, and recurrent otitis media. Genomic DNA was extracted from the patient and parents and mutation screening of coding exons and intron-exon junctions of the *MLL2* gene was performed by direct sequence analysis using a 3130XL Genetic Analyzer. All found changes were *in silico* analyzed (Polyphen 2.0) to estimate a possible damaging effect in the protein. We identified, for the first time in a Spanish patient, a mutation in exon 34 of *MLL2* gene causing the disease. The nucleotide change is a C>T substitution (c.9961C>T) causing a nonsense mutation in the exon 34 producing a truncated protein by the change of an Arginine by a stop codon (p.R3321X). This mutation is absent in both parents and the *in silico* analyses showed that this change is potentially damaging the protein function. This mutation has been previously described but this is the first genetic study of a patient with KS in Spanish population.

Oro-Facio-Digital syndrome in two Iranian patients

A. Rajaee, *A. Kariminejad, F. Afroozan, M. Kariminejad;*
Kariminejad-Najmabadi Path. & Genetics Center, Tehran, Islamic Republic of Iran.

Oro-Facio-Digital syndromes (OFDS) are a heterogeneous group of disorders characterized by abnormalities of the face, oral cavity, and digits of the upper and lower limbs. We report on two patients with OFDS type IV (OFD IV) (OMIM 258860), also known as Mohr Majewski syndrome. OFD IV is differentiated from other types of OFD by its autosomal recessive mode of inheritance and severe tibial dysplasia. OFD IV is characterized by lobulated tongue, pseudo-cleft of the lip, pre- and postaxial polydactyly, severe talipes equinovarus, mesomelic limb shortness associated with tibial hypoplasia. Both cases are the first and only child of first cousin Iranian parents. They both have multiple anomalies including lobulated and bifid tongue with nodules, gingival hypertrophy, hypertelorism, low-set ears, bilateral postaxial polydactyly of hands, brachydactyly with syndactyly of fingers, preaxial polysyndactyly of toes. In addition, Case 1 has microcephaly, hypotonia, repaired median cleft lip and palate, multiple oral frenuli, left cryptorchidism. Case 2 shows prominent forehead, micrognathia and absent frenuli, and microphallus. Recently, it has been shown that TCTN3 mutations as the cause of a severe form of Mohr-Majewski syndrome associated with bone dysplasia, tibial defect, brain anomalies and cystic kidney disease. Sequencing of TCTN3 is being performed and if negative, genome sequencing will be performed on these two families.

Sonic hedgehog and sexual organ development : a case report.

U. Ullmann, *B. Grisart, C. Dugauquier, K. Dahan;*
IPG, Gosselies, Belgium.

The sex development anomalies are among the most frequent prenatal malformations. Multiple genes pathways are involved in the sexual organ development. With this case report, we focused on the sonic hedgehog (shh) role.
A 20 weeks pregnancy was terminated because of holoprosencephaly. At the fetus autopsy, the pathologist noted the presence of alobar holoprosencephaly, aortic stenosis, intestinal malrotation, bilateral hydroureteres and ambiguous external sexual organs with large labia and clitoris. The abdominal cavity examination revealed gonads in the pelvic region. Their microscopic analysis concluded to testicular tissues. A microarray analysis of the fetal DNA identified a male fetus with 7q deletion and a 13q trisomy: 46,XY,del(7)(q36) 13q33.2 x3. None of the13q33 genes had a known function. We assumed that shh found among the deleted 7 q genes explains the major sex differentiation anomalies.
Studying the role for cholesterol in early mouse embryonic development, the function of specific gene products, such as Shh signaling protein, was demonstrated in pathologies combining holoprosencephaly, limb and genitalia anomalies. Shh knockout mice lack external genitalia and have a persistent cloaca.
This case report of a 7q deletion including shh gene reminded us the early and crucial role of shh signaling pathway through the human sexual differentiation and a review of the scientific literature was done.

A case with de novo 46,XX,add(6)(p25) karyotype.

K. Delil[1], *H. Simsek*[1], *E. Cerman*[2], *F. I. Sozen Delil*[2], *M. A. Soylemez*[1], *S. Yildirim*[3], *I. Guney*[1];
[1]*Department of Medical Genetics, Marmara University Education and Research Hospital, İstanbul, Turkey,* [2]*Department of Ophthalmology, Marmara University Education and Research Hospital, İstanbul, Turkey,* [3]*Department of Medical Engineering, Karabuk University, Karabuk, Turkey.*

Chromosomal aberrations commonly cause phenotypic abnormalities. Furthermore they are associated with 50% of the spontaneous miscarriages and encountered in the 0.5% to 1% of live births. Here, we present a case with *de novo* 46,XX,add(6)(p25) karyotype.
The patient was a 9-year-old girl with suspected diagnosis of syndromic child. She was delivered by cesarean section, weighing 3300 gr. She was able to sit when she was four months old. Although she started to talk and walk around at the age of one, she occasionally had imbalance. Around five years of age, she had an ear operation because of the occurred sensorineural hearing impairment.
The parents were not related and no similar cases were seen in the family. Her height, weight and head circumference were in normal range. A small nose with a flat nasal bridge, upturned nares, and deep-set nails were found. MRI showed cerebral atrophy, a 9x31 mm arachnoid cyst in the left temporal lobe and left mastoiditis. Secundum atrial septal defect, mild mitral failure and minimal left renal pelviectasis were other findings. Ophtalmologic examination revealed bilateral embryotoxon, congenital esotropia, and a best corrected visual acuity of 0.5 bilaterally.
Cytogenetic analysis revealed a 46,XX,add(6)(p25) karyotype. As the father, mother and two sisters did not have any chromosomal abnormality, chromosal aberration of our case was regarded as *de novo*.
46,XX,add(6)(p25) karyotype of our case and the phenotypic findings may be associated with a new chromosomal syndrome. Advanced molecular and molecular cytogenetic tests have been planned to define the relevant chromosomal region.

Klippel-Feil syndrome: a case report

R. FRIKHA, *S. Daoud, T. Rebai;*
laboratory of histology, Sfax, Tunisia.

Klippel-Feil syndrome (KFS) is characterized by congenital vertebral fusion of the cervical spine resulting from faulty segmentation along the embryo's developing axis. A wide spectrum of associated anomalies may be present. This heterogeneity has complicated elucidation of the genetic etiology and management of the syndrome.
It's about a 32-year- old women complained of torticollis. Her medical and family histories were unremarkable. Physical examination reveals Pain on palpation of vertebral spine apophyses and neck muscles and limited movement in the cervical spine without any associated anomalies. A radiography show a C5-C6 fusion on the cervical spine and the isolated klippel Feil syndrome was diagnosed. It's the rarest form of congenital fused cervical vertebrae which is predisposed to the risk of spinal cord injury and neurologic problems.
We insist that clinical heterogeneity and radiographic abnormalities found in Klippel-Feil syndrome may simulate acute pathology and thus require comprehensive evaluation and delineation of diagnostic and prognostic classes.

Oro-facio-digital syndrome type 1 in child with celiac disease: coincidence or a correlation?

F. C. de Almeida, *R. Pratesi, P. M. Fritsch, L. Gandolfi, H. P. N. Safatler;*
Universidade de Brasília, Brasília, Brazil.

Oro-facio-digital syndrome type1 (OFD1[MIM#311200]) is an ectodermal dysplasia characterized by lobulated tongue, lingual harmatomas, cleft palate, hyperplastic frenulum, polydactyly, brachydactyly and syndactyly. OFD1 is transmitted as an X-linked dominant condition with lethality in males caused by a mutation in OFD1 gene (Xp22.3-p22.2). Celiac disease (CD) is an autoimmune alteration triggered by ingestion of gluten in patients genetically predisposed and have been associated with several chromosomal syndromes such as Down syndrome, Williams's syndrome and Turner syndrome. This work reports for the first time a case of a child diagnosed with celiac disease and oro-facio-digital syndrome type1 and suggest an association between OFD1 and CD. This studie shows genetic clinical features of OFD1, and sorological tests (TtG-IgA, Anti-endomisium) and HLA typing for Celiac disease.

A novel splice site mutation in the MLL2 gene in a Moroccan patient with Kabuki syndrome

I. Ratbi[1,2], *N. Fejjal*[3], *L. Micale*[4], *B. Augello*[4], *C. Fusco*[4], *J. Lyahyai*[1,2], *G. Merla*[4,5], *A. Sefiani*[1,2];
[1]*Centre de génomique humaine, Faculté de médecine et pharmacie, Université Mohammed V Souissi, Rabat, Morocco,* [2]*Département de génétique médicale, Institut National d'Hygiène, Rabat, Morocco,* [3]*Service de chirurgie plastique pédiatrique, hôpital des enfants, CHU Ibn Sina, Rabat, Morocco,* [4]*Medical Genetic Unit, IRCCS Casa Sollievo della Sofferenza, San Giovanni, Rotondo, Italy,* [5]*Scuola di Dottorato in Scienze della Riproduzione e dello Sviluppo, University of Trieste, Trieste, Italy.*

Kabuki syndrome (also known as Niikawa-Kuroki syndrome) is a rare au-

tosomal disorder, characterized by an unusual face, short stature, skeletal, visceral and dermatoglyphic abnormalities, cardiac anomalies, mental retardation, and immunological defects. Point mutations and large intragenic deletions and duplications of the mixed lineage leukemia 2 (MLL2) and exons deletions of lysine demethylase 6A (KDM6A) genes have been identified as its underlying causes.
We report on the first description of a Moroccan Kabuki syndrome patient with typical facial features, developmental delay, finger pads, and other anomalies carrying a novel splice site mutation in the MLL2 gene that produces a truncated and likely pathogenetic form of MLL2 protein.

I. Ratbi: None. **N. Fejjal:** None. **L. Micale:** None. **B. Augello:** None. **C. Fusco:** None. **J. Lyahyai:** None. **G. Merla:** None. **A. Sefiani:** None.

Uncommun Case of Trisomy 13

I. Chelly[1], *K. Lilia*[1], *K. Ichrak*[2], *M. Faouzi*[1], *G. Najoua*[2], *C. Habiba*[1];
[1]*department of heridatary and congenital disorders, Tunis, Tunisia,* [2]*department of pediatrics, Bizerta, Tunisia.*

Trisomy 13, or Patau syndrome is a rare chromosomal disorder characterized by a triad of cleft lip and palate, postaxial polydactyly and microcephaly. It was described firstly in 1960. Complete, partial, or mosaic forms of the disorder can occur.
Here, we report on a case of five months old girl with feeding difficulties, uncommon facial dysmorphy of trisomy 13: microcephaly, high forehead with facial cleft, hypertelorism, horizontal palpebral fissures, epicanthal folds, bifid nose with anteverted nares, posterior cleft palate, long philtrum, low-set and dysplastic ears. She has also short neck, overlapped fingers and toes with hypoplastic thumbs, dislocated hips, hypotonia and she has no epilepsy, nor congenital heart defect, or visceral malformation. Cytogenetic analysis demonstrated trisomy 13 with Robertsonian translocation. The karyotype of the parents was normal. There was no holoprosencephaly in Brain CTScan. Genetic counseling and prenatal diagnosis were offered to the parents.

I. Chelly: None. **K. Lilia:** None. **K. Ichrak:** None. **M. Faouzi:** None. **G. Najoua:** None. **C. Habiba:** None.

J02.71
Partial trisomy 4p due to the maternal translocation t(4;22)(p15.2;p11.2)

M. Ikbal[1], *T. Tos*[2], *M. Y. Alp*[1,3];
[1]*Department of Medical Genetics, Medical Faculty, Karadeniz Technical University, Trabzon, Turkey,* [2]*Department of Medical Genetics, SB Sami Ulus Women's and Children Hospital, Ankara, Turkey,* [3]*Department of Medical Genetics, SB Ali Osman Sönmez Oncology Hospital, Bursa, Turkey.*

We report on a 5 year and 4 months old boy with 46,XY,der(22)t(4;22)(p15.2;p11.2) due to the maternal reciprocal translocation t(4;22)(p15.2;p11.2). The patient was referred to the department of medical genetics because of mental retardation and facial dysmorphism. He had microcephaly, brachycephaly, triangular mouth, low frontal hairline, hypotelorism, strabismus, prominent simple ear. Developmental milestones were delayed. Also he had pes equinovarus of the right foot and unilateral simian crease. MRI showed partial agenesis of the corpus callosum. X-ray imaging revealed bilateral femoral coxa valga and fusion defects on the posterior arcus of the C6-C7. In our patient, balanced reciprocal translocation of mother resulted to partial trisomy 4p and partial monosomy 22p. Trisomy 4p syndrome is characterized by mental retardation, pre and postnatal growth retardation, facial dysmorphism, brain anomalies, and limb defects. It is suggested that monosomy 22p11.2 has no clinical significance.

M. Ikbal: None. **T. Tos:** None. **M.Y. Alp:** None.

J02.72
Case report of unbalanced tpanslocation involving chromosome 3 and 7.

V. Rumyantseva[1], *N. Oparina*[2], *Z. Sabirzyanova*[3], *A. Pavlov*[3], *E. Zaklyazminskaya*[1];
[1]*Petrovsky Russian Research Centre of Surgery RAMS, Moscow, Russian Federation,* [2]*Moscow Regional Research Clinical Institution, Moscow, Russian Federation,* [3]*Federal State Budget Establishment Russian Scientific Center of Roentgenoradiology (RSCRR) of Ministry of Health Development of Russian Federation, pediatric urology department, Moscow, Russian Federation.*

Background: The most common familial chromosomal rearrangements are translocations. In case of an unbalanced segregation in offsprings, the resulting imbalances consist of a combination of partial trisomy and partial monosomy. Phenotypic reports of chromosomal imbalances are an important source for genetic counselling.
Clinical case: We've performed clinical and genealogical examination of five month-old boy with primary diagnosis "bilateral ureterohydronephrosis" and unusual phenotypes: overweight (growth 60cm,weight 8,6 kg) disproportionately short limbs, microcephaly, micrognathia and short neck. At the first month of life, he had a perirectitis. During the heart examination, the foramen ovale with the extension of the right ventricle was determined. A case of the dextrocardia was reportes in the family pedigree. Moreover, the mother was treated Hodgkin's disease eight years ago.
Results: An additional material of unknown origin was detected on a distal part of a long arm (q) of the chromosome 7 in blood lymphocytes culture (analized with GTG- banding). Proband's arrangement was a result of maternal reciprocal translocation t(3;7)(p25;q36). Thus the proband's karyotype was 46,XY,der(7)t(3;7)(p25;q36)mat. So partial trisomy of the short arm chromosome3 and partial monosomy of the long arm chromosome7 were found.
Conclusion: Unbalanced tranclocation in proband chromosomes3 and 7 was cause of rare phenotype of ureterohydronephrosis. Multiply congenital malformation in family members got explanation. Clinicians should give more consideration to rare genetic chromosomal syndromes, especially in the case of unusual combinations symptoms.

J02.73
Identification of unbalanced translocation 4;8 characterized by metaphase CGH

M. Minzhenkova, *N. Shilova, Z. Markova, S. Korostelev, Y. Kozlova, T. Zolotukhina; Federal State Budgetary Institution "Research Centre for Medical Genetics" under the Russian Academy of Medical Sciences, Moscow, Russian Federation.*

We report a case of a 2-year-old child with growth retardation, physical abnormalities, hypotonia and development delay. G-banding chromosome analysis showed a normal karyotype. Molecular cytogenetic investigations were performed to revealed a chromosomal abnormalities. Metaphase comparative genomic hybridization (CGH) analysis showed loss of chromosome 4p16.1 and gain of chromosome 8p23.1. FISH with subtelomeric probes of chromosome 4 and 8 confirmed the deletion of the distal short arm of chromosome 4 and the duplication of the distal short arm of chromosome 8. This finding was found by reinspection of the G-banded karyotype at the 500 band level. GTG-banding allowed to interpret proband´s karyotype as: 46,XY, der(4)t(4;8)(p16.1;p23.1). The mother´s karyotype was normal, father was not available for karyotyping. This case of unbalanced translocation 4;8 demonstrates the usefulness of the metaphase CGH method. The aberration had previously been missed by routine analysis of G-banded karyotyping. This clearly illustrates a weakness of the GTG-banding technique in comparison to CGH. G-band analysis is dependent on the qualifications and the actual performance of the cytogeneticist and this makes the technique somewhat subjective. CGH technique has some advantages for of unbalanced chromosome aberrations: it gives a global approach which allows an objective analysis of all chromosomes in a single in situ hybridization experiment without cell culture. Metaphase CGH is non expensive and rapid technique which can be used routinely to explore patients with mental retardation and dysmorphic features.

The ADAMTS18 gene is responsible for autosomal recessive early onset severe retinal dystrophy

I. Peluso[1], *I. Conte*[1], *F. Testa*[2], *M. Pizzo*[1], *R. W. J. Collin*[3], *N. Meola*[1], *S. Barbato*[1], *M. Mutarelli*[1], *F. Simonelli*[2], ***S. Banfi***[1,2];
[1]*TIGEM, Naples, Italy,* [2]*Second University of Naples, Naples, Italy,* [3]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: Inherited retinal dystrophies, including Retinitis Pigmentosa and Leber Congenital Amaurosis among others, are a group of genetically heterogeneous disorders that lead to variable degrees of visual deficits. They can be caused by mutations in over 100 genes and there is evidence for the presence of as yet unidentified genes in a significant proportion of patients. We aimed at identifying a novel gene for an autosomal recessive form of early onset severe retinal dystrophy in a patient carrying no previously described mutations in known genes.
Methods: An integrated strategy including homozygosity mapping and who-

le exome sequencing was used to identify the responsible mutation. Functional tests were performed in the medaka fish (Oryzias latipes) model organism to gain further insight into the pathogenic role of the ADAMTS18 gene in eye and central nervous system (CNS) dysfunction.
Results: This study identified, in the analyzed patient, a homozygous missense mutation in the ADAMTS18 gene, which was recently linked to Knobloch syndrome, a rare developmental disorder that affects the eye and the occipital skull. In vivo gene knockdown performed in medaka fish confirmed both that the mutation has a pathogenic role and that the inactivation of this gene has a deleterious effect on photoreceptor cell function.
Conclusion: This study reveals that mutations in the ADAMTS18 gene can cause a broad phenotypic spectrum of eye disorders and contribute to shed further light on the complexity of retinal diseases.

A novel gross deletion in DFNB1 locus involving GJB2 and GJB6 genes is recurrent in Russian patients

E. A. Bliznetz[1], *O. N. Makienko*[1], *E. G. Okuneva*[1], *T. G. Markova*[2], *A. V. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*National Research Centre for Audiology and Hearing Rehabilitation, Moscow, Russian Federation.*

Mutations in *GJB2* gene are the most commonly identified cause of congenital, recessively inherited, sensorineural nonsyndromic hearing loss (DFNB1). More than 300 mutations in *GJB2* gene are known and were detected in the most patients with DFNB1. In several countries the gross deletions in DFNB1 locus are observed with a considerable frequency. Among four known deletions in DFNB1 only one deletion involves *GJB2* gene and was observed in single family. Here we report about a novel 101.4 kb deletion involving *GJB2* and *GJB6* genes. This deletion, NC_000013.10: g.20,757,021_20,858,394del, was revealed in three unrelated Russian patients, probably has a Ingush descent. Additional population studies are necessary to estimation of the deletion frequency. If the novel deletion is frequent, a molecular testing for it is very important to genetic counseling.

J03.03

Examination of the genetic background of aminoglycoside induced and non-syndromic, hereditary sensorineural hearing loss

G. M. Milley[1], *A. Gál*[1], *L. Noszek*[2], *P. Prekopp*[2], *L. Tamás*[2], *M. J. Molnár*[1];
[1]*Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary,* [2]*Department of Otorhinolaryngology, Head and Neck Surgery, Semmelweis University, Budapest, Hungary.*

Objectives: With the development of molecular genomics we can recognise the connection between more and more genetic variations and medications side effects and we can discover
an increasing number of genetic differences behind idiopathic symptoms. The mutations of 12S rRNA gene which encoding by mitochondrial genome are frequent causes of both aminoglycoside induced and non-syndromic sensorineural hearing impairment. The transitions make the human mitochondrial 12S ribosomes more bacteria-like and alter binding sites for aminoglycosides.
Aims: To define the frequency of occurrence in the Hungarian population of A1555G and C1494G substitutions of the mtDNA.
Methods: Participants of the research were: (1) 300 patients suffering in sensonerual syndromatic or non-syndromic hearing loss (37 patients with aminoglycoside induced, 144 with mitochondrial disease and 119 with non-syndromic) and 200 volunteering control participants. Among the patients both sporadic and familial cases were present. The mtDNA substitutions were screened by PCR-RFLP methodology.
Results: Out of examined 500 participants, the A1555G mutation appeared in 12 cases (5 patients and 7 control persons). The frequency of the mutation in the population was 2.4%. In 2 of these patients maternally inheritable hearing loss could have been discovered. The C1494G substitution was not present in these cohorts.
Conclusion: The targeted examination of mtDNA may render the screening of carriers possible in the future, which may serve as the basis for the appearance of personalized therapies. However further investigations are also necessary to detect other genetic risk factors for aminoglycosid induced ototoxicity.

J03.04

Prevalence of GJB2 (Connexin-26) and GJB6 (Connexin-30) mutations in a 123 Iranian Azeri Turkish hearing-impaired individuals: implications for diagnosis and genetic counseling

M. S. khaniani, *S. Mansouri Derakhshan, S. Taghizadeh, N. Lotfalizadeh, S. Shiri Torkamani,;*
Tabriz university of Medical Science, Tabriz, Islamic Republic of Iran.

Hearing impairment (HI) is the most common heterogeneous neurosensory disease in humans. More than 50% of cases have a genetic etiology, including syndromic and non-syndromic forms. For many populations, mutations in two connexin (Cx) genes, GJB2 (Cx26) and GJB6 (Cx30) have been identified 50 % to cause hearing impairment
In this study, we report our 4-year experience of over 123 unrelated Azeri Turkish patients with hearing impairment, who were not affected by known deafness related syndromes.
123 Azeri Turkish unrelated subjects clinically diagnosed with HI from various clinics from North West of Iran were referred by specialists to the Medical Genetic Centre of Tabriz University of Medical Sciences. A clinical diagnosis of HI was made according to published criteria. Mutation screening of the GJB2 and GJB6 genes were performed by using direct sequencing method.
54 (% 43) of these patients had one or two mutations. Of those with mutations, 22 were compound heterozygous, 19 were homozygous, and 13 had only one identifiable mutation.
The most frequent mutations were c.35delG and V153I (25% and 16% respectively) of the alleles, followed by V27I, V71K, A171T, V114G, R127H, M163V, G160S, c.119delC, c.120delA, and c.51insA mutations in GJB2 gene and no mutation in GJB6 gene was detected in our population.
The present study demonstrates that mutations in the GJB2 are important cause of hearing impairment and mutations in the GJB6 gene don't play any important role of hearing impairment in Iranian Azeri Turkish population, thus justifying their screening in a routine basis.

Prenatal ultrasound diagnosis of cataract congenital in two siblings with microduplication 22q11.23

D. Raskova, *M. Hynek, M. Trkova, D. Stejskal;*
Centre for Medical Genetics and Reproductive Medicine GENNET, Prague 7, Czech Republic.

The case report presents the prenatal ultrasound findings of cataract oc. utr. in two brothers. Microduplication 22q11.23 was detected in both fetuses and their healthy mother. The beta-crystallin genes CRYBB2 (crystallin betaB2) and CRYBB3 (crystallin betaB3) lie within the region 22q11.23 and are therefore candidate genes. The relationship between the mutations of these genes and nonsyndromal cataract is known. Different beta-crystallin proteins can interact with each other to form oligomers of different sizes ranging from dimers to octamers and can also interact with other lens proteins. The protein-protein interactions are predicted to be key in maintaining the transparency of the lens.

D. Raskova: None. **M. Hynek:** None. **M. Trkova:** None. **D. Stejskal:** None.

The analysis of the GJA8 gene in patients with isolated form of congenital cataract from Bashkortostan Republic (Russia).

I. I. Khidiyatova[1], *I. M. Khidiyatova*[1], *T. P. Fedorova*[1], *S. R. Avkhadeeva*[2], *M. T. Aznabaev*[2], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Introduction: Cataracts are one of the leading causes of blindness in humans, and mutations in the connexin 46 (GJA3) and the connexin 50 (GJA8) genes cause congenital cataract. Different mutations in these genes lead to the development of distinct cataract phenotypes. The aim of the study was to analyze the GJA8 gene in patients from Bashkortostan Republic affected with congenital cataract.
Objective: DNA samples of 40 unrelated patients with isolated form of hereditary congenital cataract from Bashkortostan Republic were analyzed.
Methodology: The analysis was performed by direct sequencing of coding regions of the GJA8 gene.
Results: Four different nucleotide alterations were detected. In one patient of Russian ethnic origin with zonular form of cataract nucleotide substitution c.179G>A (p.Gly60Asp) was detected; one patient of Bashkir ethnic origin

with anterior capsular cataract carried the deletion c.133-142delTGGGGGGATG (p.Trp45SerfsX72). Both of these changes were found in the heterozygous state, have not been described in the literature earlier, and presumably are functionally significant mutations. In one patient new nucleotide substitution c.288G>A (p.Ala96Ala) in the homozygous state was found. Two patients demonstrated nucleotide substitution c.68G> T (p.Arg23Thr), known as polymorphic variant (rs80358203).
Conclusion:Thus, three previously undescribed structural changes in the gene GJA8 were detected in patients with hereditary isolated cataract from Bashkortostan Republic. To determine their functional significance further investigation are required.

Genetic Linkage Analysis of DFNB loci in ARNSHL pedigrees in Southern Khorasan Province in Iran

M. R. Noori-Daloii[1], *N. Jalilian*[1], *M. Tabatabaiefar*[2], *F. Alizadeh*[1], *L. Kialashaki*[1], *A. Ahmadi*[3], *Z. Roshani*[1];
[1]*Department of Medical Genetics, School of Medicine, Tehran Univ. of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetics, School of Medicine, Ahvaz Jundishapur University of Medical Sciences,, Ahvaz, Islamic Republic of Iran,* [3]*Department of Genetics, Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.*

Hearing loss is the most common sensory birth defect with an incidence of about one in 650 newborns. Approximately 70% of genetic HL cases are autosomal recessive non-syndromic (ARNSHL) and it may become even higher in countries with high rate of consanguineous marriage. Iran has a heterogeneous population due to different ethnicities and also a high rate of consanguineous marriage (38.6%). The fact that many loci are involved together with the heterogeneity of the status, necessitate studying further loci in various Iranian ethnic groups. 22 large deaf pedigrees originating from the Southern Khorasan province of Iran were selected. The families analyzed for *GJB2*, exon I & II, mutations and *GJB6* large deletions. Pedigrees negative for *GJB2* mutations were then subject to linkage analysis for loci DFNB2, DFNB3, DFNB4, DFNB7/11, DFNB9, DFNB21 & DFNB59. DFNB4, DFNB3, DFNB21 & DFNB59 have been analyzed and the project is proceeding for other loci.
Four out of the 22 families showed *GJB2* mutations. One family carried homozygous c.35delG mutation and another one carried homozygous p.W24X mutation. The third pedigree patients were compound heterozygous for p.W77X/IVS1G>A. c.380 G>A mutation. The fourth pedigree showed heterozygote mutation of p.V27I+E114G/wt. GJB6 deletions were not detected. One family showed linkage to DFNB3 and the remaining did not show linkage to the studied loci.
Our results once again emphasize the heterogeneity of HL among different Iranian ethnic groups. These results could be applied to a more efficient genetic screening and genetic counseling. This study proceeds with more loci and more families.

J03.08

Analysis of a conserved GJB2 intronic region in nonsyndromic sensorineural hearing loss patients with only one previously identified GJB2 variant

T. D. Matos[1], *H. Simões-Teixeira*[1], *A. C. Gonçalves*[1], *J. R. Chora*[1], *H. Rosa*[2], *L. Monteiro*[3], *A. O'Neill*[4,5], *Ó. P. Dias*[6], *M. Andrea*[6], *H. Caria*[1,7], *G. Fialho*[1];
[1]*Centre for Biodiversity, Functional, and Integrative Genomics (BioFIG), Faculty of Science, University of Lisbon, Lisboa, Portugal,* [2]*ORL Service, Hospital Garcia de Orta, E.P.E., Almada, Portugal,* [3]*ORL Service, Hospital Dona Estefânia (Centro Hospitalar Lisboa Central), Lisboa, Portugal,* [4]*Department of Head and Neck, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental, E.P.E.), Lisboa, Portugal,* [5]*Department of Anatomy, Faculty of Medical Sciences, New University of Lisbon, Lisboa, Portugal,* [6]*Department of ORL, Voice and Communication Disorders, Hospital Santa Maria (Centro Hospitalar de Lisboa Norte, E.P.E.), Lisboa, Portugal,* [7]*School of Health, Polytechnic Institute of Setúbal, Setúbal, Portugal.*

The DFNB1 locus (GJB2 and GJB6 genes) is a major cause of nonsyndromic sensorineural hearing loss (NSSHL), being responsible for over 1/5 of the Portuguese cases. However, some patients present only one recessive mutation. The frequency of such individuals is, in several instances, higher than the expected if they were only carriers. This fact suggests the existence of an accompanying DFNB1 mutation in some cases. We have noticed a conserved region in the GJB2 intron, which might be a potential location of pathogenic mutations.
We have thus investigated that conserved region in 27 NSSHL Portuguese patients (previously analysed regarding the basal promoter, exon 1, donor splice site, coding region and 3'UTR) harbouring one pathogenic, controversial or unclear GJB2 mutation, and none of the two common GJB6 deletions (del1830 and del1854). The control sample consisted in 42 normal-hearing individuals from the general population. The 69 subjects were analysed by direct sequencing.
A total of seven known variants in the intronic region analysed (c.-22-1207G>C, c.-22-1203A>G, c.-22-1198G>A, c.-22-1157A>T, c.-22-1153G>A, c.-22-1108G>A, c.-22-1073A>G) were identified among patients and controls, of which four were found only in controls. No variant was identified exclusively in the patients. A novel variant (c.-22-1415A>G) was found in a control individual.
The investigation here presented did not reveal, in the individuals analysed, any novel potentially pathogenic variant in the conserved intronic region. However, this region could be further investigated in other patients with only one GJB2 mutation, since it might play a role in the regulation of the gene.

Reduced expression of the OPA1 gene due to a novel nonsense mutation leads to autosomal dominant optic atrophy

M. Oldak[1], *A. Federowicz*[1], *K. Szulborski*[2], *K. Rydz*[1], *J. Wierzbowska*[3], *J. Kosinska*[4], *M. Rekas*[3], *R. Ploski*[4], *J. P. Szaflik*[2], *J. Szaflik*[2];
[1]*Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland,* [2]*Department of Ophthalmology, Medical University of Warsaw, Warsaw, Poland,* [3]*Departament of Ophthalmology, Military Health Service Institute, Warsaw, Warsaw, Poland,* [4]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.*

Purpose: Autosomal dominant optic atrophy (ADOA) is the most prevalent dominantly inherited optic neuropathy. The aim of the study was to identify the genetic etiology of inherited optic neuropathy in a Polish family.
Methods: We report on a 2-generation Polish family with ADOA in which nine family members are affected. MRI and detailed ophthalmological examination with visual field and electrophysiological testing were performed. DNA and protein extracts were obtained from blood samples. Linkage to OPA1, the main ADOA locus, as well as sequencing of all *OPA1* exons were conducted. Amplified fragments were analyzed on an automatic DNA sequencer. OPA1 expression was analyzed by Western blot.
Results: MRI and ophthalmological examination confirmed the diagnosis of bilateral optic neuropathy. Pattern visual evoked potentials (PVEP) presented abnormally delayed P100 wave latency. Pedigree analysis demonstrated a dominant mode of inheritance. Linkage studies revealed linkage to the major OPA1 locus in the investigated family. Sequencing of the *OPA-1* gene identified a novel C-to-T transition in exon 2 predicting a premature stop codon (*p.Q31Ter*). The mutation co-segratated with the phenotype in this family. Expression of OPA1 at the protein level was strongly reduced as compared to control samples from healthy individuals.
Conclusion: Occurrence of the premature termination codon at the beginning of the transcript, which leads to a strong reduction of OPA1 protein expression, confirms that ADOA in the investigated family is a consequence of OPA1 haploinsufficiency. The novel variant broadens the spectrum of the reported *OPA1* mutations causing ADOA.

Frequency of the p.Q829X *OTOF* mutation in Greek patients suffering from sensorineural, non-syndromic hearing loss

I. Zorba[1], *M. Grigoriadou*[2], *M. Petersen*[2], *H. Kokotas*[2], *K. Lamnissou*[1];
[1]*Dept of Genetics & Biotechnology, University of Athens, Athens, Greece,* [2]*Department of Genetics, Institute of Child Health, Athens, Greece.*

Approximately one or two in 1,000 children suffer from deafness that appears at birth or before the age of two (prelingual deafness). About 50% of the cases presenting with non-syndromic prelingual hearing loss in the developed world are due to genetic causes, making genetic deafness one of the most frequent hereditary conditions in humans. Most mutations associated with the disease in Caucasians have been mapped in the DFNB1 locus, with the *GJB2* gene having the most important role. Several studies

have shown that the point mutation p.Q829X in the *OTOF* gene located in the DFNB9 locus is responsible for up to 3% of the cases with non-syndromic deafness in the Spanish population, while similar results have been reported in studies from South American countries and the USA. In the present study we investigated the frequency of the p.Q829X *OTOF* mutation in the Greek deafness population. A total of 100 unrelated Greek patients suffering from non-syndromic, sensorineural hearing impairment with an age of onset in childhood, were recruited. We employed the PCR-RFLP method in order to genotype our samples. Our results showed that all patients were tested negative for the p.Q829X *OTOF* mutation, indicating that the mutation is rare in the Greek population. The study is proceeding in order to explore a geographic correlation among allele frequencies in the Mediterranean region.

Microdeletion 2q11.1q11.2 including haploinsufficiency of SNRNP200 gene: two families report without clinical manifestations of retinitis pigmentosa

E. Matoso[1,2,3], *J. B. Melo*[1,3], *L. M. Pires*[1], *S. I. Ferreira*[1], *E. D. Silva*[4], *J. Sá*[5], *F. Ramos*[5], *I. M. Carreira*[1,2,3];

[1]*Laboratory of Cytogenetics and Genomics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [2]*Laboratory of Cytogenetics, Paediatrics Hospital, Coimbra, Portugal,* [3]*CIMAGO – Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [4]*Serviço de Oftalmologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal,* [5]*Serviço de Genética Médica , Departamento Pediátrico- CHUC, Coimbra, Portugal.*

Deletions involving the proximal region of chromosome 2q11 have been rarely reported to date. We describe two patients with overlapping microdeletions at 2q11.1q11.2 encompassing SNRNP200 gene recently associated with autosomal dominant retinitis pigmentosa (adRP).

The patient 1 is a 10 year-old boy and patient 2 is a 7 year-old girl, both referred to our department because of global psychomotor development delay. The patients exhibit minor dysmorphisms including downslating palpebral fissures and slight micrognathia. However patient 1 is macrocephalic and patient 2 has microcephaly with the stature below the 3rd centile.

Array-CGH (180K Agilent) was performed and Fluorescence in situ hybridization using specific BAC clones. A similar deletion spanning about 1,5Mb was observed in both patients, with the involvement of 12 genes described in OMIM database, three of them associated with disease: TMEM(OMIM#613403); SNRNP200 (OMIM#601664) and CNNM4 (OMIM#607805). Patient 1 deletion was inherited from his father and in patient 2 the deletion was de novo.

The patient 1 and his father were submitted to complete ophthalmological examination that failed to demonstrate pigmented changes in the retinal periphery. Patient 2 examination also revealed normal results. In the families already reported with adRP the average age of onset is different, from 7 to 17 years of age .However, the father of patient 1 has already 36 years old and to date has no clinical manifestations of RT. It is difficult to ascertain if the phenotypic effect of the missence mutations already reported could be different from the haploinsufficiency of the SNRNP200 gene.

Prevalence of the GJB6 gene deletion in nonsyndromic hearing loss in Mexican population

M. Martinez-Saucedo[1], *M. R. Rivera-Vega*[2], *F. Loeza-Becerra*[1], *L. M. Gonzalez-Huerta*[1], *H. Urueta-Cuellar*[1], *P. Berruecos*[2], *S. Cuevas-Covarrubias*[2];

[1]*Hospital General de Mexico, Mexico, D.F., Mexico,* [2]*Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico, D.F., Mexico.*

About 1/1000 children are affected by pre-lingual deafness. Several genes have been associated with recessive hearing impairment. The GJB6 gene deletions are one of the causes of hereditary, prelingual, nonsyndromic hearing loss; they present an autosomal recessive inheritance. More than 90 GJB2 mutations affecting Cx26 expression have been reported and linked to hearing loss. Objective: To identify the prevalence of GJB6 deletion in a sample of Mexican patients. Methods The study included 246 patients from 105 non-related families with hereditary, prelingual, nonsyndromic hearing loss, all of them were analyzed through PCR and DNA sequencing from genomic DNA. Results and Discussion: We found only in one family the presence of GJB6 gene deletion in heterozygous state. We discuss the prevalence of this type of mutations in the Mexican sample and compare with the data previously reported in other populations.

Genetic studies in deaf individuals with inconclusive diagnostic molecular.

S. M. da Silva-Costa, *C. Svidnicki, R. M. Alves, T. Marconi, R. Secolin, E. L. Sartorato; UNICAMP, Campinas, Brazil.*

Hearing impairment is the most common sensory impairment affecting approximately one in five hundred newborns. Despite the enormous heterogeneity of genetic hearing loss, up to 50% are associated with mutations in the locus DFNB1. This locus contains the *GJB2* and *GJB6* genes, which codes for the connexin 26 (Cx26) and connexin 30 (Cx30) proteins, respectively. However, a large number of affected individuals carry only a single recessive mutation in locus DFNB1, which causes problems in molecular diagnostic. The aim of this study was to elucidate the genetic cause of hearing loss in 48 monoallelic individuals for recessive mutations in the *GJB2* gene or in *GJB6* gene. Thus, mutations that are not routinely screened were investigated in these individuals. The del(CHR13 :19,837,344-19, 968698) deletion in *GJB6* gene, mutations in the cluster *miR-183* and a large number of mutations in fourteen mitochondrial genes were screened in these samples. Additionally, we investigated the presence of deletions in the DFNB1 locus, not yet described. In this study, the deletion del(CHR13 :19,837,344-19, 968698) have not been found in subjects analyzed. Five single nucleotide polymorphisms (SNP) were identified in the *miR-183* cluster. Probable deletions in the DFNB1 locus were found in 4 heterozygous individuals for mutations in *GJB2* using mass spectrometry system MassArray, Sequenom®. Besides, among the subjects studied were still found eight mitochondrial alterations detected in eighteen cases. Detection of mutations in different genes reduces the number of cases with diagnosed inconclusive. However, due to heterogeneity of genetic hearing loss many still remain without diagnosis.

Genetic counselling in ametropia

A. Gugu[1], *R. M. Dragotoiu*[2];

[1]*Polytehnic University of Bucharest, Bucuresti, Romania,* [2]*Medical and Pharmacy University „Carol Davila", Bucuresti, Romania.*

Ametropia, a state where a refractive error is present, can be myopia when the eyeball is too long and a point at infinity focuses in front of the retina; hyperopia when the eyeball is too short and an image focuses behind the retina; and astigmatism when the eye has different focal points in different planes.

The purpose of this study is to present the difficulties of genetic counselling in familial nonsyndromic ametropia.

31 patients with different types of ametropia where sent to a genetic consultation between 2011 and 2013. 22 had sporadic ametropia. 30 cases had no other signs or symptoms associated. In 25.80% of cases, there was at least one more family member affected by the same or a different type of ametropia. From the four cases of myopia only one was a high grade type (-10 diopters) and had an autosomal dominant inheritance pattern. One other case diagnosed with myopia and astigmatism had the mother with multiple sclerosis. 2 more cases had hyperopia and astigmatism and one case had hyperopia at one eye and myopia at another.

We discuss the inheritance pattern in each of the familial cases, considering that genetic factors play a significant role in the development of nonsyndromic ametropia irrespective of the degree of the illness. Pedigrees are selectively analyzed, and biases (because of genetic heterogeneity, phenocopy, and environmental factors) interpreted.

In conclusion, usually a careful family history may reveal the inheritance pattern of an isolated refractive error for a given family, making counselling easier.

A new mutation in*SCN9A* gene in a Moroccan patient with congenital insensitivity to pain

M. Mansouri[1,2], *S. E. Chafai*[1,2], *b. o. ben cheikh*[3], *j. lyahya*[2], *P. Dion*[4], *a. Sefiani*[1,2], *G. Rouleau*[4];

[1]*Department of Medical Genetics, Hygiene National Institute, Rabat, Morocco,* [2]*Human*

Genome Center, Faculty of Medicine and Pharmacy of Rabat,, Rabat, Morocco, [3]CHUM Research Centre, Montreal, QC, Canada, [4]CHUM Research Centre, montreal, QC, Canada.

Pain is a highly conserved sensory modality among all vertebrate species which confers protection against noxious and dangerous stimuli. Loss of pain sensation or hypersensitivity to pain can compromise survival.
SCN9A (Sodium channel protein type 9 subunit alpha) encodes the voltage-gated sodium channel Nav1.7, a protein highly expressed in pain-sensing neurons. Mutations in SCN9A cause three human pain disorders: bi-allelic loss of function mutations result in Channelopathy-associated Insensitivity to Pain (CIP, OMIM: 243000), whereas activating mutations cause severe episodic pain in Paroxysmal Extreme Pain Disorder (PEPD OMIM: 167400) and Primary Erythermalgia.
Congenital insensitivity to pain is an autosomal-recessive disease caused by inactivating mutations in the Nav1.7channel. To date, almost mutations in SCN9A are protein truncating and presumably lead to no protein being produced. Recently, the study proved that Nav1.7 is an essential requirement in olfactory pathway.
Here, we confirm this suggestion bye describing a 2 years old girl with CIP and a congenital general anosmia confirming bye a novel homozygous nonsense mutation in SCN9A.

Polymorphous ophthalmologic symptoms of patients with Down syndrome

M. O. Mkheidze[1]*, O. K. Janvareva*[2]*;*
[1]North-West State Medical University named after I.I.Mechnikov, St.Petersburg, Russian Federation, [2]Medical centre of St.Petersburg University, St.Petersburg, Russian Federation.

Aim of the work. Investigation of ophthalmic status of patients with Down syndrome (DS)
Material and methods. There were 11 patients (22 eyes, 8 males and 3 females aged 6 mo to 16 yr) with DS (full trisomy 21) under our observation. Observation period was from 2 mo to 6 yr. Routine basic ophthalmic and pediatric investigations were performed for all patients.
Results. Ophthalmic status of all patients included up-slanting palpebral fissures, bilateral medial epicanthal folds. 4 children (8 eyes) had congenital inverted eyelid with early corrective surgery (2 cases) and conservative keratoplasty therapy (2 cases). 2 patients aged 8 mo and 1 yr (4 eyes) were operated on congenital diffuse cataract without IOL and corrected with aphakic glasses. 3 patients (6 eyes) had hypermetropia of high degree. One patient (2 eyes) had myopia of high degree. 1 patient (2 eyes) had incomplete congenital central corneal opacity without surgical
intervention.
Conclusion. Early ophthalmic examination and specific treatment help to ensure adequate vision and social adaptation, including family adaptation of the patients with DS.

Medullary cystic kidney disease - report on two novel *UMOD* mutations and pitfalls of diagnostics

G. Miltenberger-Miltenyi[1]*, F. Carvalho*[2]*, H. Viana*[2]*, A. R. Santos*[2]*, C. Ferreira*[2]*, L. Ejarque*[3]*, E. Ars*[3]*, E. Almeida*[4]*, J. Calado*[2]*;*
[1]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, [2]Serviço de Nefrologia, Hospital de Curry Cabral-Centro Hospitalar de Lisboa Central, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisboa, Lisbon, Portugal, [3]Laboratori de Biologia Molecular, Fundació Puigvert, Barcelona, Barcelona, Spain, [4]Serviço de Nefrologia, Hospital Beatriz Angelo, Loures, Loures, Portugal.

Background: Medullary cystic kidney disease (MCKD) is a rare autosomal dominant renal disease characterized by medullary cysts, tubulointerstitial nephritis, gout and progressive chronic renal failure leading to end-stage renal disease (ESRD). Mutations in the UMOD gene (16p12.3), encoding the Tam-Horsfall glycoprotein, were found to associate with MCKD type 2. We report two families with the unusual characteristics of members affected by a nephropathy distinct from the MCKD.
Methods: Pedigrees' evaluation included renal ultra-sound and pathology with immuno-histochemical evaluation for Tam-Horsfall glycoprotein. Genetic screenings were performed by PCR, direct sequencing and MLPA.
Results: In both MCKD families, clinical findings showed intra-familial variability. Two novel UMOD mutations segregating with the phenotype were identified. However, both families included individuals presenting a non-MCKD renal phenotype: for pedigree 1, a case of polycystic kidney disease displaying a novel PKD1 mutation; for pedigree 2, an adult-onset nephrotic syndrome with a membranous pattern on the renal specimen. No UMOD mutations were found in these individuals.
Conclusions: We present two families demonstrating simultaneous occurrence of different kidney diseases, all potentially causing ESRD and with three novel mutations in total. Our results show that a) if two rather common nephropathies, like ADPKD and membranous nephropathy, can concur with MCKD, the latter is probably more prevalent than previously anticipated; b) for a given pedigree, the diagnosis of an inherited "*reno*type" should not be *a priori* extended to all affected members, particularly if the phenotype presents with variable expressivity or if ESRD is considered the sole undisputable renal phenotype characteristic.

J04.02
VEGFA gene expression in liver cells after mesenteric ischemia and the possible affects of montelukast

E. Kocaman[1]*, **Z. Ocak***[1]*, A. Duran*[2]*, T. Ocak*[2]*, S. Tasdemir*[3]*;*
[1]Department of Medical Genetics, Abant Izzet Baysal University Medical School, Bolu, Turkey, [2]Department of Emergency Medicine, Abant Izzet Baysal University Faculty of Medicine, Bolu, Turkey, [3]Department of Medical Genetics, Atatürk University Medical School, Erzurum, Turkey.

Objective: The aim of our study was to investigate the effect of mesenteric ischemia on *VEGFA* gene expression in rats liver cells, and the possible affects of montelukast on this process
Material - Method: The study protocol was approved by the Local Ethical Committee of Laboratory Animals at Abant Izzet Baysal University. A total of 24 female Wistar albino rats were used in our study. The rats were randomized into four groups as follows: group A: Sham-controls (n:6), group B: Ligation (n : 6), group C: Ligation and montelukast (n :6), group D: control and montelukast (n : 6). RNA was extracted from the liver cells. The expressions of *VEGFA* were analyzed using the Reverse Transcription Polymerase Chain Reaction. Relative quantification of mRNA was carried out using the comparative CT method.
Results: When the gene expression values of all groups were compared, a significant difference was observed at group D. It showed %100 percent increased VEGFA gene expression according to the reference group, while the expression levels of group C and group B were lower than that of group D. Also, when groups C and B were compared, the expression level in group C was found to be higher than that of group B, although the difference was not statistically significant.
Conclusion: This study demonstrates that montelukast supplementation may have a protective effect from ischemia induced liver toxicity in rat liver by causing an incremental effect on *VEGFA* gene expression in rat liver cells.

Hereditary Intrahepatic Cholestasis of Pregnancy and Low Phospholipids Associated Cholelithiasis: prevalence of ABCB11 variants in ABCB4 non- mutated patients.

F. DUFERNEZ[1]*, K. Belabbas*[1]*, E. Fernandez*[1]*, C. Corpechot*[2]*, O. Chazouillères*[3]*, O. Lascols*[4]*, C. Housset*[3]*, V. D. Barbu*[4]*;*
[1]AP HP HUEP HOPITAL ST ANTOINE, LCBGM, PARIS, France, [2]AP HP HUEP HOPITAL ST ANTOINE, CRMIVB, PARIS, France, [3]AP HP HUEP HOPITAL ST ANTOINE, CRMIVB & UPMC Univ Paris 06, PARIS, France, [4]AP HP HUEP HOPITAL ST ANTOINE, LCBGM & UPMC Univ Paris 06, PARIS, France.

Inherited intrahepatic cholestasis and cholelithiasis represent a heterogeneous group of autosomal recessive liver disorders that may become symptomatic in adulthood. These disorders affect secretion of the main bile constituents and genetic studies identified sequence variations in biliary transporter genes. We aimed to 1) identify the ABCB4 and ABCB11 sequence variations in patients from Saint Antoine Hospital rare metabolic biliary diseases centre. 2) determine the prevalence of ABCB4 and/or ABCB11 sequence variations in 2 related cholestatic/cholelithiasic diseases i.e.: Low Phospholipids Associated Cholelithiasis (LPAC) or Intrahepatic cholestasis of Pregnancy (ICP). Methods: Patients were diagnosed LPAC (n=580) or ICP (n=200). DNA was extracted from blood using the Puregene kit (Qiagen). Specific PCR of 27 exons and adjacent junctional introns were run and

sequenced by Sanger technology. Whole BSEP gene was sequenced in 112 patients. Moreover, the bi-allelic status of the variant c.1331T>C of ABCB11 gene was studied in 490 patients. Fisher Test was performed for statistics. Results: ABCB4 variants were found in 50% of LPAC, and 27% of ICP. Homozygous polymorphous ABCB11 c.1331T>C was found in 94 of 290 ABCB4 non-mutated LPAC patients and 71 of 148 ABCB4 non-mutated ICP (32,4% vs. 48,0%, respectively, p<0.002). Other ABCB11 mutations were found in 3 of 60 ABCB4 non-mutated LPAC and 11 of 52 ABCB4 non-mutated ICP (5% vs. 21.2%, respectively, p<0,02). The presence of ABCB11 variants in non-mutated ABCB4 patients was found significantly more frequent in ICP than in LPAC, supporting a relationship between ABCB11 sequence variation and ICP.

Association study of cytokine genes polymorphisms revealed a strong association of rs1143634 of IL1B gene with peptic ulcer disease in Volga-Ural region of Russian Federation

A. Nurgalieva[1], *E. Khalitova*[1], *L. Bagautdinova*[1], *L. Gabbasova*[2], *A. Krukova*[2], *E. Khusnutdinova*[1,3];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Bashkir Medical State University, Ufa, Russian Federation,* [3]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation.*

Ulcer disease, that is, gastric (GU) and duodenal (DU) ulcers, is a focal mucosal defect with inflammatory cell infiltration and coagulation necrosis extending through the muscularis mucosa. The genes that encode proinflammatory and anti-inflammatory cytokines are good candidate markers of host susceptibility to gastroduodenal disease.
The present study was performed to evaluate whether or not the five genetic polymorphisms of IL1B (3953C>T; rs1143634), IL1-RN (VNTR polymorphism; rs71941886), IL8 (-251T>A; rs4073), IL10 (-627C>A; rs1800872) and TNFA (-308G>A; rs1800629) genes are associated with peptic ulcer disease (PUD) in Volga-Ural region of Russian Federation.
This study enrolled 264 patients with gastric and duodenal ulcers, the control group included 282 unrelated individuals without gastro-duodenal pathology with different ethnic origins (Russians, Tatars, Bashkirs). Genotyping was performed by polymerase chain reaction - restriction fragment length polymorphism analysis.
The analysis has revealed a strong association of *C/*C genotype of the 3953C>T of the IL1B gene with PUD in common group (OR=1,7; P=0,003; $\chi2$=1,7). The control individuals had significant higher frequency of *C/*T heterozygous genotype of this SNP than patients (OR=0,6; P=0,02; $\chi2$=5,7). We have also detected in Tatars that frequency of *A/*A genotype of the -627C>A of the IL10 gene are significant more prevalent in healthy donors than in PUD-individuals (OR=0,3; P=0,05; $\chi2$=3,8). No significant difference was observed in allele or genotype frequencies of other investigated polymorphisms between PUD patients and control group (p>0,05).
Thus, we have determined statistically significant association between IL1B gene polymorphism and peptic ulcer in Volga-Ural region of Russia.

Relationship between ADRB2 gene polymorphism and bronchial asthma course.

S. Melnik[1], *M. Zhdanova*[2], *E. Ysupova*[2], *G. Novik*[2], *K. Sergeeva*[1], *M. Nikitin*[3], *V. Larionova*[4];
[1]*Saint-Petersburg State Medical University, Saint-Petersburg, Russian Federation,* [2]*St. Petersburg State Pediatric Medical University, Saint-Petersburg, Russian Federation,* [3]*Lumex-Marketing Ltd., Saint-Petersburg, Russian Federation,* [4]*North-Western State Medical University named after I.I.Mechnikov, Saint-Petersburg, Russian Federation.*

Background: functional activity of β_2-adrenoreceptor (ADRB2) can determine susceptibility of bronchial muscles to endogenous and exogenous β-agonists and influences on bronchial conductance.
Objectives: In the present study we have investigated G/R polymorphism in 16th codon of ADRB2 in bronchial asthma patients and the relationships of these polymorphic genotypes with BA course.
Methods: G/R polymorphism in 16th codon of ADRB2 was detected by RFLP in 337 children with BA. According disease course all children were divided in 3 subgroups: mild, moderate and severe.
Results: we haven't revealed significant differences in polymorphic genotypes distribution according to disease course. In analysis of genotype distribution depending disease onset we found that GG genotype was more frequent in children who developed severe BA in 1st year of life (p=0.039). Also GG genotype was associated with mild disease course in children with BA onset after the 5th year (=0.001). Prevalence of GG genotype due to disease course and onset in table is shown below.
Conclusions: GG genotype of ADRB2 associated with severe disease course in early onset BA and mild course in children who had onset after 5th year.

Table 1

BA onset, years	Mild BA course n (%)	Moderate BA course n (%)	Severe BA course n (%)

The contribution of polymorphisms of ACE, SLC6A4, AGT, ANK3, APOE, COMT, LMX1A, MTHFR and NGF genes to the cognitive dysfunction (CD) in patients with metabolic syndrome (MS)

A. S. Ulitina[1,2], *I. B. Zueva*[2], *N. V. Moroshkina*[2], *M. M. Mitupova*[1], *D. N. Ghorab*[3], *M. V. Moskalenko*[4], *M. V. Dubina*[1,3];
[1]*I.P.Pavlov State Medical University, St.Petersburg, Russian Federation,* [2]*Almazov Federal Heart, Blood and Endocrinology Centre, St.Petersburg, Russian Federation,* [3]*Academic University – Nanotecnology Research and Education Centre of Russian Academy of Sciences, St.Petersburg, Russian Federation,* [4]*Centogene GmbH, Rostock, Germany.*

Background. Inherited risk factors of cardiovascular and endocrinological diseases also play a role in the CD. Early diagnosis of CD in patients with MS is an important medical and economic problem.
Design. Pilot case-control study.
Aim: to determine the role of mutations in 9 genes (table 1) in the CD in patients with MS.
Materials and methods. 883 unrelated Caucasian participants (at working age) were screened for MS and CD by anthropometry, weighing, blood pressure test, blood chemistry (glucose, cholesterol, triglycerides), and neuropsychological tests. Then 30 males and 25 females (46,6±5,9 years old) with the most representative symptoms were underwent detailed examination with PCR-RFLP analysis of 9 genes (table 1). Statistical analysis was performed by Statistica 8.0.
Results. Allele *D* of *ACE* was associated with MS, but not with CD. Other eight genes demonstrated association of their polymorphisms with CD; see table 1 for unfavourable alleles.

Table 1

Gene	Polymorphism	CD-associated allele
ACE	*I/D*	*n/a*
SLC6A4	*L/S*	*S*
	rs25531	*G*
AGT	*rs699*	*C*
ANK3	*rs10994336*	*T*
APOE	*rs429358, rs7412*	*E4*
COMT	*rs4680*	*A*
LMX1A	*rs4657412*	*C*
MTHFR	*rs1801133*	*T*
NGF	*rs6330*	*C* for females, *T* for males

Furthermore, authors revealed six clinical phenotypes caused by sex and *rs6330* (table 2):

Table 2

Sex	*NGF* genotype		
	CC	*CT*	*TT*
Males	↑MS	↓ MS, ↓ CD	↑ CD
Females	↓ MS	↑MS, ↑ CD	↓ CD

Conclusion. Alleles of *SLC6A4*, *AGT*, *ANK3*, *APOE*, *COMT*, *LMX1A*, *MTHFR*, *NGF* contributed to the CD in patients with MS, and for *NGF* that association was sex-related.

APOE polymorphisms are not associated with the risk of coronary artery disease and in-stent restenosis in patients undergoing coronary artery stenting

P. Plevova[1,2], *L. Pleva*[3], *P. Kusnierova*[1,2], *M. Karpisek*[4], *J. Zapletalova*[5];
[1]*Department of Biomedical Sciencies, Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic,* [2]*Faculty Hospital, Ostrava, Czech Republic,* [3]*Cardiovascular Department, Faculty Hospital, Ostrava, Czech Republic,* [4]*BioVendor – Laboratory Medicine, Brno, Czech Republic,* [5]*Department of Medical Biophysics, Faculty of Medicine*

and Dentistry, Palacký University, Olomouc, Czech Republic.

Association of *APOE* polymorphisms with coronary artery disease (CAD), the risk of in-stent restenosis and correlation with plasma apolipoprotein E levels were assessed in patients undergoing coronary artery stenting. There were 269 subjects undergoing coronary artery stenting included. The *APOE* genotype frequencies were compared to the control group including 98 normal cholesterol non-CAD subjects; correlation with in-stent restenosis occurrence was also performed. *APOE* genotype was determined using real-time PCR. In 137 CAD patients, apolipoprotein E plasma levels were measured using ELISA method. In CAD patients, the distribution of *APOE* genotypes was following: ε3/ε3, 177 (65,8%); ε3/ε4, 58 (21,6%); ε4/ε4, 3 (1,1%); ε2/ε3, 26 (9,7%); ε2/ε4, 5 (1,8%); ε2/ε2, 0. There was no statistically significant difference in genotype distribution both compared to the control group (p=0,732) and between the in-stent restenosis (n=97) and non-in-stent restenosis groups (n=134) (p = 0,432, Fisher' exact test). Apolipoprotein E levels were significantly higher in patients with ε2/ε3 and ε2/ε4 genotypes (median 29,2 μg/ml) compared to ε3/ε3 (median 18,4 μg/ml) and ε3/ε4+ε4/ε4 (median 12,5 μg/ml) ones (p=0,017 and p=0,015, respectively, Mann-Whitney U test with Bonferroni correction). In conclusion, our results do not support the hypothesis that *APOE* genotypes are associated with an elevated risk of CAD or the risk of in-stent restenosis in patients undergoing coronary artery stenting. ε2/ε3 and ε2/ε4 were associated with higher plasma apolipoprotein levels than ε3/ε3 and ε3/ε4+ ε4/ε4 genotypes.

Genetic basis and clinical symptoms of Azeri patients suspected with the risk of Fanconi Anemia

B. Sadeghi[1], *E. Sakhinia*[2], *M. Asghari Estiar*[3], *A. Rezamand*[4], *M. Sakhinia*[5];
[1]*Tabriz Genetic Analysis Center (TGAC), Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Faculty of Medicine, Tabriz Genetic Analysis Centre (TGAC) and Tuberculosis and Lung Diseases Research Center, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [3]*Students Scientific Research Center, Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Department of Paediatric Haematology and Oncology, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [5]*University of Liverpool., Liverpool, United Kingdom.*

Fanconi anemia is the most prevalent inherited aplastic anemia. A diagnosis based wholly on the recognition of clinical symptoms is not reliable. The aim of this study was to investigate the clinical symptoms and points of possible chromosomal breakage in people with the risk of FA in the Azerbaijan region of Iran. A cross-sectional descriptive-analytic study was conducted on 20 patients,

suspected with the risk of FA, in which were confirmed with medical examinations. The type and number of chromosomal disorders were determined. The clinical disorders of the patients were studied with reference to their medical records. The average age of the patients within the study was 9.6 years. 8 of the cases had familial relations, 7 of which were cousins. 9 patients had co-morbid anemia, 8 patients suffered from platelet deficiency and 9 patients had hand and/or finger deformities. Using cytogenetic testing, FA was diagnosed in 5 of the cases. The percentage of mitotic abnormalities in the chromosomeswithout administration of mitomycin C varied between 5-30% in the cultures of the 5 affected patients and between 0-4% in the 15 unaffected patients. With the administration of mitomycin C, these percentages increased to 35-78% and 0-20%, respectively. The percentage of mitotic abnormalities and average numbers of chromosomal breakages in patients with Fanconianemia is higher to that of unaffected patients and control samples. Considering the variety of clinical symptoms for this illness, it is of great importance to conduct cytogenetic testing in order to obtain a definitive diagnosis.

Blood pressure and M235T AGT gene polymorphism in children with hypertrophic cardiomyopathy

O. Gromyko, *N. Beresneva, T. Sorokina, N. Averyanova, O. Kustova, N. Vashakmadze, E. Basargina, V. Pinelis;*
Scientific center of Children's Health, Russian Academy of Medical Sciences, Moscow, Russian Federation, Moscow, Russian Federation.

The polymorphism of adrenoreseptors, bradycardin and renin-angiotensin systems (RAS) genes play a significant role in the pathogenesis of essential hypertension and cardiovascular diseases.
We investigated the association the genes polymorphisms with the clinical course and changes in blood pressure over time in russian children with hypertrophic cardiomyopathy (HCM).
The association study was performed in 34 children age from 1 year to 12 years with HCM and in 150 population controls. The polymorphisms of REN (-83G>A), AGT (M235T), AGTR1 (1166A>C), AGTR2 (3123C>A), BKR2 (-58T>C), ADRB2 (48A>G, 81C>G) and MTHFR (677C>T) were studied using method hybridization with oligonucleotide biochips (BIOCHIP Ltd, Russia).
As a result, TT genotype of M235T polymorphism in the AGT gene were more frequent in patients than in the population (p = 0.028). It was revealed that the presence of the 235T allele of the AGT gene was a high degree of hypertrophy of the interventricular septum.
In conclusion we suggested that M235T polymorphism of the AGT gene may contribute to the higher risk of arterial hypertension in children with HCM.

Human IL28B polymorphism detection allows an interferon antiviral treatment for patients with hepatitis C virus

P. Gurban[1], *V. Celmare*[1], *G. Tardei*[2], *G. Cardos*[1], *E. Ceausu*[2], *P. I. Calistru*[3], *G. Oprisan*[4];
[1]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [2]*Victor Babes Hospital of Infectious and Tropical Diseases, Bucharest, Romania,* [3]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania,* [4]*Cantacuzino National Institute of Research-Development for Microbiology and Immunology, Bucharest, Romania.*

Patients infected with HCV genotype-1 undergoing standard of care treatment with pegylated interferon (PEG-INF) and ribavirin (RBV) achieve sustained viral response (SVR) at a rate of approximately 45% internationally and of approximately 56% in Romania. The patients who do not achieve SVR need to be identified as early as possible, in order to avoid unnecessary side effects and high costs.
Recently, it has been reported the impact of the IL28B rs12979860 polymorphism on response to therapy, the CC genotype being considered a predictive factor for achieving SVR.
The aim of our study has been to indentify the -3176C/T IL28B genotypes in order to contribute in selection of HCV infected patients for the personalized combined therapy.
The DNA was extracted from peripheral blood sampled from 22 HCV diagnosed Caucasian patients from Bucharest and nearby, with Invitrogen DNA Extraction Kit. The IL28B genotype identification was performed by Real-Time PCR method using Light Cycler 2.0 and LightMix IL28B Kit.
Our preliminary results identified the following IL28B rs12979860 genotype distribution: CC=4 patients (18,18%), CT=14 patients (63,64%) and TT=4 patients (18,18%). The IL28B rs12979860 C allele frequency observed in our patients (50%) is similar with some east European populations (Poland-46,5%), but lower than other neighboring populations (Russians -61.4-64.1%, Hungarians -65.1%).
Our study will continue with a larger HCV infected patients spectrum in order to analyze for the first time in SE Romania the correlation between the IL28B genotype of patients and their response to an interferon antiviral treatment.

Association of the MMP1 gene single nucleotide polymorphism with peptic ulcer in Volga-Ural region of Russia

E. Khalitova[1], *A. Nurgalieva*[1], *L. Gabbasova*[2], *A. Krukova*[2], *E. Khusnutdinova*[1,3];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Bashkir Medical State University, Ufa, Russian Federation,* [3]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation.*

Peptic ulcer (PU) is a chronic disease of the gastrointestinal tract, the main

manifestation of which is the formation of a stable enough ulcer in the stomach and / or duodenum. This disease is widespread throughout the world and get 7-10% of the adult population in different countries. Inflammatory reactions of ulceration are regulated by many metalloproteinases (MMP) and MMP-1 is a well-known destructive metalloproteinase. PU has a genetic background and the aim of this study was to investigate the allele and genotype distribution of -519A>G polymorphism in the MMP-1gene in patients with PU and healthy donors from Volga-Ural region of Russia.
The patient group consisted of 248 individuals with peptic (64) and duodenal (184) ulcer (DU) with different ethnic origins (Russians, Tatars, Bashkirs), the control group included 273 unrelated subject without gastroduodenal ulcer. Genomic DNA was extracted from peripheral blood leucocytes by standard phenol/chloroform method. Genotyping was performed by polymerase chain reaction with specific primers followed by restriction digestion and gel electrophoresis.
The analysis revealed that control subjects have significant higher frequency of *A*A genotype than patients with PU and DU in common group (P=0,03; $\chi 2$=4,49; OR=0,54; 95%CI=0,30 - 0,96). It was also detected the association of *G*G genotype and *G allele with gastro-duodenal ulceration in Russians (P= 0,02;$\chi 2$=5,17; OR=2,05; 95%CI= 1,10 - 3,81 and P= 0,05;$\chi 2$=3,8; OR=1,56; 95%CI= 1,00 - 2,45, respectively).
Thus, we have determined significant association -519A>G polymorphism of MMP-1 gene and gastro-duodenal ulcer in Volga-Ural region of Russia

Thyroid hormone resistance in presence or absence of abnormal thyroid hormone receptor

R. Bircan[1], *T. Güran*[2], *S. Turan*[2], *L. Akın*[3], *A. Altıncık*[4], *S. Kurtoğlu*[3], *E. Böber*[4], *A. Bereket*[2];
[1]*Namik Kemal University, Faculty of Arts ans Sciences, Department of Molecular Biology and Genetics, Tekirdag, Turkey,* [2]*Marmara University, School of Medicine, Department of Pediatric Endocrinology, İstanbul, Turkey,* [3]*Erciyes University, Faculty of Medicine, Department of Pediatric Endocrinology, Kayseri, Turkey,* [4]*Dokuz Eylül Üniversity, Faculty of Medicine, Department of Pediatric Endocrinology, İzmir, Turkey.*

Background: Resistance to thyroid hormones (RTH) syndrome is characterized with decreased response to thyroid hormones at target organs and it shows autosomal dominant inheritance pattern. The syndrome is also characterized with elevated thyroid hormone and nonsuppressed TSH levels in blood. Mainly, thyroid hormones (TH) show their effect on target tissues via thyroid hormone receptor beta (TRβ) and alpha (TRα). Generally, RTH etiology is based on TRβ gene mutations. Thyroid hormones could not bind to TRβ receptors. Subsequently, thyroid hormone-activated genes are not able to be expressed.
Aim: The purpose of this study is to investigate TRβ gene mutation prevalence in RTH cases in Turkey.
Material and Methods: Members of 14 families diagnosed as RTH syndrome were enrolled to this study. TRβ gene mutations located on Exon 7-10 were screened by using PCR and automated DNA sequencing system.
Results: Of 14 families, it is detected that members of 7 families (50%) were carrier of well-known TRβ gene mutations. Only 2 cases were sporadic among these 7 families.
Conclusion: As a result, RTH etiology is based on TRβ and TRα mutations. But in 15% of the patients, who resemble each other phenotypically, TRβ and TRα mutations could not be detected. So, it might refer to mosaicism. In this circumstance, genetic analysis might be performed on skin fibroblast cells or buccal epithelial cells in these patients. If any TRβ and TRα mutations could not be found in them, MCT8 and SECISBP-2 gene mutations should be investigated.

Association study of Interferon Induced with Helicase C Domain1 (IFIH1) polymorphisms with type 1 diabetes in a Tunisian population

F. Ben Hadj Slama[1], *A. Boumiza*[1], *I. Boussaid*[1], *I. Slim*[2], ***E. Chabchoub***[1], *L. Gueddah*[1], *N. Mahfoudh*[3], *K. Euch*[2], *L. Chaieb*[2], *R. Zemni*[1];
[1]*faculty of medicine of sousse, Sousse, Tunisia,* [2]*Farhat Hached Hospital, Sousse, Tunisia,* [3]*faculty of medicine of sfax, Sfax, Tunisia.*

Type 1 diabetes (DT1) is a multifactorial disease involving both genetic and environmental factors. IFIH1 senses and initiates antiviral activity against enteroviruses which are suspected in the etiology of DT1. Several polymorphisms have been studied within the IFIH1 gene such as rs1990760, rs2111485 and rs3747517. The aim of this study was to examine the association of these three polymorphisms with DT1 in the Tunisian population.
This study concerned 116 diabetic subjects and 168 controls that were recruited from Tunisia. The genotyping of rs2111485 and rs3747517 was realized by PCR followed by an enzymatic digestion and rs1990760 by MS-PCR.
The results did not show statistically significant association between the three polymorphisms and DT1 (rs1990760 p = 0,99 ; rs2111485 p = 0,44 and rs3747517 p = 0,11) although it was found that the AA genotype of rs3747517 was more frequent among controls than in diabetic subjects (p = 0,054). Furthermore the genotype GG seems to have a protective role against the diabetic retinopathy (p = 0,046). We also analyzed the association of these three polymorphisms with other clinical and biological criteria, whereas no significant association was found.
Our data indicate that the three polymorphisms of the IFIH1 gene are not associated to the DT1 and that the rs3747517 seems to influence predisposition to diabetic retinopathy in the Tunisian population.

Woodhouse-Sakati syndrome (WSS) is a rare autosomal recessive disorder, caused by mutations of the DCAF17 gene, located in 2q31.1. With the wealth of knowledge acquired since the original clinical description in 1983 and the discovery of the responsible gene in 2008, and because of the heterogeneity of the cases reported previously, it is necessary to better identify the phenotype.
The first exhaustive literature review permitted us to highlight, among the 72 patients from 29 families identified as WSS, 37 patients from 12 families whose clinical diagnosis was confirmed by the presence of one of the 9 DCAF17 mutations described. We also reported two new sibs identified with the c.127-3_127-1del(TAG)ins(AA) mutation.
WSS always encompasses (100%) hypogonadism (which is peripheral in female patients and central or mixed in male patients, with delayed puberty), low IGF1 without abnormality of GH rate and a fronto-temporal alopecia. It also combines intellectual disability of variable severity (87%), bilateral deafness (76%), cervico-facial and axial dystonia (42% of all cases, 89% after 25 years old,) and diabetes mellitus (66% of all cases, 96% after 25 years old). Symptoms occur mainly in adolescence. Patients also have discrete facial features, with a triangular elongated face, hypertelorism and a prominent nasal root.
Ubiquitous nucleolar expression of the DCAF17 protein, with overexpression in the brain, liver and skin, is compatible with the redefinition of phenotype including the 7 major signs.
Physiopathology, which may involve the role of ribosomes in the cellular activity, remains unclear.

New Genetic abnormalities in Mexican population affected by non-21-hydroxylase-deficiency Congenital Adrenal Hyperplasia

G. Queipo, *M. Martin, N. Garibay, N. Najera;*
Hospital General de México-Facultad de Medicina UNAM, México DF, Mexico.

Congenital Adrenal Hyperplasia (CAH) is a group of autosomal recessive disorders of sex differentiation development, resulting from deficiencies in one of five specific enzymes involved in the cortisol pathway within the adrenal gland. Deficiency in 21 α-hydroxylase, account for 90-95% of the overall CAH, the rest of these enzymatic defects is rare in most populations. The major clinical features are hypertension and virilization defects; in newborn

females, ambiguous genitalia may be seen and heterosexual precocious puberty may be a consequence. Among males, peripheral isosexual precocious puberty is frequent. Over 50 mutations in the CYP11B1 gene have been associated with this adrenal phenotype. The 17 α-hydroxylase/17, 20-lyase defect affects both the adrenal gland and the gonads, interfering with the synthesis of both cortisol (derived from adrenal 17 α-hydroxylase activity) and androgen (derived from adrenal and gonadal 17, 20-lyase activity). In female patients, the clinical picture includes hypertension, hypokalemia, lack of pubertal development and primary amenorrhea; in males, affected individuals shown impaired virilization and lack of pubertal development. More than 54 mutations have been described in CYP17A1. We described two new CYP17A1 gene mutations, in two 46, XY phenotypic females. Together with molecular findings we suggest that one the mutants could be secondary to a founder effect. We present the clinical and molecular data in new genetic abnormalities in Mexican population affected by non-21-hydroxylase-deficiency Congenital Adrenal Hyperplasia

J04.16
Development of methodological approaches to DNA diagnostics of CAH in Ukraine

S. Chernushyn, *L. Livshits;*
Institute of Molecular Biology and Genetics, Kiev, Ukraine.

The cause of 95% of the congenital adrenal hyperplasia (CAH) is a 21-hydroxylase deficiency. CAH is an autosomal recessive genetic disorder with a frequency of 1:5000 to 1:15000. The CYP21A2 gene, encoding 21-hydroxylase, is located on the short arm of chromosome 6 at position 21.3, there also located CYP21A1P pseudogen. Group of genes RP2-C4A-CYP21A2-TNXB has high homology with the corresponding pseudogenes, which located in the same chromosom region. It makes analysis of CYP21A2 gene mutations quite complicated.
The aim of our study was to develop methods for analysis of different mutations of the CYP21A2 gene.
Gene mutations P30L, I2G, G110_8nt, E6 cluster, Q318X, R356W, V281L were investigated by allele specific PCR and RLFP. Deletion/convertion of CYP21A2 gene was investigated with a help of long range PCR. The method was tested on control samples with known mutations in the CYP21A2.
The analysis of the CYP21A2 gene mutations was performed for five CAH patients. 4 of them have homozygous gene deletion/convertion, another patient has I2G compound with R356W.

A Case Report: Hirschsprung's Disease in three sisters

Y. Goto[1,2], *A. Kondo*[3,2], *S. Sato*[1,2], *Y. Ohnuki*[2], *H. Moriya*[2], *K. Tsuji*[2], *H. Yokoyama*[2], *S. Izumi*[1,2];
[1]*Dept. of Obstetrics and Gynecology, Tokai University School of Medicine, Kanagawa, Japan,* [2]*Dept. of Genetics, Tokai University Hospital, Kanagawa, Japan,* [3]*Dept. of Obstetrics and Gynecology, Kagawa National Children's Hospital, Kagawa, Japan.*

Hirschsprung's Disease (HD) occurs in about one in 5,000 children. The affected infant frequently present such symptoms of impaired intestinal motility as constipation, emesis, abdominal pain or distention, and occasionally diarrhea in the first two months of life with typically a failure to pass meconium within the first 48 hours of life.
A healthy couple who had got two girls with HD came to us. The first daughter was diagnosed as short-segment aganglionosis and the second daughter had total colonic lesion. Both of them did not have syndrome-cognitive features. Unfortunately, their second daughter died because of severe pneumonia in spite of successful operation. The couple suspected some relation between daughters' similar conditions and sought to a medical counseling on next pregnancy. They had lost their daughter just before they came, so followed with psychological care with clinical psychologist we have talked about the cause of HD. As for genetics, we discussed sporadic cause and the possibility of single gene cause because two girls did not have any further features. They decided not to undergo any genetic test and they told us they would like to accept if the next child has HD.
About a year later, she has got pregnant naturally and came to maternity service again. Her pregnancy went well and had another daughter. The third daughter was suspected HD and needed an operation. The diagnosis was confirmed by colon biopsy. When HD was observed repeatedly in the same family, we have to consider genetic cause of HD carefully.

J04.18
A novel *SRD5A2* gene mutation in a Turkish patient with 46,XY disorder of sex development

M. Boyraz[1], *K. Ulucan*[2], *T. Akcay*[3];
[1]*Fatih University, Faculty of Medicine, Department of Pediatric Endocrinology, Ankara, Turkey,* [2]*Üsküdar University, Faculty of Engineering and Natural Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey,* [3]*Dr. Sadi Konuk Education and Research Hospital, Department of Pediatric Endocrinology, Istanbul, Turkey.*

Introdution: 5-alpha-reductase type 2 deficiency (264600) is a rare autosomal recessive inherited disorder. Affected 46,XY individuals usually present with ambiguous genitalia characterized by pseudovagina, microphallus, cryptorchidism and perineoscrotal hypospadias, at birth and are often raised as females. The abnormal 5-alpha-reductase type 2 as a result of mutations in the *SRD5A2* gene could lead to 46,XY disorders of sex development. Therefore, genetic testing of *SRD5A2* is a useful tool for the definitive diagnosis of 5-alpha-reductase type 2 deficiency. In this study, we report a novel mutation in *SRD5A2* gene in a Turkish patient with 5-alpha-reductase type 2 deficiency
Materials and Methods: Five of the coding regions of SRD5A2 gene, including exonic- intronic boundaries, were amplified by using spesific primers and sequenced directly.
Results: Two heterozygous mutations, c.164T>A that leads to a amino acid substitution p.Leu55Gln and c.269A>C, leading to a amino acid substitution p.His90Pro were detected in the examined patient. The latter one, c.269A>C, was a novel mutation found in the patient.
Discussion: It is important to determine the genetic factor leading to 5-alpha-reductase type 2 deficiency in patients for the proper treatment. In this report, we detected a novel mutation which can cause to the anomaly, but in order to have a proper understanding about the effect of the mutation, functional analysis should be carried out and this will be our future subject.

J04.19
Association of VDR (rs731236) and NFKB1 (rs28362491) gene polymorphisms with aggressive periodontitis

T. Natsvlishvili, *T. I. Kadurina, A. V. Tsimbalistov;*
North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation.

Background: Aggressive periodontitis (AgP) is rare but rapidly progressive periodontal disease which affects systematically healthy individuals less the 30 years of age. It is still unclear leading etiologic and pathogenic risk factors for this disease. The aim of this study was to investigate the association between *VDR* (rs731236) and *NFKB1* (rs28362491) gene polymorphisms and AgP in Russian population.
Materials and methods: Genotyping of peripheral blood samples of 98 subjects (AgP - 43, chronic periodontitis (CP) - 20 and healthy subjects - 35) was performed with standard polymerase chain reaction-restriction fragment length polymorphism assay (PCR-RFLP). Gene-gene interaction among loci of two genes was studied by using the multifactor dimensional reduction method (MDR).
Results: There was an association between the del/del genotype of *NFKB1* gene and AgP (p=0,027). MDR test has shown a statistically significant association of combined genotypes del/del (*NFKB1*) and T/T (*VDR*) with AgP (p=0.0004) compared with CP.
Conclusion: del/del genotype of *NFKB1* (rs28362491) gene is associated with AgP and has gene-gene interaction with T/T genotype of *VDR* (rs731236) gene.

Gene expression profile of TGF-β Signaling and Extracellular Matrix and Adhesion Molecules pathways in human end stage Heart Failure.

M. Szperl[1], *A. Parulski*[1], *E. Stankiewicz*[2], *M. Franaszczyk*[1], *M. Roszczynko*[1], *A. Rozanski*[1], *M. Fedorowicz*[2];
[1]*National Institute of Cardiology, Warsaw, Poland,* [2]*Children's Memorial Health Institute, Warsaw, Poland.*

Although fibrosis was enhanced, collagen content in end-stage HF was only slightly higher than in control tissue. We hypothesis that alteration in genes expression is the major cause of interstitial fibrosis. Using the TGF-β Signaling and Extracellular Matrix PCR Array, we examined the gene expression. Methods: End -stage heart failure tissue (LV) was taken during heart transplantation. The controls were myocardial tissue from multi-organ donors. Cardiac fibrosis was evaluated by Picrosirius red staining. Total RNA was

converted into cDNA. Each PCR Array is a 96-well plate containing RT qPCR primer assays set of 84 related genes. Expression of SMADs proteins was investigated by immunohistochemistry (IHC) staining. Genes demonstrated at least 4-fold differences were taken into account. Results: Among the 84 ECM and Adhesion Molecules related genes, up-regulated was observed in 23 genes while 7 genes were down-regulated. Among the 84 TGF-β signaling related genes, up -regulated was observed in 23 genes while 4 genes was down-regulated. A subset of 8 of the 23 genes represent TGF-b and TGF-β superfamily cytokines, and 12 genes represents SMADs and SMAD target genes. All the results presented were highly significant statistically. IHC confirmed on protein level overexpression and translocation to the nucleus SMADs complexes. Although all patients received β-blockers and ACE inhibitors in all we observed interstitial fibrosis. Our results suggest that interstitial fibrosis mainly results from increased activity of TGF-β signaling pathway. Upon activation, the SMAD1 forms a complex with SMAD4 and translocates to the nucleus to regulate transcription.

A novel homozygous mutation in the GCMB gene in a patient with hypoparathyroidism

B. Erturk[1], *E. Karaca*[1], *C. Silve*[2], *F. Ozkinay*[1];
[1]*Ege University Faculty of Medicine Department of Medical Genetics, Izmir, Turkey,*
[2]*Genetic and Biochemical Laboratory, Bichat Claude Bernard Hospital, Paris, France.*

Mutations in the calcium-sensing receptor gene (CaSR), in the parathyroid hormone gene (PTH), or in the glial cells missing gene (GCMB) may cause familial isolated hypoparathyroidism. The condition may be inherited either autosomal dominant or autosomal recessive. Here, we present a case of autosomal recessive hypoparathyroidism with a novel mutation in the GCMB gene.

A 22 year-old male was referred to Medical Genetics Department due to mental retardation and seizures. His parents were not consanguineous and there was no family member having similar findings. He first presented at age 3 with seizures due to hypocalcemia and hypomagnesemia. On physical examination he had short stature, motor, mental, growth retardation, and chronic tetany. Brain magnetic resonance imaging (MRI) showed calcifications in basal ganglia. Ophthalmologic examination revealed bilateral cataract. Cranial computered tomography (CT) imaging showed diffuse cerebral atrophy. He had a chronic hypoparathyroidism with hypocalcemia and hyperphosphatemia. No mutation was found in 2-7 exons of the CaSR gene. A novel homozygous mutation (c.90+1 G>A) affecting intron 2 donor splice site was identified in the GCMB gene.

Therefore, we concluded that patient had autosomal recessive hypoparathyroidism due to absence of functional GCMB protein.

Study of mutations in exons 12-15 and 19-23 MYH7 gene in HCM (Hypertrophic Cardiomyopathy) patients in Chaharmahal Va Bakhtiari province

S. Heydari[1], *R. Pour Ahmad*[2], *A. Khaledi Far*[3], *M. Hashem Zadeh*[1], *S. Heydari*[3], *F. Azadegan*[1];
[1]*Cellular and Molecular Reaserch center, Shahrekord, Islamic Republic of Iran,*
[2]*Sharekord University, Shahrekord, Islamic Republic of Iran,* [3]*Sharekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran.*

Background: Hypertrophic cardiomyopathy (HCM) is the most common kind of Mendelian inherited heart disease, affects 0.2% of the global population and also is the most common cause of sudden cardiac death in individuals younger than 35 years old. Approximately in %35 of cases, exons 8-24 of MYH7 gene, which encoded heavy chain of β-Myosin, are affected. The aim of present study was to investigate the possible presence of mutation in exons 12-15 and 19-23 MYH7 gene, which has already been reported to accommodate some mutations, in 30 patients with HCM in Chaharmahal Va Bakhtiyari province. Method: DNA was extracted using standard phenol-chloroform method and then was used for amplification and gel electroploresis by PCR- SSCP/HA procedure. Finally, the suspected cases containing possible mutations were selected for the direct sequencing and the results were seen by chromas software. Results: In exons 13, 14, 15, 20, 21 and 23 there was no change, but two polymorphisms including 5811 C>T and 5845 G>A were found in exon 12 of one and six patients, respectively. And two mutations including 9692 C>T and 10824 G>A were found in exons 19 and 22 of two and one patients, respectively. Conclusion: Based on present study, we've concluded that changes in exons 12, 19 and 22 are involved in HCM disease in this province. However, further study on much more cases of disease and in other exons of this gene is essential, to determine the role of this gene and its relationship with HCM in this province.

A case of Thalassemia major and gastric cancer

S. Meduri, *E. Moschella, M. I. S. Crapanzano, B. Piraino, S. Briuglia, C. D. Salpietro, L. C. Rigoli;*
Genetics and Pediatric Immunology, Messina, Italy.

β-Thalassemias are hereditary blood disorders characterized by abnormalities in the synthesis of the β hemoglobin chains. This disease causes excessive storage of iron in all organs. Treatment of β-thalassemia major consists of regular blood transfusions, iron chelation and management of secondary complications of iron overload. Iron and its binding proteins have immunoregulatory properties, but iron excess may produce several effects. The oxidative damage, in correlation with elevated ferritin levels, occurs in thalassemia through the production of oxygen-free radicals. In turn, oxidative damage can give rise to a neoplastic clone through genetic or epigenetic alterations. These theories could indicate a pathogenetic correlation between thalassemia and cancer. We describe the first report of a gastric cancer in thalassemic patients. A 40-year-old male with thalassemia major presented 7 Kg weight loss in a month and began to complain of intense stomach pain, nausea and bloat. The determination of CA 19.9 showed abnormal levels. Gastrointestinal endoscopy demonstrated a irregular ulcer in the pericardial gastric fundus. Biopsy of the gastric mucosa showed: "adenocarcinoma scraps, intestinal type, moderately differentiated, infiltrating with reaction desmoplastic stroma (HER score 2=1) which was associated with chronic gastritis and findings of haemosiderosis"; H. pylori was not found. CT of the chest, abdomen and pelvis showed enlarged epigastric, lymph nodes and ascites. The coexistence of malignancy and beta thalassemia is not rare. Whether there is a link between thalassemia and malignancy or whether malignancy is more frequent in thalassemic patients simply because they live longer, is still to be defined.

S. Meduri: None. **E. Moschella:** None. **M.I.S. Crapanzano:** None. **B. Piraino:** None. **S. Briuglia:** None. **C.D. Salpietro:** None. **L.C. Rigoli:** None.

Evaluation of the Verigene warfarin genotyping kit: Buccal swab as an applicable sample

A. Kwon[1], *j. Kim*[1], *H. Lee*[1], *J. Park*[1], *H. Chae*[1], *M. Kim*[1], *Y. Kim*[1], *Y. Oh*[2];
[1]*Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,* [2]*Department of Internal Medicine and Cardiovascular Center and Cardiolgy Division, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of.*

Warfarin is the most widely used prescribed oral anti-coagulant for the treatment of thromboembolism. However, warfarin dosing is problematic because of its narrow therapeutic range and large inter-patient variability. We assessed the feasibility of the Verigene Warfarin Metabolism Nucleic Acid Test (Nanosphere, Inc., Northbrook, IL), a automated microarray-based assay, compared to bidirectional sequencing, to evaluate the analytical performance of the Verigene test. Fifty samples were included; 36 healthy persons and 14 patients with arrhythmia who treated with warfarin. The genotype of *CYP2C9* and *VKORC1* analyzed by Verigene test was completely agreeable with direct sequencing method. *CYP2C9**1*1 allele was detected in 90% (45/50) and remaining 10% (5/50) presented *CYP2C9**1*3 allele. *VKORC1* 1173TT allele and 1173CT were found in 78% (39/50) and 22% (11/50), respectively. The frequencies of combined genotype were as follows: *CYP2C9* wild type plus *VKORC1* 1173TT was 68% (34/50), *CYP2C9* *1*3 plus *VKORC1* 1173TT was 10% (5/50), and *CYP2C9* wild type plus *VKORC1* 1173CT was 22% (11/50). We also evaluated the potential of buccal swab as an applicable sample for Verigene test because peripheral blood cannot be used in some patients such as post-hematopoietic stem cell transplantation status. Genotyping was successfully performed using suspension of buccal swab when the sample contains at least 0.3×10^6 epithelial cell/mL. As conclusion, the Verigene test offers advantages for the detection of *CYP2C9* and *VKORC1* polymorphisms such as easiness of use and rapid detection time, and the buccal swab can be an excellent alternative sample of peripheral blood in case of need.

The Approach to the Case of Rarely Seen Adult Morque Syndrome at Emergency Service

T. Ocak[1], *Z. ocak*[2], *A. Duran*[3], *M. Bilgi*[4], *A. Demirhan*[4], *M. Şit*[5];
[1]*Abant Izzet Baysal University Medical Faculty, Department of Emergency Medicine, Bolu, Turkey,* [2]*Abant Izzet Baysal University Medical Faculty, Department of Medical Genetics, Bolu, Turkey,* [3]*Abant Izzet Baysal University Medical Faculty, Department of Emergency Medicine, Bolu, Turkey,* [4]*Abant Izzet Baysal University Medical Faculty, Department of Anesthesiology and Reanimation, Bolu, Turkey,* [5]*Abant Izzet Baysal University Medical Faculty, Department of General Surgery, Bolu, Turkey.*

Morquio syndrome (MPS IV) which is a kind of mucopolysaccharidosises is a hereditary lysosomal storage disease. These patients generally pass away due to cardiopulmonary

and neurologic function disorders at young adult period. However,

medical care and close clinical observation developing recently have extended the life time of the patients until sixth decade. The adults who have congenital genetic disease apply to adult emergency clinics as a result of these developments. It is aimed in this case to present a case of morque syndrome patient who came to our emergency clinic with the complaint of abdominal distension and got the diagnosis of strangule umbilical hernia.The male patient who was 27 years old and had morquio syndrome (MPS IV) was brought to our emergency clinic by his family due to the complaints of nausea, vomit, abdominal distension existing for 4 days. As a result of general surgery consultation, etrangule umbilical hernia was detected and operation decision was taken. Necessary preparations for difficult intubation were made due to existing dysmorphologic appearance, being 4 of mallampati score, being restricted of mouth opening and being big of tongue.

Firstly, the operation of the patient was performed with successful spinal anesthesia instead of planned gegional anesthesia. The patient who did not need postoperative intensive care was sent to general surgery service without any problem. Development of early diagnosis methods, starting to treatment early, progress of rehabilition studies improve the the patients' quality of life who have severe genetic diseases.

NPHS2 R229Q polymorphism in children with nephrotic syndrome

C. Duicu[1], *F. Tripon*[2], *O. Marginean*[1], *C. Banescu*[3];
[1]*Pediatric Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [2]*University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [3]*Genetic Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.*

The podocin (NPHS2) gene encodes podocin protein, which has an important role in glomerular ultrafiltration and controlling slit membrane permeability. Mutations in NPHS1, which encodes nephrin, are the main causes of congenital nephrotic syndrome (CNS) in Finish patients, whereas mutations in NPHS2, which encodes podocin, are typically responsible for childhood-onset steroid-resistant nephrotic syndrome in European populations.**Material and method**: The study group consisted of 48 children diagnosed with nephrotic syndrome (NS) in a Romanian population. This cohort included 3 samples of congenital or infantile onset NS cases and 45 samples of sporadic cases of NS (10 cases with steroid-resistant nephrotic syndrome and 35 cases with steroid-sensitive nephrotic syndrome). Fifty healthy children were enrolled as the control group.
All children were genotyped for NPHS2 R229Q polymorphism. **Results**: Three cases were diagnosed with congenital nephrotic syndrome (CNS) with typical histological exam, and the others 45 had idiopathic nephrotic syndrome.
NPHS2 R229Q polymorphism was detected only in two cases of CNS and in none patient with other type of NS or in control group. **Conclusions:** This study demonstrates that mutation of NPHS2 R229Q can be responsible for CNS in this population. Further studies with a larger number of patients are needed.

Cardiovascular events in patients with thrombophilia

R. Buzas[1], *G. Borzak2*[2], *C. Gug*[1], *I. Mozoş*[1], *C. Şerban*[1], *R. Mihăescu*[1];
[1]*University of Medicine and Pharmacy ,, Victor Babes" Timisoara, Timisoara, Romania,* [2]*Oncomed –Onco-hematology Clinic, Timisoara, Romania.*

Background: Cardiovascular events, particularly in young people, are part of the research areas in thrombophilia pathology. The aim of our study was to evaluate cardiovascular events in patients with thrombophilia.
Material and method: A total of 12 patients with thrombophilia (diagnosed based on a combination of up to 3 mutations) from the Oncology Clinic "Oncomed" Timisoara, Romania were consecutively enrolled in the study between 2010-2013. We excluded pregnant women and patients undergoing anticoagulation therapy.
Results: 58.3% of the patients were homozygous and 41.7% were heterozygous. By all patients, 4 patients were with cardiovascular events: 2 with myocardial infarction (EKG documented), one with ischemic stroke (MRI documented) and one with portal vein thrombosis - (CT documented). All cardiovascular events occurred in patients under 32 years old. Homozygous patients had a significantly increased number of cardiovascular events compared with the heterozygous patients ($p<0.001$).
Conclusion: Myocardial infarction, ischemic stroke, or portal vein thrombosis occured more frequently in patients with thrombophilia, especially in homozygous forms. Thrombophillia may be a cause of cardiovascular events in young patients with no cardiovascular risk factors, but with a hereditary history of thromboembolic events.

The effect of 17-Beta Estradiol on the male rat heart electrophysiological parameters

Y. Kucukbagriacik[1], *M. Ayaz*[1], ***D. Dursunoglu***[2];
[1]*Selcuk University, Medicine Faculty, Department of Biophysics, Konya, Turkey,* [2]*Selcuk University, Medicine Faculty, Department of Histology-Embryology, Konya, Turkey.*

Premenopausal women have a significantly lower risk of coronary artery disease than men or postmenopausal women, suggesting that estrogens have cardioprotective effects. The underlying mechanism of this protection remains unknown. The aim of this study was to investigate the effect of 17-Beta Estradiol on the male rat heart. Effect was tested by means of electrophysiological responses through the intracellular recording of action potential (AP), contraction and by the evaluation of the immunohistochemical expressions of calcium and potassium channels. Experiments were carried out on three mounts old 27 male Wistar Albino rats. In order to achieve the planed purpose, 3 experimental groups were organized: Control (Con), Castrated (E-) and 17-Beta Estradiol given to castration (EX). Immunohistochemistry was performed with L-type calcium and potassium channel antibodies. Our results have shown that; body weights of E- and EX group decreased with an increase blood glucose levels. Recorded AP of E- and EX groups have shown to decrease maximum depolarization, resting membrane potential and the amount of depolarization. Concomitantly, measurements of the repolarization phases of AP's were found to be increased in E- and EX groups. Immunohistochemical results on the experimental groups have shown that the expression of calcium channels increased in E- group, decreased in EX group. Whereas, the expression of potassium channels decreased in E- group while did not change in EX group. This prolong repolarization phase was due to increased in the expression of the calcium channels while decreased in the expression of the potassium channels.

Y. Kucukbagriacik: None. **M. Ayaz:** None. **D. Dursunoglu:** None.

Malignant infantile osteopetrosis and pericentric inversion of chromosome 9 in an infant with severe dysmorphic features

E. Pop[1], *R. Stroescu*[1,2], *M. Puiu*[1,2], *O. Marginean*[1,2], *I. Micle*[1];
[1]*Louis Turcanu Emergency Hospital for Children, Timisoara, Romania,* [2]*V. Babes Medicine and Pharmacology University, Timisoara, Romania.*

Background: Malignant infantile osteopetrosis (MIOP) is a rare autosomal recessive bone disease, characterized by reduced or dysregulated osteoclastic activity and increased bone mass. Major consequences include bone marrow failure and nerve compression. The pericentric inversion of chromosome 9 is the most frequently seen (1-3%) in general population and has a role in abnormal phenotype development. Material and methods: Case report of a 3 months old boy admitted to the clinic for seizures due to severe hypocalcemia. A dysmorphyc phenotype was noticed. Based on the presence

of anemia, hypocalcemia, hepatosplenomegaly, failure to thrive, mental retardation, ventriculomegaly, optic nerve atrophy and the typical radiological images diagnose of MIOP complicated by rickets was established. Genetic evaluation for chromosome abnormalities revealed apericentric inversion of chromosome 9. Conclusions: Chromosome 9 inversion has no important clinical significance .The association of osteopetrosis complicated by rickets and chromosome 9 inversion led in our case to severe dysmorphic feature. The prognosis in this case remains very poor, death occurs in the first decade of life as a complication of bone marrow supression.

Congenital Rett syndrome: study of FoXG1 impact on adult brain.

G. Livide[1], *L. Massimino*[2], *F. Ariani*[1], *I. Meloni*[1], *E. Frullanti*[1], *V. Broccoli*[2], *A. Renieri*[1,3]; [1]*Medical genetics, University of Siena, Siena, Italy,* [2]*San Raffaele Scientific Institute, Milan, Italy,* [3]*Azienda Ospedaliera Universitaria Senese, Siena, Italy.*

Mutations in the Forkhead box G1 (FOXG1) gene, a brain specific developmental transcription factor, are responsible for congenital Rett syndrome. FoxG1 plays a fundamental role in early telencephalon development by sustaining proliferation of the progenitor pool and preventing premature cortical neural differentiation. Due to perinatal lethality of Foxg1-/- mice the function of Foxg1 in adult brain has remained unexplored for many years. Recently, Tian et al. studying conditional mutant Foxg1 mice demonstrated that this factor is espressed continuously in postnatal and adult hippocampus playing an essential role in the development of the dentate gyrus. In order to characterize Foxg1 dependent signalling during neuronal maturation and activity, we firstly compared gene expression profiles of wild-type and Foxg1+/− P30 brain. Foxg1 heterozigous mice can reach adulthood though they display microcephaly, altered hippocampal neurogenesis and behavioural and cognitive deficiencies. In order to evaluate the effects of a stronger reduction of Foxg1 specifically in the hippocampus, we then silenced Foxg1 in primary hippocampal neurons by shRNA technology and evaluated the effects of Foxg1 down regulation on gene expression, neuronal morphology, differentiation and spine formation. By cDNA microarray experiments, we identified two sets of partially overlapping deregulated genes, one related to Foxg1+/− whole brain and the other to Foxg1 silenced hippocampal neurons. Possible key co-factors underlying Rett phenotype have emerged with important consequences on therapeutic strategies (Nnat, Oxt, Avp, Mef2c, Tubb2b, Marcksl1, Acot7). Interestingly, Foxg1 silenced hippocampal neurons exhibit alterations in dendrite development suggesting a function of this gene during early post-mitotic morphogenesis and wiring.

Functional polymorphisms in *VEGF*, *MMP-2*, and *MMP-9* genes and intraventricular hemorrhage of prematurity

P. Prasun[1,2], *M. Callaghan*[1], *V. Kalra*[1], *S. Puthuraya*[1], *D. W. Stockton*[1], *N. Chouthai*[1]; [1]*Wayne State University, Detroit, MI, United States,* [2]*Children's Hospital of Michigan, Detroit, MI, United States.*

Background: Intraventricular hemorrhage (IVH) is a major complication of prematurity. It is primarily ascribed to fragility of vasculature in the germinal matrix where relative hypoxia induces expression of vascular endothelial growth factor (VEGF) promoting angiogenesis. The matrix metalloproteinase (MMP) system is also activated by hypoxia that may contribute to hemorrhage. In this study, functional polymorphisms in the *VEGF* and *MMP* genes were assessed for their correlation with IVH.
Methods: *VEGF* (-2578 C/A, -1154 G/A, -634 G/C, +936 C/T), *MMP2* (-1306 C/T, -735 C/T), and *MMP9* (-1562 C/T) polymorphisms were assayed in 189 premature newborns (62 with IVH) and 187 term newborns by RT-PCR and PCR-RFLP. Genotype distribution, clinical characteristics, and laboratory parameters were compared between newborns with and without IVH.
Results: Significant association was found in newborns of < 28 weeks gestation between IVH and TT/CT genotype of *VEGF* +936 C/T (P = 0.046), and AA/AG genotype of *VEGF* -1154 G/A (P=0.011). There was no significant association between IVH and polymorphisms in *MMP2* or *MMP9*. Patent ductus arteriosus, hypotension, and maternal history of chorioamnionitis were also significantly associated with IVH. Logistic regression analysis showed that TT/CT genotype of *VEGF* +936 C/T was the strongest predictor of IVH amongst clinical and potential genetic risk factors studied.
Conclusions: The +936 C/T polymorphism in *VEGF* is associated with higher frequencies of IVH in newborns <28 weeks gestation. This polymorphism is associated with decreased expression of VEGF and may result in delayed maturation of blood vessels as an underlying etiology.

Diagnostic investigations in Rwandan patients with intellectual disability and/or multiple congenital abnormalities

A. Uwineza[1,2], *J. Hitayezu*[2], *A. C. Hellin*[1], *M. Jamar*[1], *J. H. Caberg*[1], *L. Mutesa*[2], *V. Bours*[1]; [1]*Center for Human Genetics, CHU Sart-Tilman, University of Liège, Belgium., Liège, Belgium,* [2]*National University of Rwanda, Butare, Rwanda.*

Multiple congenital anomalies and Intellectual Disability (MCA/ ID) affect approximately 3% of newborns. There is no available data on genetics of ID and MCA in Central Africa.
The aims of this study was to detect chromosomal abnormalities such as submicroscopic microdeletion/microduplication and subtelomeric imbalance in this group of patients. Newborn, children and young adults were recruited from the Teaching University Hospitals of Kigali and Butare, Rwanda. All individuals were clinically examined and karyotype was done in Rwanda and a blood sample was obtained for genetic testing in Belgium (Center for human genetics, Liege). All patients with trisomy 21, 13 and 18 and were excluded from the study.
Karyotype analysis of the remaining 52 patients was normal. Fragile-X was excluded in all these patients and we found premutation in 2 male patients. Thus the MLPA was performed and identified (SALSA MPLA P245 Microdeletion and MLPA P0 36 and P070 Human Telomere, MRC Holland) one chromosome 10q duplication, one chromosome 9p duplication, one deletion of the 22q11.22 region and one 7q11.23 microdeletion (William-Beuren syndrome). For the remaining cases array-CGH was performed and seven patients showed microdeletion and microduplication such as del 8q23, duplication 1p31.1q35.2.
This study will allow to identify the etiology of ID/MCA in Rwandan patient and will show the importance of genetic testing in low income countries.

A Synonymous Change, p.Gly16Gly in MECP2 Exon 1, Causes a Cryptic Splice Event in an Atypical Rett Syndrome Patient

J. B. Vincent[1], *T. I. Sheikh*[1], *K. Mittal*[1], *M. J. Willis*[2]; [1]*Centre for Addiction and Mental Health, Toronto, ON, Canada,* [2]*Clinical Genetics Dept., Naval Medical Center, San Diego, CA, United States.*

Mutations in MECP2 are the main cause of Rett Syndrome. To date, no pathogenic synonymous MECP2 mutation has been identified. Here we investigated a de novo synonymous variant c.48C>T (p.Gly16Gly) identified in a girl displaying an atypical RTT phenotype. In silico analyses to predict effects of sequence on mRNA splicing were employed, followed by sequencing and quantification of lymphocyte mRNAs from the subject for splice variants MECP2_E1 and MECP2_E2. Analysis of mRNA confirmed predictions that this synonymous mutation activates a splice-donor site at an early position in exon 1, leading to a deletion (r.[=, 48_63del]), codon frameshift and premature stop codon (p.Glu17Lysfs*16) for MECP2_E1. For MECP2_E2, the same premature splice site is used, but as this is located in the 5'untranslated region, no effect on the amino acid sequence is predicted. Quantitative analysis specific to this cryptic splice variant also revealed a significant decrease in the quantity of the correct MECP2_E1 transcript, which therefore suggests that this is the etiologically significant mutation in this patient. These findings suggest that synonymous variants of MECP2 as well as other known disease genes_and de novo variants in particular_ should be re-evaluated for potential effects on splicing.

Intellectual Disability Cell Bank (Lymphoblast & Fibroblast)

N. Bazazzadegan[1], *Z. Fattahi*[1], *R. Tayyebifar*[2], *S. Banihashemi*[1], *K. Kahrizi*[1], *H. Ropers*[3], *H. Najmabadi*[1]; [1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran,* [3]*Department of Human Molecular Genetics, Max Planck Institute for Molecular Genetics, Berlin, Germany.*

The rapid advance of genetic research and applied technologies has led to a

considerable increase in interest in collections of human biological material. Collection of tissue samples and cell lines from which additional vivo study can be performed is very essential. These biobanks represent an important resource for diagnosis and basic research. Currently, there are a large number of „culture collections and bioresource centers" that serve an individual part of the process of bioengineering.
The Genetics Research Center(GRC) Intellectual Disability Cell Bank (IDCB) of the University of Social Welfare and Rehabilitation Sciences (USWRS) in joint effort with Max Planck Institute (MPI) have constantly provided an essential internal service establishing, analyzing and banking cell cultures derived from patients affected by intellectual disability (ID). According to ethical and legal recommendations, the samples are being taken for analysis and cell banking after written donor informed consent, approved by the regional ethics committee of the USWRS for medical research. This bank provides the storage of biological samples and specimens (dermal fibroblast, lymphoblast) derived from patients with ID, for whom the causing genes and mutations have been identified as known and candidate genes. This bank also provides cell lines for functional studies, involved in transcription and translation of specific genes which expressed in brain or other genes which their proteins are involved in brain function. The cell bank website can be visited via „idcb.uswr.ac.ir"

A new case of 15q26.3 deletion in a patient with unbalanced translocation t(15;16)(q26.3;q23.3)

M. Budisteanu[1,2], *S. Papuc*[2], *A. Tutulan-Cunita*[2], *I. Borcan*[2], *M. Cristea*[2], *A. Arghir*[2]; [1]*"Prof. Dr. Alex. Obregia" Clinical Hospital of Psychiatry, Bucharest, Romania,* [2]*"Victor Babes" National Institute of Pathology, Bucharest, Romania.*

Objective: We present a case of 15q26.3 unbalanced translocation t(15;16)(q26.3;q23.3) in a boy with a complex phenotype.
Material and methods: The patient is a 1- year -old boy, born to healthy, unrelated parents, with growth retardation, an Apgar score of 9, delayed psychomotor development. Clinical evaluation showed: growth retardation (weight 5,540 kg, height 64 cm), microcephaly, dysmorphic facial features; mild mental retardation. Heart ultrasound showed atrial septal defect. Abdominal ultrasound showed polysplenia, and transfontanelar ultrasound was normal. Wrist X ray showed normal bone age. Thyroidian and growth hormons were in normale range. Cytogenetic investigations, including karyotype, FISH and array-CGH were performed.
Results and discussions: Array CGH showed a deletion on chromosome 15 (15q26.3) and a duplication on chromosome 16 (16q23.3-q24.3). FISH testing confirmed the above-mentioned anomalies in our patient and detected a balanced translocation t(15;16)(q26.3;q23.3) in his mother. Terminal deletions of chromosome 15q represent a rare condition, only several cases with or without ring chromosome being described. The phenotype is heterogeneous and includes growth retardation, microcephaly, dysmorphic features, renal abnormalities, lung hypoplasia, failure to thrive, developmental delay, mental retardation, and skeletal abnormalities. The IGF1R gene was considered as responsible for the phenotype.
Conclusions: Our report brings new insights in the phenotype of this rare syndrome. The phenotype of our patient will be compared with those of other patients with the same deletion previously described to further delineate the 15q26 deletion syndrome. Also, the role of 16q23 duplication on the phenotype will be discussed.

Identification of MECP2 gene duplications in female patients with intellectual disability and speech delay

O. O. Soloviov[1], *N. V. Hryschenko*[1], *N. O. Afanasieva*[2], *E. J. Patskun*[3], *L. A. Livshits*[1]; [1]*Institute of Molecular biology and Genetics, Kiev, Ukraine,* [2]*Crimean Republican Medical-Genetic Center, Simferopol, Ukraine,* [3]*Medical genetic consultation of Trans-Carpathian Nowak Regional Clinical Hospital, Uzhgorod, Ukraine.*

Intellectual disability (ID) is substantial limitations in cognitive functioning that manifests before the age of 18. The worldwide prevalence of ID (IQ < 70) is 1.5-2%, and 0.3-0.5% are severely impaired, with IQs of <50. Severe ID has a strong genetic component; increasing numbers of single genes are being discovered in which mutations are associated with both syndromal as well as non-syndromal forms : ARX, MECP2 and FMR1.
During the participation in the FP7 CHERISH project (grant agreement N223692), we have collected the cohort of the 96 patients with ID. CNV analysis using array CGH and MLPA analysis for known microdeletion syndromes was conducted. Pathogenic rearrangements, revealed during this investigation, were confirmed using qPCR.
In the analyzed cohort three female patients with mild ID and speech delay carrying de novo duplications in Xq28 chromosomal region including MECP2 gene were identified using SALSA MLPA P245-A2 Microdeletion-1 kit. Female patients with Xq28 duplications are rare and usually asymptomatic, due to skewed X-chromosome inactivation (XCI) pattern with preferential inactivation of the rearranged chromosome. X inactivation test showed random XCI in all cases, therefore we suggest that the chromosomal region with duplication is functional and causes the phenotype. Further studies, including the confirmation of the presence of mutations and their borders identification using array CGH will be conducted. In order to confirm the hypothesis, that the association of duplication found in this study with phenotypic manifestations of ID, it is necessary to study the MECP2 gene expression level in our patients.

Mowat-Wilson syndrome: report on a patient with marfanoid habitus and arachnodactyly

A. C. Tutulan-Cunita[1], *S. M. Papuc*[1], *A. Arghir*[1], *I. Borcan*[1], *M. Cristea*[1], *M. Budisteanu*[1,2]; [1]*Victor Babes National Institute of Pathology, Bucharest, Romania,* [2]*Prof. Dr. Alex. Obregia Clinical Hospital of Psychiatry, Bucharest, Romania.*

Mowat-Wilson syndrome (MWS) is a rare genetic disorder of unknown incidence, consequence of loss-of-function mutations of *ZEB2* (*ZFHX1B, SIP1*) homeobox zinc-finger transcriptional repressor. Recent studies indicate that Zeb1 protein is required to generate cortical interneurons in embryos; in its absence, cells appear to transform toward a subtype of GABAergic striatal interneurons.
Here, we report on a 10 year old male patient with partial deletion of *ZEB2* and phenotype suggestive of MWS. The patient presented psychomotor retardation (he sat at 18 months, walked alone at 6 years, and uttered first syllables at 7 years) and dysmorphic features: large ears, up-slanted palpebral fissures, thick eyebrows, long eyelashes, large nose, short philtrum, thick lips, micrognathia, marfanoid habitus, and arachnodactyly. Additionally, he was diagnosed with pyramidal syndrome, ventricular septal defect and epilepsy and had frequent episodes of respiratory infections. His cerebral CT scan was normal. He was severely intellectually disabled (IQ 32), not sociable, and exhibited hyperkinesia with aggressivity. aCGH on an 105K Agilent platform resulted in the following molecular karyotype: arr 2q22.2(144,909,193-145,157,644)x1,4q13.2(69,431,473-69,483,227)x1,5p15.33(733,455-795,803)x1,6p21.32(32,487,424-32,552,156)x1,8p11.22(39,237,438-39,380,654)x3,15q11.2(20,849,110-22,304,655)x1. Deletion at 2q22.2 included the 5'terminus of *ZEB2*, while the only other OMIM gene affected by the above-mentioned anomalies is *BCL8*, suggested to be linked to diffuse large cell lymphoma.
The spectrum of MWS features is relatively narrow and well characterized. Here, we first report on a patient that associates MWS with marfanoid habitus and arachnodactyly, thus adding new insights to the tableau of this disease.

Three-way unbalanced translocation leading to 1q duplication and 10q deletion in a child with severe psychomotor retardation, dysmorphic features and congenital malformations

S. Papuc[1], *M. Budisteanu*[2,1], *A. Tutulan-Cunita*[1], *I. Borcan*[1], *M. Cristea*[1], *A. Arghir*[1]; [1]*Victor Babes National Institute of Pathology, Bucharest, Romania,* [2]*Prof. Dr. Alex. Obregia Clinical Hospital of Phychiatry, Bucharest, Romania.*

Complex chromosomal anomalies, involving more than two breakpoints on two different chromosomes are rare events. Balanced rearrangements in healthy carriers are associated with reproductive failures, while the unbalanced anomalies present with psychomotor retardation, dysmorphic features and/or congenital malformations, in most cases.
We present the clinical and cytogenetic findings in a 4-year-old girl referred for genetic investigations due to dysmorphic features and psychomotor re-

tardation.
The clinical evaluation revealed: height 85 cm (<2DS), weight 8,2 kg (<2DS), occipitofrontal circumference 44 cm (<2DS); dysmorphic features (hypertelorism, down-slanting palpebral fissures, long eyelashes, synophrys; big, malformed ears; anteverted nostrils; short philtrum, thin upper lip, high-arched palate, micrognathia; single palmar crease, congenital talipes equinovarus; pectus excavatum; external genital organs hypoplasia). Neurological examination showed hypotonia, severe psychomotor retardation. Heart ultrasound showed atrial septal defect. Cerebral computed tomography showed cerebral and cerebellar atrophy. Abdominal ultrasound was normal.
Classical cytogenetic investigation was performed on peripheral blood lymphocytes by GTG-banded karyotyping, for the child and her parents. Array-CGH studies (Agilent platform) for molecular characterization are on-going. Chromosomal studies revealed a complex unbalanced translocation in the proband, leading to 1q32-qter duplication and 10q26-qter deletion. A balanced three-way translocation t(1;8,10)(q32;q13;q26) was detected in the proband's healthy mother.
In this paper we report on a new case with an unbalanced, three-way translocation, harboring partial trisomy 1q32-qter and partial monosomy of 10q26-qter. The correlations of the clinical findings with the genomic imbalances in our case will be discussed; we will also compare our case with others reported by date.

The absence of polymorphic variants associations of catalase (CAT), catechol-O-methyltransferase (COMT), and serotonin transporter (SLC6A4, 5HTT) genes with the risk of alcoholism in the Russian population of the West Siberian region

A. V. Marusin, *V. A. Stepanov;*
Institute for Medical Genetics, Siberian Branch of the Russian Academy of Medical Sciences, Tomsk, Russian Federation.

Alcoholism is a severe multifactorial mental disorder. At the present time genetics of alcoholism remains an actual problem for predictive (personalized) medicine, because of uncertainty of risk assessment of multifactorial diseases. The purpose of this study was to analyze the associations of ethanol-metabolizing and antioxidant enzyme CAT and two enzymes of the serotonergic system (COMT and SLC6A4) with the alcoholism risk at the allele and haplotype levels in Russians of the West Siberian region. Polymorphisms rs11032700, rs34964953, rs10836244, rs769217, rs2420388 in the gene CAT, rs174695, rs35617967, rs6267, rs4986871, rs165774 in the gene COMT, and rs3794808, rs140700, rs2228673, rs6354, 5HTTLPR in the gene SLC6A4 have been studied by the Real Time PCR. Alcoholism was diagnosed according to the International Classification of Diseases Tenth Revision (ICD-10). Russian cohorts of alcoholics (n=96) and controls (n=95) did not differ either in allele frequencies or the haplotype frequencies of all three genes. Therefore, these two cohorts were combined for further analysis of the haplotype structure. It was shown that the first common haplotype AGCG (66.5%) is separated from the second most frequent haplotype CTTA (20.2%) by four mutations (recombinant steps). The third haplotype CGCG (11.3%) is separated from the first one by one mutation step. All haplotypes are in a single block, therefore, they can recombine with a very low frequency only. So the revealed fact of the presence of four hypothetical mutational steps between haplotypes AGCG and CTTA is surprising. This work was supported by RFBR grant #09-04-99083-r_ofi and #12-04-00595-a.

A regulatory path associated with X-Linked Intellectual Disability and Epilepsy links the histone demethylase KDM5C to the Polyalanine expansions in the transcription factor ARX

L. Poeta[1,2], *F. Fusco*[1], *C. Shoubridge*[3,4], *G. Manganelli*[1,5], *S. Filosa*[1,5], *A. Padula*[1], *M. Courtney*[6,7], *P. Collombat*[6,7], *M. Lioi*[2], *J. Gecz*[3,4], *M. Ursini*[1], *M. Miano*[1];
[1]*IGB-CNR, Naples, Italy,* [2]*University of Basilicata, Potenza, Italy,* [3]*Department of Paediatrics, University of Adelaide, Adelaide, Australia,* [4]*Department of Genetics and Molecular Pathology, SA, Pathology, Adelaide, Australia,* [5]*IRCCS, Neuromed,, Pozzilli, Italy,* [6]*Universitè de Nice-Sophia Antipolis, Nice, France,* [7]*Inserm U1091, IBV, Diabetes Genetics Team, Nice, France.*

Polyalanine expansion mutations of Aristaless-related homeobox gene (ARX) cause a spectrum of X-chromosome phenotypes with Intellectual Disabilily (ID) and various forms of malignant paediatric epilepsy. We have established that ARX regulates and binds a CNE element in the 5' region of the lysine (K)-specific demethylase 5C (KDM5C), a known XLID gene involved in chromatin remodeling and neuronal maturation. By in vitro studies, we have analyzed five Polyalanine mutants establishing a decreased trans-activating activity and a reduced, but not abolished, binding to the KDM5C regulatory region. By quantitative RT-PCR, we have showed in murine Arx-KO ES cells and neurospheres a dramatic downregulation of the Kdm5C mRNA levels that leads to a decrease of the KDM5C protein. In Arx KO GABA-oriented model, which presents severe abnormalities in dendrite formation and GABAergic maturation, we have found a KDM5C reduction in coupling with a global increase of H3K4me3 signalling, potentially due to a compromised KDM5C activity. Since H3K4me3 is the hallmark of open chromatin, ARX-dependent KDM5C defects could compromise cyclical rounds of methylation-demethylation and consequently the chromatin remodelling. Starting from these data, we are now able to break up a unique ARX-dependent epigenetic road involved in epileptogenesis, suggesting that the molecular pathogenesis of ARX Polyalanine mutations may be in part caused by aberrant histone demethylation as a result of KDM5C defect. As chromatin modifications are reversible, it is possible that epigenetic drugs could compensate KDM5C-H3K4me3 deregulation opening further studies to cure or ameliorate ARX Polyalanine-related epilepsy.

Allele-specific programming of Npy and epigenetic effects of physical activity in a genetic model of depression

P. A. Melas[1], *A. Lennartsson*[1], *H. Vakifahmetoglu-Norberg*[2], *Y. Wei*[1], *E. Åberg*[1], *M. Werme*[1], *M. Rogdaki*[1], *M. Mannervik*[2], *G. Wegener*[3], *S. Brene*[1], *A. A. Mathe*[1], *C. Lavebratt*[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Stockholm University, Stockholm, Sweden,* [3]*Aarhus University Hospital, Risskov, Denmark.*

Neuropeptide Y (NPY) has been implicated in depression, emotional processing and stress response. Part of this evidence originates from human single nucleotide polymorphism (SNP) studies. In the present study, we report that a SNP in the rat Npy promoter (C/T; rs105431668) affects in vitro transcription and DNA-protein interactions. Genotyping studies showed that the C-allele of rs105431668 is present in a genetic rat model of depression (Flinders Sensitive Line; FSL), while the SNP's T-allele is present in its controls (Flinders Resistant Line; FRL). In vivo experiments revealed binding of a transcription factor (CREB2) and a histone acetyltransferase (Ep300) only at the SNP locus of the FRL. Accordingly, the FRL had increased hippocampal levels of Npy mRNA and H3K18 acetylation; a gene-activating histone modification maintained by Ep300. Next, based on previous studies showing antidepressant-like effects of physical activity in the FSL, we hypothesized that physical activity may affect Npy's epigenetic status. In line with this assumption, physical activity was associated with increased levels of Npy mRNA and H3K18 acetylation. Physical activity was also associated with reduced mRNA levels of a histone deacetylase (Hdac5). Conclusively, the rat rs105431668 appears to be a functional Npy SNP that may underlie depression-like characteristics. In addition, the achieved epigenetic reprogramming of Npy provides molecular support for the putative effectiveness of physical activity as a non-pharmacological antidepressant.

J06.02
Association analysis of YWHAE gene polymorphic loci and suicide in two ethnic groups of Bashkortostan (Russia).

Z. Khalilova, *A. Zainullina, A. Valiullina, E. Khusnutdinova;*
IBG, Ufa, Russian Federation.

Recently, M.Yanagi et al. (2005) genome-wide study identified YWHAE gene as susceptibility gene for suicidal ideation and completed suicide. To examine whether the YWHAE gene plays a significant role in pathogenesis of suicide, we conducted a replicative study to investigate the association between three SNPs (rs1532976, rs3752826, rs9393) of this gene and attempted suicide in Russian and Tatar patients from Bashkortostan (Russia). We genotyped DNA samples of 236 cases (Russians - 127, Tatar -109) who had suicide attempts and 362 control subjects (Russians - 134, Tatar - 228) using PCR-RFLP technique. For pairwise linkage disequilibrium and haplotype analysis, the Haploview 4.1 program was used. Odds ratios (OR) with

95% confident intervals (CI) were calculated.
We found a strong allele association between YWHAE rs3752826 and suicide: C was significantly overrepresented in patients with suicide as compared to controls (P=0,02, OR=1,91, 95%CI 1,09-3,36) regardless of the ethnicity. Moreover we observed in Russian ethnicity group YWHAE rs9393 allele T (P=0,002, OR=2,21, 95%CI 1,32-3,57), YWHAE rs1532976 genotype T/T (P=0,018; OR=2,73, 95%CI 1,17-6,50) and YWHAE rs1532976 allele T (P=0,025; OR=1,52, 95%CI 1,037-2,22) were significantly overrepresented in patients with SB as compared to controls. Haplotype analysis showed a significant overrepresentation of the YWHAE (rs1532976 and rs9393) A-T haplotype (P=0,025, OR=1,54; 95%CI 1,06-2,24) in suicide attempters as compared to controls. This result suggests YWHAE as a potential suicide-susceptibility gene, and confirms ethnic specificity of this association.
This work was supported by grant of the Russian Foundation for Humanities (11-06-00554a).

Frequency of the polymorphisms of the genes of the enzymes alcohol dehydrogenase (ADH1B and ADH1C) and aldehyde dehydrogenase (ALDH2) in Brazilian alcohol abusers woman.

*G. Antonialli, B. Coprerski, R. Minillo, **M. MIGLIAVACCA**, D. Brunoni, A. B. Perez;*
UNIVERSIDADE FEDERAL DE SÃO PAULO, SÃO PAULO, Brazil.

Introduction: The influence of polymorphisms in loci encoding the enzyme alcohol dehydrogenase (ADH) and aldehyde dehydrogenase (ALDH) is known to be associated with alcohol dependence, however this influence is not yet characterized for the Brazilian population. Objectives: Determine the frequency of the polymorphisms ADH1B (ADH1B*2 - Arg47His and ADH1B*3 - Arg369Cys), ADH1C (ADH1C*2 - Ile349Val), and ALDH2 (ALDH2*2) in Brazilian alcohol abusers woman. Methods: 56 alcohol abusers woman were screened for alcohol dependence by CAGE, T-ACE, TWEAK and Short Alcohol Dependence Data - SAAD. The region of interest of the genes were amplified by PCR and analyzed by electrophoresis gel.Results: According to the CAGE, T-ACE and TWEAK evaluation 66,67% of the woman were classified as severe alcohol depedence; 45% as moderate and 5,88% as mild. The polymorphisms distribution were: ADH1B*2 : ADH1B*1/1 94,34%; ADH1B*1/2 5,66%; ADH1B*3: 94,23% ADH1B*1/1; 3,85% ADH1B*1/3 and 1,92% ADH1B*3/3; ADH1C*2: 64,15% ADH1C*1/1; 32,08%; ADH1C*1/2 and 3,77% ADH1C*2/2. ALDH2* :100% ALDH2*1/1. There were no significant differences between the distribution of the genotypes ADH1B*2, ADH1B*3 and ALDH2*2 between the alcohol abusers to the healthy Brazilian population. The ADH1C * 2 allele was significantly less frequent among alcohol abuser as compared to the healthy Brazilian population (p=0,0058). Conclusions: Although it is still a small sample, we can suggest that the presence of ADH1C * 2 allele might be a protective factor to alcohol dependence among women in Brazil.Sponsor: FAPESP 2011/08960-8.

Analysis of polymorphisms in GABRA2 and CHRM2 genes in patients with alcoholism from Russia

***G. Faskhutdinova**, E. Khusnutdinova;*
Institute of Biochemistry and Genetics USC RAS, Ufa, Russian Federation.

Several recent studies have provided strong evidence that gamma-aminobutyric acid (GABA) A receptor subunit genes clustered on chromosome 4 are implicated in alcoholism in humans. The cholinergic muscarinic 2 receptor (CHRM2) gene has been considered a candidate gene for the alcohol dependence in that it might underpin certain risk factors for this condition. We designed a classical case-control association study for polymorphisms in GABRA2 gene (rs279858, rs495818) and CHRM2 gene (rs1824024, rs1455858). Population stratification and ancestry differences within populations may compromise the success of association studies. Therefore we performed analysis in three homogeneous ethnic groups from Russia.
333 men with diagnosis of alcoholism (122 Russians, 101 Tatars, 110 Bashkirs) and matched control groups were typed for the above-mentioned gene variants using PCR-RFLP and TaqMan assay techniques.
Analysis of the rs1455858 polymorphism in the CHRM2 gene showed significant association of CHRM2*T allele with acute alcoholic psychosis in Russian population (p<0.05;OR= 1.95). In total sample the frequency of individuals carrying the CHRM2*G/*G genotype of the rs1824024 was significantly higher in the group of alcoholics compared to the healthy controls (p<0.05;OR=2.35). Analysis of the rs279858 in the GABRA2 gene revealed that GABRA2*G allele was the marker of high alcoholism risk in young adults (p<0.05; OR=1.40).
Our findings are in line with a number of recent studies questioning the association between alcoholism and polymorphisms in GABRA2 and CHRM2 genes. rs1455858, rs1824024 and rs279858 SNPs are probably involved in the development of alcoholism in some populations from Russia. This work was supported by RFBR (grant#11-04-97032-r_povolzhye_a).

Pharmacogenetic Study of Second Generation Antipsychotic Therapy in Autism Spectrum Disorders

***D. Bauze**[1], L. Kevere[1], Z. Kronberga[1], A. Rizevs[1], K. Viksna[2], R. Andrezina[3], B. Lace[2];*
[1]Children's University Hospital, Riga, Latvia, [2]Latvian Biomedical Research and Study Centre, Riga, Latvia, [3]Riga Stradins University, Riga, Latvia.

Background: Autism spectrum disorders (ASD) are among the most common children neurodevelopment disorders. ASD patients often have co-morbid conditions, such us obsessive-compulsive, sleep disorders, self-destructive behavior, increased irritability, aggression and self-injury. One third of ASD patients take an antipsychotic medication. One of the most popular second-generation antipsychotic is risperidone. Two cytochrome P450 genes, CYP2D6 and CYP2C19, are involved in metabolization of psychotropic medications.
The aim of the study was to determine the incidence of CYP2D6*4, CYP2D6*41, CYP2C19*2 alleles in the case and control groups, and prognostic assessment of risperidone therapy in association with defined alleles.
Methods: Ninety-five patients with ASD participated in the study. The control group consisted of 190 healthy, non-related individuals without ASD. CYP2C19*2, CYP2D6*4, CYP2D6*41 were genotyped by the TaqMan method. Alleles' and haplotype frequency differences in case and control groups were compared by chi-square (χ^2) test. Frequency of adverse reactions and therapy corrections were evaluated in the patient group.
Results: Association with ASD pharmacotherapy was not found for the haplotypes CYP2D6*41C/T – CYP2D6*4C/T (p=0.4), therefore these cannot be safely used in the drug therapy prognostics. In the case group CYP2D6*41 allele T was observed more frequently than in the control group (p=0.01).
The most common adverse drug reaction was hyperprolactinemia, the cause of which may be associated with ASD neurotransmitter defects, and not with the primary phase of xenobiotic metabolism.

Abnormal growth and dysmorphic features in children with autism spectrum disorders

***D. Avdjieva-Tzavella**[1], S. Hadjidekova[2], B. Rukova[2], H. Kathom[3], R. Tincheva[3], D. Toncheva[2];*
[1]Department of Clinical Genetics, University Pediatrics Hospital, Medical University, Sofia, Bulgaria, Sofia, Bulgaria, [2]Department of Medical Genetics, Medical Faculty, Medical University, Sofia, Bulgaria, [3]Department of Clinical Genetics, University Pediatrics Hospital, Medical University,, Sofia, Bulgaria.

Autism spectrum disorders (ASDs) are very heterogeneous neurodevelopmental disorders of children diagnosed solely on the basis of the triad of persistent social and language deficits and stereotypic behaviors. Several lines of evidence have indicated the strong role of genetics in the etiology of ASDs. Progress in understanding the genetic and biological basis of autism has been impeded by the variability among individuals with autism. Clinical morphology might be used as a biomarker for ASDs to clarify the complexity of the disorder.
In an effort to delineate more homogeneous autism subgroups for genetic study, we evaluated 83 autistic individuals. The clinical examination consisted of standard morphological measurements and comprised a broad range of qualitative and quantitative physical measurements. Our findings show that morphological features are associated with autism and a comprehensive clinical morphology examination that classifies autistic children as either phenotypically normal or abnormal is the first step needed for separating autism into causally distinct subgroups. Exploring potential underlying genetic mechanisms of this association might lead to a better understanding of autism. Identifiable endophenotypes and reliable biomarkers within ASDs would help to focus molecular research and uncover genetic causes and developmental mechanisms.

Cytogenetic analysis in autistic disorder

E. Dronca[1], *M. S. Militaru*[1], *O. Popescu*[2];
[1]*Department of Medical Genetics, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [2]*Babes-Bolyai University, Cluj-Napoca, Romania.*

Autistic disorder (AD) is a very complex and severe neuropsychiatric condition, increasingly frequent among children, with intricate and yet uncertain etiology, defined by impairments in communication and social skills, with onset prior to age 3 years. Genetic and cytogenetic studies revealed that most of the chromosomes are associated with autism, abnormalities of chromosomes 15 and X being most frequently documented.
AIM OF THE STUDY: Cytogenetic analysis on peripheral blood samples from children with autism was performed to identify possible structural or numerical chromosomal abnormalities by GTG-banding.
RESULTS: The study revealed normal karyotypes in most cases (47 out of 50 individuals). Two of the male patients had modified karyotypes (2% mosaicism): chromosome 9qh+ polymorphism and terminal deletion on chromosome 15q, respectively. One of the female patients had an extra chromosome 8 (2% mosaicism).
CONCLUSION: This is the first cytogenetic testing performed specifically on autistic children in Romania.
Our results show that karyotyping analysis is not conclusive in most cases with autism. Nevertheless, the test should be proposed and performed for every autistic patient, in order to eliminate possible numerical or structural chromosomal abnormalities as the cause for AD.

Marfan syndrome with Asperger disorder and schizophrenia in an adolescent boy

C. Pienar, *S. Dumitriu, M. Puiu;*
University of Medicine &Pharmacy Victor Babes, Timisoara, Romania.

Aim: To present the rare association of 2 psychiatric disorders in an adolescent with Marfan syndrome. Methods: A 17 years old boy was evaluated in our neuropsychiatry department for a psychotic episode. Results: The adolescent was in a state of extreme agitation and presented auditory and visual hallucinations. Furthermore, he had persecution delirium, was highly suspicious and anxious and feared for his life. The symptoms appeared gradually during the 3 weeks prior to admission. His medical history revealed he was previously diagnosed with Marfan syndrome and Asperger disorder. The physical examination was suggestive for the connective tissue disorder and otherwise unremarkable. The EEG didn't show abnormal electrical activity, while a heart ultrasound confirmed a mildly dilated aortic bulb. He received antipsychotic and sedative treatment with a favorable outcome and remains in psychiatric follow-up. Conclusions: Although, several cases with Marfan syndrome and different psychiatric disorders are reported in the literature, to our knowledge this is the first time both schizophrenia and Asperger disorder are found in such a young patient with Marfan syndrome

Exceptional case of a partial deletion of a long shoulder of a chromosome 18

A. R. Shorina[1], *T. A. Gayner*[2], *V. A. Makasheva*[1];
[1]*Novosibirsk Regional Children's Clinical Psychoneurological Dispensary, Novosibirsk, Russian Federation,* [2]*Center of New Medical Technologies SB RAS, Novosibirsk, Russia., Novosibirsk, Russian Federation.*

Carrying out classical cytogenetic and molecular and genetic research is of great importance for identification of the reasons of emergence of many hereditary diseases at patients, especially in children's psychoneurological practice. Even small chromosomal reorganization can have the expressed clinical manifestations.We give diagnostics case at the girl of nine years of an exceptional case of a partial monosomiya of a long shoulder of a chromosome 18. The child is observed at the psychiatrist with the diagnosis: easy intellectual backwardness (F70), IQ 67, syndrome of a motive hyperactivity with deficiency of attention, a delay of speech development. At survey small anomalies of development were noted: mikrotsefaliya, high forehead, gipertelorizm, epikant, large antihelix and antitrestle, the long and flat filter, makrostomiya, the high sky, the low growth, the reduced mass of a body, partial skin sindaktiliya of fingers of hands.
At cytogenetic research at the girl the partial deletion of a long shoulder of a chromosome 18 is revealed. Karyotype of the patient
46,XX, del(18)(q22). Parents of the child are inaccessible to cytogenetic research.
Generally the phenotype of our patient corresponds
to clinical descriptions of patients available in literature with a deletion of a long shoulder of the chromosome 18. However the patient has only small anomalies of development and intellectual backwardness while accompanying somatic pathology described in literature and rough developmental anomalies are
absent.

Replicative association analysis of schizophrenia in Kazakh population

A. Bocharova[1], *A. Marusin*[1], *K. Simonova*[1], *K. Saduakasova*[2], *G. Svyatova*[3], *G. Berezina*[3], ***V. A. Stepanov***[1];
[1]*Institute for Medical Genetics, Tomsk, Russian Federation,* [2]*Kazakh National Medical University, Almaty, Kazakhstan,* [3]*Republican Scientific Centre for Obstetrics, Gynecology and Perinatology, Almaty, Kazakhstan.*

Ethnic background is an important factor in personalized health care and predictive medicine directed to prevention of common diseases. Common psychiatric and neurological disorders including schizophrenia are the subject of intensive genetic research based on genome-wide association studies (GWAS) and targeted resequencing of genomic regions of interest. Genetic variants associated with cognitive impairments, which are an important endophenotypes for schizophrenia, also have been revealed by GWAS. The aim of this study was to replicate the GWAS findings in European and Chinese populations in ethnic populations of Kazakhs. Kazakhs, the Mongoloid Turkic-speaking population, represent the major ethnic group of Republic of Kazakhstan and also a significant ethnic minority in neighboring Russia, Uzbekistan, Mongolia and China.
15 SNPs strongly associated with schizophrenia and cognitive performance according to recent GWA studies were genotyped by real-time PCR in Kazakh patients with paranoid schizophrenia and in healthy control group (N= 302). The association of rs2312147 located in the region of vaccinia-related kinase 2 (VRK2) gene, previously reported in GWAS by Stefansson et al. (2009), was confirmed in Kazakhs (OR = 1.72, p = 0.008). Rs2247572 located in the vicinity of KCNB2 (potassium voltage-gated channel) gene found in genome-wide association with cognitive performance traits (Need et al, 2009) was also associated with schizophrenia in Kazakhs (OR = 1.64, p = 0.016).
Association of genetic markers in loci for TLR4, SLCO6A1, NOTCH4, TCF4, ZNF804A, AGBL1, RELN, ZFP64P1, CSMD1, CPVL, NRG and NRIP1 was not replicated in Kazakh population.
This work is partially supported by RFBR grant #12-04-00595.

Muscle-specific FXR1P isoforms regulate p21 levels: Implications for the pathophysiology of Facio-Scapulo Humeral Dystrophy

B. Bardoni[1], *H. Moine*[2], *S. Sacconi*[3], *L. Davidovic*[1];
[1]*Institut de Pharmacologie Moléculaire et Cellulaire, Valbonne, France,* [2]*IGBMC, Illkirch, France,* [3]*Centre de Référence pour les Maladies Neuromusculaires, CHU de Nice,, Valbonne, France.*

The Fragile X-Related 1 gene (FXR1) is a paralog of the Fragile X Mental Retardation 1 gene (FMR1), whose absence causes the Fragile X syndrome, the most common form of inherited intellectual disability. FXR1P plays an important role in normal muscle development and its absence causes muscular abnormalities in mice, frog and zebrafish. A reduction of muscle-specific isoforms is found in myoblasts from Facio-Scapulo Humeral Dystrophy (FSHD) patients. FXR1P is an RNA-binding protein involved in translational control. In the present study, gene expression profiling of C2C12 myoblasts reveals that transcripts involved in cell cycle and muscular development pathways are modulated by Fxr1-depletion. We observed an increase of p21 - a regulator of cell-cycle progression - in Fxr1-knocked-down mouse C2C12 and FSHD human myoblast. This phenotype is rescued by re-expressing human FXR1P muscle-isoforms. FXR1P muscle-specific isoforms bind p21 mRNA via direct interaction with a conserved G-quadruplex located in its 3' untranslated region. The FXR1P/G-quadruplex complex reduces the half-life of p21 mRNA. In the absence of FXR1P the upregulation of p21 mRNA determines the elevated level of its protein product that affects cell-cycle progression inducing a premature cell-cycle exit and generating a pool of cells blocked at G0. Our study describes a novel role of FXR1P that has crucial

implications for the understanding of its role during myogenesis and muscle development since we show here that in its absence a reduced number of myoblasts will be available for muscle formation/regeneration, shedding new light into the pathophysiology of FSHD.

J07.02
Molecular-genetics research of the common form of sarcoglycanopathies in Russia

D. Poliakova;
RNRMU, Moscow, Russian Federation.

Sarcoglycanopathies - diseases in a group of lap-limb muscular dystrophies with autosomal recessive inheritance. There are four forms of sarcoglycanopathies (LGMD2C-2F), depending on the type of the affected protein. The most common of them is LGMD2D due to mutations in the SGCA gene. Mutations in the genes of sarcoglicans lead to the clinical picture, similar to Duchenne myodystrophy (DMD).
The aim of the work: study of the coding sequence of SGCA gene in the samples of some girls, whose guide diagnosis was DMD. All samples from the base of the Laboratory of DNA-diagnostics RCMG RAMS.
By direct automated DNA sequencing we studied 34 probands. The study identified previously described mutations (c.271G> A, c.229C> T, c.518T> C) in 14.7% of cases (5 probands). We detected two „common" mutations (c.271G> A, c.229C> T). Replacing c.229C> T met at 2 of the probands in the homozygous and 1 proband in the heterozygous state, replacing c.271G> A met at one of the proband in the homozygous and 1 proband in the heterozygous state. Theese two „common" mutations encountered in 4 of 5 patients (80%), 8 of the 10 affected chromosomes (80%).
This research shows the need of study SGCA gene for girls with DMD clinics. The first step in the molecular genetics diagnosis of the gene should be a study of two „common" mutations, and only in the case of absence of them, study whole the coding sequence.

D. Poliakova: None.

J07.03
Frequency of non-distrophic myotonias in RF

E. Ivanova*, A. Polyakov;*
Russian Research Center for Medical Genetics, Moscow, Russian Federation.

The cohort of 84 unrelated patients with different non-distrophic myotonias was formed in laboratory of DNA diagnosis of MGC RAMS. And for all of them direct sequencing of CLCN1 gene or SCN4A gene in tandem was performed depending of diagnosis. Tomsen's (TM) and Becker's (BM) myotonias with mutations in CLCN1 gene were revealed in 66 patients. Paramyotonia of Eulenburg, hyper- and hypokalemic paralisys and other sodium channel myotonias were revealed in 14 cases. So fractions chloride channel and sodium channel myotonias were 82% and 18%. There were only 5 cases of AD TM (8%) and 61 cases of AR BM (92%) in group of chloride channel myotonias. It is interesting that the most prevalence mutation in CLCN1 gene was recessive nonsense-mutation c.2680C>T (p.Arg894*) - 36 chromosomes out of 118 chromosomes with all revealed CLCN1 gene mutations. There were 112 chromosomes with recessive CLCN1 gene mutations, so fraction of p.Arg894* in all BM patients is 32% (95%Confidence Interval (CI) = 24% - 42%). Allelic frequency of p.Arg894* in population RF is 1,2%, so frequency of all carriers of recessive CLCN1 mutations is 1/13 (95%CI = 1/35 - 1/6). In result of this investigation we calculated the frequencies of AD and AR forms of myotonias and in RF: TM - 1:710 (95%CI = 1/5000 - 1/145) and BM - 1:8165 (95%CI = 1/31746 - 1/26). Summarized frequency of chloride channel myotonia in RF estimated as 1: 653 (95%CI = 1/4320 - 1/22).

Frequent mutations and new allelic variants of congenital merosin-deficient muscular dystrophy in Russia

T. B. Milovidova*, E. L. Dadali, G. E. Rudenskaya, A. V. Polyakov;*
Research centre for medical genetics, Moscow, Russian Federation.

Congenital muscular dystrophy, merosin-deficient (MDCMD) is a severe form of CMD with absence merosin around muscle fibers, specific MRI features, elevated serum creatine kinase in early months of life. Common clinical features are severe hypotonia, weakness and contractures, respiratory insufficiency.
Eighteen patients with clinical features of MDCMD, MRI and immunohistochemistry data were investigated for LAMA2 gene sequence analysis. Mutations were found in 72% of cases (13 patients of 18). Seven new allelic variants of MDCMD were found in this investigation. Interesting, that three mutations occurred more, than one time. Mutations c.2049_2050delAG and c.7732C>T were found on two chromosomes (8% each of confirm cases either). This mutations continually were described in literature. Mutation c.7536delC was found on seven chromosomes (27% of confirm cases) including one monozigotes stage, that allows to suppose existence of founder effect for Russian patients. Signally, that the mutation was described in literature only once. Also we separatet "hot" exons for top-priority search of mutations for Russian patients, that is important for time and cost saving of research. On findings and literary data the system of identification most frequent mutations in LAMA2 gene was created by us for time and cost saving of research too.
At present huplotype analysis for three frequent mutations and calculation of population carrier state of MDCMD are realizing by us.

Role of thrombophilic genetic markers in Ischemic Stroke patients from North India

V. Arya*[1], P. Correia[2], C. S. Agarwal[2], M. Bhargava[1];*
[1]Department of Hematology, Sir Ganga Ram Hospital, New Delhi, India, [2]Department of Neurology, Sir Ganga Ram Hospital, New Delhi, India.

Background:Very few attempts have been made to study the role of genetic variation in development of stroke in Indian population. This study looked at correlations, if any, between the thrombophilic genetic markers and severity of the stroke.Methods:This study was conducted on 120 adult patients of ischaemic stroke underwent gene mutation analysis for FactorVLeiden ,MTHFR(C677T),Prothrombin(G20210A),GPIIb/IIIa(PLA1/A2) and PAI-1-(4G/5G) polymorphisms by PCR RFLP.Severity of stroke was assessed on admission based on National Institute of Health Stroke Scale (NIHSS).Multiple risk factors for ischemic stroke were also included.Results:The mean age of the patients was 52 years(range 20-92 years)included 77 males and 53 females.As per NIHSS scoring the severity of stroke was mild in 24.1%(29), moderate in 63.3%(76), moderately severe in 5%(6) and severe in 7.5%(9). The T allele frequency of MTHFR among mild, moderate, moderately severe and severe groups were 17.4,17.7,33.3 & 33.3% respectively which was not significantly distributed. A2 allele of PLA1/A2 was significantly associated with moderately severe and severe phenotype(p=0.02).Frequencies of 4G allele of PAI-1 were 50% in mild, 62.5% in moderate,91.6% in moderately severe and 72% in severe phenotype, was not quite significant(p=0.06).FVL mutation was present in only two patients each from mild and moderate group.Whereas,prothrombin mutation was completely absent in our patients.Among all the risk factors chronic alcoholism, obesity and vitamin B12 levels were significantly associated with the high severity (p=0.03,0.04 & 0.03 respectively).Conclusion:A2 allele of PlA1/A2 polymorphism is associated with moderately severe and severe group of patients.Chronic alcoholism, Obesity and Vitamin B12 levels are associated with the severity of the stroke.

J07.06
Mutational analysis of NEFL gene in hereditary motor and sensory neuropathy patients from Bashkortostan Republic (Russia)

I. Skachkova*[1], I. Khidiyatova[1,2], E. Saifullina[3], R. Magzhanov[3], E. Khusnutdinova[1,2];*
[1]Institute of Biochemistry and Genetics, RAS, Ufa, Russian Federation, [2]Bashkir State University, Ufa, Russian Federation, [3]Bashkir State Medical University, Ufa, Russian Federation.

Hereditary motor and sensory neuropathy (HMSN) is a clinically and genetically heterogeneous disorder of peripheral nervous system. The HMSN frequency in Bashkortostan Republic (BR) is 10,3 :100000. We examined HMSN patients from BR and detected spectrum and frequency of specific mutations in the NEFL gene using direct sequencing of its coding regions. The NEFL gene cause the demyelinating (1F) and axonal (2E) subtypes of HMSN. The NEFL gene (8p21) codes neurofilament light protein - an important factor in determination of the axonal diameter, axonal transport, regeneration of axons and conduction velocity of peripheral nerves. Molecular-genetic investigation of HMSN was conducted in 125 of the 197 unrelated families with previously excluded mutations in genes PMP22, GJB2, MPZ,

EGR2, GDAP1 and MFN2. We detected 4 different nucleotide changes in the NEFL gene. One nucleotide substitution c.488A>T (p.Glu163Val) which hadn't been described previously was found in the heterozygous state in the HMSN I patient and was not detected among healthy family members and controls (n=100). This change is supposed to be the disease causing mutation. Three nucleotide changes revealed in HMSN patients appeared to be polymorphic variants: c.639C>G (rs35575466), c.1402G>A (rs57153321), and 1168-11T>C (rs76347846) (5% among all HMSN types in total of patient sample). Thus, NEFL gene alterations are rare causes (<1%) of HMSN. The received data will contribute to optimization of medical and genetic consulting of HMSN families in our region.

Point mutation analysis of SMN1 gene in patients with spinal muscular atrophy in four unrelated Russian families.

V. V. Zabnenkova, *G. E. Rudenskaya, E. L. Dadali, A. V. Polyakov;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

INTRODUCTION: Most patients with the clinical diagnosis of SMA (95%) have homozygous deletion of *SMN1* gene. The remaining 5% are compound heterozygous with a deletion of the *SMN1* gene on one of their alleles and a point mutation on the other allele.
OBJECTIVE: To identify the point mutations in *SMN1* gene and confirm the diagnosis SMA in the patients with heterozygous deletion of *SMN1* gene.
METHODS: MLPA was carried out to measure the copy number of *SMN1* and *SMN2* genes in the patients. The point mutation analysis of *SMN1* gene was performed by direct sequencing.
RESULTS: (Tab. 1).
CONCLUSION: The mutations IVS6-2A>T and p.Gln15X caused severe clinical phenotype SMA I. This study suggested that it is necessary to detect the point mutations in *SMN1* gene in the patients with heterozygous deletion of *SMN1*. It would be beneficial for prenatal diagnosis and genetic counseling in such families.
Table 1. The results of current study.

Patient	Identified mutations in *SMN1* gene	Parents data	Copy number of *SMN2* gene	Type SMA
P.6805	IVS6-2A>T + 7-8 exons deletion	father: IVS6-2A>T / N mother: 7-8 exons deletion / N	2	I
P.7413	p.Gly275Ala + 7-8 exons deletion	father: IVS6-2A>T / N mother: 7-8 exons deletion / N	3	II
P.7830	p.Gln15X (de novo) + 7-8 exons deletion	father: N / N mother: 7-8 exons deletion / N	2	I
P.7864	p.Thr274Ile + 7-8 exons deletion	father: p.Thr274Ile / N mother: 7-8 exons deletion / N	3	III

SMN1, SMN2 and NAIP gene deletions in Romanian patients with spinal muscular atrophy

M. Stavarachi[1], *M. Toma*[1], *P. Apostol*[1], *S. Spandole*[1], *N. Butoianu*[2], *C. Iliescu*[2], *C. Burloiu*[2], *M. Budisteanu*[2], *D. Craiu*[2], *D. Iancu*[3], *L. Bărbării*[3], *D. Cimponeriu*[1];
[1]*Department of Genetics, University of Bucharest, Bucharest, Romania,* [2]*Clinical Psychiatric Hospital „Prof. Dr. Alexandru Obregia", Bucharest, Romania,* [3]*Institute of Forensic Medicine „Prof. Dr. Mina Minovici", Bucharest, Romania.*

Spinal muscular atrophy (SMA) is characterized by degeneration of motor neurons that cause progressive muscle weakness and muscle atrophy. SMN1 homogizot gene deletion is present in most patients with SMA (~95%). The objective of this study was to evaluate the SMN1, SMN2 and NAIP gene mutational status in SMA romanian patients. In this study, we analyzed by PCR-RFLP 53 patients with suspected SMA and 32 relatives. We also performed a prenatal test fetal with DNA obtained by amniocentesis from mother, who had prior history of another child diagnosed with SMA.
We identified homozygous deletion of exons 7 and 8 of SMN1 and SMN2 genes in 23 patients, and only deletion of exon 7 at 2 patients. Homozygous deletion of exon 7 and 8 of SMN2 gene was identified in 2 patients and one relative of a patient. NAIP gene deletion was identified in 8 patients and 3 relatives. For prenatal testing, we identified homozygous deletion of exon 7 and 8 of SMN1 gene.
Molecular diagnosis of SMA by identifying of SMN1 gene deletion is a useful tool for the diagnosis of SMA in Romania, being necessary deermination of SMN copies for a better matching phenotype - genotype.
This work was supported by CNCSIS - UEFISCDI, project number PN II - IDEI 2152/2008 and Program 8, the project „Intervention for diagnosis and management of spinal amiotrophy and muscular dystrophy type Duchenne and Baker, and the prevention of their hereditary transmission" 2011.

Molecular and prenatal diagnosis of spinal muscular dystrophy in the Iranian population

R. Valian Boroujeni[1], *S. Vallian Broojeni*[2];
[1]*University of Isfahan, Isfahan, Islamic Republic of Iran,* [2]*Isafahan Medical Genetics Center, Isfahan, Islamic Republic of Iran.*

Spinal muscular atrophy (SMA) is an autosomal recessive disease, caused mutations in several genes named SMN1, SMN2 and NAIP. Here we report the results of our study on the frequency of mutations in SMN1 and NAIP genes in the Iranian patients with different types of SMA. A total of 126 patients with clinical diagnosis of SMA (36 patients type I, 7 type II, 7 type III and 7 older than 20 years patients). Also, prenatal diagnosis was performed on 57 CVS samples form carrier parents with an affected child. Our results on patients with type I SMA showed deletion in NAIP4, NAIP5, Exon7, Exon8 with frequency of 80%,20%, 80%, 80% and 20% , respectively. In patients with type II SMA, the results were 86%, 28%, 28%, 43% and 14% deletion/mutation in NAIP4, NAIP5, Exon7, Exon8 (SMNI), respectively. The data of our prenatal diagnosis indicated five one out of 57 has deletions in NAIP4 and Exon8 , two fetuses only in NAIP4 and the rest showed no deletion. Together, our data show that deletion in NAIP5 always was associated with other deletions in the exon 7 and 8 of the SMNI gene, which could be used as a molecular marker in diagnosis of the Iranian SAM patients.

A novel mutation in RYR1 causes severe congenital form of central core disease

I. Micule[1,2], *J. Strautmanis*[1,2], *N. Pronina*[1], *B. Lace*[2];
[1]*Children's University Hospital, Riga, Latvia,* [2]*Latvian Biomedical Research and Study centre, Riga, Latvia.*

Central core disease (CCD) is the first described congenital myopathy. It is characterized by central cores in most type 1 muscle fibres on muscle biopsy. A large phenotypic variability has been demonstrated including almost asymptomatic and severe congenital forms. CCD is caused by mutations in *RYR1* gene, which are inherited in autosomal dominant fashion, but among more severe also autosomal recessive forms have been reported. Here we report a patient with a congenital form of CCD and a *de novo* mutation in *RYR1*, which has not been previously reported.
The patient was an eight months old girl, born to unrelated Caucasian parents after uneventful term pregnancy with a negative family history. At birth the child was hypotonic, had reduced movements, contractures of wrists, bilateral hip dislocation, and scoliosis, and she was oxygen dependent. The girl received invasive ventilation briefly, now replaced for non-invasive respiratory support during sleep or illness. She received partial nasogastric tube feeding for four months. By age 8 months she had not yet achieved head control and had no antigravity movements.
Among other investigations a muscle biopsy was done, which showed a pattern characteristic for CCD. The DNA sample was obtained for sequencing of *RYR1*. By sequencing four exons of *RYR1* in the mutational hotspot a novel missense mutation c.14759C>T (T4920I) was found, located in a highly conservative region for vertebrates. The mutation was not detected in parents showing a *de novo* event. Autosomal recessive inheritance cannot however be fully excluded before full gene sequencing is performed.

J07.11

Duplication of 17p12 region (PMP22 duplication) in demyelinating CMT neuropathy in very early infancy

M. Hejtmankova, *M. Trkova, V. Becvarova, L. Hnykova, H. Machkova, D. Stejskal;*
GENNET, Praha 7, Czech Republic.

CASE REPORT: We are reporting on a female infant (2yrs) with early onset out developmental delay, hypotonia and without dysmorphism. In her 24 months of age she cannot independently sit, walk and speak. She is only able to crawl on her back. Distal weakness of lower legs is dominating. Her karyotype is 46,XX and mutations in SHOX and SMA1 genes have been excluded. Inborn errors of metabolism investigations were negative. Family history was negative. Congenital CMV infection was suggested in different diagnosis. Brain MRI has showed diffuse CNS hypomyelination. The clinical features called for more precise genetic testing.
We provided the whole-genome screening by SNP array analysis (Illumina HumanCytoSNP-12v2.1) as the most recent effective method. We identified a 1.4Mb duplication in 17p12 region covering 16 RefSeq genes, which includes the PMP22 gene. From the clinical point of view is the duplication of the gene PMP22 the most important. The finding of the PMP22 duplication is consistent with a diagnosis of Charcot-Marie-Tooth disease type 1A (CMT1A, OMIM 118220) or subset 1E with deafness (CMT1E, OMIM 118300) or hypertrophic neuropathy of Dejerine Sottas (DSS, OMIM 145900), which are supported by clinical features in this patient. The parents of child are being tested.
Establishing the diagnosis of a very early demyelinating neuropathy with sensory impairment will enable clinicians to evaluate and manage more specific examination and health supervision by a multi-disciplinary team. However this hereditary CMT form is non-treatable.

Duchenne/Becker muscular dystrophy: First report on clinical, biochemical and genetic study in Gujarat population, India

G. M. Sindhav[1], *M. V. Rao*[1], *J. J. Mehta*[2];
[1]*Gujarat Genetic Diagnostic Center(GenDiCe), Department of Zoology,School of Sciences,Gujarat University, Ahmedabad, India,* [2]*Indian Muscular Dystrophy Society, Ahmedabad, India.*

Background: Duchenne muscular dystrophy (DMD) is one of the most common inherited neuromuscular diseases, affecting 1 in 3500 males. It is an X-linked disorder caused by mutations in the dystrophin gene. Mutations leading to a truncated protein cause the severe phenotype of DMD, whereas mutations retaining the mRNA reading frame cause the more benign phenotype of Becker muscular dystrophy (BMD).
Material and Methods: In this study 60 clinically suspected D/BMD patients were tested by M-PCR (26 exons) for genetic analysis whereas biochemical indices were measured by using the COBAS 400 analyzer.
Results: Of the 60 suspected D/BMD patients. The diagnosis of D/BMD was confirmed by M-PCR in 57 patients. The mean age of onset was 4.6±0.19 years and the mean age at presentation was 10.6±0.43 years. The mean CK, myoglobin, LDH and calcium level were 7934.5±822.82 u/l, 875.55±47.14 ng/ml, 852.78±60.89 u/l and 9.15±0.12 mg/dl respectively. Of 57 cases, 8.8% were found deletion in proximal hotspot while remaining in distal hotspot. Most frequent deletion was found in exons 47, 48, 49, 50, and 51. The deletion rates were 36.84%, 47.36%, 54.38%, 57.89% and 42.1% respectively. Out of these, 7% had in-frame mutations.
Conclusions: This significant analysis has been carried out first time for D/BMD patients particularly from Gujarat, India. This study also emphasizes the need for further investigation into the genotype/phenotype aspects of the Gujarat D/BMD population.

Hereditary motor and sensory neuropathy type 1B and multiple exostoses type II of Monozygotic twins - a family case report

S. A. Kurbatov[1], *V. P. Fedotov*[1], *N. M. Galeeva*[2], *T. B. Milovidova*[2], *A. V. Polyakov*[2];
[1]*Genetic counseling, Regional Clinical Hospital, Voronezh, Russian Federation,* [2]*Russian Research Center for Medical Genetics, Moscow, Russian Federation.*

Hereditary motor and sensory neuropathy type 1B (HMSN 1B) is a rare autosomal dominant disease with mutations in the *MPZ* gene and dramatically disrupted of myelin compaction (MIM#118200), with late onset of independent walk, uncertain shaky gate, ataxia, distal paresis, sensory loss, generalized tendon areflexia of clinical phenotypes and very low nerve conduction velocity (NCV) of Electrophysiology. Multiple exostoses type II (EM II) is a rare autosomal dominant disease (MIM#133701) with mutations in *EXT2* gene and multiple bony spurs/lumps and deformities of long bones of patients.
We present a family (father aged 32 and his two daughters monozygotic twins aged 6) with two diseases HMSN 1B and EM II. The clinical phenotypes of are the same in all the patients they all have sensory ataxia, sensory loss, generalized tendon areflexia and distal paresis. Superficial palpation and X-ray examination revealed bilateral multiple exostoses shoulders, femurs and ribs. Median motor NCV was less than 6 m/s and sensor NCV was absent in all the patients.
In three DNA samples direct sequencing detected missense mutation c.389A>G (Lys130Arg) in exon 3 of *MPZ* gene (locus 1q23) and missense mutation c.678C>A (Tyr226Stop) in exon 4 of *EXT2* gene (locus 11p11) all of them in heterozygous state.
The HMSN 1B and EM II, occur independently of one another, however, their coexistence in the same patient are not described before.

Implementation of triplet repeat primed PCR (TP PCR) in the molecular diagnosis of myotonic dystrophy type 1 (DM1)

S. Bichev[1], *A. Shopova*[2], *T. Todorov*[3], *A. Todorova*[3], *T. Chamova*[2], *V. Guergueltcheva*[2], *A. Savov*[1], *I. Tournev*[2,4];
[1]*National Genetic Laboratory, Sofia, Bulgaria,* [2]*Clinic of Neurology, University Hospital „Alexandrovska", Sofia, Bulgaria,* [3]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [4]*Department of Cognitive Science and Psychology, New Bulgarian University, Sofia, Bulgaria.*

Background: Myotonic Dystrophy type I (DM1) is a dominantly inherited disorder with a multisystemic pattern affecting skeletal muscle, heart, eye, endocrine and central nervous system. DM1 is associated with the expansion and instability of CTG repeat in the 3' untranslated region of the DMPK gene located on chromosome 19q13.3. Unequivocal molecular characterization of the DM1 triplet expansion requires the use of different PCR protocols to amplify normal and mutated alleles combined with Southern blotting analysis to accurately size the expansion. Nevertheless, expansion detection by PCR may be somewhat problematic in homozygous individuals. The purpose of this study was to evaluate triplet repeat primed PCR (TP-PCR) as a screening method for DM1 diagnosis in the diagnostic laboratory.
Aim: implementation of routine method for diagnosis of DM1 patients in Bulgaria.
Materials and methods: Our cohort consists of 120 patients from 63 families with clinical symptoms referred to those of the disease. We used short range PCR and TP- PCR to identify CTG expansion. Expansion was confirmed by Southern blot.
Results: From 120 analyzed patients TP-PCR assay identified the DM1 expansion in 66 individuals form 28 families, with one normal allele and one expanded allele. We used Southern blot to confirm CTG expansion in 32 of the positive cases.
Conclusion: TP- PCR proved to be reliable method for routine diagnosis of DM patients. However it is not able to estimate the exact number of CTG repeats it is able to detect large expansions which are related with manifestation of DM symptoms.

Rigid spine congenital muscular dystrophy produced by selenoprotein N, 1 (*SEPN1*) mutations (RSMD1): long-time course in a young adult patient

V. A. Kadnikova, *G. E. Rudenskaya, A. V. Polyakov;*
Medical Genetics Research Centre, Moscow, Russian Federation.

RSMD1 is a rare autosomal recessive disorder with several distinctive features. Unlike many congenital muscular dystrophies, early motor improvement and normal CPK are typical, while in contrast to structural myopathies there is no specific muscle morphology. Rigid spine, early scoliosis and joint contractures are characteristic. We diagnosed RSMD1 in a 27-year-old Russian female with previous diagnosis of unspecified myopathy. She had severe congenital muscle weakness with no head control in 12 months, and motor prognosis was considered poor. However, she walked independently in 15 months (though typical 'dropped head' persisted for some time), and her motor abilities were relatively satisfactory later on. Since 7-8 years scoliosis rapidly progressed. Spine surgery at the age of 15 was complicated by

cardiac arrest, while scoliosis did not improve. Soon persistent nocturnal hypoventilation with necessity of device support developed (one more RSMD1 typical feature). The patient has higher education, works part-timely in office, exercises regularly in gym. Lately she noticed some increase of weakness but walks independently. Apart from proximal myopathy and severe scoliosis her signs are: short stature (147 cm corrected for scoliosis), small feet 32 cm, long face, high palate, nasal speech, moderate dysphagia, stiff neck and forced abnormal head position, mild elbow contractures. CPK is normal. DNA test detected compound heterozygosity for two earlier described *SEPN1* mutations: c.683_689dup7 and c.1397G>A (p.Arg466Gln). This is our second RSMD1 case. In first patient, a 4-year-old boy from Uzbek (Central Asia) consanguineous family, homozygosity for *SEPN1* novel mutation c.998delC (p.Arg330GlyfsX71) was found out.

Novel p.Gly484Asp mutation in *SPAST* gene is associated with infantile-onset autosomal dominant spastic paraplegia

G. Scharer[1], *A. Pickart*[2], *D. Helbling*[3];
[1]*CHW-Genetics Center, Medical College of Wisconsin, Milwaukee, WI, United States,* [2]*Dept. of Pediatrics, Section of Clinical Genetics, Children's Hospital of Wisconsin, Milwaukee, WI, United States,* [3]*Human and Molecular Genetics Center, Medical College of Wisconsin, Milwaukee, WI, United States.*

Hereditary spastic paraplegia (HSP) is a disorder with heterogeneous genetic etiology and variable phenotypic expression, typically presenting with progressive lower extremity spasticity and weakness. Autosomal-dominant (AD), autosomal-recessive, and X-linked inheritance has been reported and symptoms can occur in isolation or with other neurologic abnormalities. Spastic paraplegia type4 (SPG4) due to mutations in the *SPAST* gene is the most common AD form of HSP.
We report a 6 year old male with lower leg stiffness/spasticity, in whom symptoms developed in early infancy. Torso and upper extremity are unaffected at this time; growth and cognitive development is age appropriate. Family history analysis revealed similar symptoms in the patient's biological father and paternal grandfather, which were contributed to other disease processes (i.e. cerebral palsy, multiple sclerosis). The father's symptoms also started in infancy and were obvious at onset of walking.
Genetic work-up included sequencing of genes commonly associated with AD-HSP, including *SPAST* (Spastin), *ATL1* (Atlastin), *NIPA1* (SPG6), and *REEP1* (SPG31). No mutations were found in the latter 3 genes; while a novel heterozygous sequence variant (SNV) was detected in *SPAST*. This SNV (c.1451G>A, p.G484D) affects a highly conserved amino acid, was not found in HGMD, or the Exome Variant Server, and is predicted to be damaging/not tolerated by POLYPHEN/SIFT. Family studies are ongoing to link the SNV to the affected individuals in 3 generations. This case indicates a new pathogenic mutation in *SPAST* associated with infantile-onset autosomal-dominant spastic paraplegia.

Molecular genetic testing of SMA in the Republic of Bashkortostan, Russia

A. Aupova, *H. Karavanova, H. Gysina, A. Frolov;*
Republican Perinatal Center, Ufa, Russian Federation.

Spinal muscular atrophy is a severe autosomal recessive disease of the nervous system. SMA is caused by a progressive loss of motor neurons of the anterior horns of the spinal cord that occurs due to deletions 7 and/or 8 exons SMNt.
For 10 years (2003-2012) we studied 114 patients with a clinical diagnosis of SMA and 178 family members. The survey revealed that one-third of families (50 families out of 134) the disease is associated with the presence of 55-probands homozygous deletion of 7-8 exons SMNt. In 58 patients with suspected spinal muscular atrophy SMNt gene mutations not found, but this does not exclude the presence of mutations in other genes that cause SMA.
We have carried out 22 prenatal diagnostics performed in families where one child has spinal muscular atrophy. In four cases identified homozygous deletions. In other families found heterozygous deletions. Search for mutations was performed using the restriction fragment length polymorphism according to the protocol „Center for Molecular Genetics", Moscow.
Thus, the combination of clinical and molecular-genetic research methods helps the correct diagnosis of spinal muscular atrophy and allows medical genetic counseling families, including prenatal diagnosis.

Establishing a Registry of Inherited Neuromuscular Disorders in Kuwait:A Preliminary Report

L. A. Bastaki;
Kuwait Medical Genetic Center, Kuwait, Kuwait.

Inherited neuromuscular diseases are broad category of disorders that affect all age groups worldwide. They, as a group, are relatively common with a prevalence of one in 3000. Many of these disorders were described since the nineteenth century but the advances in the imaging and other diagnostic techniques improved our understanding and classification of them. Broadly, these disorders can be classified into three categories. These categories are that affects peripheral nerve (neuropathy), diseases of muscle (myopathy and dystrophy) and diseases of spinal cord motorneurons (motor neuron disease). The prevalence of these disorders is not well characterized in Kuwaiti population. Kuwait Medical Genetic Center is the only medical genetic center in Kuwait which serves all Kuwaiti districts. I will present our experience in establishing the first registry for inherited neuromuscular disorders in Kuwait to know the burden of the disorder in our community as a step towards improving the quality of life for such patients.

Decade of raised awareness of neuromuscular diseases in Latvia

B. Lace[1], *I. Inaskina*[1], *M. S. Naudina*[2], *J. Stavusis*[1], *I. Vasiljeva*[1], *Z. Krumina*[3], *N. Pronina*[3], *I. Micule*[3], *J. Strautmanis*[3], *E. Jankevics*[1];
[1]*Latvan Biomedical Research and Study centre, Riga, Latvia,* [2]*Pauls Stradins Clinical University Hospital, Riga, Latvia,* [3]*Childrens' University Clinical Hospital, Riga, Latvia.*

Numbers of neuromuscular diseases (NMD) are inherited conditions affecting muscle, nerve and neuromuscular junction, and caused by mutations in the nuclear and mitochondrial genes. Every year expanding knowledge of these conditions add new genes to this list. In 2002, there was established a strategy in Latvia, to increase availability for diagnostics in patients with NMD, which included new diagnostic techniques, open NMD clinic for all patients and education for medical professionals.
Objective of the study was to evaluate diagnostic efficiency of NMD patients in Latvia in the past ten years.
Patient information was obtained from Medical Genetics clinic register, Molecular Biology laboratory and Latvian Biomedical Research and Study centre data in the two time periods: 2002-2008 and 2010-2012. Incidence, standard deviation and confidence interval at 95% calculated.
Results. Steady 6% increase was observed each year since 2002, due to the introduction of the new molecular biology techniques for DMD, CMT1a and SMA. In 2010 added new tests for MD, mtDNA sequencing and LGMD, which increased clinically or molecularly confirmed diagnosis up to 70% since 2002. The most common diagnosis were CMT (CI95%-0.07, SD-15), SMA (CI95%-0.06, SD-14) and FSHD (CI95%-0.01, SD-3.5), not DMD.
Conclusions. New diagnostic techniques complimented with education of medical professionals are the most effective instrument to increase diagnostic availability for the patients in the long term.

Management and molecular diagnosis in romanian patients with Duchenne/Becker muscular dystrophy

L. Tamas, *M. Puiu, N. Andreescu, A. Anghel, C. Gug, C. Samoila, I. M. Ciuca, S. Dumitriu;*
University of Medicine and Pharmacy „Victor Babes", Timisoara, Romania.

Duchenne and Becker muscular dystrophy (DMD/BMD) are the most common muscular dystrophies with X-linked inheritance caused by mutations in the DMD gene. DMD is the most severe form with a complete absence of dystrophin synthesis. The most frequent DMD gene mutations are large deletions and duplications of one or more exons.
Method. For molecular diagnosis of patients diagnosed with DMD/BMD only on the base of clinical symptoms, family history and creatine kinase levels we used MLPA (Multiplex Ligation-dependent Probe Amplification) technique. Genomic DNA was extracted from blood samples and 35 unrelated patients and 20 relatives were analyzed. The MLPA products were quantified by capillary electrophoresis and interpreted using Coffalyser software.
Results. Large deletions were identified in 24 patients (68,57%) and large duplications in four patients (11,42%). 14 female patients with heterozy-

gous genotypes confirmed previously identified mutations in male patients and in 6 subjects, relatives of DMD patients, no mutations were found. In one case prenatal diagnosis was performed on a patient having a child with DMD, confirmed by molecular diagnosis. In 7 patients (20%) no deletions or duplications were identified and they were further investigated by sequencing.
Conclusions. Our results showed an overall frequency of large deletions and duplications of 80%. MLPA technique is particularly effective if Duchenne disease, allowing the detection of mutations in most cases and both prenatal diagnosis and diagnosis in children with specific symptoms of disease. A larger group of patients needs to be investigated for a more accurate evaluation on DMD gene mutations spectrum.

Role of medical rehabilitation program in chromosome 2 deletion with hypotonia - case study

F. Cioara[1], *M. I. Cevei*[2], *C. Avram*[3], *D. Stoicanescu*[4];
[1]*Clinical Rehabilitation Hospital,Baile Felix, University OF Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania,* [2]*Clinical Rehabilitation Hospital, Baile Felix, University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania,* [3]*Clinical Medical Rehabilitation Hospital,, Baile Felix, Romania,* [4]*University of Medicine and Pharmacy „ Victor Babes,„ Timisoara, Romania.*

Many genetic conditions are related to changes in different genes on chromosome 2. Recent studies suggest that genes on chromosome 2 may be involved in intelligence determination. Partial deletion or loss of genes from specific regions of chromosome 2 is characterized by intellectual disability, epilepsy and autism spectrum disorder, which may be associated with syndromes. In this paper we report the case of a young girl, admitted in our hospital for severe retardation in motor acquisitions, at 1 year just active rolling, with severe hypotonia, specific symptoms and signs related to autism, severe mental retardation, microcephaly and mild facial dysmorphism, who was found to have a rare genetic condition represented by a small deletion of the long arms of chromosome 2. We included her in a complex rehabilitation program from the age of fourteen months. The objective was obtaining age appropriate functional independence. At the first admission she had a severe hypotonic syndrome, severe retardation in the acquisition of motor skills and mental retardation. After 7 hospitalizations of 21 days each, during 2 years, with complex rehabilitation programs-pool with thermal water and hydrokinetotherapy, individual kinetotherapy, electrotherapy, general massage, occupational therapy, the evolution was favorable with motor improvement. Independent standing, alternating steps, wider support base, ability to rise after falling and walking on short distances were achieved.
Rehabilitation treatment is effective in improving motor skills and must be an early intervention. Early diagnosis and improvements in management of such patients by a multidisciplinary team will improve prognosis and quality of life.

Novel mutation in IGHMBP2 gene causing spinal muscular atrophy with respiratory distress, type 1

T. Todorov[1], *I. Litvinenko*[2], *A. Kirov*[3,1], *A. Todorova*[3,1], *V. Mitev*[3];
[1]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [2]*University Pediatric Hospital, Medical University Sofia, Sofia, Bulgaria,* [3]*Medical University Sofia, Sofia, Bulgaria.*

Spinal muscular atrophy with respiratory distress, type 1 (SMARD1, MIM# 604320) is an inherited condition that causes muscle weakness and respiratory failure, typically beginning in infancy. Early features of this condition are difficult and noisy breathing, especially when inhaling; a weak cry; problems feeding; and recurrent episodes of pneumonia. Typically, between the ages of 6 weeks and 6 months, infants with this condition will experience a sudden inability to breath due to paralysis of the the diaphragm. The muscle weakness is progressive and predominately affects the lower distal extremities. Other symptoms, although not always presented include intrauterine growth retardation, seizures, autonomic nervous system dysfunction, decreased pain perception, excessive sweating, constipation, and bladder incontinence. The genetic basis of SMARD1 is unrelated to the 5q-linked SMN-related classical SMA, and is due to mutations in another gene called IGHMBP2 (MIM*600502). Mutations in this gene occur in approximately 1% of patients with diaphragmatic SMA and the disease is characterized by autosomal recessive inheritance. Here we report on a family with two severely affected SMARD1 sibs. Both patients developed progressive muscular weakness and respiratory distress and died before 6 months of age. SMN gene was negative, but two mutation were detected in IGHMBP2 gene: one novel deletion c.780delG; p.(Gln260Hisfs*24), inherited from the father and a nonsense mutation c.1488C>A; p.(Cys496*) inherited from the mother.
To the best of our knowledge, this case might be considered as the most severe form of SMARD1, reported so far, presumably due to total absence of IGHMBP2 enzyme activity.

J07.23
Detecting exon mutations of the DMD gene using Multiplex Ligation-dependent Probe Amplification (MLPA)

A. Shevtsov[1], *A. Borovikova*[1], *M. Bayanova*[1], *B. Kamaliyeva*[1], *Z. Abdrahmanova*[2], *G. Abildinova*[1];
[1]*National Research Center Maternal and Child Health, Astana, Kazakhstan,* [2]*Astana Medical University, Astana, Kazakhstan.*

In order to explore the impact distinct genetic polymorphisms implicated in Duchenne myodystrophy on disease severity and age of onset were carried out molecular genetic tests of 33 patients with clinical manifestations of disease.
Material for the study was DNA samples extracted of standard protocol using «Qiagen» (USA). Detecting exon mutations of the DMD gene using Multiplex Ligation-dependent Probe Amplification (MLPA; P-034 and P-035 kits from MRC Holland) and capillary electrophoresis. Results of study were interpreted using the program «Coffalyser.Net».
Analysis of results of MLPA showed that from 9 (33%) patients had diagnosed the deletions of exons DMD gene. The detecting deletions were from 41 to 60 exons of DMD gene and it had the length from one to four exons. 11 % patients had the deletions the 13 exons of DMD gene with early debut and severity of disease.
In conclusion, the using of MLPA allows to determine the bigger length of deletions and duplications of exons of DMD gene, which in turn is the important stage of differentiated diagnosis and the prognosis of the treatment.

Rare Duplications in the DMD gene: Report of two Cases from Southwest Iran

H. Galehdari[1], *G. Shariati*[2,3], *M. Hamid*[4], *H. Saberi*[5], *M. Mohammadi Anaei*[2], *A. Hafizi*[6], *N. Abdolrasouli*[2];
[1]*Genetics, Ahwaz, Islamic Republic of Iran,* [2]*Narges Genetic Center, Ahwaz, Islamic Republic of Iran,* [3]*Medical School of Ahvaz Jundishapur University, Ahvaz, Islamic Republic of Iran,* [4]*Pasteur institute, Tehran, Islamic Republic of Iran,* [5]*Medical School of Ahvaz Jundishapur University, Ahwaz, Islamic Republic of Iran,* [6]*Shahid Chamran University, Ahwaz, Islamic Republic of Iran.*

Duchene muscular dystrophy (DMD) is a common X-linked recessive neuromuscular disorder, affecting 1 in 3,500 live male births. About 65% of cases are caused by deletions; ~5% to 8%, by duplication; and the remaining, by point mutations of the dystrophin gene. The frequency of complex rearrangements (double-deletion and non-contiguous duplications) is reported to be 4%. Becker muscular dystrophy (BMD) is a milder allelic form, with a lower prevalence. DNA deletion and duplication were determined as the major mutation underlying DMD and BMD.
DMD gene, located at Xp21, is the largest identified gene in the human genome, spanning 2.4 Mb and 79 exons. It has a high mutation rate, with approximately one-third of all cases resulting from a spontane[[Unsupported Character - Codename]]ous mutation. Its transcript is 14 kb long and is expressed in skeletal muscle and brain.
Applying multiplex ligation-dependent probe amplification (MLPA), we have analyzed 2 unrelated DMD subjects from Iran.
Genomic DNA was extracted using standard procedures from the peripheral blood leukocytes, and MLPA was applied to detect DMD gene to identify genetic mutation.
using MLPA technique, in the first case were seen a duplication spanning from exon 2 to exon 9 of the dystrophin gene. In the second we observed a duplication of exons 10 and 11. The important point in this report is that none of the two duplications observed in this patients have been reported in Iran as yet, and these duplications are nearly rare cases in the world.

Variable expression of myotonic dystrophy type 1 in a three-generation family

E. Sukarova Stefanovska[1], *E. Sukarova-Angelovska*[2], *N. Angelkova*[2], *D. Plaseska-Karanfilska*[3];
[1]*Macedonian Academy of Sciences and Arts, RCGEB „Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of,* [3]*Macedonian Academy of Sciences and Arts, RCGEB, Skopje, Macedonia, The Former Yugoslav Republic of.*

Myotonic dystrophy type1 (MD1), is a common dominantly inherited neuromuscular disorder, involving muscle wasting, myotonia, cataracts, hypogonadism. MD1 is result of a tandemly repeated expansion of trinucleotide CTG in the 3'UTR of DMPK gene (19q13.3). Normal alleles usually less than 35 repeats, can expand from 50 up to several thousand, showing variable clinical manifestation, from adult-mild to severe congenital form. We present a three generation affected family with MD1 with clinical symptoms indicating consequtively worsening of the disease. Index case was a newborn approached to clinic due to the poor sucking and hypotonia. He had all signs of congenital MD1- muscle weakness, dysmorphic face, relative macrocephaly, talipes equinovarus, hypogonadism. He had frequent respiratory infections. MRI showed global cerebral atrophy and severe developmental delay. The mother had mild symptoms: mild mental retardation, expressionless long face, ptosis, nasal speech, frontal balding, open mouth appearance. EMG confirmed myotonia. Both eyes have lenses opacities. The grandmother had normal intelligence, long face, ptosis and minor muscular weakness on arms after her 40's. Cataract was operated at 58. The diagnosis was confirmed in all three cases using TP-PCR method. PCR and Long range PCR using flanking primers of the repeated sequence gave only normal fragment of 13 repeats in propositus and 14 in mother/grandmother. TP-PCR method gives a characteristic ladder on the fluorescence enabling identification of large pathogenetic repeats that cannot be amplified using normal PCR procedure. Southern blot analysis should be performed in order to determine the exact expansion of pathogenic allele.

Study of relation between NAIP gene deletion, TTV infections and spinal muscular atrophy in Romanian patients

M. Toma[1], *S. Spandole*[1], *M. Stavarachi*[1], *P. Apostol*[1], *N. Butoianu*[2], *D. Cimponeriu*[1];
[1]*Department of Genetics, University of Bucharest, Bucharest, Romania,* [2]*Clinical Psychiatric Hospital „Prof. Dr. Alexandru Obregia", Bucharest, Romania.*

Proximal spinal muscular atrophy (SMA) is a genetically heterogeneous disease with paresis and muscle atrophy due to loss of anterior horn cell function. The survival of motor neuron gene (SMN) and neuronal apoptosis inhibitory protein (NAIP) play a primary role. Torque teno virus (TTV) seems to be able to interfere with production of some proinflammatory cytokines and was associated with some neurodegenrative diseases. The objective of this study was to evaluate the relation between NAIP deletion, TTV infections and SMA in Romanian patients. In this study, we included 25 SMA patients and analyzed by PCR the NAIP deletion and TTV infection status. We identified the deletion of NAIP gene in 8 patients (32%), and TTV infections in 21 patients (84%). We didn't find any relation between distribution of TTV infections and NAIP deletion ($p > 0.05$).
This work was supported by CNCSIS - UEFISCDI, project number PN II - IDEI 2152/2008 and Program 8, the project „Intervention for diagnosis and management of spinal amiotrophy and muscular dystrophy type Duchenne and Baker, and the prevention of their hereditary transmission" 2011.

Astrocyte dysfunction triggers neurodegeneration in a lysosomal storage disorder

C. Di Malta[1,2], *J. D. Fryer*[3], *C. Settembre*[1,2], *A. Ballabio*[1,2,4];
[1]*Telethon Institute of Genetics and Medicine, Naples, Italy,* [2]*Jan and Dan Duncan Neurological Research Institute, Houston, TX, United States,* [3]*Department of Neuroscience, Mayo Clinic, Jacksonville, FL, United States,* [4]*Department of Pediatrics, Federico II University, Naples, Italy.*

The role of astrocytes in neurodegenerative processes is becoming increasingly appreciated. Here we investigated the contribution of astrocytes to neurodegeneration in Multiple Sulfatase Deficiency (MSD), a severe Lysosomal Storage Disorder (LSD) caused by mutations in the *Sulfatase Modifying Factor 1 (SUMF1)* gene. Using Cre/Lox mouse models, we found that astrocyte-specific deletion of *Sumf1 in vivo* induced severe lysosomal storage and autophagy dysfunction with consequential cytoplasmic accumulation of autophagic substrates. Lysosomal storage in astrocytes was sufficient to induce degeneration of cortical neurons *in vivo*. Furthermore, in an *ex vivo* co-culture assay, we observed that *Sumf1*$^{-/-}$ astrocytes failed to support the survival and function of wild type cortical neurons, suggesting a non-cell autonomous mechanism for neurodegeneration. Compared to the astrocyte-specific deletion of *Sumf1*, the concomitant removal of *Sumf1* in both neurons and glia *in vivo* induced a widespread neuronal loss and robust neuroinflammation. Finally, behavioural analysis of mice with astrocyte-specific deletion of *Sumf1* compared to mice with *Sumf1* deletion in both astrocytes and neurons allowed us to link a subset of neurological manifestations of MSD to astrocyte dysfunction. This study indicates that astrocytes are integral components of the neuropathology in MSD and that modulation of astrocyte function may impact disease course.

In addition to pure Parkinson disease and pure dystonic syndromes, there are a group of disorders with overlapping features. The differential diagnosis of these dystonia-parkinsonism syndromes can be complex. Various genes have been identified which may cause recessive dystonia-parkinsonism. In this study we sought to use exome sequencing in conjunction with linkage information to identify candidate causative gene in an Iranian family with dystonia-parkinsonism. Linkage analysis of this family comprising two affected and 8 unaffected individuals revealed linkage signals at 2 loci on chromosomes one and two with maximum LOD scores of 2.4 and 2.35, respectively. We captured exomes of one affected individuals from the family and performed sequencing analysis by a second-generation sequencer. The genetic variants of the affected individual in the linked loci were filtered against the 1000 Genomes Project, HapMap and the dbSNP131 database. After annotation and functional expectation, two novel genes were found to be candidates for dystonia-parkinsonism syndrome in this family. Functional studies are being performed for these two candidate genes to unravel the causative gene in this family.

Mutations in the CDKL5 and MECP2 genes, causing an atypical form of Rett syndrome

M. S. Chaplygina[1,2], *E. A. Alekseeva*[2,3], *O. V. Babenko*[2,3], *N. A. Demina*[3], *V. A. Galkina*[3], *G. E. Rudenskaya*[3], *V. Y. Voinova*[4], *V. V. Strelnikov*[2,3], *D. V. Zaletayev*[2,3,1];
[1]*The Russian National Research Medical University named after N.I. Pirogov (RNRMU), Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation,* [3]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [4]*Moscow Research Institute of Pediatrics and Pediatric Surgery, Moscow, Russian Federation.*

Rett syndrome (RTT) is a severe neurodegenerative disease that affects approximately 1 in 10000 female births. Classic RTT is diagnosed based on a set of main clinical criteria. Atypical RTT has a milder form and more severe clinical form and diagnosed when only some of criteria are present.
Milder form is presented by the preserved speech variant caused by point mutations and large deletions with phenomenon of nonrandom X-inactivation (NXI) in MECP2 gene (Xq28).
Severe form of atypical RTT include the early-onset seizure type caused by mutations in the X-linked CDKL5 gene (Xp22).
Mutation analysis of MeCP2 and of CDKL5 genes was performed in 20 patients with clinical pictures for atypical RTT.
MECP2 mutations were detected by PCR following by sequencing and by real-time PCR. We identified two pathogenic mutations in the MECP2 gene: a deletion of 45 nucleotides (p.L386fs) and a missense mutation (p.R133C). The patient with R133C mutation has NXI.
Mutations in CDKL5 have been associated with West syndrome and atypical RTT with infantile spasms. Analysis of CDKL5 mutations was conducted by PCR following by sequencing and by using SSCP analysis. We identified two pathogenic mutations in the CDKL5 gene: a frameshit mutation of exon 15

(p.H728fs) and a splice site mutation of intron 7 (c.463+1G).
Both patients demonstrated clinical pictures for atypical RTT with early-onset seizures: infantile epilepsy with onset before 6 months, stereotypical hand movements, psychomotor regression; clinical features similar to those of patients with a severe case of Rett syndrome.

Early onset Parkinson's disease caused by a novel *ATP13A2* truncating mutation

M. Malakouti Nejad[1], *E. Elahi*[2], *E. Jaberi*[2], *A. Alavi*[2], *M. Hashemi*[3], *G. Shahidi*[4];
[1]*Departmant of biology ,Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*School of Biology, University College of Science, University of Tehran, Tehran, Islamic Republic of Iran,* [3]*Department of Genetics,Islamic Azad University,Tehran Medical Branch, Tehran, Islamic Republic of Iran,* [4]*Tehran University of Medical Sciences, University of Tehran, Tehran, Islamic Republic of Iran.*

Parkinson's disease (PD) is the most common neurodegenerative movement disorder characterized by tremor at rest, rigidity , bradykinesia and postural instability whose average age of onset is 60 years. 10% of patients in whom symptoms first manifest before age of 40 years are classified as early onset PD (EOPD) cases. Mutations in *parkin*/PARK2, *PINK1*/PARK6, *DJ1*/PARK7 have been found in EOPD. A recent gene *ATP13A2*/PARK9 is related to early-onset Parkinson's disease (PD). Mutations in *ATP13A2* are the least common. *ATP13A2* is ubiquitously expressed with the highest levels in the brain. While wild-type ATP13A2 is found in the lysosome, mutant forms are retained in the endoplasmic reticulum and degrade by the proteasome. There is evidence that this protein transports multiple cations and clears α-synuclein aggregates. We screened 14 Iranian EOPD patients with age at onset of 20 years in whom mutations in *PRKN, DJ1, and PINK1* were previously ruled out. Twelve cases were sporadic and two of them were familial. In addition to several polymorphisms, *ATP13A2* sequencing revealed a novel homozygous truncating mutation in exon 23 in one familial case. The mutation created a stop codon, and is expected to result in deletion of 323 amino acids at the C-terminus of the protein. The patient has a younger brother with PD, who carries the same mutation.This mutation were not found in 100 Iranian control chromosomes.The novel truncating mutation in *ATP13A2* was associated with an increased risk of Parkinson's disease. Further studies are needed to clarify the functional role of this mutation.

OBJECTIVES: To evaluate phenotype and genetic alterations of known Parkinson's disease (PD) genes in Hungarian PD patients.
METHODS: Detailed anamnestic data, neurological status and biological materials of 144 PD patients (mean age at onset: 46 years) with early onset/familial PD were collected in a biobank. At 118 patients the LRRK2 gene p.G2019S mutation hotspot has been investigated using PCR-RFLP. In 50 patients PARK2, LRRK2, PINK1, SNCA genes were sequenced by Sanger's method. The CNVs of these genes were assessed at 49 patient by MLPA.
RESULTS: Family anamnesis was positive at 31 patients. In the LRRK2 the p.G2019S substitution in 118 patients was not present. Sequence analysis of LRRK2 detected one likely pathogenic splice site mutation. In this gene a high number of intronic and exonic SNPs were present. The homozygous rs11564148 SNP was present in 4 patients. Previously it showed associaton with increased risk of PD in Asian population. In the PRKN gene a substitution (p.R402C), with a high SIFT score, but unclear pathogenic nature was found. CNVs were present in 3 patients (SNCA: exon5, exon6, and PARK2: exon2-4 heterozygous deletion).
CONCLUSIONS: In our cohort 5 pathogenic mutations were found in the genes, most commonly altered in PD. In the Jewish population common LRRK2 p.G2019S mutation was not present in our cohort. Some of the detected SNPs in the LRRK2 in our patients, previously were associated with PD in Asian population. The genetic background of Hungarian PD need to be further studied to evaluate the genetic risk factors.

Wolfram syndrome (WS) is a rare autosomal recessive neurodegenerative disorder that might represent a considerable fraction of diabetes in childhood especially among countries in the consanguinity belt. The main responsible gene is WFS1 for which over one hundred mutations have been reported from different ethnic groups. The aim of this study was to identify the molecular etiology of WS and to perform a possible genotype-phenotype correlation in large Iranian kindred, composed of three nuclear families, from Yazd province, center of Iran.
Three alive patients from the extended family were clinically studied and WS was suspected. Genetic linkage analysis via 5 STR markers was carried out. For identification of mutations, DNA sequencing of WFS1 including all the exons, exon-intron boundaries and the promoter was performed.
Linkage analysis indicated linkage to the WFS1 region. After DNA sequencing of WFS1, one novel pathogenic mutation which causes frameshift alteration in exon 8 (c.1228-1229 del CT) was found. The genotype-phenotype correlation analysis suggests that the presence of the homozygous mutation may be associated with an early onset of disease symptoms especially urological disease. This study stresses the necessity of considering the molecular analysis of WFS1 in childhood diabetes with some symptoms of WS.

Epidemiology of hereditary spastic paraplegias in Bashkortostan Republic

R. Idrisova[1], *E. Saifullina*[1], *A. Akhmetgaleeva*[2], *R. Magzhanov*[1], *I. Khidiyatova*[2], *E. Khusnutdinova*[2];
[1]*Bashkir State Medical University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa, Russian Federation.*

Hereditary spastic paraplegias (SPG) - genetically heterogeneous group of neurodegenerative diseases, with preferentially lesion of the pyramidal tract. Prevalence of the disease varies from 1.0 to 4.0 cases per 100 000 persons in different populations. Our goal was to analyze the prevalence of SPG among citizens of Bashkortostan Republic of various ethnic origins and area of residence. According to National Genetic automated Register „hereditary spastic paraplegias" by January 1, 2013 there are 144 SPG patients in genetic counseling, and 23 possible carriers from 97 families. We have also registered 25 cases of deaths by SPG. The prevalence of SPG in Bashkortostan is 3.5 per 100,000 persons that is significantly higher than in the previous study (2,00 per 100,000 people). This is caused by improvements in diagnosis and registration of SPG. The highest prevalence rate was among Tatars (5,3 per 100,000 people), less among Russians - 2.4 per 100 000 people and Bashkirs- 0.8 per 100 000 people.
Prevalence among rural residents was 2.7 per 100 000 people, among urban residents - 3.7 per 100,000. A growth of SPG prevalence rate and its geographical expansion in Bashkortostan Republic emphasize the importance of further analyzing information of SPG patients and potential mutation carriers in National Automated Genetic Register.

Identification of new modifier genes at DMD/BMD and patient lifespan

A. Levitchi, *V. Sacara;*
National Centre of Reproductive Health and Medical Genetics, Chisinau, Moldova, Republic of.

Duchenne/Becker Muscular Dystrophy, monogenic disease with modifier genes influence, could represent a good model to describe phenotype variations which determine lifespan of the patient. It requires large data analysis, such as expression profiling.
GEO GSE465 microarray expression set was used, including data from Affymetrix Human Genome U95, A to E arrays, Affymetrix GeneChip Custom-Made Muscle Chip and Affymetrix Human Genome U95, version 2 chip, to ensure expression measure reliability (Children's National Medical Center, Washington, USA). Expression variations were estimated by index of expression (IF) as logarithmic ratio between probe signal in DMD and normal patients. Genes with IF<1 were filtered out, in several steps, followed by cross comparison between the gene lists obtained from each of the arrays. Only genes which manifested similar IE level or trend between the arrays were finally selected.
As the result, 17 genes with high positive index of expression (between 2.02 to 6.15) in male and various one (-1.59 to 5.78) in female patients were identified. The genes were grouped by their function, revealing at least five clusters, the largest being "Transcription regulation" and "Signal transduction", each comprising five genes. Four of the selected genes, were also identified in other surveys.
Thus, these genes shared similar variation of their expression, regardless to the array or chip. The genes suppose to be tested in DMD patients to understand their modifier effects, while the results will help in elaboration of the concept related to the impact of new modifier genes on the DMD patient lifespan.

J08.09

Polymorphisms in *CLU*, *CR1*, *ACE* and *catD* genes and Alzheimer's disease: a case-control study in Brazil

L. BELCAVELLO[1], *D. Camporez*[1], *C. Barbirato*[1], *M. V. D. Moraes*[1], *R. L. Morelato*[2], *M. C. P. Batitucci*[1], *F. Paula*[1];
[1]*Federal University of Espírito Santo, Vitória-ES, Brazil,* [2]*Santa Casa de Misericórdia Hospital, Vitória-ES, Brazil.*

Genome-Wide Association Studies (GWAS) have identified many genes related with increased risk to Alzheimer's disease (AD). The *ApoE-e4* allele, a known risk factor for the disease, as well as, variants in *CLU* (8p21.1) and *CR1* (1q32) genes encoding, respectively, clusterin and complement receptor 1, were reported in these studies. Moreover, variants in genes encoding angiotensin-converting enzyme (*ACE,* 17q23) and cathepsin D (*catD,* 11p15.5) were also suggested to be involved with risk to AD. In the Brazilian population ApoE-*e4* allele showed positive association with the disease. In order to research genetic variations causing susceptibility for AD in Brazil we investigated polymorphisms in *CLU* (rs11136000), *CR1* (rs6701713), *ACE* (I/D) and *catD* (rs17571) genes through PCR-FRLP in samples from Vitória (Southeast region). A total of 243 individuals were selected through clinical parameters, including 81 patients and 162 controls matched by gender, age and ethnicity. We found no statistic differences in allelic and genotypic frequencies between the groups (p>0.05), even after stratification by *ApoE-e4* status. The lack of significance in *CLU* and *CR1* genes could be due to the small sample size, since these variations only showed association with AD in GWAS studies that analysed thousand of individuals. On the other hand, variations in *ACE* and *catD* genes, even using small samples, showed controversy results between distinct populations. These results revealed the necessity of validation of genetic variations for the risk of AD among populations with distinct ethnic profile. Supported by FAPES, FACITEC and MCTI/CNPQ/MEC/CAPES.

Searching for a novel gene causing infantile neuroaxonal dystrophy

C. Koroglu, *M. Seven, A. Tolun;*
Bogazici University, Istanbul, Turkey.

Infantile neuroaxonal dystrophy (INAD) is a rare neurodegenerative disease characterized by motor, mental and visual deterioration leading to death in childhood. Axonal swelling and spheroid bodies are observed in tissue biopsy samples. Recessive mutations in PLA2G6 were shown to underlie the disease pathogenesis. Even though PLA2G6 is the only gene associated with INAD so far, rare genetic heterogeneity has been demonstrated by linkage analysis.
We investigated five consanguineous families afflicted with INAD. PLA2G6 was screened for mutations and novel homozygous mutations were identified in four families. The remaining family has two affected sibs, who are adults at present. Their longevity is unusual for INAD phenotype, albeit they both have total neurodegeneration. Another atypical feature they share is facial dysmorphism. The patients, parents and the unaffected sibling were genotyped using SNP markers, and the data were used in linkage analysis. Two candidate loci totalling 10.6 Mb were found at 9p24.1 and at 13q32.3, and none harboured a gene associated with a disease with similar characteristics as that in our patients. We launched exome sequencing on DNA sample of one of the patients to find the variants at those loci. We anticipate that exome sequencing will reveal a novel gene that is responsible for the disease in our study family and be another example that confirms that new generation genetic technologies enable discovery of new disease genes in even small families.

Association of Interleukin (IL)-4 gene intron 3 VNTR polymorphism with multiple sclerosis in Turkish population

S. Yigit, *N. Karakus, S. Kurt, O. Ates;*
Gaziosmanpasa University, Medical School, Tokat, Turkey.

Objective: Genetic risk factors are known to contribute to the etiology of multiple sclerosis (MS). Interleukin (*IL)-4* gene polymorphisms have been associated with immune-mediated diseases. The aim of this study was to explore the frequency of *IL-4* gene intron 3 VNTR (variable number tandem repeat) polymorphism in a cohort of Turkish patients with MS.
Methods: The study included 105 patients with MS and 160 healthy controls. Genomic DNA was isolated and genotyped using polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) analyses for the *IL-4* gene intron 3 VNTR polymorphism.
Results: The distribution of genotype and allele frequencies of *IL-4* gene intron 3 VNTR polymorphism was statistically different between MS patients and control group (p=0.005 and p=0.002, respectively). There were statistically significant associations between EDSS score, MS types and IL-4 VNTR polymorphism in MS patients (p=0.034 and p=0.000, respectively).
Conclusion: The results of this study suggest that intron 3 VNTR polymorphism of the *IL-4* gene was positively associated with predisposition to develop MS in Turkish population.

J08.12

Analysis of association of Parkinson's disease with polymorphic variants of MART-region (17q21.31) in three ethnic groups of the Republic of Bashkortostan (GWAS replication results)

I. Khidiyatova[1], *K. Putenikhina*[1], *G. Akhmadeeva*[1], *I. Gilyzova*[1], *A. Baytimerov*[2], *R. Magjzanov*[2], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Replication of genome-wide association analysis (GWAs) of Parkinson's disease (PD) in three ethnic groups from Bashkortostan Republic (BR) was performed using DNA collection of 550 PD patients (Russians - 215, Tatars - 243, Bashkirs - 90) and 622 control individuals (Russians - 190, Tatars - 338, Bashkirs - 94). The study included analysis of 4 polymorphic loci of chromosomal region of gene MAPT (17q21.31) - rs11012, rs2942168, rs393152 and rs1724425. The locus rs11012 was associated with PD only in Russians: genotype *G*A (p = 0,06; OR = 2,09) and allele *A (p = 0,007; OR = 2,12) were risk markers for PD development. However, this result is contrary to the GWAs result, according to which allele *A is protective for PD development in Europeans (Pankratz et al., 2009). As for the rest three loci - rs2942168, rs393152 and rs1724425, - the association with PD was found only in Tatars: genotype *C*C (p= 0,01; OR = 1,75) and *C allele (p = 0,02; OR = 1,60) of rs2942168, genotype *A*A (p = 0,001; OR = 2,06 ;) and *A allele (p = 0,01; OR = 1,92) of rs393152 and genotype *C*C (p = 0,01; OR = 1,57) and *C allele (p = 0,049; OR = 1,3) of rs1724425 were markers of the increased risk for PD development. No associations were detected in Bashkirs, that may be explained by a significant proportion of Mongoloid component in their genepool.

I. Khidiyatova: None. **K. Putenikhina:** None. **G. Akhmadeeva:** None. **I. Gilyzova:** None. **A. Baytimerov:** None. **R. Magjzanov:** None. **E. Khusnutdinova:** None.

J08.13

Methylation profile of the PARKIN/PARK2 gene in brain tissues of Parkinson´s disease patients and healthy controls.

L. De Mena, *L. F. Cardo, E. Coto, V. Alvarez;*
Genetics Unit - HUCA, Oviedo, Spain.

PARK2 gene mutations have been linked to Parkinson´s disease (PD). Abnormal expression of *PARK2* has been found in pathological tissues and could contribute to the origin and progression of PD. We hypothesised that *PARK2* silencing through promoter methylation could contribute to the pathogenesis of PD. To address this issue, we studied a CpG island in three different brain areas (occipital cortex, cerebellum, and substantia nigra) from five PARK2 non-mutated PD patients and two healthy controls. We also measured *PARK2*-transcrip levels in the same tissues. Our study revealed no difference in methylation between the brain regions or between PD patients and healthy controls. The presence of similar amounts of the transcript in all the brain regions of patients and controls agreed with this result. In conclusion, our results suggested that methylation of *PARK2* was not a hallmark of brain tissue from PD, and would thus not contribute to the pathogenesis of this common neurodegenerative disease

Identification of one novel causative mutation in exon 4 of WFS1 gene in two Italian siblings with classical DIDMOAD syndrome phenotype.

L. Rigoli[1], *C. Di Bella*[1], *F. Pugliatti*[1], *S. Cara*[1], *V. Salpietro*[1], *F. Lombardo*[1], *F. Lombardo*[1], *G. Salzano*[1], *D. Iafusco*[2], *C. Salpietro*[1], *F. De Luca*[1];
[1]*Department of Pediatrics, Medical School, Messina, Italy,* [2]*II University, Medical School, Naples, Italy.*

Wolfram syndrome (WS), also known by the acronym DIDMOAD (diabetes insipidus DI, diabetes mellitus DM, optic atrophy OA and deafness D), is an autosomal-recessive disorder usually diagnosed in childhood when non-autoimmune, insulin-dependent DM is associated with OA. Additional characteristics include ureterohydronephrosis, neuropsychiatric and endocrinological impairment and cataract.
The gene involved (WFS1), which was identified on chromosome 4p, spans 33.4 kb of genomic DNA and includes eight exons: the 1st is non-coding, 2-7 are coding and the 8th is 2.6 kb long. WFS1 mRNA encodes an 890-amino acid polypeptide with nine putative transmembrane domains and a 100-kDa molecular mass (wolframin).
The aim of the present paper is to describe a novel missense mutation (G107R) of WFS1 gene that was unexpectedly detected, in two siblings from Southern Italy, outside exon 8; a very unusual finding which has previously been reported only twice in Italian patients with Wolfram syndrome (WS). Although in Spanish pedigrees' WFS1 mutations are frequently located in exon 4, this finding is very infrequent in other pedigrees, particularly in Italian patients. Conclusions: a) our report of two siblings with one novel WSF1 mutation (G107R) expands the molecular spectrum of WS; b) this is the 3rd report of Italian patients harbouring one mutation outside exon 8 and the 2nd with one mutation in exon 4; c) on the basis of the present observations, and literature data we can infer that mutation locations outside exon 8 do not seem to be clearly associated with peculiar phenotype expressions of WFS1 gene.

J08.15

Oligomeric alpha-synuclein levels in blood plasma in LRRK2 - linked Parkinson's disease

P. A. Andoskin[1,2], *A. K. Emelyanov*[1,2], *A. F. Yakimovsky*[2], *A. A. Timofeeva*[2], *S. N. Pchelina*[1,2];
[1]*St. Petersburg Nuclear Physics Institute, St.-Petersburg, Russian Federation,* [2]*Pavlov's State Medical University of Saint-Petersburg, St.Petersburg, Russia, St.-Petersburg, Russian Federation.*

Parkinson's disease (PD) is the second of most common neurodegenerative disorders. The aggregation of alpha-synuclein in dopaminergic neurons is a critical factor PD etiology of. The increased level of oligomeric alpa-synuclein has been found not only in brain tissues of PD patients but also in extracellular fluids, such as cerebrospinal fluid. The identification of causative mutations in several genes has demonstrated the existence of monogenic forms of the disease. PD caused by mutations in the leucine-rich repeat kinase 2 (LRRK2) gene is the most frequent.
The aim of our study was to estimate the level of oligomeric forms of alpha-synuclein in blood plasma in PD patients. The dataset was composed of 13 drug-naïve PD patients (the mean age 61.3±8.8, 7 females, 6 males) and 5 patients with LRRK2-associated PD (mean age 67±5,26, 2 females, 3 males) (all cases with mutation G2019S). In all cases the blood plasma was obtained using standard method. All subjects were residents of the North-Western region of Russia. The oligomeric forms of alpha-synuclein were estimated using enzyme-linked immunosorbent assay ELISA (Human Synuclein OLIGO kit aj Roboscreen, Germany).
There were no significant differences in the levels of oligomeric alpha-synuclein between PD patients (median 0,3, range 0 - 4,8, ng/ml), patients with LRRK2 G2019S mutation (median 0,06 range 0-0,38, ng/ml) and controls (median 0,3, range 0-12,5, ng/ml) (p=0,728, p=0,156, respectively). Therefore our data suggest that the oligomeric alpha-synuclein could not be used as a suitable marker of PD.

J08.16

Novel missense ASPA mutation in a compound heterozygous state in a patient with Canavan disesase

F. Ozkinay, *H. Onay, T. Atik, A. Durmaz, M. Karakoyun, O. Çogulu;*
Ege University, Faculty of Medicine, Izmir, Turkey.

Canavan disease is a rare autosomal recessive leukodystrophy caused by mutations in the aspartoacylase (*ASPA*) gene which has been mapped to chromosome 17 pter-p13. It is more prevalent among children of Ashkenazi Jewish descent but has been diagnosed in different ethnic groups from all over the world. We report on a 12 year old Turkish boy having typical clinical manifestations of Canavan disease. He presented first symptoms at the age of 6 months. Brain magnetic resonance imaging (MRI) and magnetic resonance spectroscopy (MRS) revealed white matter degeneration specific to Canavan disease. Molecular analysis of the ASPA gene showed compound heterozygosity for a known mutation p.G27R (c.79G<A) and for the mutation p.H244Y(c.730C>T), which has not been described in Canavan disease. Since different mutations involving the same codon and causing different amino acid changes have ben described in previous Canavan cases, thisnovel mutation is considered to be deletorius and disease causing mutation.

Molecular-genetic diagnostics of Huntington's disease patients from Eastern Slovakia

J. Bernasovska, *I. Boronova, I. Bernasovsky;*
University of Presov, Presov, Slovakia.

Huntington´s disease (HD) is a progressive neurodegenerative disorder, which is clinically characterized by motor dysfunction, cognitive impairments and psychiatric disturbances. Gross pathology of HD is limited to the brain, with atrophy most prominent in the caudate, putamen, and cerebral cortex. Huntington´s disease is generally accepted that few mutational events account for the origin of the pathogenic CAG expansion. The prevalence rate of HD in the most of Europe is 5 cases per 100 000 individuals. The molecular basis of the disease is the expansion of the trinucleotide CAG in the first exon of the huntingtin gene in chromosome 4p16.3. Diagnosis of HD has been greatly simplified by the direct triplet repeat gene test. In Eastern Slovakia (2011-2012) CAG repeat lenghts in the HD gene were tested in seven patients with suspected diagnosis of HD. PCR products were resolved used genetic analyzer ABI 3500xl. In affected patients clinical diagnosis of HD was confirmed by molecular-genetic methods. The sex ratio in the cases, in which the diagnosis of HD has been confirmed was 4:3 in favor of female individuals. The mean age of patients in the time of diagnosis Huntington disease was 48.85 and ranged from 37 to 59 years. This confirm the affirmation of onset of symptoms typically in the third and fourth decade of life. Mapping the occurance of HD in Eastern Slovakia is a part of population-genetic analyses and monitoring of population health status.

Improvement of neurologic symptoms in a heterozygote case with Wilson disease after complex medical rehabilitation

M. Cevei[1], *D. Stoicanescu*[2];
[1]*University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania,* [2]*University of Medicine and Pharmacy „Victor Babes", Timisoara, Romania.*

Wilson disease is a rare disease, characterized by disturbance of copper metabolism. We present the case of a 30 years old patient hospitalized for treatment and functional rehabilitation in Medical Rehabilitation Clinical Hospital Baile Felix, Romania. At admission she had rigidity and weakness of trunk, upper and lower limb muscles, deglutition and psycho-emotional problems, ROM limitation of the hip joint, presence of Kayser-Fleischer ring. The onset of the disease was at 7 years old, with hepatic dysfunction as initial clinical manifestation, fatigue and pain in the limbs, but the diagnosis was overlooked and established later, at 23, when the symptoms were severe pain in lower limbs, difficulty in gait, abnormal synergies, hypersalivation with deglutition disorder, change of voice, psychoemotional lability. The most significant laboratory findings were very low level of serum copper and ceruloplasmin and high urine copper levels. Molecular analysis of exon 14 of ATP7B gene revealed the presence of a C3207A replacement in heterozygote state. In exon 15 no mutations were found. Main goals of rehabilitation were maintaining and increasing the range of motion in all activities, preventing joint ROM limitations and correcting the existing ones, decreasing rigidity and preventing development of muscular atrophies, improving coordination, speech, maintaining and increasing the functionality in activities of daily life, psychological adaptation to the disease. The therapeutic plan included medication, physical therapy, hydro-thermo-therapy, occupational, speech therapy, psychotherapy. Even if the diagnosis was late, extrapyramidal neuromotor syndrome remarkably improved, gaining of independence in daily activities have led to improvement of psychic state.

Screening of c.2363C>T Mutation in ATP7B Gene by Direct Sequencing in a Family with Wilson disease

Ö. Şimşek Papur[1], *S. Aşık Akman*[2], *O. Terzioglu*[1];
[1]*Department of Medical Biology and Genetics,Faculty of Medicine,Dokuz Eylül University, İzmir, Turkey,* [2]*Department of Pediatric Gastroenterology,Hepatology and Nutrition, The Ministry of Health Tepecik Teaching and Research Hospital, İzmir, Turkey.*

Wilson disease (WD, MIM#277900) is an autosomal recessive disorder of copper metabolism characterized by decreased biliary excretion of copper first described as hepatolenticular degeneration. The excess copper accumulates in various organs and tissues predominantly in the liver, brain, cornea and kidney. The disease is diagnosed on the basis of typical symptoms and conventional biochemical indicator, which include low serum concentration of ceruloplasmine and elevated excretion of urinary copper. The disease has a worldwide frequency of 1/30,000 to 1/100,000 live births and a carrier frequency of 1 in 90. To protect the patients for fatal liver cirrhosis and neurological damage, it is necessary to treat with zinc salts and copper chelating agent such as penicillamine. Prompt and appropriate treatment depends on correctly diagnosed WD in the patient and any affected siblings. Early diagnosis is critical and prevents lifelong neurological disability and liver cirrhosis. In our study DNA was isolated from index patient of Wilson disease and his family members. ATP7B gene was amplified by PCR. Mutation was detected by DNA sequencing. We found c.2363C>T mutation in both alleles (homozygous) of ATP7B gene of index patient while his father, mother and a sister have heterozygous of mutant alles. One sister has no mutation. The index patient has severe neurological abnormalities and mental retardation. He has kayser fleischer ring, low serum seruloplasmin and high urinery copper. He has score 9 of Wilson disease according to international criteria.

hnRNPA2/B1 and nELAVs regulate CDK5R1 by interecting with a poly-U stretch within the 3'-UTR

P. Zuccotti[1], *A. Barbieri*[1], *C. Colombrita*[2], *S. De Palma*[3], *S. Moncini*[1], *C. Gelfi*[3], *A. Ratti*[2], *M. Venturin*[1], *P. Riva*[1];
[1]*Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy,* [2]*Department of Pathophysiology and Medical-Surgical Transplant University of Milan. IRCCS Istituto Auxologico Italiano, Cusano., Milan, Italy,*
[3]*Department of Biomedical Sciences for Health, University of Milan., Milan, Italy.*

CDK5R1 encodes p35, an activator of CDK5, a proline-directed serine/threonine kinase that phosphorylates proteins involved in CNS development and maintenance. CDK5 and p35 were found to have an important role in neuronal migration and differentiation during CNS development and were implicated in some neurodegenerative and cognitive disorders. Both the CDK5R1 3'-UTR remarkable size and its conservation are indicative of an important function in post-transcriptional regulation. We showed that CDK5R1 3'-UTR affects transcript stability and translational efficiency. We identified within the 3'-UTR by luciferase assays a 138 bp region with a high destabilizing activity. To assess if this region interacts with RBPs and to identify possible binding site/s, we performed UV cross-linking and site directed mutagenesis assays. Following the identification of a poly-U stretch binding site, we demonstrated that nELAVs interact with this motif by UV CLIP assays. Since the over-expression and silencing of nELAVs showed a stabilizing activity on p35 expression, we search for destabilizing factors by means of pull-down experiments, allowing to detect an interaction with the hnRNPA2/B1. Through RNA immunoprecipitation experiments we confirmed hnRNPA2/B1 binding to CDK5R1 mRNA. hnRNPA2/B1 over-expression studies showed a destabilizing activity reducing p35 expression. Silencing experiments together with assays aimed to verify the mutual action of the identified RBPs, will shed light on their role on post-transcriptional regulation of CDK5R1. This study besides providing new insights in functional role of hnRNPA2/B1 at now little known, will address studies on the CDK5R1 pathogenetic implications in CNS diseases such as neurodegenerative and cognitive disorders.

Next-generation sequencing of complete mitochondrial genomes of Slovenian Lebers's Hereditary Optic Neuropathy patients revealed one novel mutation and several probable synergistic variants

D. Glavac[1], *M. Tajnik*[1], *M. Jarc-Vidmar*[2], *M. Hawlina*[2];
[1]*Department of Molecular Genetics, Faculty of Medicine, Ljubljana, Slovenia,* [2]*University Eye Clinic, Ljubljana, Slovenia.*

Purpose. Leber hereditary optic neuropathy (LHON) is maternally inherited eye disorder. It results from point mutations in highly polymorphic mitochondrial DNA (mtDNA). Although the LHON in the majority of the patients is a result of one of the three most common mutations, in some cases the genetic background is not clear. We investigated nine Slovenian patients diagnosed with LHON, from which only two were positive for one of the most common mutations. In order to find novel pathogenic variants, we performed deep sequencing of whole mtDNA.
Methods. DNA of nine LHON patients and 2 controls was extracted from whole blood samples. Patients were first screened for most common LHON mutations using Sanger sequencing. In addition, for 6 patients and 2 controls we performed whole mtDNA amplification and deep sequencing using Ion Torrent technology.
Results. Two patients were positive for T14484C and G3460A mutations. In the other patients, whole mtDNA deep sequencing detected novel homo and heteroplasmic variations. We identified 25 non-synonymous and 36 synonymous substitutions in mtDNA protein-coding regions. Their impact on protein structure and function was determined using bioinformatic prediction tools. We found 16 novel non-synonymous LHON-associated variants, from which 11 were homoplasmic and 5 were heteroplasmic.
Conclusions. The prevalence of most common LHON mutations in the Slovenian patients is lower than in other parts in Europe. Using deep sequencing approach, we identified new potentially pathogenic mtDNA variations in Slovenian LHON patients, which do not harbour one of the three most common mutations.

Genetic polymorphisms of warfarin metabolizing enzymes VKORC1 and CYP2C9 in the Greek-Cypriot population

K. Voskarides, D. Hadjipanagi, S. Chrysanthou, ***C. Deltas****;*
University of Cyprus, Nicosia, Cyprus.

Two variants in the gene encoding the cytochrome P450 2C9 enzyme (*CYP2C9*) and one variant in the vitamin K epoxide reductase (*VKORC1*) are the most significant genetic risk factors associated with bleeding after warfarin prescription. Since the prevalence of these three variants in the Hellenic population of Cyprus (Greek-Cypriots) has not yet been studied, we aimed to determine the genotypic and allelic frequencies and to compare allele frequencies with those in other major ethnic groups. All four variants

were genotyped by PCR-RFLP assays and statistically analyzed in 148 unrelated healthy Greek-Cypriot volunteers. The allele frequencies of *CYP2C9*2* and *CYP2C9*3* were 0.162 and 0.112 respectively, whereas *VKORC1*–1639A was 0.534. The latter frequency differs significantly when compared with Caucasians, Asians and Africans and is still significant when compared with the geographically and culturally closely related to Greek-Cypriots, Hellenes of Greece. Interestingly ~18% of our population are carriers of four or three risk alleles regarding warfarin metabolism, therefore they have a high predisposition for bleeding after taking high or even normal warfarin doses. Generally, our data show no significant difference in the frequency of *CYP2C9* allelic variants when compared to the Caucasian population, but differ significantly when compared with Africans and Asians. Also, the frequency of variant *VKORC1*–1639A differs between Greek-Cypriots and every other population we compared. Finally, about 1/5 Greek-Cypriots carry three or four risk alleles and ~50% of them carry at least two independent risk alleles regarding warfarin metabolism, a potentially high risk for over-anticoagulation.

Studying the functions of heterologous intron-derived fragments within and outside the coding region on the expression of the human coagulation factor IX in cultured mammalian cells

M. Sam[1], *A. Zomorodipour*[2], *G. Kardar*[3], *M. Ghorbani*[2], *M. Shokrgozar*[4], *A. Amanzadeh*[5];
[1]*Institute of Biotechnology, Urmia University, Urmia, Islamic Republic of Iran,* [2]*National Institute of Genetic engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [3]*Immunology, Asthma & Allergy Research Institute, Tehran, Islamic Republic of Iran,* [4]*National Cell Bank of Iran, Pasture Institute of Iran, Tehran, Islamic Republic of Iran,* [5]*National Cell Bank of Iran, Pasture Institute of Iran, Tehranehran, Islamic Republic of Iran.*

Hemophilia B is attractive candidate for gene therapy. In order to produce functional protein an efficient expression vector is required. In this study, eight CMV-regulated hFIX-expressing plasmids with different combinations of two human beta-globin (*hBG*) introns (in their corresponding locations inside the *hFIX*-cDNA) and liver-specific rat aldolase B intronic enhancer (*rABE*; upstream the CMV promoter) were constructed and used for the hFIX expression analysis in cultured HepG2 and Hek-293T .
In HepG2, *rABE* increased the hFIX expression levels when it was combined with the CMVp in different clones. Potential of the *rABE* in the intron-less construct was evidenced by 3 to 32.5-fold increase of the hFIX expression levels in comparison with other constructs.
In Hek-293T, the highest hFIX expression level was obtained from the intron-less construct.
Evaluation of the intron removal from pre-mRNAs of different transfected cells revealed that the *hBG* introns are spliced either partially or improperly in both of the examined hosts which could explain the reduced hFIX expression levels from intron- containing plasmids.
Interestingly, mature hFIX mRNA was generated from the *hBG* intron-II containing construct in Hek-293T, whereas no detectable product of proper splicing was evidenced from the same construct in HepG2. Our results support the gene- and host-dependence of fate and function of heterologous introns in a protein expression cassette. Based on data, the *rABE* is attractive element to achieve a higher expression level of therapeutic proteins in hepatocytes. Such a hybrid regulatory element might be able to prevent the inactivation of the CMVp *in vivo*.

The HMGCL gene mutation c.504_505delCT causes two transcripts that are subject to Nonsense Mediated mRNA Decay

B. Puisac[1], *E. Teresa-Rodrigo*[1], *M. Gil-Rodríguez*[1], *M. Hernández*[1], *C. Baquero*[1], *A. Pié*[2], *G. Bueno-Lozano*[1,2], *F. J. Ramos*[1,2], *J. Pié*[1];
[1]*University of Zaragoza Medical School, Zaragoza, Spain,* [2]*Hospital Clinico Universitario „Lozano Blesa", Zaragoza, Spain.*

Eukaryotic cells can be protected against mutations that generate stop codons by nonsense-mediated mRNA decay (NMD) which eliminates the affected transcript and decreases the mRNA levels. Here, we study these phenomena in the stop codon mutation c.504_505delCT, the third most frequent mutation in HMG-CoA lyase deficiency (MIM #246450). This mutation determines the occurrence of three mature transcripts: the mRNA transcript corresponding to the CT deletion itself, another containing a frameshift deletion of exon 6 and the physiological transcript with exon 5 plus 6 deletion.
As a model we used fibroblasts from a patient homozygous for the mutation c.504_505delCT which were treated with puromycin, a NMD mechanism inhibitor. After 6 hours of incubation with 100 µg/ml of puromycin, fibroblasts were harvested and total RNA extraction and quantitative real-time PCR experiments were performed to analyze the level of three alternative mRNA transcripts before and after puromycine treatment.
The results showed that two mRNA transcripts which gave rise to a stop codon, one with CT deletion and other with exon 6 deletion, were affected by this process, increasing their levels by 10-fold after treatment. This is surprising because the mRNA transcript bearing the CT deletion generates a stop codon 31 nucleotides upstream the 3' exon-exon junction and does not follow the rule that the stop codon must be located further than 50 nucleotides to be affected by NMD. This is, according to a new model of regulation of NMD, more complex and takes into consideration other sequence signals or distance parameters.

Evaluation of 454 Patients referred for Molecular Analysis of Alpha1-antitrypsin Deficiency

S. Tunc, *H. Onay, E. Karaca, A. Durmaz, A. Aykut, B. Durmaz, F. Ozkinay;*
Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey.

Alpha1–antitrypsin (AAT) is a serin proteinase inhibitor that protects the connective tissue of the lungs from the elastase released from leucocytes. The AAT enzyme deficiency is a common autosomal codominant disorder characterized by a predisposition to emphysema and cirrhosis. The cause of the liver damage is not the deficiency of the protease inhibitor. Liver damage arises from the pathological polymerization of the AAT variant before its secretion from hepatocytes. AAT is encoded by the SERPINA1 gene on chromosome 14. The variants within the AAT gene are classified according to the protease inhibitor (PI) system in which M is the normal allel and the inheritance of S and Z alleles is associated with decreased levels of the protein.
The objective of this study is to investigate the presence of S and Z alleles in the patients tested for AAT mutations and having various indications. Between the period of 2006-2013, 454 patients were tested for SERPINA1 gene using reverse hybridization assay in the molecular genetics laboratory at the Depertmant of Medical Genetics, Ege University.
Among 454 patients, 433 patients (95,3%) were found to be normal MM genotype, whereas 8 patients (1,76%) were PIMZ, 7 patients (1,54%) were PIMS, 6 patients (1,3%) carried homozygous mutations with PIZZ genotype. Mutation detection rate was found to be low in our study group. It is considered that careful examination and laboratory work of the patients are needed before the molecular genetic analysis for alpha1–antitrypsin deficiency.

Association of fibroblast growth factor (FGF-21) as a biomarker with primary mitochondrial disorders, but not with secondary mitochondrial disorders (Friedreich Ataxia) in human patients

M. Salehi[1], *M. Houshmand*[2], *M. Sadeghizadeh*[3], *O. Aryani*[4];
[1]*Tarbiat Modares University - National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [2]*National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [3]*Tarbiat Modares University, Tehran, Islamic Republic of Iran,* [4]*Special Medical Center, Tehran, Islamic Republic of Iran.*

Mitochondrial respiratory chain deficiencies (RCD) are a group of more than 100 disorders of adults and children, with highly variable phenotypes. The high prevalence of mitochondrial disorders (MIDs) urges the clinician to diagnose these disorders accurately, which is difficult in the light of highly variable and overlapping phenotypes, transmission patterns and molecular backgrounds.
Fibroblast growth factor 21 (FGF-21) is an important endocrine and paracrine regulator of metabolic homeostasis. FGF-21 could play a role in the metabolic alterations that often are associated with mitochondrial diseases. The aim of this study was to define the association of FGF-21 biomarker with human primary MIDs and secondary MIDs in the suspected patients in Iran.
Serum FGF-21 levels were determined using ELISA in 47 mitochondrial pati-

ents including 32 primary MIDs, 15 secondary MIDs and 30 control subjects. We choose the Friedreich Ataxia (FA) as a model of secondary MIDs in this study. Serum FGF-21 levels were significantly ($p < 0.05$) higher in subjects with the primary MIDs compared to subjects without the MIDs. However, serum FGF-21 level did not show significantly increase in secondary MIDs with FA subjects. In conclusion, there is an association between increasing concentrations of FGF-21 with mitochondrial diseases and FGF-21 can be used as a biomarker for diagnosis of primary MIDs in human. This biomarker is not appropriate choosing for diagnosis of FA patients.

Group	Control	Primary MIDs	FA
Number of subjects	30	32	15
Gender (M/F)	17/13	17/15	9/6
FGF-21 level in male (pg/ml)	86.6	261.4	69.2
FGF-21 level in female (pg/ml)	88.7	422.4	75.1
FGF-21 level in all (pg/ml)	87.1	346.2	71.6

Course and outcomes of Hurler syndrome in patients with later start of enzyme replacement therapy with human recombinant alpha-L-iduronodase (ERT).

N. V. Buchinskaya, *O. V. Kalashnikova, M. M. Kostik, V. G. Chasnyk;*
State Pediatric Medical University, Saint-Petersburg, Russian Federation.

Background: Mucopolysaccharidosis type I (MPS) is a genetic disease with a severe progressive multi-organic involvement and fatal prognosis. Early diagnostics and treatment, particularly ERT and hematopoietic stem cell transplantation improve quality and duration of life by delay of organ damage.
Objective: to evaluate the course of the disease in cases of later start of ERT.
Materials and methods: 3 children aged 69,3 ±6,4 months at the beginning of ERT with the same mutation Q70X/ Q70X (2 girls - identical twins and 1 boy) were monitored .
Results: the total number of infusions was 55 and 181 in twins and 127 in boy. Urine glycosaminoglycan during ERT decreased to 33%, 56% and 71%, respectively and reductions of hepatosplenomegaly, limitation of motion in affected joints, frequency of sleep apnea as well as absence of hydrocephalus progress and hypertrophic cardiomyopathy were observed. In the end stage of the disease all children had respiratory failure (obstructive in boy, chronic restrictive in one girl and due to acute pulmonary oedema in the other), hypertrophic cardiomyopathy, relapse of hepatosplenomegaly, hypocalcaemia and seizures. Few side effects, including low-grade fever and urticarial rashes were observed after the infusions 6-7.
Conclusions: the main cause of death in MPS I (Hurler) with later start of ERT was heart or respiratory failure after 15 - 45 months of ERT, growing steadily during the last 3 - 6 months of life despite the efficacy of ERT during the first period of treatment.

Exome sequencing revealed a NPC2 mutation in an Iranian Niemann Pick C-type 2 disease family

A. Alavi[1], *E. Elahi*[1], *S. Nafissi*[2], *H. Shamshiri*[2], *M. Houshmand*[3], *M. Malakooti Nejad*[4];
[1]*University of Tehran, School of Biology, College of Science,, Tehran, Islamic Republic of Iran,* [2]*Department of Neurology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [4]*Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.*

Niemann-Pick type C (NPC) disease is a severe autosomal recessive neurovisceral disease that cause of mutation of the NPC1 or NPC2 gene resulting in accumulation of unesterified cholesterol in late endosomes and lysosomes. NPC disease is difficult to be diagnosed and treated. We found an Iranian consanguineous family with two affected individuals with a recessively inherited juvenile Niemman-Pick C-type 2 disease. Exome sequencing of these two affected siblings led us to identify a homozygous mutation in the NPC2 gene. The confirmation of NPC disease was assessed by filipin staining. Fibroblasts from the two NPC siblings showed a massive accumulation of unesterified cholesterol in the lysosomal compartment. MRI of patients showed white matter signal change and frontal lobe atrophy.

Non-classical PKU: report of a known missense mutation for the first time in iran

A. Saberi[1,2], *G. shariati*[1,3], *M. Hamid*[4,3], *H. Galehdari*[5,3];
[1]*Ahvaz Jundishpour university of medical sciences, Ahvaz, Islamic Republic of Iran,* [2]*Narges Genetics Lab, Ahvaz, Islamic Republic of Iran,* [3]*Narges Genetic Lab, Ahvaz, Islamic Republic of Iran,* [4]*Pasteu Institute, Tehran, Islamic Republic of Iran,* [5]*Ahvaz Shahid Chamran university, Ahvaz, Islamic Republic of Iran.*

PTPS deficiency is caused by mutations in PTS gene that encodes the 6-pyruvoyl-tetrahydropterin synthase, which is required for the second step of the de novo biosynthesis of BH4 starting from GTP. It is inherited as an autosomal recessive trait. We described here a germ line homozygous missense mutation in exon 6 of PTS gene that determines an amino acid substitution (Gly-> Arg) at codon 125. The index case was 4- year- old patient with an apparent deficiency of tetrahydrobiopterin (BH4), microcephally, psychomotor retardation, seizure and swallowing difficulties. PTS gene mutations screening was performed in exons 1-6, and the corresponding intro/exon boundaries by sequencing analysis. A rare homozygous GGA->AGA point mutation was found at codon 125 in exon 6. As expected on the basis of the homozygosity of the index case, the parents were consanguineous (second-degree cousins). His mother and father were positive for heterozygous PTS mutation.
In conclusion, we identified a known germ line PTS gene mutation responsible for non-classical phenylketonuria (PKU) during a routine screening of a patient referred for classical PKU.This is the first report of a nonclassical PKU due to PTS gene mutation in Iran.

Biotinidase deficiency: Novel mutations in Algerian patients.

A. Tiar[1], *A. Mekki*[2], *M. Nagara*[1], *F. Ben Rhouma*[1], *O. Messaoud*[1], *N. Ben Halim*[1], *R. Kefi*[1], *M. Hamlaoui*[3], *A. Lebied*[2], *S. Abdelhak*[1];
[1]*Institut Pasteur de Tunis, Laboratoire de Génomique Biomédicale et Oncogénétique, Tunis, Tunisia,* [2]*Pediatric Department, Hussein Dey Hospital, ,, Algiers, Algeria,* [3]*Pediatric Critical Care Unit, Hussein-Dey Hospital, Algiers, Algeria.*

Biotinidase deficiency (BD) is an autosomal recessive disorder of biotin metabolism leading to varying degrees of neurologic and cutaneous symptoms when untreated. The disorder is characterized by mutational heterogeneity; indeed more than 100 mutations causing profound BD have been described. In the present study, we report the clinical and molecular investigation of BD in Algerian population.
We investigated four unrelated consanguineous Algerian families including five patients with profound BD and one child characterized as partial BD. Molecular investigation was performed by direct sequencing of BTD gene. Mutation analysis revealed three novel mutations, c.del631C and c.1557T>G within exon 4 and c.324-325insTA in exon 3 of BTD gene.
To our knowledge, the present study is the first reporting clinical and molecular investigation of BD in Algeria. Since newborn screening is not available, cascade screening in affected families would be very helpful to identify at risk individuals.

The association between Factor V G1691A mutation and obstructive sleep apnoea syndrome: Preliminary results from Turkey

G. Bagci[1], *H. K. Kurtulgan*[1], *O. T. Dogan*[2], *O. Ozdemir*[3];
[1]*Department of Medical Genetics, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey,* [2]*Department of Chest Diseases, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey,* [3]*Department of Medical Genetics, School of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey.*

Obstructive sleep apnoea syndrome (OSAS) is a chronic complex disorder and characterized by recurrent episodes of complete or partial collapse of the upper airway during sleep, resulting in apneas or hypopneas, respectively. Factor V Leiden G1691A is an autosomal dominant nucleotide transition resulting in an R506Q amino acid missense mutation that causes activated protein C resistance. In the present study, we aimed to investigate the association between Factor V Leiden G1691A mutation and the susceptibility and clinicopathological development of obstructive sleep apnoea syndrome.
For diagnosing OSAS, at least one full-night polysomnography was performed in the patients. Factor V Leiden G1691A mutation was genotyped among 28 patients in comparison with 100 healthy individuals in case-con-

trol study. The mutation analysis was performed by StripAssay technique using the ViennaLab CVD StripAssay.
There were 22 (78,6%) subjects with GG genotype and 6 (21.4%) subjects with GA genotype in patients and there were 93 (93%) subjects with GG and 7 (7%) subjects with GA genotype in healthy controls. We did not detect any homozygote for AA genotype in 128 subjects. There were 50 (89.2%) G allele and 6 (10.8%) A allele in OSAS Patients and 193 (96.5%) G allele and 7 (3.5%) A allele in healthy controls. (p: 0.036 OR: 0.276 95% CI 0.084-0.9030 for genotype distribution and (p: 0.041 OR: 0.302 95% CI 0.086-1.070) for allele distribution.
There were statistically significant difference between patients and controls in terms of FV Leiden genotype and allele distributions in the preliminary results of our study.

The potential association between IL6 -174G>C polymorphism and obesity

D. Cimponeriu[1], *C. Serafinceanu*[2], *P. Apostol*[1], *M. Toma*[1], *M. Stavarachi*[1], *I. Radu*[1], *A. M. Craciun*[2], *S. Spandole*[1], *N. Panduru*[3], *L. Rusu*[4], *D. A. Ion*[3], *G. Mihaescu*[5];
[1]*Department of Genetics, University of Bucharest, Bucharest, Romania,* [2]*Department of Dialysis, Nicolae Paulescu National Institute of Diabetes, Bucharest, Romania,* [3]*Pathophysiology II, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania,* [4]*Laboratory of Molecular Biology, National Institute of Research and Development for Food Bioresources, Bucharest, Romania,* [5]*Department of Microbiology, University of Bucharest, Bucharest, Romania.*

Polymorphisms in IL6, ACE and ATR genes are associated with obesity. Torque teno virus (TTV) seems to be able to interfere with production of some proinflammatory cytokines associated with obesity and related phenotypes.
The aim of this study was to test the potential association between obesity, TTV infection and the IL6 -174G>C (rs1800795), ACE I/D (rs4646994), AT1R A1166C (rs5186) polymorphisms.
The polymorphisms and the presence of TTV were detected in blood samples from 150 obeses and 150 normoponderal, healthy subjects using PCR based methods.
IL6 -174 CC genotype was more frequent in all obese patients (P=0.02) and in patients without TTV infections (P=0.03) than in controls. Obese women had more frequent TTV infections compared with normoponderal women (P=0.046). Obese subjects, regardless of gender (women P=0.03, men P=0.04), and healthy men (P<0.01) carriers of AT1R C allele had higher triglycerides levels compared with non-carriers. The frequency of TTV in control group (70.67%) was similar with data reported in other populations.
The present study indicated that IL6 -174 CC genotype and TTV infections in women can be associated with common form of obesity.

The protective effect of MCP-1 -2518 A>G promoter polymorphism in chronic renal failure patients requiring long-term hemodialysis in the central region of Turkey

B. Koksal[1], *G. Bagci*[2], *H. K. Kurtulgan*[2], *O. Ozdemir*[3];
[1]*Department of Molecular Biology and Genetics, Faculty of Science, Bartin University, Bartin, Turkey,* [2]*Department of Medical Genetics, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey,* [3]*Department of Medical Genetics, Faculty of Medicine, Canakklale On Sekiz Mart University, Canakkale, Turkey.*

Objective: Monocyte chemoattractant protein-1 (MCP-1), is a member of the CC chemokine family and responsible for monocyte and T lymphocytes recruitment in acute inflammation conditions. MCP-1 plays a major role in the pathogenesis and progression of different types of human renal disease. -2518 A>G polymorphism of the MCP-1 enhances expression of MCP-1 gene. In this study, we aimed to investigate the frequencies of MCP-1 gene -2518 A>G promoter polymorphism among chronic renal failure (CRF) patients requiring long-term hemodialysis.
Patients and methods: Study population consisted of 201 unrelated, consecutive adult chronic renal failure patients requiring long-term hemodialysis and 194 healthy controls living in city of Sivas in Turkey. The polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique was used for genotyping of MCP-1 -2518 A>G polymorphism. Differences between genotype distribution of two groups were compared by using χ^2 test.
Results: Genotype frequencies of the MCP-1 -2518 A>G were 103 for AA, 79 for AG, and 19 for GG in the chronic renal failure patients and 67 for AA, 110 for AG, and 17 for GG in healthy controls. There were statistically significant difference in terms of genotypic (χ^2=12.69, p=0.02) and allelic (χ^2= 5.36, p: 0.02) frequencies of MCP-1 -2518 A>G between CRF patients and control subjects.
Conclusions: According to our results, in the patients group MCP-1 -2518 AA genotype frequency was significantly higher than that of control group. Current data shows that AA genotype may cause susceptibility to CRF while G allele may have a protective effect on CRF patients.

The common polymorphism Val109Asp in the omentin gene is associated with daily energy intake in the Central-European population

Z. Splichal[1], *J. A. Bienertova Vasku*[1], *F. Zlamal*[1], *J. Tomandl*[2], *M. Tomandlova*[3], *M. Forejt*[4], *S. Havlenova*[4], *A. Jackowska*[4], *J. Dobrovolny*[1], *O. Slaby*[5], *A. Vasku*[1];
[1]*Faculty of Medicine, Masaryk University, Department of Pathological Physiology, Brno, Czech Republic,* [2]*Faculty of Medicine, Masaryk University, Department of Biochemistry, Brno, Czech Republic,* [3]*Faculty of Medicine, Masaryk University, Department of Biochemistry, Brno, Czech Republic,* [4]*Faculty of Medicine, Masaryk University, Department of Preventive Medicine, Brno, Czech Republic,* [5]*Central European Technological Institute, Laboratory of Solid tumours, Brno, Czech Republic.*

Background: Omentin was originally described in 2003 and was reported to be expressed specifically in human omental adipose tissue. Later on, it was reported that omentin is predominantly expressed in visceral adipose tissue, with adipose tissue stromal cells being the main source. Very little is known about the relationship between the genetic variability of the omentin gene and pathophysiology of obesity, although omentin is believed to play an important role in visceral obesity development. The aim of the study was to investigate two common polymorphisms in the omentin gene (rs2274908 and rs2274907) and dietary composition and anthropometric parameters of obesity in the Central European population.
Material and methods: The total of 495 subjects were included into the study (F/M 368/127, 46.0+-13.6y) that were further divided into the obese and non-obese cohorts (F/M 224/79, 50.3+-11.7y and F/M 144/48, 39.3+-13 .7y, respectively). Dietary habits were established using the 7-d food records and anthropometric parameters were measured.
Results: In the multivariate modelling, the rs2274907 polymorphism expressed independent prediction role for the daily energy intake, independently on the age and gender distribution (p = 0.03), whereat the TT genotype was associated with the lowest average energy intake (7877+- 2780 J/day) and the AA genotype with the highest daily intake of energy (8764+-2467 J/day).
Conclusion: This is so far the first study to investigate the polymorphisms in the omentin gene in a large population cohort of obese and non-obese individuals. Based on our results, the rs2274907 polymorphism could be associated with the daily energy intake.

J09.15

MTHFR, MTR and MTRR polymorphism in Moldavian patients with phenylketonuria

K. R. Boiciuc, *N. M. Usurelu, V. C. Sacara;*
Institute of Mother and Child Care, Chisinau, Moldova, Republic of.

In a previous study on PKU Moldavian children the high level of Homocystheine and low levels of Methionine and Taurine have been appreciated. The aim of our research is to appreciate the frequency of folate metabolizing genes in PKU and in control groups.
Materials and Methods: 80 Moldavian PKU patients and 165 healthy children as a control group have been tested. The PCR-RFLP assay was used to indentify the *MTHFR* C677T, *MTR* A2756G, *MTRR* A66G polymorphisms with HinfI, HaeIII and NdeI enzymes respectively. The distribution of genotypes in case and control groups was tested for deviation from Hardy-Weinberg equilibrium (HWE).
The results: Genotype frequencies in case group was conformed to HWE

expectation for *MTHFR, MTR* and *MTRR*. There was identified no significant differences in frequency in case and control groups in heterozygous state of *MTHFR* (47.5% vs 37.6%) and of *MTRR* (56.3% vs 63.0%) genes. The emphatic differences of heterozygous frequency there was determined in *MTR* gene (28.2% vs 42.4%). Patients with the *MTR* AG genotype may be show a lower risk of severe manifestation of disease (OR 0.53, 95% CI 0.29, 0.95) and these data were statistically significant (p=0.031). Individuals with *MTRR* GG genotype were suspected to have an increased risk of severe PKU manifestations (OR 4.62, 95% CI 0.4, 53.2) compared to individuals with AA (Ref) or AG genotypes (OR 0.80, 95% CI 0.4, 1.45), but this data were not significant.**Conclusion**: Methionine cycles genes may be as a genetic modifier of PKU severity.

Mass-specrometry and fluorimetry in diagnostics lysosomal storage diseases

M. Bayanova, *B. Kamaliyeva, A. Vibe, D. Samatkyzy, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

In order to explore the activity of the enzymes α-galactosidase and α - iduronidase in patients with deficiency of lysosomal enzymes, the diagnosis from dry blood spot was introduced.
The dry blood spots we investigated using the method of mass spectrometry so to determine the activity of the enzymes α-galactosidase (GLA), α-iduronidase (IDUA) by mass spectrometer ABI. The following pathologies were diagnosed: MPS I type in 43%, MPS II type in 14%, MPS IV type in 14%, MPS VI type in 29%. The external quality control samples were from the Center for Disease Control and Prevention.
The selective screening in the dry blood spots of healthy newborns using fluorimetry was conducted to identify the activity of the enzyme α-galactosidase and α - iduronidase. The optical density of the studied enzyme extracts and standards were measured using the immunofluorescence with wavelength of excitation 365 mm, 450 mm emission.
The standard calibration curves were constructed, thus the regression equation was obtained: y = 22385x +80,679; R2 = 0, 9975 for measuring the activity of the enzyme α - galactosidase and y = 0, 0064 x +0, 5179; R2 = 0, 9821 for measuring the activity of the enzyme α - iduronidase. The preliminary reference values for the activity of the enzyme α - iduronidase consisted in range 0, 1-2,47 pmol were obtained.

J09.17
Genetic screening of Iranian families with phenylketonuria

M. Hosseini[1,2], *T. Nazari*[1], *N. Izadi*[1], *H. Najmabadi*[1,2];
[1]*Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran,*
[2]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran.*

Abstract
Phenylketonuria (PKU) is the most prevalent inborn error of metabolism an autosomal recessive disorder resulting from a deficiency of phenylalanine hydroxylase. PKU and non-PKU mild hyperphenylalaninemia (HPA) caused by mutations in the PAH gene. Untreated PKU can lead to mental retardation, so early diagnosis is very important to prevent severe mental illness. About 1–2% of cases of HPA are due to mutation in gene coding for tetrahydrobiopterin (BH4) which is PAH cofactor.
The incidence of PKU varies in different population. PKU occurs in about 1 in 10,000 births in Caucasians. The incidence of the disease varies between 1.7:10000 and 1:4000 in Iranian population. Due to relatively high prevalence of PKU in Iranian population of which the most severe forms are preventable by prenatal diagnosis, PKU carrier detection and PND has become part of national health program since September 2012. Among 20 families who referred to our laboratory since then, 15 known mutations including 10 homozygote and 5 compound heterozygote mutations have detected using indirect RFLP analysis and direct DNA sequencing. A total of 5 families with incomplete genotype findings from both methods were further analyzed for existence of mutations in BH4 coding genes in non-classic PKU.
Molecular analysis for the remaining families is underway in order to determine the prevalence of the most frequent mutations in PAH gene in Iranian population.

Genetic association studies between known PTPN22 and SUMO4 gene variants and Type 1 diabetes (T1D) in Tamil, Indian population

S. R. Manyam[1], *U. Ratnamala*[2], *K. R. S. S. Rao*[1], *S. K. Nath*[3], *U. Radhakrishna*[4];
[1]*Department of Biotechnology, Acharya Nagarjuna University, Guntur, India,*
[2]*Department of Pharmacology, Creighton University, Omaha, NE, United States,*
[3]*Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, United States,* [4]*Green Cross Pathology and RIA laboratory, Ahmedabad, India.*

Type 1 diabetes (T1D), also known as 'insulin-dependent diabetes mellitus (IDDM)' results from a cellular-mediated autoimmune destruction of the β cells of the pancreas. Recently an increased incidence of gene polymorphisms such as PTPN22, SUMO4, CTLA4 and IL2RA associated with T1D was reported, however no common gene mutations or pathogenic causative genomic variations have been identified until. We have recruited 800 sporadic cases with T1D patients, and an equal number of age-matched controls from south India. Recently we completed an initial targeted two known and well-associated their polymorphism in its involvement in the pathogenesis of Type-1 diabetes (i.e. PTPN22 and SUMO4) in 100 selected T1D individuals and equal controls using SNP array. The data showed PTPN22 polymorphism (SNP rs2476601, 1858C>T) was not associated with in any of the TD1 subjects of Indian origin as the SNP marker rs2476601 was monomorphic (G/G) in both T1D subjects and controls. The data of SUMO4 gene variation (rs237025, 163A>G, M55V) which has been shown to be a susceptibility marker in type-1 diabetes showed a higher frequency of combined AG and GG genotypes (64%) in the affected individuals than in matched controls (56%) of Indian origin. However, the "G" allele frequency between cases and controls are not statistically significant (40% in cases vs. 35% in controls, OR (C.I.) = 1.23 (0.82-1.85), chi2=1.07, p=0.30), probably due to small sample sizes. To the best of our knowledge, this is the first targeted genetic study on the association of genetic loci in Type 1 diabetic patients in India.

11 β-hydroxylase deficiency: identification of two novel CYP11B1 mutations in a Tunisian family

I. Ben Charfeddine[1], *F. G. Riepe*[2], *N. Kahloul*[3], *A. E. Kulle*[2], *L. Adala*[1], *O. Mamaï*[1], *A. Amara*[1], *A. Mili*[1], *F. Amri*[3], *A. Saad*[1], *P. M. Holterhus*[2], *M. Gribaa*[1];
[1]*Laboratory of Human Cytogenetics, Molecular Genetics and Reproductive Biology, Farhat Hached University Hospital, Street Ibn El Jazzar, Sousse, Tunisia,* [2]*Department of Pediatrics, Division of Pediatric Endocrinology and Diabetes, University Hospital Schleswig-Holstein, Christian-Albrechts University of Kiel, Kiel, Germany,* [3]*Department of Pediatrics, Ibn El Jazzar Hospital, Kairouan, Tunisia.*

Steroid eleven beta hydroxylase deficiency (11β-OHD) is the second most common form of congenital adrenal hyperplasia, accounting for 5-8% of all cases. It is an autosomal recessive enzyme defect impairing the biosynthesis of cortisol. Virilization and hypertension are the main clinical characteristics of this disease.

In Tunisia, the incidence of 11β-OHD appears higher due to a high rate of consanguinity (17.5% of congenital adrenal hyperplasia). The identical presentation of genital ambiguity (females) and pseudo-precocious puberty (males) can lead to misdiagnosis with 21 hydroxylase deficiency. The clinical hallmark of 11β-hydroxylase deficiency is variable, and biochemical identification of elevated precursor metabolites is not usually available.

In order to clarify the underlying mechanism causing 11β-OHD, we performed the molecular genetic analysis of the *CYP11B1* gene in a female patient diagnosed as classical 11β-OHD. The nucleotide sequence of the patient's *CYP11B1* revealed two novel homozygous mutations in exon 4: a missense mutation c.650G>T (p.S217I) combined with an insertion of a thymine at the c.652-653 position (c.652_653insT), leading to a reading frame shift, multiple incorrect codons, and a premature stop codon, that drastically affects normal protein function leading to a severe phenotype with ambiguous genitalia and hypertension characterizing the congenital adrenal hyperplasia disease due to 11β-hydroxylase deficiency.

Cystic fibrosis and severe liver disease

I. M. Ciuca[1], *L. L. Pop*[1], *L. Tamas*[2], *Z. Popa*[3], *Z. L. Popa*[2];
[1]*Pediatric II Department, Timisoara, Romania,* [2]*University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [3]*National Cystic Fibrosis Centre, Timisoara, Romania.*

Background: Liver cirrhosis is the end stage of cystic fibrosis liver disease (CFLD) with an important implication on disease's outcome. Vascular complication, with occurrence of portal hypertension is an alarming stage considering the risk of variceal bleeding.
Objective: Evaluation of severe liver disease with portal hypertension (PH) in CF patients and identification of its prevalence and risk factors.
Methods: Study evaluated prospectively, 159 patients for five years. They were routinely followed-up by clinical assessment, liver biochemical tests, ultrasound examinations (US); transient elastography , magnetic resonance MRI and endoscopy in some cases.
Results: Fifty five patients, with the median age at diagnosis 12.4 years were diagnosed with cystic fibrosis associated liver disease, with slight predominance of boys. Severe liver disease occurred in 11 patients (20%) of which 5 with oesophageal varices. All of them had history of meconium ileus and homozygous for F508 del; with an important boys predominance in patients with portal hypertension (80%). CF associated liver cirrhosis occurred more frequently in patients aged over 10 yrs. Pancreatic insufficiency and severe mutations was strongly associated with portal hypertension.
Conclusion: Children with cystic fibrosis older than 10 year, with history of meconium ileus, pancreatic insufficiency and severe mutation were more likely predisposed to liver cirrhosis with portal hypertension. Further studies should follow risk factor for development of cystic fibrosis liver disease and how they can be influenced, in order to prevent the development of liver cirrhosis.

Bulgarian newborn screening program and selective screening for inherited metabolic diseases - improvements by tandem mass spectrometry

M. B. Ivanova;
National Genetic Laboratory, University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.

Introduction: National Genetic Laboratory offers modern and widely applicable genetic services for diagnosis and prevention of Inherited Metabolic Diseases in Bulgaria. The Laboratory performs: mass neonatal screening for Phenylketonuria (up to now more than 2 million newborns were screened); selective screening for over 70 Inherited Metabolic Diseases; Prenatal metabolic and enzymatic diagnosis. Aims: improvement of newborn screening program in Bulgaria, while preparing to expand the program. And development of selective screening program for kids and adults in risk, using the method for analysis of Amino Acids and Acylcarnitines by Tandem mass spectrometry. Results: more than 40% recall rate reduction for neonatal screening program. The cut-offs for Bulgarian population for 11 amino acids and 29 acylcarnitines were found. Samples from more than 400 patients with clinical symptoms for Inherited Metabolic Diseases were tested. Two cases of Medium-Chain Acyl-CoA Dehydrogenase Deficiency were found positive and confirmed on DNA level. The samples from the newborn cards of the patients were analyzed retrospectively and the specific profile of acylcarnitines was found, which prove the reliability of the method for newborn screening in asymptomatic phase of the disease. Conclusions: a reliable MS-MS method, which covers up to 30 disorders, has been developed. Currently the method is used for selective screening of patients with clinical symptoms. And as second tier analysis in the newborn screening program.

Differential diagnosis of MODY diabetes in patient population from Bosnia-Herzegovina

N. Lojo - Kadric[1], *Z. Velija - Asimi*[2], *S. Hasanbegovic*[2], *J. Ramic*[1], *K. Radic*[1], *L. Kapur - Pojskic*[1];
[1]*Institute for genetic engineering and biotechnology, Sarajevo, Bosnia and Herzegovina,* [2]*Clinical Center University of Sarajevo, Sarajevo, Bosnia and Herzegovina.*

MODY (maturity-onset diabetes of the young) is an autosomal dominant form of diabetes that is usually manifested before the 25-year of life. This type of diabetes is caused by defects in the primary insulin secretion. There are several types of MODY, which could be described as „monogenic" diseases, where mutations in a single gene are responsible for a particular type of MODY. Currently, there are eleven types of MODY, from which the most common types are MODY 2 and MODY 3 (with mutations on GCK and HNF1A genes, respectively).
There is no known incidence of MODY in diabetic population in Bosnia and Herzegovina, since until recently genetic testing for this type of diabetes was not available in this country. Goal of this ongoing study was to determine incidence of MODY and most common type of MODY in population of diabetics in Bosnia and Herzegovina.
As the material for this study 3 ml of whole blood from 20 diabetic subjects is used. Isolation of DNA was performed by salting-out method. Identification of mutations was made with MLPA (multiplex ligase-dependent probe amplification) technique, with MLPA kits P24 and P357 (Mrc-Holland). Statistical analyses were performed with Coffalyser software (Mrc-Holland).
All samples were typed successfully. Of the twenty subjects analyzed, mutations are identified in only two subjects, which correspond to 10% incidence of MODY in Bosnia and Herzegovina. Both subjects had mutation in the HNF1A gene, so they were diagnosed with MODY 3 type.

N. Lojo - Kadric: None. **Z. Velija - Asimi:** None. **S. Hasanbegovic:** None. **J. Ramic:** None. **K. Radic:** None. **L. Kapur - Pojskic:** None.

J09.23

A rare R151S missense mutation in MEFV gene in a Turkish FMF patient

H. K. Kurtulgan*, G. Bagci, G. E. Goktolga;*
Department of Medical Genetics, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disease and characterized by recurrent fever and inflammation of peritoneum, synovium and pleura. The disease primarily affects populations surrounding the Mediterranean basin: Jews, Armenians, Arabs, Turks and Greeks. The responsible gene, MEFV located chromosome 16p13.3 and consists of 10 exons and encodes a protein of 781 amino acids called pyrin or marenostrin.
Up to date, 250 sequence variants in MEFV gene have been reported in Infevers database (accessed 12 Feb. 2013). The most frequent mutation M694V followed by E148Q, M680I (G/C) and V726A in Turkish FMF patients. During MEFV gene mutation screening among FMF patients for molecular diagnosis we identified a rare R151S (c.453G>C; p.Arg151Ser) missense mutation in 2th exon of MEFV gene which shown compound heterozygosity with E148Q mutation in a 18 years-old Turkish male patient with bilateral wrist arthritis and who lived in Sivas, the central region of Turkey. According to Infevers database, our case is the second R151S mutation, other case have been reported on 2008 by Berdeli et al. in Turkey.
We used direct DNA sequencing method for sequencing in two exons (2,10) of MEFV gene. SeqScape 2.0 sequence analysis software was employed for evaluation of two exon's sequences.
It is important to identify missense mutations in order to clarify their importance in FMF pathogenesis. Detailed clinical and molecular analyses are helpful for providing data to be used in genetic counseling for FMF patients.

Analysis of mitochondrial DNA polymorphism in Tunisian Type 2 Diabetes

S. Hsouna[1,2,3], *N. Ben Halim*[1,3], *K. Lasram*[1,3], *I. Arfa*[1,3], *A. Abid*[4], *S. Abdelhak*[1,3], *R. Kefi*[1,3];
[1]*Institut Pasteur de Tunis, Laboratoire de Génomique Biomédicale et Oncogénétique, Tunis, Tunisia,* [2]*Faculté de Médecine de Tunis, Unité des Maladies Neurologiques de l'Enfant, Tunis, Tunisia,* [3]*Université Tunis El Manar, Tunis, Tunisia,* [4]*Institut National de Nutrition, Tunis, Tunisia.*

Background: Type 2 diabetes (T2D) is a complex metabolic disorder characterized by hyperglycemia as a result of impaired insulin secretion and/or insulin resistance. The phenotypic expression of the disease may be influenced by ethnic differences, environmental and genetic factors. Genetic variations in the non-coding region of mitochondrial DNA may play an important role in the pathogenesis of T2D and its complications. Nevertheless, the implication of certain mitochondrial variants in T2D is still controversial.
We aimed to explore whether mitochondrial DNA variants contribute to the susceptibility to T2D in Tunisian population.
Patients and methods: A case control association study was performed on 64 T2D patients and 77 controls. The hypervariable region 1 (HVS1) from np16069 to np16400 of the mitochondrial DNA was amplified and sequenced. Statistical analysis was carried out using STATA program.

Results: Analysis of the T16189C variant showed that this SNP is common in Tunisia with a frequency of (~30%) in both T2D patients and controls. Statistical analysis showed that T16189C variant was unlikely to be associated with T2D in Tunisians. In addition, the remaining studied SNPs (87) from the HVS1 region showed that only the distribution of the G16390A variant was significantly different between T2D and controls (p = 0.04). Multivariate logistic-regression analysis with adjustment for age, sex and BMI revealed that G16390A variant was not associated with susceptibility to T2D.
Conclusion: We found no statistical evidence to support an association between T2D and HVS1 polymorphism in the studied Tunisian population.

A rare case of Hunter syndrome

O. Marginean[1], *C. Banescu*[2], *C. Duicu*[1];
[1]*Pediatric Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [2]*Genetic Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.*

We present a rare case of mucopolysaccharidosis (MPS) with an atypical presentation of high stature, mental retardation and absence of corneal clouding.This report is of a 2.7 year-old boy who presented to hospital with a history of recurrent respiratory tract infections and frequent ear infections. On examination he was high statured (SDS + 3.46), moderately overweight (+ 25.94% on his height). His neck was short, he had coarse facial features, a depressed nasal bridge and small stubby fingers with flexion of distal interphalangeal joints, joint stiffness, protruding abdomen with umbilical hernia, hepatomegaly and splenomegaly. There was mild mental retardation. The clinical appearance was suggestive of a mucopolysaccharidosis. Dosage of enzymes playing role in mucopolysaccharide lysosomal metabolism revealed low levels of iduronate-2-sulfatase (IDS), changes suggestive of type II mucopolysaccharidosis. Enzymatic diagnosis was confirmed by molecular DNA analysis that revealed that mutation IDS gene in intron 3 (c.419-2A> G) in homozygous form. Enzyme replacement therapy with recombinant human iduronate-2-sulfatase (Elaprase®) was started.

Case of Hutchinson-Gilford Progeria syndrome from Russia

N. V. Komarova[1], *T. Adyan*[1], *V. P. Fedotov*[2], *A. V. Polyakov*[1];
[1]*Research Center for Medical Genetics, Moscow, Russian Federation,* [2]*Regional Clinical Hospital, Genetic counseling,, Voronezh, Russian Federation.*

Hutchinson-Gilford Progeria syndrome (HGPS) is a rare sporadic autosomal-dominant disorder (MIM 176670) an incidence of ~1 in 4000000 live births characterized by short stature, low body weight, early loss of hair, lipodystrophy, scleroderma, and facial features that resemble aged persons. The leading cause of death is cardio-/cerebro-vascular accidents associated with atherosclerosis. The genetic basis in most cases is a mutation at the nucleotide position 1824 of the lamin A gene.
We herein report a girl aged 2 years 8 months with a weight of 10.5 kg and a length of 76 cm. She was a child of the second pregnancy, 34 weeks of gestation with a mass of 2600 g and a length of 46 cm from young and healthy parents. Physical development of the girl proceeded to a year delay, no backlog of psychomotor development. Proband had typical phenotypic features: alopecia (loss of hair including scalp and eyebrows), prominent scalp veins and forehead, micrognathia, significant loss of subcutaneous fat, a violation of depigmentation in patches of irregular shape, camptodactyly hands and short stature. Cardiovascular disease during the examination of the child has not been identified.
The genetic study of peripheral blood-derived DNA of patient with classical progeria showed a typical de novo single-base pair substitution c.1824C>T (GGC>GGT, p.Gly608Gly) within the exon 11. This mutation creates an abnormal splice donor site, leading to the formation of a truncated lamin A protein progerin.
Future research into HGPS could also provide important clues about the general process of aging and aging-related diseases.

Familial case of c.413T>C *PHEX* gene mutation leading to X-linked hypophosphatemic rickets

L. Cimbalistiene, *O. Liaugaudiene, A. Utkus;*
Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

We report on a 3 years old girl referred for evaluation because of familial skeletal abnormalities (short stature, lower extremity bowing). The proband is the first child of non-consanguineous parents, born after uncomplicated pregnancy with birth weight 3600 g, height 57 cm. Her psychomotor development was normal; she has got prophylactic doses of vitamin D. At the 5 months old varum deformity of legs was observed. Hypophosphatemia, increased alkaline phosphatase level, lower level of 25-OH vitamin D and normal level of calcium were detected in serum; parathyroid hormone level was slightly increased. Proband`s hearing and dentition were normal, her stature was short (3-10‰).
Skeletal abnormalities were observed in proband`s father`s side of the pedigree: genu varum and short stature (proband`s father height is 162 cm, his brother - 149 cm, their mother (proband`s grandmother) - 149 cm). The extremity bowing was more severe in males. The teeth of proband`s father were irregular size and position.
Clinical diagnosis of X-linked hypophosphatemic rickets (XLHR) was formulated. The sequencing of all exons and exon-intron boundaries of *PHEX* gene detected c.413T>C missense mutation, leading to p.Leu138Pro substitution, which is predicted to cause changes in three-dimensional protein structure. Substituted leucine is strictly conserved not only human, but also in mammals' endopeptidases. c.413T>C mutation was first published by Rowe et al. in 1997, since then it was described as pathogenic in two more papers. To our knowledge, it is the second reported case of familial c.413T>C *PHEX* gene mutation. The clinical diagnosis of XLHR was confirmed.

Gonadal mosaicism with a New Mutation in the Wilson Disease Gene, ATP7B in a Family

M. A. Soylemez, *A. I. Guney;*
MARMARA UNIVERSITY MEDICAL SCHOOL, ISTANBUL, Turkey.

OBJECTIVE: Wilson disease (WND), an autosomal recessive disorder of copper transport with a broad range of genotypic and phenotypic characteristics, results from mutations in the ATP7B gene. We report a new mutation in the Wilson disease gene ATP7B in a family.
CASE PRESENTATION: Mutation analysis was carried out on 5 subjects in one family and new mutation not previously reported was identified: c.3106G>A. This new mutation was carrying by mother and two siblings. However, father was carrying heterozygous c.2128G>A mutation with two siblings. Interestingly, one of the siblings was not carrying c.3106G>A mutation, but was carrying c.2128G>A and c.3007G>A mutations, and showed clinical and biochemical characteristics of the Wilson disease. The mutation c.3007G>A was related with gonadal mosaicism. There was no clinical findings with youngest sister but molecular genetics and biochemical results showed concordance with Wilson disease. The oldest sister (proband) did not have clinical findings and biochemical results with Wilson disease, but had compound heterozygosity, one of the mutation was new, and the other mutation was related with gonadal mosaicism. The proband was 27 years old, and new mutation was not showing biochemical and clinical findings of the Wilson disease, however it must not exclude the age-dependent effect.
CONCLUSIONS: We do not know genetic effects of the new mutation c.3106G>A and clinical future of patients, but we must monitor carefully the biochemical abnormalities and clinical picture of the Wilson disease. The discovery of the new Wilson disease gene could open up a new molecular diagnostic approach.

Exploring the role of microRNAs in multiple sclerosis: an unexpected anti-inflammatory potential?

J. Perez;
Cem-cat, Barcelona, Spain.

Abstract

In the past years, microRNAs (miRNAs) have arisen as novel regulators of most cellular processes in homeostasis and disease. Lately, their involvement in autoimmune diseases has become of interest, particularly in mul-

tiple sclerosis (MS). To investigate the contribution of miRNAs to this heterogeneous disease and study their role as potential therapeutic targets, we have conducted an in-depth analysis of the cellular pathways regulated by the potentially most relevant miRNAs in MS.
For this purpose, we performed an extensive and stepwise search on published data in order to identify miRNAs that, on one hand, were known to play key roles in naïve T cells and differentiated pathogenic, memory and regulatory CD4+ T cell subsets (Th1 / Th2 / Th17/ Tregs) and, on the other hand, were found to be dysregulated in MS patients, obtaining a shortlist of 13 candidate miRNAs. In a second step, by using online databases and restrictive filtering we generated a set of 903 validated and highly predicted gene targets from these miRNAs. Functional annotation studies conducted with Ingenuity Pathway Analysis led to the identification of a number of cellular pathways regulated by candidate miRNAs that are known to play important roles in MS etiopathogenesis. Overall, our results point to an immune-suppressive role of miRNAs in T cells during MS and provide a rationale for future research studies of selected candidate miRNAs in the disease.

J10.02
Protective effects of Interleukin (IL)-6 gene polymorphisms against recurrent aphthous stomatitis

N. Karakus[1], *S. Yigit*[1], *A. Rustemoglu*[1], *G. Kalkan*[2], *N. Bozkurt*[1];
[1]*Gaziosmanpasa University, Faculty of Medicine, Department of Medical Biology, Tokat, Turkey,* [2]*Gaziosmanpasa University, Faculty of Medicine, Department of Dermatology, Tokat, Turkey.*

Recurrent aphthous stomatitis (RAS) is a common ulcerative disease of the oral mucosa. The aim of the present study was to examine the possible role of Interleukin (IL)-6 gene polymorphisms in the development of RAS. This study comprised 184 RAS patients, 118 females and 66 males, and 150 healthy controls, 88 females and 62 males. Peripheral blood samples were genotyped using polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) analyses for the IL-6 gene -174G/C and -572G/C polymorphisms.
The distributions of genotype and allele frequencies of IL-6 gene -174G/C and -572G/C polymorphisms were statistically different between RAS patients and control group (genotype p=0.000 and p=0.001, allele p=0.000 and p=0.000, respectively). The genotype and allele frequencies of variant type of both the polymorphisms were higher in control group. So it seems that these polymorphisms had protective effect against RAS. After stratifying RAS patients according to clinical and demographical characteristics, no significant association was observed.
In conclusion we demonstrated that genotype and allele frequencies of IL-6 gene -174G/C and -572G/C polymorphisms were statistically different between RAS patients and controls and were protective against RAS. Further studies with larger number sizes of patients are needed.

Circulating levels of RANTES and -403G/A promoter polymorphism in association to acute heart failure after STEMI and to cardiogenic shock

J. Lipkova[1], *J. Parenica*[2], *K. Helanova*[3], *J. Tomandl*[4], *P. Kala*[5], *J. Spinar*[5], *A. Vasku*[1], *M. Pavkova Goldbergova*[1];
[1]*Department of pathological physiology, Faculty of medicine, Masaryk university, Brno, Czech Republic,* [2]*Masaryk Univesrsity, University Hospital Brno, University Hospital St Anne's, Brno, Czech Republic,* [3]*Masaryk University, University Hospital Brno, Brno, Czech Republic,* [4]*Masaryk University, Brno, Czech Republic,* [5]*Masaryk University, University Hospital Brno, University Hospital St Anne's, Brno, Czech Republic.*

Chemokines, including RANTES, play crucial role in processes of inflammation during cardiovascular disorders. They have been associated with increased risk of atherosclerotic progression and therefore an increased risk of acute myocardial infarction and subsequent complication - cardiogenic shock, heart failure. This study aimed to evaluate the role of RANTES -403G/A polymorphism and levels in circulation in processes of development and progression of myocardial infarction and cardiogenic shock. A total of 609 patients with ST segment elevation myocardial infarction, 43 patients with cardiogenic shock and 130 control subjects were enrolled in the study. RANTES -403G/A promoter polymorphism and baseline serum RANTES levels were analyzed. In present study, we associated RANTES -403 G/A promoter polymorphism with acute heart failure and ejection fraction in patients with myocardial infarction (p = 0.006; p = 0.02). A difference in circulating RANTES levels was observed between controls and STEMI subjects (p = 0.03). We found a decreasing tendency of serum RANTES levels with the severity of myocardial infarction and progression, with the lowest levels in patients with cardiogenic shock. Further, in STEMI patients the serum RANTES levels were correlated to levels of BNP and NTproBNP (p = 0.003; p = 0.03), and to ejection fraction (p = 0.05). Our results suggest the role of RANTES in cardiogenic shock and acute heart failure in hospital phase after myocardial infarction. RANTES might be considered as a marker of cardiogenic shock and acute heart failure in hospital phase after myocardial infarction at the time of admission.

Is individual susceptibility to periprosthetic osteolysis associated with differences in cytokine expression-response of peripheral mononuclear cells (PBMC) to pro-inflammatory stimulus?

P. Schneiderova[1], *T. Tomankova*[1], *F. Mrazek*[1], *J. Gallo*[2], *E. Kriegova*[1];
[1]*Dept. of Immunology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic,* [2]*Dept. of Orthopaedics, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic.*

Individual susceptibility to periprosthetic osteolysis around total hip arthroplasty (THA) may be associated with genetic variations in cytokine genes. Here, we investigated whether cytokine expression-response of PBMC to pro-inflammatory stimulus differ between patients with severe/mild osteolysis and in subgroups according to the presence of TNF-238*A, an allele associated with severe osteolysis.
PBMC obtained from 32 THA patients (severe osteolysis, n=23; mild osteolysis, n=9) were stimulated with lipopolysaccharide; further subgroups were formed according to the TNF-238 genotype (11 carriers/21 non-carriers of TNF-238*A allele). Protein concentrations of IL-2, IL-5, IL-10, IFN-γ, TNF-α, VEGF, OPG and RANKL in supernatants were measured using Luminex and ELISA.
Of studied cytokines, elevated expression of IL-2, IL-5, IFN-γ, VEGF, OPG, RANKL ($p<0.05$) was observed in supernatants from patients with severe osteolysis compared to those with mild osteolysis, irrespective of TNF-238 genotype. Patients with TNF-238 GG genotype with severe osteolysis showed up-regulated expression of all studied cytokines, except IL-10 and VEGF, comparing to those with mild osteolysis. In severe osteolysis, the carriers of rare TNF-238*A allele showed lower expression of IL-2, IL-5, IFN-γ, TNF-α, RANKL ($p<0.05$) when comparing to non-carriers.
In conclusion, carriers of TNF-238*A allele with severe osteolysis showed different cytokine expression pattern in response to pro-inflammatory stimulus comparing to non-carriers of TNF-238*A allele with severe osteolysis as well as THA patients with mild osteolysis. Molecular mechanism by which TNF-238*A allele increases a risk of severe osteolysis should be further investigated.
Grant support: IGA MZ CR NT/11049 and IGA LF_2013_13.

J10.05
Expression profiling revealed similar cytokine-expression profiles in pseudosynovial tissues retrieved from aseptically failed hip and knee arthroplasties

T. Tomankova[1], ***E. Kriegova***[1], *J. Gallo*[2];
[1]*Dept. of Immunology, Faculty of Medicine and Dentistry, Palacky Univesity, Olomouc, Czech Republic,* [2]*Dept. of Orthopaedics, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic.*

Aseptic loosening accompanied by osteolysis is the most frequent long-term complication of total hip (THA) and knee (TKA) arthroplasties. Despite anatomic, kinematic and biomechanical distinctions between THA/TKA, there is no information on differences in cytokine-expression profiles between periprosthetic tissues retrieved from aseptically failed THA and TKA.
We therefore investigated mRNA expression profiles of candidate cytokines and their receptors involved in the inflammation (TNF-α, IL-2, IL-2R, IL-6, IL-10, IL-10R, TGF-β) and osteoclastogenesis (RANKL, OPG, SOCS3, DC-STAMP) in pseudosynovial tissues obtained from 36 patients with aseptically failed THA/TKA and 31 control patients with hip/knee primary osteoarthritis using quantitative RT-PCR.
When compared to controls, the expression of OPG, TNF-α, IL-10, IL-10R was lower in failed arthroplasties, however the difference reached significance only in TKA ($p\leq0.05$). IL-2, IL-2R, IL-6 and TGF-β mRNA expression did not

differ between patients and controls (p≥0.05). DC-STAMP was upregulated only in THA (p=0.0008), while reduced expression of RANKL (p<0.005) and elevated expression of SOCS3 (p<0.01) was detected in both THA and TKA tissues comparing to controls. Higher number of mRNA transcripts for all investigated cytokines and receptors was detected in THA comparing to TKA tissues. Although similar cytokine-expression profiles were associated with aseptically failed TKA and THA, higher cytokine-gene expression was detected in tissues from failed THA comparing to TKA. In general, our data support the hypothesis about the "inactive inflammatory response" in periprosthetic tissues during the later stages of disease leading to the reoperation. Grant support: IGA MZ CR NT/11049 and IGA LF_2013_13.

The investigation of Killer cell immunoglobulin like receptor (KIR) genotyping in patients with Systemic Lupus Erytematosus and Systemic Sclerosis.

J. Duymaz, *H. Gurkan, H. Tozkir, S. Donmez, D. Eker, G. E. Pamuk, O. N. Pamuk;*
TRAKYA UNIVERSITY, EDIRNE, Turkey.

Systemic lupus erythematosus (SLE) is an autoimmune disease characterised by the production of autoantibodies and the involvement of multiple organ systems. The etiopathogenesis of SLE is unknown. Systemic sclerosis (SSc) is another autoimmune disease that effects mainly connective tissue. Its pathogenesis is unknown too. We will aim to analyse the role of killer cell immunoglobulin-like receptors (KIRs) genotypes and their existence with the respective HLA ligands in the pathogenesis of SLE and SSc. We examined the presence/absence of KIR2DL1, 2DL2, 2DL3, 2DL4, 2DL5A, 2DL5B, 2DS1, 2DS1, 2DS2, 2DS3, 2DS4, 2DS5, 3DL1, 3DL2, 3DL3, 3DS1, 2DP1, 3DP1 and their known HLA ligands in 45 SLE, 25 SSc and 40 healhty controls. The KIR2DL5B (46.8% vs 25%, P = 0.036; OR = 2.6, 95% CI 1.05-6.6) and KIR2DS3 (42.6% vs 22.5%, P = 0.048; OR = 2.5, 95% CI 0.99-6.5) gene phenotype frequencies were found to be significantly increased in SLE patients compared to healthy controls. KIR2DS3 gene frequency was observed significantly increased in SSc patients too (48% vs 22.5%, P = 0.032; OR = 3.1, 95% CI 1.08-9.36).We did not find any associations of other observed KIR genes between the patients groups and controls. No significant difference was observed for KIR ligand between the patient groups and controls as well. KIR2DL5B and KIR2DS3 genes may have an role in autoimmune mechanisms. We are investigating this KIR genes epigenetic variations between the study groups. *This study was supported by TUBITAK (111S153).*

Genetic variation in L-selectin might prone the individuals to atopic dermatitis

A. Rafiei, *Z. Hosseini khah, Z. Hajheydari, J. Ghaffari, R. Sharbafi;*
Molecular and Cell Biology Research Center, mazandaran university of medical sciences,mazandaran, Iran, sari, Islamic Republic of Iran.

Background and aim: Atopic dermatitis (AD) is a common chronic or relapsing inflammatory skin disease, which often precedes asthma and allergic disorders. Chronic inflammation is the main pathogonomic feature of AD. Selectin adhesion molecules participate in the interaction between leukocytes and the endothelium, as well as in inflammatory cell recruitment. Genetic factors have an important influence on the risk of developing atopic disease. The aim of this study was to evaluate the association between genetic variants of L-selectin and susceptibility of AD.
Materials and Methods: This case-control study recruited 122 patients with AD; aged 8.92±5.07 years old and 151 age, sex, and ethnic background matched healthy controls. Genomic DNA was isolated, and amplification of L-selectin 206 Phe/Leu polymorphic region was performed by PCR incorporating sequence-specific primers (PCR-SSCP) to distinguish the genotypes.
Results: The frequency of the 206 Phe/Leu polymorphism was significantly more prominent in AD patients compared to the controls (27.9% 15.2%, p=0.003). Logistic regression analysis when fixed for covariates sex, age, self and familial histories of atopy revealed that the presence of Leu/Leu genotype increased the disease risk up to 2.75 (95% CI; 1.4-5.4).
Conclusion: The higher frequency of L-selectin 206 Leu genetic variant in patients with AD than in control individuals suggests that the F206L polymorphism could make individuals more vulnerable to atopic dermatitis.

Interferon induced helicase (IFIH1) rs1990760 polymorphism with Systemic lupus erythematosus in Tunisian population

A. BOUMIZA[1], *b. imen*[1], *n. idriss*[1], *i. ben saad*[1], *r. zemni*[1], *e. chabchoub*[1], *l. gueddah*[1], *F. Bahri*[2], *N. Mahfoudh*[3], *F. Ben Hadj Slama*[1];
[1]*Faculty of Medicine of Sousse, Sousse, Tunisia,* [2]*2department of internal medicine, Farhat Hached Hospital Sousse, Sousse, Tunisia,* [3]*department of genetics Faculty of Medicine of Sfax, Sfax, Tunisia.*

Systemic lupus erythematosus (SLE) is a complex autoimmune disease, characterized by the production of a wide range of autoantibodies and a broad spectrum of clinical presentation encompassing almost all organs and tissues. The etiology of this disease includes genetic and environmental factors. The aim of this study was to examine the association of a single-nucleotide polymorphism, rs1990760, of the IFIH1 gene in a Tunisian population.
The study population consisted of 87 SLE patient and 126 healthy controls from Tunisia. The polymorphism of rs1990760 was detected with the Ms PCR. The genotype and allele frequencies were calculated and analyzed.
Our study showed a statistically significant association between IFIH1 rs1990760 and SLE (p = 0.002). It was also found that the TT genotype was significantly more frequent in SLE patients than in healthy controls [odds ratio, 3.17 (95% confidence interval, 1.61-6.26); P = 0.001]. No statistical significance was observed in the comparisons amongst SLE patients with and without the main clinical and biologogical characteristics.
The results suggested that the rs1990760 TT genotype was associated with susceptibility to SLE and that the IFIH1 polymorphism analyzed did not seem to be implicated in the pathology and clinical manifestation of the lupus in the Tunisian population.

Sequencing 306 bp region of ANXA11 gene including rs1049550 polymorphism for sarcoidosis susceptibility in Turkish Patients

T. Tuncel[1], *M. Özdemir*[2], *E. Kurt*[3], *F. Saydam*[1], *O. Çilingir*[2], *H. Güneş*[1], *S. Artan*[2], *&. Değirmenci*[1];
[1]*Eskisehir Osmangazi University Faculty of Medicine, Department of Medical Biology, Eskisehir, Turkey,* [2]*Eskisehir Osmangazi University Faculty of Medicine, Department of Medical Genetics, Eskisehir, Turkey,* [3]*Eskisehir Osmangazi University Faculty of Medicine, Department of Chest Diseases, Eskisehir, Turkey.*

Sarcoidosis is a multisystemic immune disorder with unknown etiology. The disease characterized by noncaseating epithelioid granulomas across body invasion especially lungs, skin and eyes. Recently, genetic susceptibility to sarcoidosis counted as a important factor to disease progression. Latest GWAS datas pointed out a new sarcoidosis susceptibility gene, ANXA11. According to these studies, a nonsynonymous SNP (rs1049550) in this gene is strongly associated with sarcoidosis. Our aim was to determine the association between rs1049550 SNP and sarcoidosis in Turkish patients and to scan other variations associated with sarcoidosis within 306bp region of ANXA11. Genomic DNA isolated from peripheral leukocytes of the 53 sarcoidosis patients and 52 controls. 306bp region of ANXA11, including rs1049550 amplified with PCR. Amplicons sequenced with Sanger method (Applied Biosystems 3110). The sequence data of both patients and controls analysed in BLAST database for identification of variations. Allele frequencies and genotype distribution of the groups were analyzed with the chi-square test. No other genetic variation was observed except rs1049550 polymorphism in the 306bp region. There was no statistically difference (x2=2.689 p=0.273) when the frequencies of CC, CT and TT genotypes in sarcoidosis group (58.5%, 30,2%, 11.3%, respectively) were compared with genotypes of control group (65.4%, 17.3%, 17.3%, respectively). When allele frequencies of sarcoidosis patients (C= 73.6%, T = 26.4 %) are compared with controls (C = 74.0 %, T=26.0 %,), no statistically significant difference (X2=0.006, p=0.940) observed for the rs1049550 polymorphism. According to our results ANXA11 rs1049550 polymorphism is not a genetic predisposition marker for Turkish population.

MTNR1B polymorphism rs10830962 influences the reproductive outcomes in women with SLE

S. Andonova[1], *R. Robeva*[2], *D. Tanev*[3], *V. Decheva*[1], *A. Savov*[1], *P. Kumanov*[2], *R. Rashkov*[3], *Z. Kolarov*[3];

[1]*National Genetic Laboratory, Medical University, Sofia, Bulgaria,* [2]*Clinical Center of Endocrinology and Gerontology, Medical University, Sofia, Bulgaria,* [3]*Clinic of Rheumatology, Medical University, Sofia, Bulgaria.*

Background: Systemic lupus erymathosus (SLE) is an autoimmune disease that affects predominantly females of child-bearing age. SLE increases the risk for pregnancy complications and is important to find possible genetic factors, affecting the reproductive outcomes. Recent studies have shown the important role of melatonin receptor polymorphism in reproductive disorders. However, the impact of these polymorphisms on the reproduction in young women with autoimmune diseases is unclear.

Methods: A total of 101 SLE patients were genotyped for MTNR1B rs10830962C/G gene polymorphism. The reproductive history of all patients concerning menstrual, infertility, number of pregnancies, miscarriages and live-births was obtained, and genotype-phenotype relationships were determined.

Results: 85.1% of the patients with MTNR1B rs10830962 genotypes GC or GG had at least one pregnancy in comparison to 67.6% of CC genotype carriers (p=0.067). Accordingly, the G-allele-carriers with at least one live-birth were significantly more than the CC women (83.6 vs. 55.9%, p=0.004). The presence of GG/GC genotypes was related to significantly more live-births even after adjustment for age and disease activity (OR 3.209, 95%CI 1.034-9.959, p=0.044). However, the rs10830962G allele did not influence the development of menstrual disorders, self reported infertility or miscarriages.

Conclusions: Our preliminary results showed that MTNR1B rs10830962C/G polymorphism could influence the reproductive outcomes in lupus patients. The beneficial effect of G allele on the reproductive success could be related to greater ovarian reserve in the patients or to other biological/psychological features that remain to be established.

The study was supported by research grants 26/2010 and 59/2011 - MU Sofia, Bulgaria

Quantitative analysis of GSDMB and ORMDL3 gene expression in peripheral blood leukocytes of asthma patients

Y. Fedorova[1], *A. Karunas*[1,2], *G. Gimalova*[1], *R. Murzina*[3], *R. Gatiyatullin*[3], *E. Khusnutdinova*[1,2];

[1]*Institute of Biochemistry and Genetics, Ufa Scientific Centre of RAS, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation,* [3]*Bashkir State Medical University, Ufa, Russian Federation.*

The genome-wide association study of bronchial asthma in the Volga-Urals region of Russia discovered a significant association with SNPs located in gasdermin B (GSDMB) and orosomucoid 1-like 3 (ORMDL3) genes (Karunas A.S. et al., 2011). Using RT-PCR, we performed gene expression analysis of GSDMB and ORMDL3 in peripheral blood leukocytes of 13 patients with asthma and 13 healthy control subjects. Nine patients had a severe form of the disease. A highly sensitive quantitative real-time PCR method for GSDMB and ORMDL3 mRNA quantification was performed using the SYBR Green. In accordance with «delta-delta Ct» method, the mRNA amounts of a target gene were normalized to an endogenous control (GAPDH). Normality of quantitative data was assessed using the Kolmogorov-Smirnov test. T tests were used when normality assumptions were satisfied, otherwise the Mann-Whitney test was utilised. The statistical analysis was done using the GraphPad Software and statistical significance was obtained with $p<0.05$. Specimens from peripheral blood leukocytes of patients with asthma showed higher level of GSDMB mRNA expression (M±SEM: 1,76±0,32) than those from healthy patients (M±SEM: 1,16±0,17). Expression analysis demonstrated a significant increase in the expression of GSDMB in peripheral blood leukocytes of patients with severe asthma (M±SEM: 2,10±0,44) as compared with controls. ORMDL3 transcript levels did not differ between patients with asthma (M±SEM: 1,59±0,72) and controls (M±SEM: 1,84±0,73). In sum, these results support an important role for the GSDMB in susceptibility to bronchial asthma in the Volga-Urals region of Russia. Supported by the Russian Foundation for Basic Research, RFBR №11-04-97063.

Hemochromatosis revealing severe combined immunodeficiency

C. CLADOVAN, *A. Szilagyi, G. Szilagyi;*

UNIVERSITY OF ORADEA, FACULTY OF MEDICINE AND PHARMACY, ORADEA, Romania.

Severe combined immunodeficiency (SCID) is a life-threatening syndrome of recurrent infections and failure to thrive, caused by numerous molecular defects that lead to severe compromise in the number and function of T cells, B cells, and occasionally natural killer cells.

We will present the case of a three months old infant who was admitted for poor weight gain and repeated fever in the last four weeks. Family history identified two cases of infant deaths caused by infections (the mother's brothers). Physical examination showed a good general condition, normal weight for age, mild jaundice and generalized muscle hypotonia. Routine analysis showed increased transaminase level, so the next step of investigation was directed towards four main entities: hepatitis, sepsis, hemolysis, myolysis. The following laboratory tests were modified: moderate cholestasis, extremely high serum ferritin and rapidly increasing transaminases, while no evidence of hemolysis, anemia or any hepatic viral infection occurred. Since repeated episodes of fever were the main complain, a more profound examination of the immunity was realized, revealing severe combined immunodeficiency.

The particularity of the case rises from the early diagnosis, determined by the investigation of a chronic liver disorder with hemochromatosis.

Analysis of cytokines in the serum of women with breast cancer

E. M. Vasilyeva, *G. F. Galikeeva, O. V. Gumerova, E. V. Vorobyeva, V. Y. Gorbunova;*

Bashkir State Pedagogical University of the name M. Akmulla, Ufa, Russian Federation.

In the study, were determined by ELISA concentration IL-1β, IL1RA, IL2, IL4, IL-6, IL10, TNF- α and CRP (C-reactive protein) in the sera of 44 women with breast cancer, tumor stage T2-3N0-2M0 (serum taken before surgery to remove the tumor) and 56 healthy women. In women, breast cancer patients showed a significant decrease in IL-2 (p <0,0001), decreased production of IL2 is associated with the suppression of growth of natural killer cells and weakening of their cytolytic function, which ultimately leads to a lack of anti-tumor defense. Defined enhancement products IL6 (p <0,0001), which is an unfavorable factor and inducer of tumor growth. Also, we observed a significant increase in the concentration of IL6 (p <0,0001). According to the literature elevated concentrations IL6 considered as an adverse factor and inducer of tumor growth. In breast cancer patients showed a significant increase in the production of anti-inflammatory cytokines - IL10, which, according to some authors, leads to a weakening of the effector responses of T-cell immunity.

Cytokine status in women with breast cancer before surgery and healthy women, pg/ml (CRP-mg/L)

indicators	n	breast cancer patients	breast cancer patients	n	healthy women	healthy women	p
		χ±m	δ		χ±m	δ	
IL-1β (0-11)	44	2,5±0,21	1,4	56	3,8±0,28	2,1	<0,0001

Cytokines gene expression in human lung epithelial A549 cells induced by non-structural NS1 protein of influenza A viruses

M. Plotnikova, *S. Klotchenko, A. Shurygina, A. Vasin;*

Research Institute of Influenza, St. Petersburg, Russian Federation.

NS1 protein of influenza A virus is a multi-functional protein that participates in suppression of host immune response via dysregulation of cytokine expression. In the present study we investigated relative levels of mRNA expression of IL1B, IL2, IL4, IL6, IL10, IL12B, IL18, IFNG and TNF by quantitative RT-PCR. All reactions were run in duplicate, relative quantification analysis was done using comparative Ct (ΔΔCt method) with GAPDH as a reference gene.

To evaluate NS1 induced cytokines mRNAs production, A549 cells were infected with wild type recombinant H5N1 A/Kurgan/5/05 (wtNS) and A/Kurgan/5/05 with deletion of NS1 gene open reading frame (delNS1) vi-

ruses. Cytokine response was measured after 8 hours since stimulation.
Earlier it has been demonstrated that NS1 protein inhibits pro-inflammatory cytokine and chemokine responses. In our research we revealed approximately ten-fold increase in gene expression of IL1B, IL6 and TNF for cells stimulated with delNS1 in comparison to wtNS viruses. The mRNA levels of IL12B and IL18 were comparable to all wtNS-, delNS1- and mock-infected cells. Interestingly, delNS1 virus infection induced IL10 expression, which was not detected in wtNS- and mock-infected cells. In contrast, expression of IL4 was observed only in wtNS-infected cells. IL2 and IFNG were not detected in either infected or mock epithelial cells.
The study was supported by scholarship of the President of the Russian Federation №СП-1580.2012.4.

Paradoxical reaction during antituberculosis treatment in a patient with Down syndrome. A case report

M. I. S. CRAPANZANO[1], *E. Moschella*[1], *I. Loddo*[1], *A. Costa*[1], *A. Cascio*[2], *S. Briuglia*[1], *R. Gallizzi*[1], *C. Salpietro*[1];
[1]*Genetics and Paediatric Immunology Policlinico G. Martino, MESSINA, Italy,* [2]*Policlinico G. Martino, MESSINA, Italy.*

Introduction: The paradoxical reaction (RP) is characterized by the deterioration of clinical and radiological signs of pre-existing tuberculous lesions or by development of new lesions in patients who initially responded to tuberculosis treatment.
Case-Report: We describe a case of a 7 year old girl with Down Syndrome with recurrent fever and cough for a month. The patients presented fever (39°C), inspiratory triage and dyspnea. Laboratory tests showed neutrophilia, increase in CRP and ESR. Chest X-Ray and CT-scan showed bilateral interstitial thickening with reticulo-nodular appearance. Gastric aspirated and acid-fast bacilli culture were positive. The patient started standard antituberculosis therapy and methylprednisolone. We have seen a slow improvement in respiratory symptoms on the 15th day of therapy. In the 21th day there was a worsening of clinical (fever and dyspnea) and radiological signs. The second gastric aspirates was negative.
The study of lymphocyte subsets showed initially CD4+ 13% (n.v. by age 33-41%), after 15 days 29%. This condition is described as a Paradoxical Reaction; it was observed in patients with HIV-TB co-infection as an immune reconstitution syndrome and is characterized by worsening of the general clinical condition with exacerbation of symptoms. The dose of methylprednisolone was increased, with gradual improvement in symptoms.
Conclusion: The Paradoxical Reaction can be suspected in patients with Down syndrome if there is worsening of general clinical condition during tuberculosis treatment. In this patients the corticosteroid therapy was essential.

BRCA mutation carriers do not have compromised ovarian reserve

R. Michaelson-Cohen*, P. Mor, N. Srebnik, U. Beller, T. Eldar-Geva, E. Levy-Lahad;*
Shaare Zedek Medical Center, Hebrew University, Jerusalem Israel, Jerusalem, Israel.

Background: Controversy exists about impact of BRCA1/2 mutations on female fertility, an issue of great interest to mutation carriers and their caregivers. Previous studies are small, or based on indirect parameters (e.g., self-reported infertility), which depend on additional factors unrelated to true fertility potential. None of the previous studies used strict fertility markers.
Objective: To evaluate the relation between carrying BRCA mutations and fertility, using AMH level, which has been previously shown to be one of the most accurate markers of fertility potential.
Patients, Methods: 40 healthy BRCA1/2 mutation carriers, aged 26-40 years, attending a multidisciplinary breast & ovarian cancer surveillance clinic, were tested for AMH levels, using a two-site-ELISA. Levels were compared to well-established normograms of the general fertile population.
Results: Mean age and parity of carriers was 33.2years (26-40, SD3.99) and 1.97 (0-7, SD1.49), respectively. All carried at least 1 Ashkenazi-Jewish founder mutation. AMH levels for most carriers were in normal range (mean2.6ng/ ml; SD3.73ng/ml, approximately 50th percentile).
Conclusions: AMH levels of healthy BRCA1/2 mutation carriers are similar to that of non-carrier women matched for age; therefore we conclude that BRCA mutation carriers do not have compromised ovarian reserve. This is the only study, to the best of our knowledge, which directly examines ovarian reserve in carriers, by an accurate marker. This study has important clinical applications, as it provides reassurance for female carriers of these mutations, regarding their fertility potential.

Retinoblastoma (RB) is the most common primary intraocular malignancy in children. Two-hit inactivation of RB1 gene is necessary for tumor development. Sixty percent of RB cases show two somatic mutations, while 40% are hereditary with patients carrying one germline mutation and one somatic mutation. In order to improve life quality of RB patients, worldwide tendency is to develop different kind of targeted therapies. Since 2008 the Superselective Ophtalmic Artey Infusion of Melphalan (SOAIM) was introduced in Siena for RB treatment. Our aim is to evaluate the correlation between SOAIM therapy outcome and RB1 germline mutation. Among 35 RB patients under SOAIM treatment, 18 had complete remission, 8 underwent enucleation, 4 had relapse, 4 had discordant outcomes in the 2 eyes, and 1 had technical failure. Next Generation Sequencing and Multiplex Ligation-dependent Probe Amplification were performed to detect point mutations and deletions/duplications of the RB1 gene, respectively. The analysis reveals one RB1 germline mutation in 17 out of 35 patients. Considering remission versus enucleation and RB1 mutation presence versus absence and using Fisher exact test, a significant P value (0.03) is obtained. These results suggest that having a germinal mutation predisposes to a better outcome of Melphalan therapy. Since RB samples without a germline mutation have been shown to harbor an higher number of genomic somatic rearrangements (P value 0.002), we could hypothesize that this genomic mutational burden might influence Melphalan metabolism resulting in a lower response to drug therapy.

Genetic abnormalities in diagnostics of BCR-ABL-negative myeloproliferative neoplasms

M. Kozlovskaya*, I. Martynkevich, E. Petrova, L. Martynenko, M. Ivanova, N. Cybakova, S. Gritsaev, V. Shuvaev, K. Abdulkadyrov;*
Russian Research Institute of Haemotology and Transfusiology, St.-Petersburg, Russian Federation.

The goal of the study was to assess frequencies of JAK2, MPL mutations and cytogenetic aberrations in group of 567 patients with BCR-ABL-negative MPNs. The investigated group included 224 cases of Polycythaemia vera, 102 cases of Essential thrombocythemia, 102 cases of Primary myelofibrosis and 140 cases of Chronic myeloproliferative disease, unclassified (CMPD-U). Polymorphisms of JAK2 and MPL (W515L/K) were detected by realtime PCR and the sequence analysis. Conventional cytogenetics of bone marrow with chromosome banding analyses were performed for 129 patients.
The frequencies of JAK2 617F allele have been detected as follows: 89,7% in PV, 56,4% in ET, 49,7% in PMF, 8,6% in CMPD-U that confirmed MPN diagnosis for 12 patients. The mutations rate of JAK2 exon 12 was 2,9% in PV. The frequencies of MPL 515L allele were 2,3% in ET, 2% in PMF. Normal karyotypes were defined in 85,3% cases. Aberrant karyotypes were defined in 14,7% cases and included 3,9% with isolated chromosomal aberrations (favourable prognosis), 6,2% karyotypes (intermediate prognosis), 4,7% with complex abnormalities (unfavourable prognosis).

Isolated chromosomal aberrations were defined reliably more often in PV than in PMF (p<0,0000). The frequency of the complex karyotypes was statistically higher in PMF as compared to PV and ET (p<0,0000). 2 of 6 patients carrying karyotype with complex abnormalities had transformation from MPN to AML.
Point mutations in JAK2 and MPL genes are specific markers for the patients with BCR-ABL-negative MPNs. The integration of molecular genetics with cytogenetics helps to stratify patients into different prognostic groups and optimize treatment strategy.

Allelic imbalance on 1p36 (RUNX3), 16p22 (CDH1) and 17p13 (TP53) and microsatellite instability in gastric tumor.

***A. Udilova**, T. Kchorobrich, M. Nemtsova, D. Zaletaev;*
I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Gastric cancer is one of the most common cancers in the world and the second leading cause of global cancer mortality. Two major gastric cancer histological subtypes are recognized with distinct morphology, epidemiology, pathogenesis and clinical behavior, the intestinal and diffuse subtypes.
We investigated the clinical and prognostic importance of allelic imbalance (AI) of tumor-related genes CDH1, RUNX3, TP53 and microsatellite instability (MSI) for gastric cancer patients.
We examined allelic imbalance on 1p36 (RUNX3), 16p22.1 (CDH1) and 17p13.1 (TP53) and microsatellite instability (BAT26) in 100 paired samples of gastric tumor and morphologically normal gastric mucosa, 57/100 of which have been identified as diffuse type of gastric cancer, 43/100 tumors belonged to the intestinal type gastric cancer. Frequency of allelic imbalance was: 26% for 1p36 (RUNX3), 20% for 16p22.1 (CDH1) and 31% for 17p13.1 (TP53). We have not detected allelic imbalance in 38/100 (38%) of the tumor samples.
We have shown a significant difference in the frequency of allelic imbalance of the studied loci among different types of gastric cancer. Frequency of allelic imbalance in patients with intestinal gastric cancer was significantly higher than in patients diffuse type GC (p=0.0265). Frequency of AI in 16p22.1 (CDH1), 17p13.1 (TP53) and microsatellite instability (BAT 26) was significantly higher in intestinal type of gastric cancer than in diffuse type (p = 0.04, p = 0.016 and p = 0.01, respectively).

Progressive cavernous hemangiomatosis in a patient with neurofibromatosis type 1

***A. Bolcekova**[1], M. Nemethova[2], A. Zatkova[2], A. Hlavata[1], L. Kovacs[1], D. Ilencikova[1];*
[1]2nd Pediatric Department of the Comenius University, Medical School and University Children's Hospital, Bratislava, Slovakia, [2]Laboratory of Genetics, Institute of Molecular Physiology and Genetics, Bratislava, Slovakia.

Apart from typical diagnostic criteria of neurofibromatosis type 1 (NF1, OMIM # 162200), some minor NF1 signs such as cavernous hemangiomas may cause severe complications. We present a case report of a male patient with NF1 and a severe haematological complication as a result of progressive cervical hemangiomatosis. A male with an uneventful pre- and perinatal history, presented at the age of three years with numberous café-au-lait spots, several neurofibromas and visible cavernous hemangiomas in the area of the scalp and axilla. From the age of 7 years until now these painless lessions progressed, reached the thoracic area and infiltrated or suppressed several organs including cervical intervertebral spaces, submandibular salivary glands and the thyroid. Oncomarker testing showed no malignancy. The extensive growth of hemangiomas recently led to severe life-threatning anemia and consumptive thrombocytopenia. Treatment with cyclophosphamide has been initiated. Genetic testing revealed the presence of NF1 gene mutation in exon 24 c.4226_4227delAGinsT NF1 gene, leading to a shift of the reading frame and premature stop codon after 10 amino acids (p.Lys1409Ile fsX10). Hemangiomas in patients with neurofibromatosis type 1 occur in about 5-6% of patients. This is a rare case with an extremely progressive hemangiomatosis with the novel mutation leading to life-threatning consumptive thrombocytopenia.

Diagnostic value of molecular cytogenetics and multiplex RT-PCR for risk stratification in acute myeloid leukemia

***K. Orendi**[1], W. Emberger[1], G. Hoefler[2], M. R. Speicher[1], H. Sill[3];*
[1]Institute of Human Genetics, Medical University Graz, Graz, Austria, [2]Institute of Pathology, Medical University Graz, Graz, Austria, [3]Division of Hematology, Medical University Graz, Graz, Austria.

Introduction
In addition to conventional cytogenetics, the European Leukemia Network recommends mutation analysis of *NPM1*, *CEBPA* and *FLT3* genes for genetic risk stratification in those AML cases with normal karyotype. However, due to technical limitations in cytogenetics this strategy cannot be realized in about 20% of cases. In this study, we evaluated whether Interphase-FISH and RT-PCR are of additional benefit.
Materials and Methods
In 131 AML patients an RT-PCR panel with 28 leukemia specific translocations (HemaVision®) as well as FISH analyses with selected probes were performed in addition to conventional cytogenetics. Only diagnostic material from peripheral blood or bone marrow was used that contained a minimum of 20% leukemic cells.
Results
Whilst FISH analysis was throughout feasible, cytogenetics failed in 13% due to an insufficient number of metaphases and HemaVision® in 3% due to poor RNA quality. Chromosomal aberrations were detected in a total of 71/131 cases (54%). Of the latter, cytogenetic, FISH and multiplex RT-PCR analyses were concordant in 25/71 cases (35%), whereas in 45/71 patients (64%), only cytogenetics and FISH showed a positive, concordant result. In one case a translocation was detected by HemaVision® only, since no metaphases were obtained at cytogenetic analysis and the FISH panel did not cover a probe for this specific translocation.
Conclusion
These data show that risk stratification by conventional cytogenetics in addition to a well defined FISH panel is successful in almost all AML patients. HemaVision® should be performed in a second step when initial cytogenetic/FISH analyses were uninformative.

J11.07

CDKN2A germline mutations detected in Czech melanoma cancer families

***P. Vasickova**, E. Machackova, E. Stahlova Hrabincova, J. Hazova, L. Foretova;*
Masaryk Memorial Cancer Institute, Brno, Czech Republic, Brno, Czech Republic.

CDKN2A gene, Cyklin-dependent kinase inhibitor type 2A, has been identified as major melanoma susceptibility gene based on the presence of germline mutations in high-risk melanoma-prone families. The lifetime risk of melanoma in CDKN2A mutation carriers is ranging from 58% in Europe to 91% in Australia.
By the direct sequencing of CDKN2A gene, 73 melanoma families indicated by clinical geneticists were analysed.
Three germline mutations were detected. A novel germline frameshift mutation c.15_20del6insC in exon 1α of the p16/INK4a transcript variant was detected in a family with mother and daughter diagnosed with primary melanoma at age of 31 and 38, respectively. Both were mutation carriers.
A novel germline splice site mutation c.457+4delAG was detected; it is predicted to result in a cryptic splice site 88bp downstream in exon 2 of the p16/INK4a transcript variant. Other transcript variant p14/ARF might not be influenced because of ARF termination codon located 27bp upstream from the predicted cryptic splice site. cDNA analysis is pending. The c.457+4delAG mutation was detected in woman with multiple primary melanoma at age of 29 and 34.
A worldwide spread missense mutation c.71G>C, p.Arg24Pro in exon 1α of the p16/INK4a transcript variant was detected in family with father diagnosed with melanoma at age of 42 and his daughter diagnosed with multiple primary melanoma at age of 24 and 35. Both were mutation carriers.
In three families frequent polymorphism p.Ala148Thr was detected; in some studies it is presented as low penetrance susceptibility allele.Supported by OP VaVpI - RECAMO, CZ.1.05/2.1.00/03.0101.

Investigation of OCT1 mRNA expression in colorectal cancer

N. Sadeghipour[1], *M. Heidari*[2], *M. R. Noori-Daloii*[2], *C. Azimi*[3];
[1]*Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Genetics Group, Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Colorectal cancer is an important public health problem. There are over one million new cases of colorectal cancer diagnosed worldwide each year and half a million deaths. It accounts for over 9% of all cancer incidences. It is the third most common cancer among men (after lung and prostate), and the second amongst women (after breast) worldwide and the fourth most common cause of death.
The OCT1 transcription factor is a member of POU-domain containing family of homeodomain proteins whose expressions have been implicated in normal and abnormal development. POU proteins are expressed in early developmental procedures as transcriptional regulators. This family comprises six classes which OCT1 belongs to the POU protein class II and identifies its target sequences by the octamer-binding site. This study aimed to detect the expression of OCT1 mRNA in clinical samples of colorectal cancer and analyze the correlations of its expression with the clinicopathological features of colorectal cancer.Twenty-six pairs of colorectal cancer tissue and adjacent nontumoral tissue were obtained at the time of surgery from patients diagnosed with colorectal cancer. The expression of *OCT1* gene was detected by real time reverse transcriptase polymerase chain reaction (RT-PCR).
The results showed that *OCT1* was significantly downregulated in colorectal carcinoma samples in both males (58.33%) and females (57.14%). *OCT1* expression was not significantly associated with the gender and site of primary tumor (P>0.05).
The conclusion was dysregulation of *OCT1* gene might be a novel prognostic biomarker for patients with colorectal cancer.

Aberrant DNA methylation of VHL, P16, GSTP1 genes in renal cell carcinoma patients from Bashkortostan Republic of Russia.

E. Klimentova[1], *I. Gilyazova*[2], *L. Kutlyeva*[2], *V. Pavlov*[3], *A. Khaliullin*[4], *A. Zagidullin*[4], *A. Shafigina*[1], *E. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [3]*Bashkir Medical State University, Ufa, Russian Federation,* [4]*Bashkir State Medical University, Ufa, Russian Federation.*

Renal cell carcinoma (RCC) is most common neoplasm affecting the adult kidney. Renal carcinoma develops as a consequence of accumulation of several genetic aberrations. The frequent molecular abnormality in RCC is inactivation of tumour suppressor genes by methylation of CpG islands of promoters. Since RCC is curable when it is confined to therenal capsule, early diagnosis is extremely important. Promoter hypermethylation is the most common mechanism for the inactivation of the tumor suppressor genes (TSG) in the development of human cancer. The aim of this study was to analyze CpG methylation status of promoter regions of VHL, p16 and GSTP1 genes in 110 renal cell carcinoma patients from Bashkortostan Republic. Then, we evaluated the association between methylation at the promoter regions of these genes and the clinicopathological parameters of the RCCs. The tumours were predominantly low stage and low grade.
Gene promoter methylation was determined by methyl-sensitive PCR. As template for polymerase chain reaction genomic DNA extracted from tumor and normal tissues, pre-hydrolyzed methyl-sensitive restriction enzyme HpaII (CCGG) was used. Verification of PCR was performed in 7% polyacrylamide gel electrophoresis using 30% acrylamide. Documentation of electrophoresis was performed using video Geldoculant. Hypermethylation of the VHL gene was detected in 3,8% of the patients. Methylation of promoters in CpG islands p16 gene found in 18% and in GSTP1 gene in 13,6% cases. Of the genes tested, not a single gene showed age- or outcome-related differences. Future studies of epigenetic modifications are needed to establish diagnostic panels for early diagnosis of RCC.

Epidermal growth factor receptor (EGFR) mutations identified in Romanian patients with non-small cell lung cancer

A. C. Ratiu[1,2], *A. M. Stan*[2], *I. A. Visanoiu*[2], *L. Savu*[2];
[1]*University of Bucharest, Department of Genetics, Bucharest, Romania,* [2]*Genetic Lab, Bucharest, Romania.*

People harboring mutant EGFR alleles are prone to develop lung and anal cancers. The last years witnessed a crescent interest in identifying EGFR mutations that could function as molecular predictors of clinical outcomes when experimental EGFR-tyrosine kinase inhibitors (TKI) are used in cancer therapy. We screened for such mutations in 114 Romanian patients with non-small cell lung cancer (NSCLC).
We performed two distinct genomic DNA extractions from each paraffin embedded lung tissues collected from our NSCLC Romanian patients. Using two different sequencing systems, we searched for variations within exons 19 and 21 of EGFR gene.
Our study revealed 25 mutations associated with a good response to TKI based cancer therapy in 24 patients with a median age of 61 years. About 80 percent of this mutations are located in exon 19, the most preeminent being delE746-A750. Four of the other mutations located in exon 19 (i.e. K739Q, L747S, E749* and K757N) are not indexed in EGFR Mutation Database. The majority of the mutations residing in exon 21 fall within the L858 somatic mutations category.
This screening represents one of the first compelling studies that aim to extensively map EGFR mutations in Romanian patients suffering of NSCLC. The most frequent mutations that we identified are also reported to be worldwide most frequent, according to EGFR Mutation Database. The fact that by far the most prevalent mutations are located in exon 19 of EGFR gene could represent a characteristic of the Romanian patients, but further investigations are required in this direction.

Methylation profiles of CpG-islands of seven miRNAs genes (*miR-9-1*, *miR-9-3*, *miR-34b/c*, *miR-129-2*, *miR-193a*, *miR-212*, *miR-203*) in non-small cell lung cancer (NSCLC), clear cell renal cell carcinoma (ccRCC) and colorectal cancer (CRC) were defined using methylation specific PCR. Significant (P≤0.05 by Fisher) increase of methylation frequency of four genes (*miR-9-1, miR-9-3, miR-34b/c, miR-129-2*) in NSCLC, ccRCC and CRC was shown, and data on methylation of *miR-129-2 in these tumors was not reported earlier. For the first time, tumor-specific differences in methylation of miR-212* and *miR-203* genes were revealed, for example, significant increase of methylation frequency of *miR-212 in NSCLC and significant decrease in ccRCC were found. It was shown that methylation frequencies of miR-9-1* and *miR-34b/c* were significantly increased in NSCLC of different histological types - squamous cell carcinoma (SCC) and adenocarcinoma (AD). Significant increase of methylation frequency of *miR-129-2*, *miR-193a* and *miR-212* was also shown in SCC, what was reported here firstly and may be useful in the differential diagnosis of SCC and AD.

MEN1 gene mutation in a family with ectopic cushing syndrome associated with thymic carcinoid tumor

M. M. Amoli, *A. Ebrahim-Habibi, S. Hasani Ranjbar, M. Rahmanian;*
EMRC, Tehran, Islamic Republic of Iran.

Subject: Multiple Endocrine Neoplasia type 1(MEN1) is an autosomal dominant syndrome. Although thymic carcinoid tumor is recognized as part of MEN1 but functioning thymic carcinoid tumor in MEN1 has not been reported as the first presentation of the MEN1. In this report, we present mutation screening in a 29 year-old male who developed ectopic cushing syndrome secondary to thymic carcinoid tumor and also further genetic

evaluation in his family.
Methods: A large family was evaluated for routine biochemical tests, calcium profile, parathyroid hormone (PTH), hypothalamus-pituitary axis and brain magnetic resonance imaging (MRI) besides abdominal computed tomography (CT scan) was performed.The coding region of MEN1 gene from exon 1 to 10 was screened for the presence of mutations using PCR amplification followed by direct sequencing. For protein modeling the sequence of menin (NP_570711.1) was submitted to the I-TASSER server. The best computed model (based on the 3U84.pdb file) was used consecutively.
Results: A single nucleotide substitution in exon 10 of MEN-1 gene at position 1689 C/T (rs104894261) was found. The same mutation was detected in three other family members. On the protein level, this substitution leads to a deletion of Arginine 527 (R527X), which would ultimately result in a truncated protein.
Conclusion: This presentation showed that thymic neuroendocrine tumor can be the first manifestation of the MEN1 syndrome and it could be diagnosed as a dominant manifestation of this syndrome in family members. We suggest biochemical or genetic screening for MEN-1 syndrome in patients with thymic carcinoid tumor.

Allelic imbalance and microsatellite instability in papillary renal cancer

A. E. Mikhalchenko[1], *L. V. Moskvina*[2], *D. S. Mikhaylenko*[1,3], *D. V. Zaletaev*[1,4];
[1]*Research Centre for Medical Genetics RAMS, Moscow, Russian Federation,* [2]*Hertzen Moscow Oncological Research Institute, Moscow, Russian Federation,* [3]*N.I. Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [4]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.*

Renal cancer is one of 10 most common adult malignancies and is an actual problem in oncourology. There currently exists no panel of molecular-genetic markers for renal cancer. Data about genetic alterations mainly refer to the most frequent form of renal cancer - clear cell carcinoma that includes 80% of cases. Papillary carcinoma (second major type: 15% of cases) is studied less than clear cell tumor, therefore search of genetic abnormalities with diagnostic and prognostic characteristics in papillary carcinoma is particularly actual. The purpose of our work is analysis of allelic imbalance in locus 1q32 and microsatellite instability by using STR-markers in different groups of patients with papillary renal cancer to assess the prognostic relevance those alterations. We have selected 48 paired samples of papillary carcinomas (fragments of tumor and adjacent morphologically intact tissue), then analyzed these using D1S2142 and D1S3465 polymorphic repeats (locus 1q32) by PCR with fluorescent labeled primers and fragment analysis in sequencer ABI3100 „Applied Biosistems". Allelic imbalance was observed in 31.9% of informative cases, also correlation of allelic imbalance and tumor grade was obtained for the first time (Spearman's coefficient r = -0,304, p = 0,047). Analysis of paired samples using D1S2142 and D1S3465 (tetra-), CGG-GIPC1 (three-) and D9S168 (dinucleotide) repeats revealed microsatellite instability in 54.2% of tumor samples. As a whole, it was demonstrated that allelic imbalance in 1q32 and microsatellite instability are frequent events in the papillary renal cell carcinomas, and allelic imbalance in 1q32 could be considered as a prognostic marker.

Methylation profile of group of miRNA genes in clear cell renal cell carcinoma; involvement in cancer progression.

V. I. Loginov[1], *E. V. Beresneva*[2], *S. V. Rykov*[2], *I. V. Pronina*[1], *D. S. Khodyrev*[2], *T. P. Kazubskaya*[3], *E. A. Braga*[1];
[1]*Medical Genetic Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*State Research Institute of Genetics and Selection of Industrial Microorganisms, Moscow, Russian Federation,* [3]*Blokhin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

MicroRNA regulates gene expression, is involved in many cellular processes, and plays an important role in the development of cancer. The regulation of the expression of miRNA genes can be achieved by methylating their CpG islands, which is shown in different types of tumors. The methylation of miRNA genes in clear cell renal cell carcinoma (CCRCC) has mainly been studied for the *miR-9* and *miR-34* families. The methylation of six miRNA genes (*miR-124a-2, miR-124a-3, miR-9-1, miR-9-3, miR-34b/c, miR-129-2*) was investigated with the use of representative set of CCRCC samples (46 cases). Methylation of three genes *miR124a-2*, *miR-124a-3* and *miR-129-2* was studied in kidney tumors for the first time. Methylation analysis was performed using methyl specific PCR. It is shown that the frequency of methylation of six genes (*miR-124a-2, miR-l24a-3, miR-9-1, miR-9-3, miR-34b/c* and *miR-129-2*) was significantly higher in tumor samples than in samples of histologically normal tissue ($P<3x10^{-5}$ by Fisher's exact test). These results suggest the properties of tumor suppressors for the six miRNA genes indicated in CCRCC. We also found correlations between the methylation frequency of some miRNA genes and signs of the progression of CCRCC (tumor size, clinical stage, loss of differentiation, and metastasis).

Novel translocation t(10;14) in adult acute lymphoblastic leukemia: a case report

A. A. Arghir[1], *S. Papuc*[1], *H. Bumbea*[2], *I. Borcan*[1], *M. Cristea*[1], *A. Tutulan-Cunita*[1];
[1]*Victor Babes National Institute of Pathology, Bucharest, Romania,* [2]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.*

Acute lymphoblastic leukemias (ALLs) are characterized by clonal proliferation of lymphoid progenitor cells. Besides hematologic and immunophenotypic data, essential for assigning the blast lineage, the cytogenetic findings provide valuable diagnostic and prognostic information.
We report on an adult patient with B ALL and monosomal karyotype (loss of chromosome 7 and t(10;14)(p13;q21)), at presentation.
Bone marrow aspirate was used for morphological, cytochemical, flow cytometry and chromosomal studies. Cytogenetic investigations were performed on GTG-banded slides. FISH with BAC FISH probes, centromeric, locus specific and painting probes were applied for molecular characterization.
Hematological investigations at diagnosis showed severe anemia (haemoglobin 6.3 g/dL), moderate leucocytosis (20x109/L) and decreased platelet count (63x109/L). Bone marrow analysis confirmed the diagnosis of ALL, and immunophenotyping revealed positivity for common precursor B cell markers.
The chromosomal studies detected a single malignant clone bearing a reciprocal translocation t(10;14)(p13;q21) and chromosome 7 monosomy. Normal cells were also detected (5 out of 29 analyzed). BCR/ABL1 fusion and MLL rearrangements were ruled out by FISH studies.
To the best of our knowledge, this is the first reported adult ALL case with a translocation t(10;14)(p13;q21), as part of a monosomal karyotype. Adding new cases with well characterized, rare chromosomal abnormalities might contribute to a better understanding of disease biology and underlying pathomechanisms. Also, the cytogenetic data contributed, in our case, to prognosis evaluation, monosomal karyotype being associated with a poor prognosis.

Frequency of BCR-ABL Fusion Transcript Variants in Iranian Patients with Chronic Myeloid Leukemia (CML)

N. Karimi Ansari[1], *L. Emrahi Govar*[2], *L. Rostamizadeh*[2], *R. Ahangari*[1], *M. Sakhinia*[3], ***E. Sakhinia***[2];
[1]*Tabriz Genetic Analysis Centre, Tabriz, Islamic Republic of Iran,* [2]*Department of Medical Genetic, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [3]*Faculty of Medicine, University of Liverpool, Liverpool, United Kingdom.*

Chronic myeloid leukemia (CML) is a chronic myeloproliferative disease, represented in 1 - 2 per 100,000 of the population and about 15-20% of all cases of adult leukemia. 95% cases of CML are caused by a t(9;22)(q34;q11) chromosome reciprocal translocation which fuses the ABL proto-oncogene with the BCR gene, resulting in the *BCR-ABL* fusion gene (Philadelphia chromosome) which acts as an oncogene.
The fusion gene is associated with two major forms of fusion transcripts including b2a2 (e13a2) and b3a2 (e14a2). Both fusion mRNAs are translated into the p210 BCR-ABL protein which enhances tyrosine kinase activity, allowing the cell to become cancerous. The incidence of one or the other rearrangements in CML patients differs according to varying series.
Detection of mRNA chimeric transcript can be used as a marker in molecular monitoring of patients and in the selection of the appropriate management. The aim of this study was to determine the frequency of these various types of *BCR-ABL* transcripts in Iranian patients with CML. RNA was extracted using Qiagen kit and BCR-ABL transcript assessed by RT-PCR. Out of 172

patients, 77 (44.76%) were female, and 95 (55.23%) were male. Among this patients, b3a2 was the most commonly detected variant (41.86%), followed by b2a2 (13.95%) and 38.37 % of the cases negative for BCR-ABL rearrangement. In contrast to other reports, we did not see any co-expression of the b3a2 and b2a2 variants. In conclusion, RT-PCR assay is a useful tool for the detection of BCR-ABL fusion transcript and helpful in clinical practice.

Analysis of p.R145W mutation of the CHEK2 gene in patients with breast and ovarian cancer from Bashkortostan Republic of Russia.

Takhirova Z.R., Prokofyeva D.S., Bermisheva M.A., Khusnutdinova E.K.

***Z. Takhirova**, D. Prokofyeva, M. Bermisheva, E. Khusnutdinova;*

Institute of Biochemistry and Genetics, Ufa, Russian Federation.

CHEK2 is a tumor suppressor gene, which participate in the inhibition of cell cycle and apoptosis following DNA damage. Mutations in CHEK2 are associated with cancers at many sites, including breast and ovarian cancers. Different CHEK2 mutations have a particular range and frequency in various populations. Previously four mutations in CHEK2 (1100delC, IVS2+1G>A, del5395, I157T) were genotyped in BC and OC cases. In this study we analyzed mutation p.R145W in 977 BC cases, 243 OC cases and 689 cancer free controls. Detection of mutation was performed by high resolution melting curve analysis (HRM) and confirmed by direct sequencing. The p.R145W mutant form within the FHA domain Chk2 cannot be phosphorylated at ATM-depended phosphorylation site and cannot be activated by gamma radiation.

CHEK2 p.R145W mutation was found in two ovarian cancer patients (0,8%) from different ethnic groups, but it wasn't detected among patients with breast cancer and control. Thus, the p.R145W variant is rare in the population of the Bashkortostan Republic and determination of this variant in clinic should not be recommended in our population.

This study was supported by RFBR-Povolzhye 12-04-97026.

Alterations of expression levels of group of miRNA genes and the protein-coding genes RAR-beta2, and NKIRAS1 in lung, kidney and breast tumors.

***E. A. Braga**[1], I. V. Pronina[1], T. P. Kazubskaya[2], V. I. Loginov[1];*

[1]Medical Genetic Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation, [2]Blokhin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation.

The alterations of expression levels of miRNA genes: *miR-129-2*, *miR-24-2*, *miR-17*, and *miR-9-1* and protein-coding genes: *RAR-beta2*, and *NKIRAS1* (potential target genes of *miR-17* and *miR-9-1*) were determined in non-small cell lung cancer (NSCLC) including adenocarcinoma (AD) and squamous cell carcinoma (SCC), clear cell renal cell carcinoma (ccRCC) and in breast cancer (BC). Significant ($P \leq 0.05$ by Fisher) prevalence of cases with increased expression of *miR-24-2 in* AD and with reduced expression of miR-17 in SCC and BC was revealed. Significant prevalence of elevated gene expression of *NKIRAS1* was shown in NSCLC, including SCC and AD, but a reduced expression of *NKIRAS1* was shown in ccRCC. Significantly increased expression of *RAR-beta2* predominated in ccRCC and NSCLC. For the first time, statistically significant negative correlation ($P \leq 2 \times 10^{-12}$ by Spearman) between alterations of expression levels of *miR-17* and its potential target genes *RAR-beta2* and *NKIRAS1* in NSCLC, as well as between expression level alterations of *miR-17* and *NKIRAS1* in BC was found, that is consistent with the known mechanism of suppression of protein coding genes expression under the action of miRNAs. These results also argue in favor of bioinformatics data that mRNA of *RAR-beta2* and *NKIRAS1* are potential targets of *miR-17*.

Identification of mutations associated with increased risk of hereditary breast and/or ovarian cancer in Colombia.

***L. Cifuentes**, C. Cortés, A. Rivera, G. Barreto;*

Universidad del Valle, Cali, Colombia.

Breast cancer is the neoplasm with the highest incidence and mortality among women in Colombia. With the aim to determine the mutacional incidence in BRCA1 and BRCA2 genes we analyzed by sequencing a total of 111 high-risk breast and/or ovarian cancer families from Colombia. Seven families were found to carry BRCA1 mutations and eleven families had BRCA2 mutations. For BRCA1 we found nine variants of uncertain significance (VUS), of which we concluded, using in silico analysis (Polyphen2, FastSNP and NNsplice), that IVS2-12C>G, T790A, R959K and E1345K are probably pathogenic. In BRCA2, we found five variants of uncertain significance (VUS), four previously described and one novel mutation (6655 T>C); using in silico analysis we concluded that 1093 A>G and 6655 T>C are probably pathogenic and 3199 A>G and IVS4-89 T>C are probably neutrals. We identify also 11 polymorphisms, 2 of them associated with a moderate increase in breast cancer risk (BRCA2 N372H and IVS21-66T>C). Our results indicate that the Colombian population has a heterogeneous spectrum of prevalent BRCA mutations.

Mapping of the small 5q deleted segment in myeloid malignancies using molecular cytogenetic techniques

***J. Brezinova**[1], M. Novakova[2], A. Oltova[3], I. Sarova[1], S. Ransdorfova[1], S. Izakova[2], E. Malinova[2], G. Vankova[3], Z. Zemanova[2], D. Bystricka[2], J. Cermak[1], K. Michalova[1,2];*

[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [2]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General Teaching Hospital and First Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Center of Molecular Biology and Gene Therapy, The Universiry Hospital Brno, Brno, Czech Republic.

Deletion 5q is frequently found in bone marrow cells of patients with myelodysplastic syndrome and acute myeloid leukemia. The size of deletion varies among the patients with the most frequent breakpoints in 5q13 in proximal and 5q33 in distal region. The aim of this study was the mapping of small deleted segments of chromosome 5 in five patients with myeloid malignancies, suspected by classical cytogenetics (CC). Combination of FISH with DNA LSI probes for 5q31/q33 regions (Abbott Molecular, Kreatech Diagnostics), thirteen BAC probes (BlueGnome) for 5q15-5q34 regions, multicolor banding for chromosome 5 (MetaSystems) and aCGH (Cytochip Focus Haematology, BlueGnome) revealed the small deletion in three patients (range 12 Mb to 23 Mb, located between bands 5q31.2-5q34) and a larger deletion in size of 48 Mb (bands 5q15-5q32) in one patient. In patient No. 5 the karyotype 46,XY,del(5)(q31q33) was identified by CC, but the molecular cytogenetic techniques proved the large deletion in size of 70 Mb. This discrepancy was caused by the cryptic translocation - a part of the long arm of chromosome 11 was translocated on the deleted long arm of chromosome 5 (partial trisomy of 11q). Most of the genes localized near the breakpoints are involved in the cell cycle regulation and their role in the malignant transformation will be discussed.

Our study confirmed the relevance of molecular cytogenetic techniques in detection of small deletions that can be overlooked by classical cytogenetic analysis.

Supported by MHCR project for conceptual development of research organization 00023736 and PRVOUK- P27/LF1, RVO-VFN64165/2012, P302/12/G157.

β-adrenoreceptor antagonists reduces cancer cell proliferation, invasion, and migration in *in vitro*

*O. Darcansoy Iseri[1], **F. I. Sahin**[2], Y. K. Terzi[2], E. Yurtcu[3], R. Erdem[4], F. Sarialioglu[5];*

[1]Baskent University Institute of Transplantation and Gene Sciences, Ankara, Turkey, [2]Baskent University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, [3]Baskent University Faculty of Medicine Department of Medical Biology, Ankara, Turkey, [4]Baskent University Faculty of Medicine Department of Pharmacology, Ankara, Turkey, [5]Baskent University Faculty of Medicine Department of Pediatrics, Ankara, Turkey.

In the present study we aimed to investigate efficacy of propranolol (non-selective antagonist), atenolol (β1-AR antagonist), and ICI118,551, (β2-AR antagonist) on cell proliferation, migration and invasion of non-stimulated breast (MCF7), colon (HT-29), and hepatocellular (HepG2) cancer cells. According to real time PCR, all cell lines expressed β-ARs. Inhibitory concentration 50 (IC_{50}) values from MTT assay revealed that the ICI118,551 was the most cytotoxic, whereas atenolol was the least effective β-blocker for

24, 48, and 72 h. Efficacy of propranolol and atenolol on MCF7 and HT-29 cells were time dependent. Boyden chamber assay demonstrated that cell invasion was inhibited by ICI118,551 (45%, 46%, and 50% for MCF7, HT29, and HepG2, respectively) and propranolol (72%, 65%, and 90% for MCF7, HT29, and HepG2, respectively) applications. Results of the in vitro scratch assay demonstrated that, propranolol and atenolol reduced migration of MCF7 and HT-29 in concentration dependent manner, wehereas inhibitory effect of ICI118,551 on cell migration was time dependent. ICI118,551 had concentration dependent inhibitroy effect on HepG2 migration, wheras effects of propranolol and atenolol were time dependent. β2-blocker seems to be the most cytotoxic β-blocker on non-stimulated cancer cells. Propranolol and ICI118,551 were more effective than atenolol in inhibiting invasion and migration of non-stimulated MCF7 and HT-29 cells; ICI118,551 being the most potent. Concordantly, β2-selective blockage seems to be more effective for non-stimulated cells. Furthermore, effect of the selective antagonsits may show variation depending on the concentration and time, as well as histological origin of cells.

J11.22
mir-140 is a Candidate Regulator of IGFBP5 Expression in Breast Cancer

G. Güllü[1], *i. Peker*[1], *A. Haholu*[2], *C. Erzik*[1], *Z. Küçükodacı*[2], *H. Baloğlu*[2], *A. S. Özer*[1], *M. Akkiprik*[1];
[1]*marmara university medical biology, istanbul, Turkey,* [2]*Haydarpaşa Gülhane Military Medicine School Pathology, istanbul, Turkey.*

IGF binding protein 5 (IGFBP5), an IGF system member, can show activity either IGF-dependent or independent, it also can show different effects on apoptosis, cell motility and survival in breast cancer. IGFBP5 inhibits cell growth in vivo and in vitro in human breast cancer. It is also associated with metastasis, poor prognosis and clinical outcome. The cellular localization of IGFBP5 affects its function in cell.
Experimentally shown that microRNA-140 (miR-140) targets IGFBP5. MiR-140 over expression leads to suppression of IGFBP5 expression and the suppression of miR-140 leads to over expression of IGFBP5.
In this study, tissue sections of the patients (n=29) with breast cancer and pheripheral normal tissue samples (n=11) analyzed by immunohistochemical assay to define IGFBP5 expression. IHC analysis also confirmed with mRNA RT-PCR. MiR-140 expression is later analyzed with Real-Time Polymerase Chain Reaction (RT-PCR). Statistical significance analyzed with Mann Whitney U test and Fisher's exact test.
We found that all IGFBP5 negative tumors express miR-140 (10/10) ; and IGFBP5 positive tumors are negative for miR-140 expression (11/19) (p=0.0035). miR-140 expression levels of IGFBP5 negative tumors is 82 fold higher than IGFBP5 positive tumors (p=0.0434). In terms of molecular subtypes of breast cancer, in 90% of the Luminal B type tumors, miRNA-140 expression was observed to be positive.
This is the first demonstration of the association of miRNA-140 with IGFBP5 expression in breast cancer tissue samples. Larger group of samples are needed to define the association of miR-140 expression levels with clinopahtological factors.

Cancer predispositions and intellectual disability: two sides of the same coin?

A. A. Kattentidt, *A. S. Brooks, C. van der Meer, J. M. Collee, M. E. H. Simon, A. Wagner; Erasmus Medical Centre, Rotterdam, Netherlands.*

The advent of array CGH raises the possibility for identification of cancer predispositions in patients with unrelated disorders such as intellectual disability or congenital anomalies. At our department two patients were analysed because of intellectual disability and birth defects. The first patient was diagnosed with an atypical 22q11 deletion, including the *SMARCB1* gene, associated with an increased risk for malignant rhabdoid tumors in children. The second patient was diagnosed with a proximal 1p36 deletion, including the *SDHB* gene, associated with a Hereditary Paraganglioma-Pheochromocytoma Syndrome. Both patients were asymptomatic for the cancer syndrome, but had an indication for surveillance now.
The third patient was analysed because of gastric cancer. Furthermore he had a (moderate) intellectual disability. Tumor analysis showed an MSI-High phenotype and loss of MSH2 and MSH6 protein staining. Additional analysis showed a 4.5 Mb deletion on chromosome 2, including the *MSH2*, *MSH6* and *NRXN1* gene. So Lynch syndrome was diagnosed in this patient. But, co-incidentally, the cause of intellectual disability was diagnosed as well. *NRXN1* deletions are associated with intellectual disability, developmental delay and psychiatric disorders.
We demonstrate that cancer predispositions can be unexpectedly diagnosed in patients with microdeletion syndromes. On the other hand, in our cancer patient the etiology of his mental retardation was found co-incidentally. Both scenario's require careful counselling of a patient and his family and may lead to additional surveillance or treatment. As unexpected findings may be considered as undesirable, we demonstrate that they can have important consequences for the patient and family members.

The Percentage of Informative STR Markers in the Turkish Population

A. Ozturk Kaymak, *C. Sonmez, S. Oztomurcuk, E. Ozcan;*
Department of Medical Genetics Ministry of Health, Dr. A.Y. Demetevler Oncology Training and Researc, Ankara, Turkey.

Multiplex fluorescent short tandem repeat (STR) analysis was used for assessing the the origin of cells after allogeneic haematopoietic stem cell transplantation. DNA was extracted from whole blood or whole bone marrow using the Rosche Blood Kit (Rosche,Germany) according to the instructions presented by the manufacturer. This column exchange. Spectrophotometry was used for DNA quantification. Polymorphic STR markers were obtained using the Promega PCR amplification kit. The following sixteen STR markers were amplified: D3S1358, FGA, D5S818, D7S820, D8S1179, vWA, D13S317, D18S51, D21S11 CSF1PO, THO1, TPOX, D2S1338, D16S539, D19S433 and Amelogenin. We followed up 61 patients within three years. We found informative markers for Turkish patients. All STR markers were informative over 50%. Eleven of STR markers were informative over 60%. Nine of STR markers were informative over 65%. Four of STR markers were informative over 70%. Two of them STR markers were informative over 75%. We showed all these table1. The most informatitive STR markers are D18S51 and D5S818 for Turkish population. Chimerism testing can be cost effective if kits could be designed according to ethnic origin.

The study of K562 cells genetic instability

V. A. Nikitina, *A. I. Chausheva, L. D. Katosova, V. I. Platonova, S. I. Kutsev;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

Resistance to tyrosine kinase inhibitor (TKI) is a major problem in the chronic myeloid leukemia (CML) therapy. There are BCR-ABL related and unrelated mechanisms of resistance which include BCR-ABL gene amplification, additional chromosomal abnormalities, duplication of Ph-chromosome, alternative signaling pathways genes mutations that underlie failure of therapy. Widespread use of K562 as a model to study efficiency and resistance to anticancer therapy has been determined the need for studying dynamics of genetic instability K562.
The aim of this continuing investigation is the study of mutagenesis endpoints in K562 cell line with exposure to TKI. To estimate K562 mutagen sensitivity the treatment with nonspecific prooxidant mutagen drug, dioxidine, will be used before and after selection of resistant cell clones.

At present we have began the first phase of this investigation to estimate the parameters of genetic stability before TKI treatment. We have assessed baseline and dioxidine (0.1mkg/ml) induced levels of DNA damage by alkaline comet assay and frequency of micronucleus by cytohalasin B micronucleus test. The levels of baseline DNA damage in K562 were 2.71% (%tail DNA), 0.60 a.u. (tail moment), 0.70 a.u. (olive tail moment), and after dioxidine exposition these parameters were 4.35%, 1.66 and 1.33 a.u., respectively. The frequency of baseline micronucleus in the mononuclear cells was 25‰, binuclear cells – 9‰, and after dioxidine treatment – 15‰ and 7‰, respectively.
Further research parameters of K562 cells genetic instability in different conditions will be important to identify mechanisms of CML progression and development of resistance to targeted therapy.

High Resolution Copy Number Variation Analysis using Droplet Digital PCR

J. R. Berman, *J. Regan, N. Heredia, L. Montesclaros, S. Hodges, D. Skvortstov, S. Tzonev, G. Karlin-Neumann, E. Hefner;*
Digital Biology Center, Bio-Rad Laboratories, Pleasanton, CA, United States.

Copy number variation (CNV) is a prominent source of inter-individual variability in the human genome. CNV has also been associated with neurologic disease, autoimmunity, and adverse drug response, while specific gene amplifications in cancer cells drive tumor progression and influence treatment outcomes. Current methods to analyze CNV, including SNP-based microarrays, comparative genomic hybridization, and qPCR, lack the sensitivity and fine quantitative discrimination required for advanced CNV analysis. This is particularly true in heterogeneous samples and samples with higher order copy number states.
Droplet digital PCR (ddPCR) enables accurate and reproducible copy number determination using a simple, cost-effective workflow amenable to high throughput. Using single-well ddPCR, consecutive copy number states can be distinguished between samples of 5 and 6 copy number at 95% confidence levels. Here we present use of ddPCR to discriminate copy number status of multiple genes with low to high copy number states, including CYP2D6, MRGPRX1, and CCL3L1. We also apply ddPCR to the evaluation of challenging cancer sample types, including samples with higher order amplifications of genes such as MYC and FGFR2. The high resolution of ddPCR CNV analysis will be demonstrated using mosaic or admixed samples heterogeneous for copy number status.

Next generation digital PCR technology: A simple, chip-based nanofluidic system for any benchtop.

P. Hegerich, *J. Wilde;*
Life Technologies, Foster City, CA, United States.

Digital PCR enables specific nucleic acid sequences to be accurately and precisely quantified without the need for a reference. This ability for absolute quantification is key to applications such as pathogen quantification and GMO detection. With the advent of novel nanofluidic PCR technologies, running the hundreds to thousands of reactions required for digital PCR has become feasible. To this end, Life Technologies has developed a new silicon chip-based digital PCR solution that can be rapidly loaded with little to no dead volume. At the heart of the nanofluidic system is a small chip that enables 20K reactions to be run on a single sample. Working with external collaborators, we will be demonstrating the performance and utility of the system across a wide variety of applications and sample types, such as the detection and enumeration of low frequency somatic mutations from various cancers.
"For Research Use Only. Not for use in diagnostic procedures."

Description of PTEN gene mutation in Saudi women with endometrial cancer

W. Al harbi[1], *M. Albalwi*[2], *F. Safi*[2], *A. Kushi*[2], *I. Alabdulkareem*[1];
[1]*King Abdullah internationla medical Research Center; NGHA, Riyadh, Saudi Arabia,* [2]*King Abdulaziz Medical City; NGHA, Riyadh, Saudi Arabia.*

Phosphatase and tensin homolog (PTEN) gene is tumor suppressor gene is mutated in a large number of cancers including endometrial cancer. It is located on Chromosome 10q23.3 and encodes for lipid phosphatase that involved in regulates cell cycle and apoptosis. This study was carried out to investigate the role of PTEN in Endometrial cancer (EC) that is the most abundant female gynecologic malignancy. The median age of patients is 63 years.
DNA was isolated from paraffin embedded sections for 48 Saudi women with EC followed by PCR-SSCP analysis and direct DNA sequencing was performed for all exons.
Four novel mutations in PTEN gene were detected in exons 1, 2, 3, 4, 5a, 5b, 6, 7, 8a, and 9. The majority of them (70%) were missense (c.440del A) (c.440A>G) and frameshift mutations (c.440del AA) (c.440del AG). A deletion of codon 420 (c.420del A) were observed in (62.5%) while missense mutations (c.297-298del C) (c.297-298 C>G) and frameshift mutations (c.297-298del AC) present (60.4%) of the patients. More than half of screened DNA (54.1%) revealed a stop codon at 465 site (c.465del T) in the most exons.
These results may apply as a valuable marker to correlate the disease severity and alterations in PTEN gene. Further study from new EC patients at KAMC will add more into PTEN role in this devastating disease.

Gene expression of HIF1A, HIF2A and HIF3A in laryngeal carcinoma cells

T. E. Goranova[1], *G. Stancheva*[1,2], *A. Mitkova*[1,2], *V. Mitev*[1,2], *R. Kaneva*[1,2], *I. Chalakov*[3], *T. Popov*[3];
[1]*Molecular Medicine Center, Medical University – Sofia, Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical University - Sofia, Sofia, Bulgaria,* [3]*Department of ENT, Clinic of ENT, UMHAT ''Tsaritsa Yoanna – ISUL'', Sofia, Bulgaria.*

Hypoxia-inducible factors (HIFs) are heterodimeric proteins that mediate the adaptive response of cells to the reduced oxygen level, which is a substantial feature of tumours. There are three forms of HIFs that differ in their alfa-subunits. While HIF1A is ubiquitously expressed, HIF2A and HIF3A appear to have a cell-specific expression. However, there are no clear data about the expression of the three HIF-As in laryngeal carcinoma.
In the present study we analyzed the expression of HIF1A, HIF2A and HIF3A genes in 60 tumour and their matched normal laryngeal tissues. The expression was studied by real-time PCR and beta-actin was used as a housekeeping control gene.
HIF1A was overexpressed in 41 out of the 60 (68.3%) laryngeal tumours. In the case of HIF2A higher levels of mRNA were detected in 7 (11.7%) cancer tissues, while a decrease compared to normal tissues was found in 23 (38.3%) tumours. In 45 (75%) carcinoma tissues HIF3A was underexpressed; only 5 (8.3%) tumours showed increase in HIF3A levels. When the three forms were analyzed together, it was found that the most common combinations were: high HIF1A with low HIF3A (19 cases) and high HIF1A with low HIF2A and low HIF3A expression (12 cases).
Our results showed that in laryngeal carcinoma cells the expression varied among HIF-A genes. Comparison with clinical features of the patients might elucidate these variations and their importance for tumourigenesis.

J11.30
Evaluation of KIT gene splice variants GNNK+ and GNNK- expression in gastrointestinal stromal tumors (GISTs).

A. Gaponova[1,2], *T. Kekeeva*[1,2], *L. Zavalishina*[1], *Y. Andreeva*[1], *G. Frank*[1];
[1]*Herzen Moscow Oncological Research Institute, Moscow, Russian Federation,* [2]*Russian State Medical University, Moscow, Russian Federation.*

GISTs are the most frequent mesenchymal neoplasms arising in digestive tract. 60-89% of GISTs are caused by oncogenic mutations in *KIT* gene, 5% - by mutations in *PDGFRA*. The *KIT* pre-mRNA alternative splicing site is located at the 3' end of exon 9 and results in the expression of two isoforms GNNK- and GNNK+ with different biological activities. The GNNK- isoform has a greater oncogenic potential than GNNK+.

Analysis of mutations in 64 GIST samples was conducted by PCR following by sequencing. Isoform expression analysis was perfomed by RT-PCR. The assessment of isoforms expression was conducted by allele-specific PCR following by fragment analysis.
We observed mutations in 56/64 (88%) tumors (*KIT* exon 9 – 14%, exon 11 – 56%, exon 13 - 2%, exon 17 – 2% , *PDGFRA* exon 18 – 14 %).
We estimated the expression of both alleles (wild type and mutant allele) for each splicing isoform in 9 GIST samples with mutation in *KIT* exon 9 (p.A502_Y503dup). There are 4 possible combinations of *KIT* splice variants and its alleles: GNNK+ with or without duplication in 9 exon *KIT* and GNNK- with or without duplication. GNNK + expression without duplication notably higher than GNNK + with duplication. Expression of GNNK- isoform with duplication and without duplication is approximately equal. Expression of GNNK- with duplication higher than expression GNNK + with the same mutation.
Thus mutant allele is predominantly expressed in GNNK- form and wild type allele in GNNK+ form. The meaning of this finding demands further investigations.

GSTM1 gene deletion as potential indicator of risk of childhood ALL development in Serbian population

R. Milicevic[1], *B. Popovic*[2], *L. Brankovic*[1], *H. Stamenkovic*[1], *D. Jugoviovic*[1], *D. Radulovic*[1], *J. Milasin*[3];
[1]*Pediatric Clinic, Nis, Serbia,* [2]*Institute of Human Genetics, School of Dentistry, University of Belgrade, Belgrade, Serbia,* [3]*Institute of Human Genetics, School of Dentistry, University of Belgrade, Belgrade, Serbia.*

The human glutathione S-transferases (GSTs), possess both enzymatic and non-enzymatic functions and are involved in many important cellular processes, such as phase II biotransformation of chemicals, stress response, cell proliferation, apoptosis, drug resistance etc. The nonenzymatic functions of GSTs involve their interactions with cellular proteins, such as, JNK,TRAF, ASK, PKC, and TGM2. In humans, 4 major subfamilies of GSTs can be distinguished and are designated as GSTa, GSTμ, GSTu, and GSTp. Within the GSTμ subfamily, the gene coding for GSTM1 exhibits a deletion polymorphism, which in the case of homozygosity (GSTM1 null genotype) leads to the absence of enzymatic activity. The aim of the present study was to determine the frequency of GSTM1 deletions and a possible association of this polymorphism with increased risk for childhood acute lymphoblastic leukemia (ALL) in Serbian population. PCR analysis of the GSTM1 gene was performed on DNA obtained from 60 ALL patients and 182 healthy individuals. The following genotype frequencies were found: 57% for the GSTM1 null genotype and 43% for GSTM1+/+ and GSTM1+/- genotypes in the group of ALL patients. Genotypes in the control group were: 34% for the GSTM1 -/- genotype and 66 % for the GSTM1+/+ and GSTM1+/- genotypes. The difference between the frequency of the "null genotype" in the ALL group and in the control group was statistically significant. The null genotype was associated with a 2.5 fold increase of the risk (OR 2.53, 95% CI 1.395-4.591, p=0.002) of developing ALL in Serbian population.

Two novel germline mutations of *MLH1* and IHC result in two siblings of a Thai family with young-onset nonpolyposis colorectal cancer

A. Tunteeratum, *C. Kunasol, N. Jinawath, A. Jinawath, J. Eu-ahsunthornwattana, M. Busabaratana, K. Srichan, T. Sura;*
Faculty of Medicine Ramathibodi hospital, Mahidol University, Bangkok, Thailand.

Background: Hereditary nonpolyposis colorectal cancer (HNPCC) or Lynch syndrome I (OMIM#120435) is an autosomal dominant trait and caused by a germline mutation in mismatch repair (MMR) genes**.** HNPCC is caused by mutations in the *MSH2* and *MLH1* genes which may account for 60% and 30% of HNPCC cases, respectively.
Objective:
1. To study the incidence and correlate the genotype-phenotype relationship of germline mutation in *MLH1* and *MSH2*
2. To correlate IHC result and germline mutation in *MLH1* and *MSH2*
3. To encourage genetic testing for *MLH1* and *MSH2* in at-risk pre-symptomatic patients.
Methods: Direct whole gene sequencing in *MLH1* and *MSH2* was applied in all cases of age < 50 years, nonpolyposis CRC after confirmed by tissue pathological report. Their tissues were also tested IHC. Their relatives at-risk would also be encouraged to have genetic test and an appropriate cancer surveillance program.
Results: In a family which fit to AmsterdamII criteria, we found CC deletion at c.1404 and G deletion at c.2210+1 in *MLH1* of two siblings. IHC result also showed absent of MLH1 protein expression. These are novel changes causing frameshift mutation in both MMR genes without clinical difference.
Conclusion: HNPCC is a genetically heterogeneous disease**.** Our preliminary result revealed two new disease-causing mutation in *MLH1*. Germline analysis may help us screen in pre-symptomatic cases and offer an appropriate cancer screening program. This will help the susceptible patients to receive early diagnosis and treatment before developing an advanced CRC.

Screening of the most frequent mutation of IDH1 gene in Turkish Glioblastoma Multiforme patients

C. Sümer[1], *H. Turgutalp*[2], *E. Kalay*[1], *B. Toraman*[1], *B. Yücel*[1], ***F. Celep Eyüpoğlu***[1];
[1]*Karadeniz Technical University Faculty of Medicine Department of Medical Biology, Trabzon, Turkey,* [2]*Karadeniz Technical University Faculty of Medicine Department of Medical Pathology, Trabzon, Turkey.*

Glioblastoma Multiforme (GBM) derived from glial cells is one of the most frequent and malignant brain tumors classified as grade IV by WHO (World Health Organization) accounts for 40% of CNS tumors. Mutations of IDH1, most commonly resulting in replacement of arginine at position 132 by histidine (p.R132H) have been described in WHO grade II, grade III diffuse glioma and secondary glioblastomas. In our study, exon 4 of IDH1 gene was sequenced by direct sequencing using DNAs obtained from paraffin embedded archival materials belongs to 54 patients diagnosed as GBM in Medical Pathology. The correlation between IDH1 mutations and age of patients was evaluated. As a result of this study, IDH1 c.395G>A (p.R132H) mutations were detected in 5 of 54 glioblastomas and the mutation frequency was found as 9.3%. The average age of the patients harboring the p.R132H mutation was calculated 46 while the average age of patients without this mutation was 56. There is no statistical significance between average age of the patients and IDH1 p.R132H mutation (Mann Whitney, p=0.078). As there is not any conducted study on genetic of the GBM in the Black Sea Region of the Turkey, this study is important and it is very unique to our region. In our ongoing study, the other exons of IDH1 gene are being sequenced.

A rare case of gastric juvenile polyposis

V. Rivero-Perdomo[1], *J. Pérez-García*[1], *Ó. Bengoechea-Miranda*[2], *J. Blázquez-Román*[1], *R. Vidal-Tocino*[3], *R. González-Sarmiento*[4];
[1]*Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Servicio de Anatomía Patológica. Hospital Clínico Universitario de Salamanca, Salamanca, Spain,* [3]*Servicio de Oncología. Hospital Clínico Universitario de Salamanca, Salamanca, Spain,* [4]*Unidad de Medicina Molecular. Facultad de Medicina. IBMCC-IBSAL., Salamanca, Spain.*

Introduction: Juvenile polyposis (JP) is a form of gastrointestinal polyposis characterized by the development of multiple hamartomatous non neoplastic polyps and predisposition to gastrointestinal cancer at an early age. In most cases polyps are present in the colon and less frequently, in the stomach and small intestine. Most of the cases of juvenile polyposis have mutations in one of the the genes associated with the disease BMPR1A, SMAD4 and PTEN. A porportion of patients with JP (20-50%) shows autosomal dominant heredity. We present a case of a 27 years-old male with gastric polyposis (JPS) diagnosed by endoscopic examination with many inflammatory hyperplastic polyps. These multiple polyps located only in the stomach appeared in a period of time less than six months. There was not family history of polyposis.
Materials and Methods: We studied SMAD4 gene in genomic DNA from this patient by PCR and subsequent automatic sequencing with Big Dye Terminators.
Results: We have detect a pathogenic c.538C>T mutation in exon 4 of SMAD4 gene that generate a truncated protein p.Q180STOP. This mutation has been previously reported in a case of colon polyposis. Nevertheless, SMAD4 gene mutations are not associate to gastric polyposis. To the best of our knowledge this is the second reported case of SMAD4.

The role of determining the status of KRAS gene in colorectal cancer

D. Caban, *A. Merkler, H. Ljubić, J. Jakić-Razumović, S. Pleština, J. Sertić;*
University Hospital Centre Zagreb, Zagreb, Croatia.

Introduction and aim: Colorectal cancer (CRC) is one of the most highly malignant tumors and is among the leading causes of death in developed countries. A very complex and longlasting process, closely related to interaction of external and genetic factors, contributes to development of this malignant disease. Activation of the KRAS oncogene is of importance in colorectal carcinogenesis.
Methods: Surgically resected colorectal cancer tissue, embedded in paraffin sections, was used for molecular analysis of the KRAS gene. DNA isolation is performed using cobas® DNA Sample Preparation Kit. The status of the KRAS gene is determined by real-time polymerase chain reaction method - Real Time PCR (cobas® 4800 System) with cobas® KRAS Mutation Test CE-IVD which is used for detection of somatic mutations of the KRAS gene.
Result: Out of the total of 40 analyzed colorectal cancer tissue samples, point mutation on codons 12, 13 or 61 was detected in 18 samples (45%). On codons 12 and 13 mutation was determined in 16 patients, and two patients had mutation on codon 61.
Conclusion: The presence of point mutations on codons 12, 13 and 61 of the KRAS gene in colorectal cancer is predictive of the lack of response to therapy with new drugs, and is determined in all patients eligible for immunotherapy. Personalized approach to CRC treatment helps avoid unnecessary side-effects and toxicity, and optimize costs in healthcare system. Combination of target therapy with predictive biomarkers improves efficacy in target patient group and the patients' benefit from applied drugs.

XRCC1 Arg194Trp and Arg399Gln polymorphisms and malignant lymphoma risk

C. Banescu[1], *A. Crauciuc*[2], *S. Demian*[3], *I. Macarie*[3], *A. Todoran*[1], *C. Duicu*[4], *M. Dobreanu*[5];
[1]*Genetic Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [2]*University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [3]*Hematology Clinic 1, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [4]*Pediatric Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [5]*Department of Clinical Biochemistry and Laboratory, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.*

X-ray repair cross-complementing group 1 (XRCC1) is a key
component of the base excision repair system. Defects in this pathways are involved in cancer pathogenesis. Therefore, XRCC1 gene polymorphism may be involved in lymphoma susceptibility. Our study aimed to evaluate the relationship between XRCC1 Arg194Trp and Arg399Gln polymorphisms and malignant
lymphoma in a Romanian population.Material and method: One hundred and nine patients with malignant lymphoma and two hundred healthy individuals were enrolled in the study as controls. The XRCC1 polymorphisms were genotyped in all patients and
controls by PCR-RFLP assays.Results: We observed that XRCC1 194Trp variant allele was more frequent in the study group with malignant lymphoma compared to controls (p = 0.003, OR = 7.78 CI = 3.85 - 18.25). Our study revealed an increased risk for lymphoma, for homozygous (Trp/Trp) variant genotypes for XRCC1 Arg194Trp
polymorphisms (p = 0.001, OR =0.23, CI = 0.11 - 0.46). Our study did not reveal an increased frequency of the XRCC1 399Gln variant allele in the malignant lymphoma group compared to controls (p =
0.082), therefore this polymorphism could not be considered a risk factor for lymphoma. Conclusions: Our study suggests that the Arg194Trp polymorphisms of the XRCC1 gene may contribute to the risk of developing malignant lymphoma.

Novel germline mutation in *MSH6* gene in a large Spanish family with Lynch Syndrome

C. de Diego[1], *R. Álvarez-Cabellos*[2], *Y. Campos-Martín*[3], *R. Rodríguez-Merlo*[3];
[1]*Hospital Virgen de la Salud, Genetics, Toledo, Spain,* [2]*Hospital Virgen de la Salud, Oncology, Toledo, Spain,* [3]*Hospital Virgen de la Salud, Pathology, Toledo, Spain.*

Approximately 10% of Lynch Syndrome (LS) families have a germline mutation in *MSH6* gene. We present here a LS family with a new mutation in *MSH6* gene where affected family members showed both colonic and extracolonic tumors (colon, endometrial and gastric). Tumor analyses resulting on microsatellite instability and negative immunohistochemical stain (absence) are frequent features but not always present in all patients with *MHS6* germline mutations. We performed both tumor analyses in a patient who fulfilled Bethesda criteria for Lynch syndrome to find out if could exist some germline mutation in one of the disease-causing genes. Patient's tumor showed both microsatellite instability (IMS) and no immunohistochemical (IHC) staining for *MSH2* and *MSH6* and these findings led us to look for mutations in *MSH2* and *MSH6* genes. Genetic analyses were negative for *MSH2* gene, however one new protein-truncating mutation, c.1894_1912del19 leading to p.Lys632fsX641, was identified in *MSH6* gene in the probandus patient. Related family members both affected by Lynch Syndrome and nonsymtomatic patients were screened for the new identified mutation with the aim to asses in genetic counselling. This novel mutation in *MSH6*, the less frequent LS gene related, is being reported and submitted to the current databases to provide additional information to the genotype-phenotype in LS. Finally, our results emphasize the suitability of a combined IHC and IMS screening as a pre-selection tool previous to genetic analysis in LS.

Allele p.Leu1007fsinsC of NOD2 gene is not correlated with the differentiated thyroid cancer among Polish population.

J. Hoppe-Gołębiewska[1], *K. Ziemnicka*[2], *M. Kaczmarek-Ryś*[1], *S. Hryhorowicz*[3], *A. Pławski*[1], *M. Gołąb*[2], *M. Szkudlarek*[2], *M. Ruchała*[2], *R. Słomski*[1,4];
[1]*Institut of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [2]*The Department of Endocrinology and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [3]*The Nanobiomedical Center, Adam Mickiewicz University, Poznań, Poland,* [4]*The Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.*

Many research in the field of oncology suggests that cancer arises from chronicle inflamed tissues. The NOD2 gene variants have been associated with susceptibility to inflammatory bowel diseases, but also was correlated with increased risk of some cancer types, in particullar p.Leu1007fsinsC variant was associated with colon cancer, lung cancer and ovarian cancer, early-onset laryngeal cancer and, breast cancer in the presence of DCIS.
Papillary and follicular thyroid carcinomas are the most frequent in endocrine system with still unidentified genetic background and 7 fold higher prevalence in women considering Polish polpulation. According to literature, one of the risk factor for thyroid cancer developing (particularly papillary carcinoma) is a history of thyroid inflammation.
The aim of the study was the analysis of 3020insC (rs5743293, p.Leu1007fsinsC) mutation among Polish patients with differentiated thyroid cancer.
DNA was extracted from whole blood leukocytes of 598 patients diagnosed with differentiated thyroid cancer (521 females and 77 males). The population group included 701 subjects (435 females and 266 males). To perform genotyping we used the pyrosequencing (PSQ96). The chi-square statistic was used to evaluate differences in genotypic and allelic frequency between patients and population group.
We didn't observed significant differences in allele frequencies in patient with differentiated thyroid cancer and population group (p=0,391). Occurrence of the insertion allele did not affect the age of onset and no major differences in the statistical analysis of the prevalence of this allele in men and women separately.

BACKGROUND: The Anaplastic lymphoma receptor tyrosine kinase (**ALK**)

gene rearrangements represent a recently identified molecular target in a subset of patients with non-small-cell lung cancer (NSCLC). EML4-ALK fusion oncogene has been reported in 2-13% of patients with **NSCLC**.
AIMS: The aims of this study are to study the ALK rearrangement in patients with non-small-cell lung carcinomas (NSCLCs) and find the frequency of this mutation in Turkish population.
MATERİAL AND METHODS: The study included samples from a large unselected 192 patients with a referred diagnosis of non-small cell lung cancer. Median age was 58,06±11,66 years (range 17-87), and sixty-seven percent were male. ALK fluorescence in-situ hybridization (FISH) was performed using the ALK break-apart probe set (Vysis). The cases with more than 15% break-apart signals in 50 evaluated cells were defined as ALK-positive.
RESULTS: We found twenty-two (10.5%) **ALK**-positive cases, and the median age was 62,05±11,36 years (range 34-75) in this group. Among 22 abnormal samples, fourteen were male and eight were female. The ALK positivity frequencies were 10,9% in male and 12,5% in female patients. The median ages in male and female ALK positive groups were 64,57±9,17 years (range 43-75) and 57,62±13,85 years (range 34-70) respectively.
CONCLUSIONS: The frequency of ALK gene rearrangement detected by FISH was found as 11,45% in a large unselected NSCLCs series in Turkey. Our result is concordant with other publications and being the first ALK prevalence report in Turkish NSCLC patients.

Association of polymorphic markers of xenobiotics biotransformation genes, tp53 and mdm2 genes with nonsmall cell lung cancer in russians of moscow region

***M. V. Atkarskaya**, A. Burdennyy;*
IBCHPH RAS, Moscow, Russian Federation.

An association of *+/-* polymorphic markers of *GSTM1* and *GSTT1* genes, polymorphic markers *Ile105Val* of *GSTP1* gene, *Arg72Pro* of *TP53* gene and *T309G* of *MDM2* gene with risk of non small cell lung cancer has been studied in Russians of Moscow region. We found a significant association of null genotype of *GSTT1* gene with non small cell lung cancer, adenocarcinoma and squamous-cell carcinoma (OR=3.28, OR=5.43 and OR=2.9, respectively). We have also showed a significant association of *Val* allele of *GSTP1* gene with adenocarcinoma (OR=1.92). We also found a strong association of the null genotype of *GSTT1* gene with non small cell lung cancer in group of smoking patients (OR=5.13) and patients with 60 and older (OR=6.03). We found an association of *Pro/Pro* genotype of polymorphic marker *Arg72Pro* (*OR* = 5.46) and *TG* genotype of polymorphic marker *T309G* (*OR* = 5.57) with non small cell lung cancer development. We have also showed a strong association of both *Pro/Pro* and *TG* genotypes with development of adenocarcinoma (*OR* = 5.32 and *OR* = 8.13) and squamous-cell lung cancer (*OR* = 4.20 and *OR* = 8.13). We have finally found highly reliable association of combined susceptible genotype *Pro/Pro* + *TG* of *TP53* and *MDM2* genes with non small cell lung cancer and both its subtypes (*OR* = 7.90, *OR* = 9.12, *OR* = 8.59, respectively).So our results show an important role of studied genes in development non small cell lung cancer and its different subtypes.

Adult recurrent pilocytic astrocytoma: clinical, histological and molecular study.

***S. Trabelsi**[1], D. H'mida-Ben Brahim[1], N. Labaied[2], M. L'Adib[3], N. Mama[4], M. Chourabi[1], M. Haddaji Mastouri[1], M. Mokni[2], K. Tlili[4], H. Krifa[3], M. Yacoubi[2], A. Saad[1];*
[1]Laboratory of Human Cytogenetics, Molecular Genetics and Reproductive Biology Farhat Hached University Hospital, Sousse, Tunisia, [2]Department of Histopathology-Cytopathology,Sousse, Sousse, Tunisia, [3]Departement of Neuro-Surgery,, Sousse, Tunisia, [4]Departement of imagery Sousse, Tunisia, Sousse, Tunisia.

Pilocytic astrocytoma (PA) is a low grade glial tumor occuring frequently in paediatric population. This predonimantly cerebellar tumor was supposed to be curative after surgical resection. However, very few adult recurrent cases were previously reported. We report here a case of a 58-year-old man presented a right with a supratentorial tumor. Two years after a first resection a recurrence was discovered in the same area. Based on histopathological and neuroimaging findings the diagnosis of pilocytic astrocytoma was suspected. Molecular investigations using multiplex ligation probe amplification (MLPA) revealed KIAA1549-BRAF fusion gene in both the primary and the recurrent tumors. Additional genetic abnormalities, that may explain the malignant transformation and bad clinical outcome, were also detected. Based on imagining, histopathological and molecular findings, we consider that our patient showed a PA with malignant transformation rather than a de novo Glioma.

A Primary myelofibrosis case with a unique chromosomal translocations

***Y. Kim**[1], J. Kim[2], K. Lee[1];*
[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of.

Primary myelofibrosis (PMF) is a myeloproliferative neoplasm and diagnosed based on bone marrow morphology, and cytogenetic pathogenesis and abnormalities are still not well studied. In this study, we identified cytogenetic abnormality that had not been reported in PMF. A 79 years old male with optic neuritis and posterior scleritis was admitted to the neurosurgery department in 21 Jun 2011 and then he transferred hematology department for evaluation of dizziness and anemia in 25 Jun 2011. The peripheral blood count revealed that WBC, hemoglobin and platelet count were 5.52 x 10^3/uL, 7.9 g/dL and 516 x 10^3/uL, respectively. BM analysis showed hypercellular marrow (more than 70% cellularity) with megakatyocytic hyperplasia and myelofibrosis. Mild splenomegaly and high LDH level (832 IU/L) was noted. *JAK2* mutation and *Bcr/abl* gene rearrangement were not detected. In conventional chromosome study, of 14 metaphases, 9 had a reciprocal 10; 13 translocation with break and fusion points at band 10q24 and 13q14. During treated with hydrea 500mg per 8 hour, he re-admitted in 27 Sep 2012 due to pneumonia and he still have been cared in ICUs. For evaluation of break point, FISH analysis was performed for the detection of translocations involving the locus at chromosome 10q24 and 13q14. And we got only deletion sign of *RB* probe [22/201] at 13q14, but could not obtained information of counterpart gene at 10q24.
So, we will further evaluate counterpart gene of *t*(10;13)(q24;q14) and it may be help to better understand the role of involved gene in PMF.

Analysis of c-erbB-2 and c-myc oncogene amplification in salivary gland tumours

***N. Nikolic**[1], B. Anicic[2], J. Carkic[1], B. Toljic[1], B. Popovic[1], J. Milasin[1];*
[1]Insitute of Human Genetics, School of Dentistry, University of Belgrade, Belgrade, Serbia, [2]Clinic for Maxillofacial Surgery, School of Dentistry, University of Belgrade, Belgrade, Serbia.

Genetic studies of salivary glands tumours were mainly focused on chromosomal changes and specific patterns of chromosome translocations have been described.
However, molecular changes in these tumours are less well characterized.
Alterations in gene copy number by amplification or deletion represent a common mechanism of gene expression deregulation and play an important role in the pathogenesis of many solid tumors.
We studied the putative role of c-erbB-2 and c-myc oncogene amplification in the development and progression of 53 cases of pleomorphic adenomas (PA) and 6 cases of carcinoma ex pleomorphic adenoma (CexPA).
The levels of gene amplification were analyzed by Real Time PCR comparative Ct method.
Amplification of c-erbB-2 was identified in 7 out of 53 (13%) cases of PA and in 2 out of 6 (33%) cases of CexPA. C-myc was amplified in 5 out of 53 (9%) PAs and in 2 out of 6 (33%) CexPAs. The amplification could not be correlated with clinical characteristics in the benign tumours group, whereas in malignant tumours c-erb amplification was related to recurrences.
In conclusion, c-erbB-2 and c-myc gene amplification might play a role in a subset of malignant salivary gland tumours (to be confirmed on a larger sample). Conversly, this alteration seems to be of minor importance for benign tumour pathogenesis, as judged from its low frequency in PA. However, a longer follow-up of the patients with
PA could uncover a potential role of c-erb and c-myc amplification as prognostic tools and predictors of adenoma transformation into carcinoma.

Comparative analysis of the telomere length in young women with breast cancer and controls in Castilla y Leon (Spain)

A. Pascual Rodríguez[1], *J. Fernández Mateos*[2], *C. Cieza Borrella*[2], *E. M. Sánchez Tapia*[1], *T. Martín Gómez*[3], *J. J. Cruz Hernández*[3], *R. González Sarmiento*[2];
[1]*Laboratorio 14, Centro de Investigación del Cáncer. Universidad de Salamanca-CSIC-IBSAL, Salamanca, Spain,* [2]*Unidad de Medicina Molecular, Departamento de Medicina. Universidad de Salamanca-IBSAL,, Salamanca, Spain,* [3]*Servicio de Oncología Médica. Hospital Clínico Universitario de Salamanca-IBSAL,, Salamanca, Spain.*

Background: Telomeres are non-coding regions of DNA at the ends of chromosomes. In humans, they consist of tandem repeats of the sequence T2AG3 and their main function is to maintain genomic stability.
It has been described that there are not significant differences in telomere shortening in patients with breast carcinoma in relation to age, although there is an association with an earlier cancer appearance in following generations, suggesting a mechanism of genetic anticipation.
Patients and Methods: With prior informed consent, we obtained genomic DNA from leucocytes of peripheral blood of 60 women under forty years old with breast cancer without mutation in BRCA1/2 genes, and 32 blood samples of young women controls. The measurement of relative telomeric length was performed by relative comparative quantitative PCR, using as endogenous control the 36b4 gene. For the statistical analysis we used the programme GenEx, suitable for qPCR data analysis.
Results: The control group showed an average telomere length of: 3.36, while women with breast cancer revealed 3.80. These results showed highly significant differences when comparing both group´s relative telomere length, presenting a p-value: 0.01.
Conclusions: Our results show a telomere shortening in peripheral blood in young women with breast cancer with respect to controls. This could be used as a prognostic marker of earlier appearance of breast cancer in women, although the explanation of these results is difficult to determine due to the big variety of molecular, physiological and biological process which are affected in cancer development.

Are rare germline variant in the TP53 3'UTR causal determinants of Li-Fraumeni-like syndrome?

I. A. Vieira[1], *G. S. Macedo*[1,2], *J. Giacomazzi*[1], *A. P. Brandalize*[1], *P. Ashton-Prolla*[1,2,3];
[1]*Laboratório de Medicina Genômica, CPE, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil,* [2]*Programa de Pós-Graduação em Genética e Biologia Molecular, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil,* [3]*Serviço de Genética Médica, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.*

The rs78378222 (A>C) single nucleotide polymorphism (SNP), a rare variant located in the 3'-untranslated region and within the polyadenylation signal of *TP53*, was recently identified in a GWAS of the Icelandic population. It occurs at a frequency = 0.0192 in that population and leads to impaired 3'-end processing of mRNA, conferring susceptibility to certain types of cancer. Considering that Southern Brazil has one of highest breast cancer (BC) incidence rates in Brazil (reaching 81.07 per 100,000 women in certain areas), the purpose of this study was to evaluate the association between this functional SNP and BC risk in a case-control cohort from this geographic area. A total of 135 BC-affected women and 302 healthy controls were genotyped using a TaqMan assay method. No homozygous mutant (CC genotype) individuals were identified in this series, and although the frequency of heterozygous genotypes did not differ between groups (P = 0,65), all C allele carriers had a family history of BC and/or other tumors. In addition, one of the SNP-positive patients, a woman diagnosed with BC at age 44 years, had a cancer family history meeting Birch criteria for LFL. No coding germline *TP53* mutations were identified in this patient. This is the first description of rs78378222[C] in an LFL family. Although previous studies reported no effect of this variant on BC risk in different European populations, further studies should be undertaken in families with the LFS/LFL phenotype to investigate the role of rs78378222[C] as a gene variant associated with LFL syndrome.

Effects of Sulfite molecule on URG4/URGCP, Cyclin D1, and Bcl-2gene expressions in SH-SY5Y Human Neuroblastoma Cells

Y. Dodurga[1], *G. Gundogdu*[2], *V. Tekin*[2], *T. Koc*[3], *N. Satiroglu-Tufan*[4], *G. Bağcı*[5], *V. Kucukatay*[2];
[1]*Pamukkale University School of Medicine Department of Medical Biology, Denizli, Turkey,* [2]*Pamukkale University School of Medicine Department of Physiology, Denizli, Turkey,* [3]*Pamukkale University School of Science, Department of Biology, Denizli, Turkey,* [4]*Pamukkale University School of Medicine, Department of Medical Genetics, Denizli, Turkey,* [5]*Pamukkale University School of Medicine Department of Medical Genetics, Denizli, Turkey.*

Sulfite is a highly reactive molecule which is commonly used in foods, cosmetics and pharmaceuticals. Although, many studies have shown that sulfite may cause toxicity both in vivo and in vitro, there is no consensus on the mechanism by which sulfite toxicity affects cells. Up-regulated gene 4/Upregulator of cell proliferation (URG4/URGCP) is a novel gene located on 7p13. URG4/URGCP stimulates cyclin D1 (CCND1) mRNA expression, and RNAi-mediated URG4/URGCP silencing diminishes CCND1 mRNA expression in HepG2 cells. In this study, the effects of sulfite treatment on URG4/URGCP, CCND1, and Bcl-2 gene expression changes on control and dose group were analyzed. SHSY5Y cells were cultured in the appropriate conditions. Cytotoxic effects of sulfite in SHSY5Y cells were detected in time and dose dependent manner with the IC50 doses within the range of 0.5-10 mM by using XTT. Genotoxic effect of sulfite was shown by commet assay. IC50 doses in the SHSY5Y cells were detected as 5mM. Total RNA was isolated with Tri-Reagent. Expression profiles of the target genes were determined by semi quantitative RT-PCR. An URG4/URGCP protein change was determined by western blot analysis. According to results, URG4/URGCP, CCND1, and Bcl-2 gene expression levels were decreased in dose group cells compared to the control cells. Our preliminary results are suggesting that sulfite treatment inhibits the proliferation of SHSY5Y cells as chemotherapeutic agents. In according to our findings, the mechanism of this result may berelated with sulfite dependent inhibition of cell cycle at the G1 phase by downregulating URG4/URGCP or CCND1 gene expression.

Y. Dodurga: None. **G. Gundogdu:** None. **V. Tekin:** None. **T. Koc:** None. **N. Satiroglu-Tufan:** None. **G. Bağcı:** None. **V. Kucukatay:** None.

Chromosome Imbalances and Alterations in p53 Gene in Uterine Myomas from the Same Family Members: Familial Leiomyomatosis

S. Hakverdi[1], ***O. Demirhan***[2], *E. Tunc*[2], *N. Inandiklioglu*[2], *I. N. Uslu*[2], *A. Gungoren*[3], *D. Erdem*[3], *A. U. Hakverdi*[3];
[1]*Mustafa Kemal University, Tayfur Ata Sökmen Faculty of Medicine, Department of Patholoji,, Hatay, Turkey,* [2]*Çukurova University, Faculty of Medicine, Dept. of Medical Biology, Adana, Turkey,* [3]*Mustafa Kemal University, Tayfur Ata Sökmen Faculty of Medicine, Department of Obstetrics and Gynecology, Hatay, Turkey.*

Uterine leiomyomas (UL) are extremely common neoplasms in women of reproductive age, and are associated with a variety of characteristic chromosomal aberrations (CAs). The p53 gene has been reported to play a crucial role in suppressing the growth of a variety of cancer cells. Therefore, the present study investigated the effects of CAs and p53 gene on ULs. We performed cytogenetic analysis by G-banding in 10 cases undergoing myomectomy or hysterectomy. Fluorescence in situ hybridization (FISH) with p53 gene probe was also used on interphase nuclei to screen the deletions in p53 genes. In patients, CAs were found in 23.4% of 500 cells analysed. This proportion was significantly different between patients and the control group ($p<0.001$). In the patients, 76% of the abnormalities were structural aberrations (deletions, translocations and breaks), and only 24% were numerical. Deletions were the most common structural aberration observed in CAs. Among these CAs, specific changes in five loci 1q11, 1q42, 2p23, 5q31 and Xp22 have been found in our patients and these changes were not reported previously in UL. The chromosome breaks were more frequent in cases, from high to low, 1, 2, 6, 9, 3, 5, 10 and 12. Chromosome 22, X, 3, 17 and 18 aneuploidies were observed to be the most frequent among all numerical aberrations. We observed a low frequency of p53 losses (2-11%) in our cases. The increased incidence of autosomal deletions, translocations, chromatid breaks and aneuploidy, can contribute to the progression of the disease along with other chromosomal alterations.

V617F mutation of Jak2 gene in patients with myeloproliferatif diseases except CML in Morocco

H. DEHBI, *S. NASSEREDDINE, N. SERBATI, A. BENMOUSSA, S. NADIFI.;*
Laboratory of Genetics and Molecular Pathology: Faculty of Medicine and Pharmacy,, Casablanca, Morocco.

The identification in 2005 of the V617F mutation of the Janus kinase 2 gene (JAK2) has been a promising discovery that changed the way myeloproliferatif disorders (MPDs).The objective of our work is to determine the prevalence of the V617F mutation in Moroccans patients with SMPs. we studied 420 individuals referred by different departments of Hematology in Morocco. The V617F mutation was investigated by PCR Allele-specific.
Our results showed that the average age of patients was 46.5 years with a male predominance, and 54.5% of patients had the mutation.The incidence of the V617F mutation in Polycythemia Vera, essential thrombocythemia and idiopathic myélofibrosis are respectively 79%, 37% and 26%. We also detected the mutation in 25% of cases of essential eosinophilia and in 15 cases of unclassified SMPs, but it was absent in patients with secondary polycythemia vera or thrombocytosis. We also found that patients with this mutation have higher levels of hemoglobin and hematocrit compared with patients without this mutation.
For patients without V617F mutation (45.5%), the other mutations (MPL W515L and W515K) are studied by the HRM and sequencing.
Our study is the first to assess the status of the V617F mutation of the JAK2 gene in patients with SMPs in Morocco. Our data seem to confirm that the JAK2 V617F mutation is specific for myeloproliferatif disorders, it help to confirm the diagnosis and guidance of therapeutic choice to improve the prognosis of MPDs in Morocco.

The effect of silencing siRNA against b-catenin on drug sensitivity of SW480 as a model of colon cancer cells

S. Hashemi[1,2], F. Gheidari[1], M. Ghadir[1], A. Mehrtash[1], ***L. Teimoori-Toolabi[1];***
[1]Molecular Medicine Department, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran, [2]1- Department of molecular and cell biology, Pharmaceutical Sciences Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.

Colon cancers are reportedly resistant to chemotherapy. In more than 90% of cases of colorectal cancers, constitutive activation of the canonical Wnt signaling pathway is an early event in tumorigenesis. Activation of this pathway is through stabilization of β-catenin and its translocation into the nucleus.
In this study, two different shRNA plasmid vectors against β-catenin, were constructed. After cloning into pSilencer neo2.1 and integration into genome, these plasmids could persistently generate shRNA against β-catenin. Cloned shRNAs were stably transfected into SW480 cells using effectene as the transfection reagent and treating the cells with G418 for 21 days. The down-regulations of β-catenin in these two clones of cells were approved by real-time PCR.
The LC50 of 5-FU in non-transfected SW480 cells was 30 mM while the LC50s of two stably transfected cells namely SW2024 and SW978 were 42.5 micromole and 22.5 micromole respectively.
Following treatment of the cells with lethal dose of 5-FU, the percentages of apoptotic cells were 4.45, 4.66 and 31.46 in SW480, SW2024 and SW978 respectively.
Conclusively silencing β-catenin in SW480 cells render SW978 more sensitive to 5-FU induced apoptosis while in SW2024 the results were vice versa. However the LC50 of SW480 and SW978 were not different so much, the LC50 of SW2024 were significantly higher than SW480. This result in SW2024 and SW978 showed that silencing different parts of mRNA would affect the efficiency of silencing differently. This effect may be due to different effect of silencing β-catenin on proliferation and apoptosis in the cells.

Frequency of 5382insC mutation of BRCA1 gene among prostate cancer patients: an experience from Bashkortostan Republic of Russia.

D. Andreeva[1]*, I. Gilyazova[2], A. Papoyan[3], A. Mustafin[3], I. Sultanov[3], A. Izmaylov[1], V. Pavlov[3], E. Khusnutdinova[1,2];*
[1]Bashkir State University, Ufa, Russian Federation, [2]Institute of Biochemistry and Genetics, Ufa, Russian Federation, [3]Bashkir State Medical University, Ufa, Russian Federation.

A family history of prostate cancer (PC) is a strong risk factor for the disease, indicating that inherited factors are important in this disease. BRCA1 and BRCA2 gene mutations cause hereditary breast and ovarian cancer syndrome and it is known BRCA mutation carriers to be predisposed to the high risk of breast, prostate, stomach cancer compared to the general population. The 5382insC mutation is the most common of BRCA1 mutations.
The study included 91 unrelated males with histologically confirmed diagnosis of PC. The mean age of PC patients was 62,1 ± 12 years. Material for the study and the results of pathologic classification of tumors were provided by urologists from Bashkir State Medical University. The control group consisted of healthy men with no signs of PC and normal PSA level. Mean age of the control group was 65,7 ± 4 years. Genomic DNA was extracted from peripheral blood lymphocytes using standard phenol-chloroform extraction. The 5382insC mutation in the 20th exon of BRCA1 gene was identified using direct sequencing. Mutation 5382insC was found in 2 cases of Russian ethnic origin (2,1%) and in 1 individual of Russian ethnic origin from the control group (1%). These data suggest that the 5382insC mutation is rare and unlikely to be pathogenic for prostate cancer in the Republic of Bashkortostan, but further investigations based on large DNA samples are necessary to confirm the results.

DNA repair gene and life style factors determines as biomarkers for breast cancer

P. Thavanati[1]*, A. Escoto de Dios[1], J. Camacho Cortes[2], I. Luna Benitez[2], J. Ángeles Sanchez[2], A. Montiel Gonzalez[1], S. Katari[3], K. Kanala[3];*
[1]Instituto de Genetica Humana, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, [2]Instituto de Jalisciense de Cancerología, Guadalajara, Jalisco, Mexico, [3]Human Genetics Unit, Dept. of Anthropology, Sri Venkateswara University, Tirupati, Andhra Pradesh, India.

MGMT gene is the only known critical gene involved in cellular defense against alkylating agents in DNA DRR pathway. The DRR pathway in breast cancer risk and potential interaction with cigarette smoking and dietary antioxidants is genotyped [C250T (Leu84Phe), A427G (Ile143Val) and A533G (Lys178Arg)] for these variants from CONACYT project blood samples of Jalisco, Mexico, included 267 cases and 673 controls. Heavy smoking (431 pack-year) significantly increased breast cancer risk for women with codon 84 variant T-allele [odds ratio, OR ¼ 3.0, 95% confidence interval (95% CI) ¼ 1.4-6.2]. Inverse association between fruits and vegetables consumption and breast cancer risk was observed among women with wild-type genotype for codon 84 (OR ¼ 0.8, 95% CI ¼ 0.6-0.9 for _35 servings of fruits and vegetables per week and CC genotype versus those with 535 servings per week and CC genotype). The association between fruits and vegetables consumption and reduced breast cancer risk was apparent among women with at least one variant allele for codon 143 (OR ¼ 0.6, 95% CI ¼ 0.5-0.9 for _35 servings of fruits and vegetables per week and AG or GG genotype versus those with 535 servings per week and AA genotype). Similar patterns were observed for dietary a-carotene and supplemental b-carotene, but not for supplemental vitamins C and E. Polymorphisms in MGMT may modulate the inverse association previously observed between fruits and vegetables consumption, dietary antioxidants and breast cancer risk, and support the importance of fruits and vegetables on breast cancer risk reduction.

J11.52

Familial case of Cowden syndrom and oncogenetic counselling

R. H. Hanitra*;*
Medical Genetics Unit 6CHU Saint Pierre La Reunion, Saint Pierre, Réunion.

A female 45-year-old patient referred to us for oncogenetic counselling after a chirurgical treatment of a renal carcinoma, with chromophobes cells began at 20-year-old for a goiter of her thyroid gland. At 43-year-old, she had a total colectomy for polyps of the colon, there were also a lipoma of the duodenum and polyps of the stomach. One of her sisters was a stillbirth and another had a cancer of the thyroid; her mother had a cancer of the brain. The clinical examination showed a tall woman with a macrocephaly, unrefined features, some oral papillomas of the tongue. She had dermal fibromas.

The clinical diagnosis of a Cowden syndrome was made and a genetic study of the PTEN gene was performed, which confirmed the diagnosis : she had a mutation of the exon 3 of the PTEN gene : c.209+1G>A. After this result, she was followed-up by a multidisciplinary staff and had a prophylactic hysterectomy with an endometrial polyp, a bilateral mastectomy revealing a bilateral and multiple intra-canalaire adenocarcinoma, and a negative bilateral annexectomy. Her son a 20-year-old was a tall boy, and was followed-up because he had the same mutation. We emphasize the interest to detect the mutation of PTEN gene, with an autosomal dominant transmission to adapt the prophylactic chirurgical treatment, permitting a longer survey for the index case ; and also the interest of the predictive test to follow up the son with the same mutation of PTEN.

R.H. Hanitra: None.

Background. Acute lymphoblastic leukemia (ALL) is the most common cancer among children, with an annual incidence rate of approximately 3.9 per 100,000 children.According to literature single nucleotide polymorphism (SNP) rs4132601 in gene - *IKZF1,* which
is located on chromosome 7, in genome wide association studies analyzing cases and controls, statistically significantly increase risk of developing childhood ALL.
Aim. To detect frequency of SNP rs4132601 G allele, in case and control groups and to evaluate it as a possible risk allele.
Material and methods. We analyzed SNP rs4132601 in the 36 pre-B ALL cases, as a control group we used age and sex matched children without leukemia. DNA was extracted from whole blood and purified by standard phenol/chloroform extraction protocol. The presence of polymorphism was analyzed using PCR with subsequent restriction enzyme *MboI* digestion and detected in polyacrylamide gel.
Results. SNP rs4132601 G allele frequency in patients was 0,458. Five out of 36 patients were homozygous for risk allele. There were statistically significant difference between ALL group and control group (p=0.042, OR=2,538, CI 95% 1,004-6,527).
Conclusions. In this study, we find statistically significant evidence about rs4132601 G allele as a risk allele. In order to detect SNP rs4132601 association with ALL have to be done larger study.

Enzymatic activity of PON1 and GST among patients with prostate cancer

M. Saiz[1], *O. Lopez-Guarnido*[1], *M. Pascual-Geler*[2], *L. Rodrigo*[1], *J. C. Alvarez*[1], *J. M. Cozar*[2], *J. A. Lorente*[1,3], *M. J. Alvarez-Cubero*[1,3];
[1]*Legal Medicine and Toxicology Department, Faculty of Medicine, University of Granada, Granada, Spain,* [2]*Service of Urology. University Hospital Virgen de las Nieves, Granada, Spain,* [3]*GENYO (Pfizer - University of Granada & Andalusian Government Centre for Genomics & Oncology), Granada, Spain.*

Prostate cancer is the most common type of cancer in men and the second leading cause of cancer death in men after lung cancer. Although prostate cancer is relatively common, there are genetic and environmental risk factors that increase the probability of developing prostate cancer. One of the factors involved in the development and aggressiveness of many cancers is the production of reactive oxygen species (ROS). Higher amounts of ROS play a role in the aging process as well as in a number of human disease states, including cancer, ischemia, and failures in immunity and endocrine functions. As a safeguard against the accumulation of ROS, several nonenzymatic and enzymatic antioxidant activities exist. Therefore, when oxidative stress arises as a consequence of a pathologic event, a defense system promotes the regulation and expression of these enzymes.
It is well known, that antioxidant processes are related to the development of prostate cancer. That is why, the study is focused in the determination of antioxidant activity by the analysis of paraoxonase 1 (PON 1) and glutation-S-transferase (GST) activity. Furthermore, genetic polymorphisms in these both enzymes will be determined in patients with prostate cancer. The enzymatic and genetic data obtained will be combined with clinical characteristics of the tumor and lifestyle of the patients, smoking habits, dietary style, exercise, etc; in order to adjust the dietary style of the patient improving their quality of life, as well as, the establishment of high-risk polymorphisms in these genes with prostate cancer aggressiveness.

Association of IGFBP5 and ERalpha with mir193b expression levels in breast cancer

I. Peker[1], *G. Güllü*[1], *A. Haholu*[2], *C. Erzik*[1], *Z. Küçükodacı*[2], *H. Baloğlu*[2], *A. S. Özer*[1], *M. Akkiprik*[1];
[1]*Marmara University Medical Biology, istanbul, Turkey,* [2]*Haydarpaşa Gülhane Military Medicine School Pathology, istanbul, Turkey.*

miRNA's are small, single stranded and non-coding RNAs that can be down or up regulated depending on the cell and cancer type. The role of miRNA's in cancer, became a new hope in cancer research.
IGF's plays an important role in tumor-genesis as well as cell growth, proliferation and apoptosis control. IGFBP5 inhibits cell growth in vivo and in vitro in human breast cancer, it is also associated with metastasis, bad prognosis and endocrine treatment.
miR-193b down-regulates in breast cancer patients and this results in tumor migration and invasion. miR-193b directly targets ERα at 3-UTR site and inhibits estrogen induced proliferation.
In this study, FFPE tissue sections of the patients with breast cancer analyzed by immunohistochemistry and confirmed with mRNA RT-PCR, to define IGFBP5 expressions. miR- 193b expression level is later analyzed with RT-PCR and the correlation between the expression levels and IGFBP5, plus ERα is analyzed.
It has been shown that Erα is regulated by mir-193b in some studies, but some studies show no correlation. In our study, we used tissue samples of 48 women with breast cancer, but we couldn't find any evidence that supports such regulation. No significant relation is found between IGFBP5 expression and mir-193b expression. The group of people that has been studied in our study showed no correlation between mir-193b expression and breast cancer sub types. There is also no difference between mir-193b expression in tumor tissue and in peripheral tissue. These results indicate that mir-193b is not a good bio-marker for breast cancer.

Association of polymorphic markers of xenobiotic biotransformation genes, tp53 and mdm2 genes with breast cancer in russian women of moscow region

A. M. Burdennyy[1], *V. Loginov*[2];
[1]*IBCHPH RAS, Moscow, Russian Federation,* [2]*RCMG RAMS, Moscow, Russian Federation.*

Abstract
The association of *+/-* polymorphic markers of *GSTM1* and *GSTT1* genes, *Ile105Val* of *GSTP1* gene, *Arg72Pro* of *TP53* gene and *T309G* of *MDM2* gene with risk of breast cancer in females of Moscow region has been studied. We have showed an association of null genotypes of *GSTT1* and *GSTM1* genes and *Ile/Val* and *Val/Val* genotypes of *GSTP1* gene with BC (*OR* = 1.89, 1.65, 1.47 and 1,33, respectively). We found an association of *Pro/Pro* genotype of polymorphic marker *Arg72Pro* with higher risk of BC development (*OR* = 1.41) and with ductal and lobular breast cancer development (*OR* = 5.32 and *OR* = 8.13 respectively). We have also found the highly significant association of the null genotype of *GSTT1* gene and *Ile/Val* and *Val/Val* genotypes of *GSTP1* gene with BC for patients with disease manifestation before 53 years (*OR* = 2.33, 2.07 and 2.31, respectively). We have found highly reliable association of combined susceptible genotypes: null genotypes of *GSTT1* and *GSTM1* genes (*OR* = 3.18) and null genotypes of *GSTT1* and *GSTM1* genes and *Val/Val* genotype of *GSTP1* gene (*OR* = 16.42) with BC. In case of combined susceptible genotype *Pro/Pro* + *TG* of *TP53* and *MDM2* genes we have found highly reliable association with BC and its most frequent subtype - ductal breast carcinoma (*OR* = 10.8 and *OR* = 12.8, respectively). The results of our study are evidence that studied genes play an important role in the development of breast cancer in Russian women living in Moscow region.

Vitis vinifera seed extract modulates temozolomide sensitivity in human glioblastoma cells via apoptosis related miRNA alterations

G. Tezcan[1], *B. Tunca*[1], *U. Egeli*[1], *G. Cecener*[1], *S. Sahin*[2], *F. Budak*[3], *A. Bekar*[4], *C. Demir*[2], *S. Ak*[1], *H. Malyer*[5], *T. Evrensel*[6];
[1]*Department of Medical Biology, Medical Faculty, Uludag University, Bursa, Turkey,* [2]*Department of Chemistry, Science Faculty, Uludag University, Bursa, Turkey,* [3]*Department of Microbiology, Medical Faculty, Uludag University, Bursa, Turkey,* [4]*Department of Neurosurgery, Medical Faculty, Uludag University, Bursa, Turkey,* [5]*Department of Biology, Science Faculty, Uludag University, Bursa, Turkey,* [6]*Department of Medical Oncology, Medical Faculty, Uludag University, Bursa, Turkey.*

One of the most attractive cancer therapy methods to date is the induction of tumor cell death by certain phytochemicals. We investigated the active component of *Vitis vinifera* (grape) seed extract (GSE) and its effect on cell death and regulation of associated miRNA expressions in Glioblastoma multiforme (GBM) which is the most lethal form of brain tumors.
The active component of GSE was identified by HPLC/DAD. The anti-proliferative activity of GSE was tested in T98G, U-138MG and U-87MG cells alone and in combination with TMZ, using WST-1 assays. The effect of GSE on cell death was analysed using FITC Annexin V and miRNA PCR array analyses in T98G cells. Potential mRNA targets were analyzed bioinformatically.
The components of GSE were Catechin derivatives, Quercetin, Gallic acid and Chlorogenic acid. One The results of Way Anova and Tukey analysis showed that, the combination of 500ug/ml GSE and 325uM TMZ significantly decreased cell proliferation ($p<0.001$) in all cell lines. According to findings of FITC Annexin V assay, 70% of cells were killed by apoptosis and necrosis. SABioscience PCR Array Data Analysis demonstrated that, miR-9, miR-10a, miR-10b and miR-455-3p were significantly inhibited ($p<0.001$). Also, miRWalk database support our findings, the target genes for these miRNAs have been defined to be related to apoptosis, the cell cycle and VEGF signaling pathways.
Even further studies and validations are required, using the combination of GSE and TMZ may provide a novel approach to treat GBM through miRNA regulation.

HER2 polymorphisms and colon cancer in Croatian population

S. Kapitanovic, *T. Catela Ivkovic, S. Valentic;*
Rudjer Boskovic Institute, Zagreb, Croatia.

Colon cancer is the third most common cancer worldwide and the second leading cause of cancer death. HER2 gene, a member of the EGF receptor family, is located at chromosome 17q21 and encodes a transmembrane protein (p185) with tyrosine kinase activity. HER2 has been associated with colon cancer development and progression. A large number of HER2 polymorphisms have been described. Any functional polymorphism can potentially affect colon cancer risk as well as cancer outcome. The aim of our study was to analyze three SNP polymorphisms in the HER2 gene, -344 C/T, +1963 A/G (I655V) and +3508 C/G (P1170A) in the Croatian population and in patients with colon cancer. DNAs obtained from 300 colon cancer patients and 300 unrelated healthy volunteers were genotyped for the HER2 SNPs using real-time PCR TaqMan® SNP genotyping assays. Allele G of I655V and allele G of P1170A polymorphism were more common in the population with colon cancer in the comparison to healthy volunteers and were associated with an increased risk of colon cancer. The role of HER2 polymorphism with colon cancer progression and prognosis has to be investigated in the future studies.

What is the actual impact of fluorescence in situ hybridization (FISH) in the diagnosis of myelodysplastic syndromes (MDS)?

H. Akin, *E. Karaca, B. Durmaz, O. Cogulu, A. E. Solmaz, A. Kavasoglu, F. Ozkinay;*
Ege University Medical Faculty, İzmir, Turkey.

Fluorescence in situ hybridization (FISH) is increasingly

being used in the cytogenetic diagnosis of myelodysplastic syndromes (MDS). Clinical MDS diagnosis is complicated. Despite the challenges related to cytogenetic analyses in MDS diagnosis, there are still some standard requirements and integrated algorithms that must be added. Due to this, in this study we would like to evaluate the FISH analysis and their outcomes of 98 MDS patients who were referred over a one year period. Conventional karyotype analysis was performed in all patients. The results showed that 13 patients (13.3%) from conventional karyotype analysis and

17 patients (17.3%) from FISH analysis presented with clonal chromosomal aberrations. Surprisingly, none of chromosomal aberrations detected via cytogenetic analysis and FISH analyses

were compatible due to the limited number of FISH analysis requests. From the 18 requests of our study group, isolated 5/5q deletion presented as the most common (43.9%). 5q deletion and trisomy 8, seen in equal rates, were the most frequent anomalies (63.2%) in the study. It was seen that with 5 FISH

analysis (5q Del, 7q Del, trisomy 8, 13q Del, TP 53 Del), we could cover all of the chromosomal anomalies that were detected in all patients in this study. It is important to determine the chromosomal rearrangements using both cytogenetic and FISH analysis in MDS patients. A more reliable approach would be to standardize

wider FISH panels in order to detect more anomalies, synchronously, in this patient group.

The *PALB2* germline genetic variants in pediatric patients with classic type of *medulloblastoma*

J. Trubicka, *M. Kania, M. Perek-Polnik, E. Ciara, W. Grajkowska, E. Moszczyńska, K. Chrzanowska, D. Piekutowska-Abramczuk, D. Jurkiewicz, S. Łuczak, M. Pelc, P. Kowalski, M. Borucka-Mankiewicz, M. Krajewska-Walasek;*
The Children's Memorial Health Institute, Warsaw, Poland.

Medulloblastoma (MB) is the most common malignant brain tumor in the children which the etiology remains unknown. Recently, multiple molecular dysfunctions were detected in patients with MB. The majority of them were somatic changes. Our previous studies indicate that germline mutations in DNA repair genes (e.g. *NBN*) seem to be particularly important in the development of MB. The next of candidate is the *PALB2* gene, a partner and localizer of *BRCA2*, therefore the essential component of DNA repair system.
The aim of our study was to identify germline genetic variants of the *PALB2* gene in patients with classical type of MB. In first stage of analysis direct sequencing of coding sequence and flanking regions of *PALB2* in 50 MB patients was performed. We identified three nonsynonymous changes: rs152451 (Q559R), rs45624036 (V932M) and rs45478192 (L939W). To evaluate their frequency a total of 100 patients and 100 control samples were screened. The control group consisted of DNA samples from healthy persons with negative cancer family history and age and sex matched to the group of patients. Our results indicate that only carriers of the rs45478192 may exhibit increased susceptibility to developing MB (OR 3.00, p-value=0.5) but account for only a small proportion of cases. All results did ***not*** have ***enough statistical power*** therefore they need to be validated on a larger group of patients, what will be implemented in the next stage of the project.
The study was financed by the NCN, project no. 6917/B/P01/2011/40 and by ERDF project POIG.02.01.00-14-059/09.

The RET protooncogene mutations in Russian patients with multiple endocrine neoplasia type 2

F. A. Amosenko[1,2], *V. N. Kozlova*[2], *V. E. Vanushko*[3], *V. Z. Brzhezovski*[3], *L. N. Lyubchenko*[2], *A. V. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*N.N. Blokhin Cancer Research Center, Moscow, Russian Federation,* [3]*Research Center for Endocrinology, Moscow, Russian Federation.*

Multiple endocrine neoplasia type 2 (MEN 2) is a very rare genetic disease characterized by medullary thyroid carcinoma (MTC) associated with other

endocrine neoplasia (MEN 2A and MEN 2B) or not (familial MTC) due to germline *RET* gene mutations. We started MEN 2 genetic study 15 years ago. DNA was isolated from peripheral blood DNA. Exons 10, 11, and 13-16 of the *RET* protooncogene were amplified by polymerase chain reaction (PCR) and examined by direct sequencing of PCR products and/or restriction enzyme analysis. So we analysed 36 unrelated families (36 probands and 29 at risk relatives). A total of 15 different missense *RET* mutations were identified. A single mutation at codon 918 was found in all MEN 2B families (n=11). All of the MEN 2A mutations affected codon 634. Mutations outside of codon 634 occurred only in familial MTC. p.M918T was the most common mutation in our cohort followed by mutations p.C634R (n=6), p.C634Y (n=3), p.V804M (n=3), p.C634F (n=2), p.C620R (n=2), p.C630R (n=1), p.C634W (n=1), p.C634G (n=1), p.S649L (n=1), p.L790F (n=1), p.Y791F (n=1), p.R833C (n=1), p. M918V (n=1), and novel p.Y791F/p.I852M double germline mutation (n=1). Codon 634 at exon 11 was the most frequently altered codon and consequently, exon 11 was the most frequently altered exon. High prevalence of p.M918T in Russia with respect to other European countries is possibly explained by the fact, that Russian doctors conduct clinical diagnostics best of all for patients with the more severe MEN 2B syndrome.

J11.62

Early detection of SOX2 and hTERC gene amplification of oropharyngeal squamous cell carcinomas by FISH on brush biopsy samples.

N. Kokalj Vokač[1,2], *B. Čizmarević*[1,2], *A. Zagorac*[1], *B. Zagradišnik*[1];
[1]*University Medical Centre Maribor, Maribor, Slovenia,* [2]*Medical Faculty, Maribor, Slovenia.*

Oral and oropharyngeal squamous cell carcinomas (OSCC) are among the most common cancers. The poor survival rate among oral cancer patients can be atributed to several factors, one of them being lack of early detection. A key approach to this problem would be to detect potentialy malignant lesion at their early stage. The only established method for their diagnosis is biopsy, which is carried out only when the lesions become symptomatic. Exfoliative cytology is an easy, non-invasive procedure and hence could be carried out even on slightest suspicion regarding the nature of the lesion. Performing FISH technique on oral brush cytology slides can be an easy and rapid screening approach for the malignant cell detection.
Gain of 3q26 region is frequently observed in various squamose cell carcinomas of mucosal origin, where hTERC and SOX2 genes are located. TERC gene amplifications were described in developement of various SCC, the laryngs, cervics, esophagus and lungs. Our resultes, obtaind on cervical smears demonstrated that TERC gene amplifications correlates with high squamouse interepithelial lessions which lead to invasive cervical cancer. SOX2 gene amplifications were also described in esophageal and lung squamous cell carcinomas. Because in oral cancer 3q26 amplifications are also regulary observed, amplifications of SOX2 gene could be important diagnostic and prognostic marker.
The present study was designed to detect hTERC and SOX2 amplifications in OSSC exfoliative mucosal cells and evaluate whether those two gene amplifications might serve as a supportive biomarker in early detection and diagnosis of oral and oropharingial SCC.

P53 mutations in Turkish bladder cancer patients

N. Ersoy Tunali, *S. Sahoglu;*
Halic University, Istanbul, Turkey.

Bladder cancer is the 7th most common cancer in men and 17th in women in the world. Two distinct pathways have been described in bladder cancer carcinogenesis; superficial papillary carcinoma and non-papillary invasive carcinoma, which are represented by FGFR3 and p53 pathways, respectively. P53 gene is the preferred target for environmental carcinogens, therefore investigation of the p53 mutation profiles may provide clues about the etiology of the tumors. In this study we aimed to investigate the p53 mutations in Turkish bladder cancer patients. For this purpose, tumor and healthy tissues were collected from 79 bladder cancer patients with ages ranging from 54 to 81 years. Upon DNA isolation, all exons of the p53 gene were amplified by PCR and sequenced. In one patient, we have identified a C>T mutation in codon 190, which changes the amino acid Pro to Ser in the p53 protein. This mutation has been shown in colorectal cancer, but this is the first study which reports cd190 mutation in bladder cancer. In addition to that, 10 more mutations in cd 181 (C>T), cd213 (A>G), cd280 (G>C), cd 238 (G>A), cd249 (G>T), cd234 (A>G), cd245 (G>A) were identified. The mutated tissues were either T1G3 or T2G3. The patients were all men and smokers for at least 20 years, 1pack/day. Screening of p53 mutations in bladder cancer patients will help in exploring the p53 mutational profile, and accordingly, expected to help in the development of screening strategies for at-risk individuals.

Optimization of RNA extraction from urine samples for use in non-invasive diagnostic procedures

J. Ramic, *L. Pojskic, N. Lojo-kadric, K. Radic, N. Pojskic, K. Bajrovic;*
Institute for genetic engeneering and biotechnology, Sarajevo, Bosnia and Herzegovina.

Conventional diagnostic procedures for prostate cancer are invasive and painful and in most of the cases unnecessary. Aversion of men towards this screening tool is generally the reason for late oncology diagnosis and unsuccesful treatment. Development of methods for low copy templates i.e. separation and characterisation of circulating tumor cells opened new oportunities for molecular detection of tumor markers in other body fluids i.e. urine. There are several national studies for validation of tumor specific molecular markers in urine, such as PSA/KLK3, PSGR / OR51E2, PCA3 and TMPRESS2/ERG, that proved a principle to be used as screening tool in order to make a targeted biopsy and avoid unnecessary painful procedures and acompanying costs. For these reasons, the isolation of mRNA and measuring the expression of these genes in urine as a noninvasive technique is aimed to assist patients in reducing stress, and doctors as a further indication for biopsy and cystoscope. Potential advantages of this method are availability and easy sampling and measuring the expression of more marker genes for this type of tumor. In this work we have optimized total RNA extraction from various individual urine samples and estimated the quality of RNA for gene expression analysis using RT PCR methods.

Impact of TPMT and MTHFR genotype on development thiopurine related toxicity in IBD and ALL patients

L. Šebest[1], *A. Šoltýsová*[1], *I. Medveďová*[1], *A. Chocholová*[2], *I. Čierna*[3], *G. Minárik*[1,4], *B. Mladosievičová*[5], *&. Kadáši*[1,6];
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [2]*Bone Marrow Transplantation Unit, Comenius University Children's Hospital, Bratislava, Slovakia,* [3]*2nd Department of Pediatrics, Comenius University Children's Hospital, Bratislava, Slovakia,* [4]*Institute of Molecular Biomedicine, Faculty of Medicine, Comenius University, Bratislava, Slovakia,* [5]*Institute of Pathological Physiology, Faculty of Medicine, Comenius University, Bratislava, Slovakia,* [6]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia.*

Thiopurine drugs are mainly and effectively used in treatment of autoimmune diseases such as Crohn´s disease and Ulcerative colitis but also in treatment acute lymphoblastic leukemia. Individual genetic variations result in differences of activity specific enzymes involved in drug metabolic pathway. Polymorphisms in TPMT gene, which is key enzyme responsible for biotransformation of thiopurines, modify activity of this enzyme. Decrease activity is responsible for observed adverse thiopurine effects such as myelotoxicity and hepatotoxicity in some patients. The aim of our work was to monitor the prevalence of the most commonly appearing deficiency alleles of *TPMT* gene as well as other deficiency alleles possibly occurring in our population. For this purpose we used direct sequencing of whole gene but our results show that *TPMT**3A, *TPMT**3B and *TPMT**3C are most frequently occurring alleles preferably found in patients with undesirable toxic effects. We also genotyped polymorphisms in *MTHFR* gene (*MTHFR* 677C>T and *MTHFR* 1298 A>T) to study the association between MTHFR and/or TPMT polymorphisms and probability of toxicity development. We develop genotyping method for quick detection of these SNPs using snapshot method. Our results suggest that there is association between TPMT and MTHFR genes and thiopurine therapy side effects.

The clinical features of the type 2 diabetes in relation to genotype rs 7903146 polymorphism of TCF7L2 gene in Uzbek populations

Y. A. Malikova[1], *G. N. Rakhimova*[2], *Z. S. Akbarov*[2], *S. U. Turdikulova*[1];
[1]*Institute of Bioorganic Chemistry, Academy of Sciences Republic of Uzbekistan, Tashkent, Uzbekistan,* [2]*Scientific-Research Institute of Endocrinology, Uzbekistan Public Health Ministry, Tashkent, Uzbekistan.*

TCF7L2 gene (chr. 10q25.3) involved in the Wnt signaling pathway, encodes a T-cell transcription factor. This factor inhibits the synthesis of proglucagon in enteroendokrin cells and glucose-induced insulin secretion, and is involved in the control of proliferation intestinal epithelial cells, adipogenesis and regulates the maturation of pancreas b-cells. The disease association studies have shown that T allele of the rs7903146 SNP TCF7L2 gene is strongly associated with T2D in various populations.
We genotyped 108 patients with T2D for rs7903146 of TCF7L2 and carried out various clinical characteristics. All patients were not related, aged over 45 years, and had disease duration for 5,78 ± 0,75 years.
It was revealed significantly higher frequency of TT-genotype: the TT genotype was verified in 56 (51.8%) patients, the CT genotype in 42 (38,9%), CC genotype in 10 (9,6%). Age and duration of diabetes of the "TT" patients were higher than "CC" patients. At "TT" patients had determined higher incidence of hypertension (82,1 ± 7,2% (P> 0.05)). The duration of hypertension was also more prolonged in this group of patients.
In the study of the glycemic parameters revealed significantly high levels of fasting plasma glucose in "TT" patients compared with the CC genotype (P> 0.05). No significant difference of blood glucose 2 hours after a meal, between CC, CT and TT genotype groups was found.

Cytogenetic studies in Acute Lymphocytic Leukemia (ALL): A study from Haryana (India)

A. Kumar;
M.D.University., Rohtak, India.

Cytogenetic studies on acute lymphocytic leukemia have led to the identification of recurrent abnormalities specific to ALL and have helped in understanding the mechanism of leukemia genesis. Cytogenetic abnormalities also provide a strong and independent prognostic factor for treatment outcome. As the cytogenetic abnormalities are poorly studied in population of Haryana (India), the present study was performed in patients of acute lymphocytic leukemia (ALL) from Department of Medicine and Department of Pediatrics, Pt. Sharma University of health sciences, Rohtak during 2008-12. Ninety four patients of acute lymphocytic leukemia were subjected to cytogenetic analysis by conventional method however a successful cytogenetic preparation could be obtained in 77(81.9%) patients due to non-availability of samples in remaining cases. There were 50 children (<15 years) and 27adults(>15 years). The most common cytogenetic abnormalities in patients of acute lymphocytic leukemia were high hyperdiploidy(>50 chromosomes), low hyperdiploidy(47-50 chromosomes), hypodiploidy(<46chromosomes) & t(9;22). Translocations t(4;11), t(1;19), t(8;14) were less common with a frequency of 3.8%,3.8%, & 2.6% respectively. The deletion of long arm of chromosome 6 was reported in only 2.6% patients. High hyperdiploidy & t(9;22) were more commonly observed in adults than children. Translocations t(4;11) & t(1;19) were found in children but not in adults. Similarly t(8;14) & deletion del6q were found only in adults. Remission duration and survival were longest in patients with normal karyotype and high hyperddiploidy, moderate with low hyperdiploidy, t(9;22),t(1;19), & deletion del 6q and shortest with hypodiploidy, t(4;11), & t(8;14).

Frequency determination of MSI mononucleotide markers in sporadic colorectal cancer patients

G. Esmail Nia[1], *M. Montazer Haghighi*[2], *G. Javadi*[3], *K. Parivar*[1], *M. Zali*[2];
[1]*Science and Research Azad University of Tehran, Tehran, Islamic Republic of Iran,* [2]*Research Center of Gastric Cancer and Liver Disease, Tehran, Islamic Republic of Iran,* [3]*Science and Research Brach Azad University of Tehran, Tehran, Islamic Republic of Iran.*

Background : Colorectal cancers (CRCs) tumors are diagnosed by microsatellite instability (MSI) due to accumulation of insertion/deletion mutations in tandem repeats of short DNA motifs (1 - 6bp) called microsatellites. Microsatellite instability (MSI) is not only a halkmark marker for screening of hereditary nonpolyposis colorectal cancer(HNPCC),but also a prognostic and predictive marker for sporadic colorectal cancer.Our objective was to determine and study the status of five mononucleotide microsatellite status among Iranian patients with sporadic colorectal cancer .
Material and Methods : In the current investigation 80 sporadic CRC patients were evaluated for MSI. The pentaplex panel consisting of 5 quasi mononucleotide microsatellite markers (NR-21,BAT-26,BAT-25,NR-27 and NR-24) was used .
Results: Our findings reveals that the NR-21 was the most frequent unnstable marker among the other markers (23%).69.6% of specimens had instability in sporadic colorectal cancer.Furthermore,the frequency of instability BAT-25 was determined in 20% sporadic CRC samples .Interestingly our results demonstrated that the frequency of instability NR-24 was 20% that was so close to istability of BAT-25 Marker. Moreover,percentage of NR-27 was 0% in sporadic CRC.Finally , we could find 6.6% instability for BAT-26 in sporadic cases.
Conclusion : It seems that among 5 mononucleotide markers NR-21 was the most useful marker for determining the status of sporadic colorectal cancer.Following NR-21,BAT-25 and NR-24 are the most effective markers. Therefore using a triple panel consisting 3 mentioned MSI markers shoud be more promising markers for identifying MSI status in patients with sporadic colorectal cancer.

ALL L2 with t(8;14)(q24;q32) associated with tetrasomy 1q and homozygous deletion of p16

E. Tuncez[1], *H. Tokgoz*[2], *A. Acar*[1], *U. Caliskan*[2], *A. G. Zamani*[1], *M. S. Yildirim*[1];
[1]*Necmettin Erbakan University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey,* [2]*Necmettin Erbakan University, Meram Medical Faculty, Department of Pediatric Hematology, Konya, Turkey.*

Acute lymphoblastic leukaemia(ALL) is the most common cancer of childhood. Recurrent chromosomal abnormalities revealed in approximately 80% of ALL and associated with distinct immunologic phenotypes of ALL and characteristic outcomes. Chromosome 1q duplications and trisomy 1q are recurrent changes mainly in B-lineage ALL and strongly associated with t(8;14)(q24;q32) which has been very occasionally reported in ALL L2. In about 15% of ALL cases have homozygous deletion of p16 gene which is associated with unfavorable clinical outcome. We present a case of ALL L2 with t(8;14)(q24;q32) associated with tetrasomy 1q and homozygous deletion of p16.
A 1-year-old female patient admitted to hospital because of weakness and skin rash. Complete blood count disclosed hemoglobin of 6.4 g/dL, white blood cell count of $21.7x10^3$/uL, and platelet count of $15x10^3$/uL. Bone marrow aspiration demonstrated ALL L2 and flow-cytometry analysis was consistent with CALLA+ Pre B cell ALL. Cytogenetic analysis of bone marrow cells revealed 47,XX,+i(1)(qter→q11::q11→qter),t(8;14)(q24;q32) which was confirmed with FISH analysis, in addition to homozygous deletion of p16. The patient treated with St Jude Total XIII ALL chemotherapy protocol. She is in good condition with remission of bone marrow and also t(8;14) found negative with FISH analysis at fourth mounth of therapy.
Altough 1q abnormalities may be found in the majority of hematological malignancies, 1q tetrasomy is very rare, with t(8;14) association, especially in ALL L2. We aimed to contribute to literature with report of this rare and interesting cases.

The study of the polymorphism Arg72Pro of TP53 suppressor oncogene in gastric cancer patients in Uzbekistan

S. Turdikulova, *M. I. Ubaydullaeva, R. S. Mukhamedov, M. D. Djuraev, D. M. Igamberdiev, U. N. Abdihakimov, A. A. Kasimov, A. N. Abdikhakimov;*
Center of High Technology, Tashkent, Uzbekistan.

Gastric cancer is the second leading cause of cancer death in the world.
The main goal of our research is to investigate the correlations between polymorphic variant of TP53 gene (Arg72Pro - rs1042522) and susceptibility to gastric cancer in Uzbekistan population. For the study we performed genotyping group of 130 patients with gastric cancer and 234 healthy individuals by means of PCR and PCR-RLFP methods. We determined the frequency of the three genotypes of the p53 gene in the patients with stomach cancer and controls: genotypes *Pro/Pro* (391- bp), *Arg/Arg* (277- and 114- bp), *Pro/Arg* (391-, 277- and 114-bp).Comparative analysis of resulting genotypes sho-

wed a statistically significant association between gastric cancer and Pro/Pro genotype in the group of young men (12-33 year) (p=0.01 Pearson's $\chi 2$ and p=0.003 according to the Fisher exact test, OR ($CI_{95\%}$) - 6.10 (1.64 - 2.71)) , but there were no association between polymorphism rs1042522 and gastric cancer in the group of elder men and women(59 ± 12 year). This study suggests that the p53 codon 72 polymorphism may be associated with gastric cancer in population of Uzbekistan.

Karyotypic identification of abnormal clones preceding morphological changes of B cell lymphoma

S. Cho;
Yonsei university, Seoul, Korea, Republic of.

We report a case with clonal cytogenetic abnormalities precede bone marrow morphological changes without definite morphological features of B cell lymphoma.
A 50 years old male who presented with intermittent fever and general weakness admitted our hospital in Jan 2010. However, we could not detect abnormal findings of malignant on physical examination and imaging studies except hepato-splenomegaly.
For evaluation of primary or concomitant disease in bone marrow, we performed bone marrow(BM) examination. The peripheral blood count revealed that WBC, hemoglobin and platelet count were 6.8 x 103/uL, 11.4g/dL and 208 x 103/uL, respectively. BM aspiration and biopsy showed about 20-30% cellularity marrow without abnormal cell clusters and cytogenetic analysis revealed 46,XY,del(6)(q16),i(8)(q10)[8]/46,XY[12]. However, morphologic changes and cytogenetic feature were insufficient to make a diagnosis. After conservative cares, he discharged. We also could not find any specific changes from follow up imaging studies and BM analysis in Jun 2010. In Aug 2010,the third BM analysis and cytogenetic study were performed and focal aggregation of intermediate to large B-cells as a suspicious morphologic features of B cell lymphoma were noted with clonal cytogenetic abnormalities 46,XY,del(6)(q16),i(8)(q10)[7]/46,XY[5]. Therefore, it was investigated for primary lesion, which was not identified.
In this case, specific morphologic features were not detectable at initial BM analysis and we got only a clonal cytogenetic abnormalities. So, we believed continuous closed follow-up with BM analysis and cytogenetic studies will be helful in some cases that showed only clonal cytogenetic abnormalities without definite morphological abnormalities.

J11.72

Characterization of BRCA1 mutations in Uzbekistan ovarian cancer patients

B. Adilov[1], *S. Nurmatova*[1], *D. Nabieva*[2], *Y. Mamadalieva*[2], *M. Isamukhamedova*[2], *S. Turdikulova*[1];
[1]*Centre of High Technology, Academy of Sciences Republic of Uzbekistan, Tashkent, Uzbekistan,* [2]*Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan.*

Ovarian cancer affects approximately 1 out of 70 women during their lifetime and is regarded as the most lethal gynaecological malignancy. Women with a germline mutation in the tumor suppressor genes BRCA1 or BRCA2 have a high risk of developing both breast and ovarian cancer. To reduce increased risk of developing cancer or to increase the likelihood of early detection, carries of BRCA1 or BRCA2 mutations are offered surveillance programs or risk-reducing surgery. Estimates of occurrence of BRCA mutations in ovarian cancer cases vary from 3% to 35%. The presence of founder mutations in some countries orethnic communities simplifies the identification of those with inherited predisposition to ovarian cancer. This will strongly facilitate the clinical application of genetic testing for these populations.
This study aimed to inves[[Unsupported Character - Codename]]tigate the contribution of BRCA1 to ovarian cancer in Uzbekistan patients. A total of 44 patients with ovarian cancer were included in this study. By means of SYBR Green based real-time allele-specific PCR we have analyzed DNA samples from peripheral blood of ovarian cancer patients for the presence of two BRCA1 mutations: 5382insC and BRCA1 300T>G.2 samples (4,54 %) were found to be positive for the heterozygous 5382insC BRCA1 mutation. We failed to register BRCA1 300T>G mutation. Taking into account a high possibility of ovarian cancer development in carriers of BRCA1 mutation, our data suggest the reasonability of the inclusion of 5382insC mutations test in screening programs for ovarian cancer prevention in Uzbekistan.

APC gene large deletions in Familial Adenomatous Polyposis patients

R. Kishani Farahani[1], *M. Montazer Haghighi*[2], *F. Keshavarzi*[1], *E. Nazemalhosseini*[3], *M. Zali*[4];
[1]*Department of biology, science and research branch, islamic azad university ,Kurdistan, Iran., Sanandaj, Islamic Republic of Iran,* [2]*Department of biology, science faculty,Islamic Azad university,east Teharn branch, Teharn, Islamic Republic of Iran,* [3]*Gastroenterology and Liver Diseases research center , Shahid Beheshti University of Medical Science,, Tehran, Islamic Republic of Iran,* [4]*Research Center for Gastroenterology and Liver Diseases, Shahid Beheshti University of Medical Science, Teharn, Islamic Republic of Iran.*

Background: Colorectal cancer is one of the most common cancers. Familial adenomatous polyposis (FAP) is one type of hereditary colon cancer with a large number of precancerous polyps .They initiate to grow in colon in age 7 to 35 years old in the patients. Large deletions are one of the important types of alteration in adenomatous polyposis coli (APC) gene which led to FAP. However, they cannot be identified entirely by traditional techniques. Among of all large deletions investigation methods, Multiplex ligation probe Amplification (MLPA) is the most effective technique. The aim of the current study was to standardize MLPA method in the screening of APC large deletions for the first time in Iranian patients with FAP.Materials and method: DNA was extracted from 34 FAP peripheral blood patients using saluting out method. All patients were screened for APC large deletions by MLPA and when the result was positive, the given region was investigated by PCR sequencing.Result: Two large deletions was detected in different sites of exon 15 in two patients. Sequence analysis did not show any point mutations in the probe binding sites.Conclusion: Rate of large fragment deletions in APC was 5.8% that is close to result of previous studies in other population like Polish, Czech, Taiwanese and Spanish. Nonetheless, it seems that the sites of alteration were different .Therefore, it would be more promising that consider of MLPA at the first step for screening the FAP patients in our population would be useful.

Centre of High Technology, Academy of Sciences Republic of Uzbekistan

D. A. Dalimova, *A. A. Abdurakhimov, S. U. Turdikulova, R. S. Mukhamedov;*
Centre of High Technology, Academy of Sciences Republic of Uzbekistan, Tashkent, Uzbekistan.

Helicobacter pylori (H. pylori) is a gram-negative pathogenic bacterium that chronically infects the stomach of approximately 25-50% of the world's human population. It is associated with the development of chronic gastritis, peptic ulcer and even gastric cancer. There is increasing evidence that the genetic variability of *H. pylori* may have a clinical importance. Several genes have been identified that may play a role in the pathogenesis of *H. pylori*, such as *vacA* and *iceA*. In Uzbekistan there is not sufficient information regarding the pattern of *H. pylori* genotypes in patients.
This study aimed to inves[[Unsupported Character - Codename]]tigate the prevalence of the *vacA* and *iceA* genotypes of *H. pylori* from patients with upper gastrointestinal diseases and the relationship with clinical outcome in Uzbekistan. A total of 135 patients with gastric cancer, gastroduodenal ulcer, chronic gastritis and ulcerative colitis were enrolled in this study. They had undergone endoscopy and gastroduodenal biopsy specimens were obtained from each patient. DNA extraction and polymerase chain reaction were used to assess the polymorphisms of *vacA* and *iceA* genes.
The obtained data indicate that *VacA* s1, *VacA* m1, *IceA1* genotypes were more prevalent among patients with gastric cancer, *VacA* s1, *VacA* m1, *VacA* m2, *IceA1* genotypes were more prevalent in patients with gastritis and *VacA* s1, *VacA* m2, *IceA1* genotypes were most common among patients with gastroduodenal ulcer and ulcerative colitis. In addition, the prevalence of *VacA*s1/*VacA*m1 and *VacA*s1/*VacA*m2 genotype combinations were found to be significantly higher in patients with gastric cancer and gastroduodenal ulcer/ulcerative colitis respectively.

Very complex karyotype and poor prognosis in AML

Y. Park, *H. Lim, H. Lee;*
Kwandong University College of Medicine, Goyang, Korea, Republic of.

Balanced translocations or inversions and specific gene mutations of acute myeloid leukaemia (AML) were known as related with prognostic significance. And AML with complex karyotype is typical type of poor prognostic AML. We present clinical and cytogenetic data on 1 case of very complex karyotype. 61 year-old man visited out-patient clinic with mild fever. Complete blood count and peripheral blood smear were performed, and pancytopenia (white blood cell, 1.8 $x10^9$/L; hemoglobin, 7.4 g/dL; hematocrit, 21%; platelet, 45 x 10^9/L) and 37% blast cells and shift to left finding in neutrophil lineage were noted. Bone marrow study was requested to diagnose leukaemia. Leukaemic blasts were admixed with three lineage hematopoietic cells and were 36.6% of all nucleated cells (ANC) from bone marrow aspirate and biopsy. In immunophenotyping, 26.7% of CD14 expressing cells and 28.4% of CD34 positive cells with negative CD14 were reported. Multiplex reverse-transcriptase polymerase chain reaction, Hemavision-7 System (DNA Technology A/S, Aarhus, Denmark), for 28 genetic abnormalities screening panel of AML were shown all negative results. Karyotype was reported as 44~46,XY,del(5)(q22q35),add(6)(p21.3),-7,add(11)(p15),del(11)(q22),der(12;17)(q10;q10),ins(12;?)(q13;?),-14,-16,add(17)(p11.2),-19,+1~3mar[cp20]. Acute myelomonocytic leukaemia was diagnosed. Patient had treated 1 cycle chemotherapy with Idarubicin, Cytarabine, and Dexamethasone. Bone marrow study was performed again 11 days after chemotherapy, and poor response for chemotherapy was shown with 19.9% blasts of ANCs. Karyotype was 41~46,XY,-3,del(5)(q22q35),add(6)(p21.3),-7,add(7)(p13),+8,-9,add(10)(q11.2),add(11)(p15),del(11)(p22),der(12;17)(q10;q10),ins(12;?)(q13;?),-14,-16,add(17)(p11.2),del(18)(q21.1),-19,+2~3mar[cp16]/46,XY[4]. To evaluate influence of specific genetic abnormalities or complex karyotype itself about poor response to treatment and poor prognosis, plentiful data from many patients would be needed.

Avenida de Madrid s/n Granada, Spain., Granada, Spain,* [4]*LORGEN G.P., PT, Ciencias de la Salud - BIC, Granada, Spain, Granada, Spain.*

Lynch syndrome is an autosomal dominant inheritance and the most hereditary form of colorectal cancer. The identification of the molecular genetic basis of Lynch syndrome enabled the implementation of predictive testing in families with a proven mutation. A prerequisite to detect patients with Lynch syndrome is the knowledge of the clinical and histopathological features of this disease. The molecular genetics underlying mechanism is a mutation in one of the mismatch-repair genes (most commonly MLH1, MSH2, and MSH6), that has added significantly important information to the recognition of this disease and the search for high-risk individuals as well as offering them a genetic counseling. We have performed an analysis in 71 patients with Lynch syndrome; some of them are cluster in a high number of family members. The main genetic analysis has been developed in MMR genes (MLH1, MSH2 and MSH6 genes) which allows us to discover some undescribed mutations, as well as, the importance of these mutations for categorize the aggressiveness of the cancer.
In this case, we focus in the importance of a previous undescribed mutation and it aggressiveness in a family with members affected and unaffected by this syndrome. After this genetic analysis unaffected members of the family are classified as high-risk and they will follow frequent clinical examination for CRC. In our patients, a total of ten members of the same family, some of them affected by Lynch syndrome but all have the presence of 117-1 G>K polymorphism.

The C515S (TGC/AGC) in a case of MEN2A

A. Chikouche[1,2], *M. Boudissa*[3], *M. Ait Abdallah*[2], *B. Ait Abdelkader*[2], *C. Daoud*[4], *K. Sbahi*[2], *F. Oukrine*[2], *N. Zeraoulia*[2], *L. Griene*[5];
[1]*Laboratory hormonology, CPMC, Algiers, Algeria,* [2]*Laboratory of Biochemistry and Molecular Genetics, University of Algiers 1, Algiers, Algeria,* [3]*Department of Endocrinology, CPMC, Algiers, Algeria,* [4]*Medical consultation, EPSP Bouchenafa, Algiers, Algeria,* [5]*Laboratory hormonology, CPMC, Laboratory of Biochemistry and Molecular Genetics, University of Algiers 1, Algiers, Algeria.*

Introduction: The multiple endocrine neoplasia MEN2A is a syndrome that presents a medullary thyroid carcinoma, with pheochromocytoma and hyperparathyroidism, is a part of MEN2, with MEN2B and MTC familial. The MEN2 are rare hereditary diseases, transmitted as an autosomal dominant form and associated with mutations of RET proto-oncogene. The genotypic diagnosis of MEN2is based on the identification of mutation in RET proto-oncogene.
Materials and Methods: Our study included 01 patient with MEN2A and two clinically heathy relatives, the son of 19 years and one brother of 45 years. Genomic DNA was extracted from peripheral blood leukocytes, and the 7 exons of the RET gene (8, 10, 11, 13, 14, 15, 16) were amplified by polymerase chain reaction (PCR) and examined by DNA sequence analysis to detect mutations. The pentagastrin test is realized for the patients and relatives and the dosage of calcitonine is effect by the IRMA-hCT of CIS-Bio-international.
Results: The genetic analysis of the 7 exons of RET gene has not permit to identify a germline mutation of RET in the index case, but has found a variation of sequence is C515S (TGC/AGC), located in exon 8, in a homozygous form. This variation was found in homozygote form in the brother and in heterozygote form in the son. The dosages of basal calcitonin and after pentagastrin test were normal.
Conclusion: After these results, we estimate that, this C515S variation of DNA sequence is a rare variant non pathogenic and cannot be considered as a mutation causing the MEN2.

Bone marraw mesenchymal stromal cells in myelodysplastic syndrome and acute myeloid leukemia patients contain genome instability

J. Kim[1], *D. Jekarl*[1,2], *Y. Kim*[1,2], *A. Kwon*[1], *H. Chae*[1,2], *M. Kim*[1,2], *Y. Kim*[3], *H. Kim*[3], *W. Min*[3];
[1]*Catholic Genetic Laboratory Center, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,* [2]*Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,* [3]*Departmet of Internal Medicine, Catholic Blood and Marrow Transplantation Center, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of.*

Genetic association between hematopoietic cell (HC) and mesenchymal stromal cell (MSC) in hematopoietic malignancies is a matter of controversy. This study compared genetic aberrations in HCs and MSCs of myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) patients to clarify this issue. A total of 80 patients (22 MDS, 58 AML) were enrolled. Chromosomal aberrations of HC were detected in 13 MDS (57%) patients and 34 AML (59%) patients. Cytogenetic abnormalities in at least one metaphase were detected in 15 samples among 72 (21%) cases with MDS and AML whereas MSCs from normal individuals revealed normal karyotype. *LINE1* global methylation level was measured by pyrosequencing. *LINE1* hypomethylation was observed in MSCs from hematologic malignancies compared with MSCs from normal control. Chromosomal microarray of HCs and MSCs was performed using CGX cytogenetic array 12x175K (Roche NimbleGen, WI, USA) in 9 patients. Four HCs and three MSCs revealed genomic abnormalities, which were comparable and/or not comparable to chromosomal aberrations. The copy number changes in MSCs were observed in chromosome 2q, 5, 13q and 17q. Our study demonstrated that MSCs from MDS and AML patients contained genetic instability, which was evidenced by cytogenetic abnormalities and copy number changes in submicroscopic level. The abnormalities were different from those in HCs. In addition, differences in global methylation level may constitute a particular pathogenesis of MDS and AML pathogenesis in epigenetic level.

Cytogenetic and moleculer cytogenetic analysis of a multiple myeloma case with complex karyotype

A. Acar[1], *A. Ugur Bilgin*[2], *A. G. Zamani*[1], *T. Akın*[1], *E. Tuncez*[1], *M. S. Yildirim*[1];
[1]*Necmettin Erbakan University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey,* [2]*Necmettin Erbakan University, Meram Medical Faculty, Department of Haematology, Konya, Turkey.*

Multiple Myeloma (MM) is characterized by accumulation of malignant plasma cells with bone marrow. Clinically patients with MM usually present bone pain related to lytic bone lesions, frequent anemia and, less often, renal impairment.
Several recurrent cytogenetic abnormalities have been reported in the literature. Informative karyotypes are usually highly complex, with two main subgroups: first subgroup characterized by hyperdiploidy and second subgroup characterized peudo, hypo- or tetraploidy with the accumulation of many structural changes. Among structural abnormalities observed in the karyotypes the most frequent one those involving the long arm of chromosome 1 and the 14q32 chromosomal region.
1q triplication is a distinct secondary chromosomal abnormality . Most repeated region of 1q is q21-q32. Recurrent translocations of 1q10 to the short arms of different acrocentric chromosomes(chromosome 15, 21, 22) and non acrocentric chromosomes (chromosome 12,16,19) have been identified. The gene involved in trp(1)(q) is unknown. However, it was suggested that the most common region of duplication, 1q23-24, harbours genes associated with tumor cell invasiveness.
Three main 14q32 translocations were observed in MM, each acounting for about 25% of the 14q32 rearrengaments: t(11;14)(q13;q32), t(4;14)(p16;q32) and t(14;16)(q23;q32). Cloning of some of 14q32 translocations showed that these translocations leaded to over expression of oncogenes. It's suggested that these recurrent chromosomal abnormalities are not randomly distributed, but present fight links.
We herein report a MM case of a 65 years old female with a complex karyotype as 45,XX,der(1)(:p35→q21:),t(1;2;?9)(q21;p23;?q34),-9,der(12)(12pter→12q24::1q21→1qter), t(14;20)(q32;q12),der(18)(18pter→18q23::1q21→1qter)[14]/46,XX[1], confirmed by FISH analysis.

Screening of *BRCA*1 (5382insC, 185deAG) and *BRCA*2 (6174delT) mutations in Breast cancer patients in Iran by Multiplex Mutagenically Separated PCR

S. Parchami Barjui[1], *N. Sadrizade*[2], *A. Salehi*[1], *N. Abdian*[1], *F. Heibati Goojani*[1], *M. Hashemzadeh Chaleshtori*[1], *M. Hajhashemi*[2];
[1]*Cellular and Molecular Research Center, Shahrekord, Islamic Republic of Iran,* [2]*Hajar Hospital, Shahrekord, Islamic Republic of Iran.*

Breast cancer is the most common cancer in women in the world. Mutation of *BRCA*1 and *BRCA*2 genes has been linked to hereditary breast and ovarian cancer. Some mutations such as 185 delAG and 5382 insC in *BRCA*1 and 6174 delT in *BRCA*2 are present in higher frequencies than other mutations. many methods have been reported for the study of *BRCA* mutations, but allele-specific PCR and PCR- mediated site-directed mutagenesis seems more efficient for screening of specific characterized mutations. **Patients and methods**: In this study 140 hereditary breast cancer women were identified. DNA of patient and control samples were extracted from peripheral blood. A particular Multiplex Mutagenically Separaded PCR method was used to screen for the 185 delAG and 5382 insC mutations in *BRCA*1 and 6174 delT mutation in *BRCA*2. For each mutation, three primers (one common, one specific for the mutant and one specific for the wild-type allele) were used. Amplification and Sanger sequencing were used to confirm the presence of mutations. **Results:** The BRCA1 5382 insC mutation was found in three individual patients, but the BRCA1 185 del AG mutation and BRCA2 6174 del T were not seen in any of the studied patients. **Conclusion:** The results show MS-PCR is a simple and reliable method to detect known recurrent *BRCA*1 and *BRCA*2 mutations. This study performed for the first one in Iran and these results could be used for detection of the frequency of *BRCA*1 and *BRCA*2 gene mutations in Iranian population.

Molecular study of gastrointestinal stromal tumors (GIST)

M. Haddaji Mastouri[1], *D. H'mida-Ben Brahim*[1], *S. Trabelsi*[1], *M. Chourabi*[1], *N. Labaied*[2], *S. Sassi*[1], *M. Yacoubi*[2], *A. Saad*[1];
[1]*Laboratory of cytogenetics, molecular genetics and reproductive biology, Farhat HACHED Hospital, Sousse, Tunisia,* [2]*Department of cytopathology, Farhat Hached Hospital, Sousse, Tunisia.*

Gastrointestinal stromal tumors (GIST) are the most common mesenchymal tumors of the gastrointestinal tract. They are characterized by the presence of gain function heterozygous mutations of the two target genes, c-Kit and PDGFRA. Throughout this work we conducted both immunohistochemical and genetic analysis of 25 gastrointestinal stromal tumors. Our study aimed to analyze c-Kit and PDGFRA activating mutations in order to establish a genotype-phenotype correlation and to implement a target therapy based on Imatinib. Immunohistochemical study revealed a positivity of c-Kit staining in 20 among 25 tumors. Tumoral DNA extracted from formalin-fixed tissues was sequenced for hot spot mutations of both genes c-Kit and PDGFRA.We were faced to poor DNA quality because of formalin tissues fixation. Thus we only managed to analyze 7 tumoral DNAs among 25. 4 activating mutations were revealed in 6 tumors. Mutations were located in exons 9 and 11 of the c-Kit gene. One tumor did not show any c-kit mutation and is then thought to be c-Kit wild type.Although we did not analyze mutations in all 25 tumors, the 4 revealed mutations should enable in 6 tumors a therapeutic benefit.

Analysis of *APC* Promoter Hypermethylation Number of Patients with Sporadic Colorectal Cancer

A. Abdollahi[1], *S. Khatami*[1], *H. Galedari*[1], *A. Forughmand*[1], *M. Ziadi*[2];
[1]*Department of Genetic,Shahid Chamran University of Ahvaz, Ahvaz, Islamic Republic of Iran,* [2]*Department of Genetic,tabriz University of medical science, tabriz, Islamic Republic of Iran.*

Colorectal cancer (CRC) is one of the most leading causes of cancer-related deaths in Iran. *Adenomatous Polyposis Coli* (*APC*) is a tumor suppressor gene and it's inactivation by hypermethylation of promoter region in CpG islands has been observed in the early development of Colorectal Cancer. Methylation of promoter CpG islands (CGIs) belonging to *APC* causes transcriptional silencing of this gene leading to carcinogenesis and other disorders. In current study, methylation of CGIs in the promoter of *APC* was analyzed using bisulfite direct sequencing method in 20 tumor tissue samples together with an equal number of normal tissues belonging to patients with confirmed diagnosis of colorectal carcinoma in south-west of Iran. Assessment of *APC* promoter methylation revealed that normal tissues were unmethylated, while 20 out of 30 (66.66%) tumor tissues were hypermethylated. Among the tissues in which methylation was detected, all of 20 were hypermethylated in one of the two alleles of *APC*. We are also studying 50 patients of CRC in north-west of Iran.

Novel nonsense mutation of BRCA2 gene in a Moroccan man with familial breast cancer

s. guaoua, *I. Ratbi, A. Sefiani;*
faculty of medicine and pharmacy rabat, Rabat, Morocco.

Abstract
Background: Breast cancer is the most common cancer among women worldwide accounting for about 30% of all cancers. The majority are sporadic, where as 5 to 10% of cases are due to an inherited predisposition in two major genes, *BRCA1* and *BRCA2*, transmitted as an autosomal dominant form with incomplete penetrance. Male breast cancer is rare and is mainly due to *BRCA2* than *BRCA1* germline mutations.
Objective: Molecular study of *BRCA2* gene in man with familial breast cancer.
Methods: PCR and direct sequencing of *BRCA2* gene.
Results: Identification of novel heterozygous germline mutation c.6428C>A ; p.Ser2143Stop of *BRCA2* gene.
Keywords: male, breast cancer, *BRCA2* gene, mutation, genetic counseling.

TP53 Arg72Pro polymorphism and bladder cancer risk

*N. Ersoy Tunali, **S. Sahoglu**;*
Halic University, Istanbul, Turkey.

TP53 is a tumor suppressor gene which regulates cellular stress response. Polymorphisms in the TP53 gene have been reported among possible genetic risk factors for various cancers. It has been shown that cells with Arg/Arg genotype tend to undergo apoptosis faster than cells with Pro/Pro genotypes. In this work, we aimed to investigate the role of TP53 Arg72Pro polymorphism in susceptibility to bladder cancer. 102 healthy controls and 79 Turkish bladder cancer patients were included in the study. The genomic DNA samples of the individulas were subjected to PCR and direct sequencing of the polymorphic region. The genotype frequencies were not significantly different (p=0.7) between patients and healthy subjects, therefore we could not find a significant association between the TP53 Arg72Pro polymorphism and bladder cancer risk. The frequency of TP53 codon72 polymorphism varies among ethnic populations, therefore genotype distribution and associated risk for cancer should be studied in different ethnic groups.

The genetic analysis in women with cancer and other pathology of female reproductive system

O. Paliychuk[1]*, N. Gorovenko*[2]*, Z. Rossokha*[3]*;*
[1]*R.E.Kavetskiy Institute of Experimental Patology, Oncology and Radiobiology National Academy Science, Kiev, Ukraine,* [2]*National medical academy of postgraduate education named after P.L. Shupik, Kiev, Ukraine,* [3]*Reference-centre for molecular diagnostic of Ministry of Public Health of Ukraine, Kiev, Ukraine.*

Introduction. The clinical and genealogical history in women with finding changes in genes can help determine individual chance of cancer development. The possible outcomes of these tests are very important for women with family history of female reproductive system cancer. The aim of the study was to compare the results of genetic analyzes among women with cancer of female reproductive system (CFRS) including cancer family syndrome and women with gynecological pathology.
Material and metods. We investigated 30 women aged 26-72 years. The genetic analyzes were performed among 14 women CFRS treated (group I) and among 16 women with gynecological pathology such as polycystic of ovary, ovarial cysts, endometrios, fibromyoma of utery (group II). The genetic analyzes included PCR-RFLP for determining T-397C, A-351G polymorphisms of ESR1 gene and G1846A polymorphism of Cyp2D6 gene. We compared the results using Fisher test.
Results. There were found no differences between two investigated groups in the frequency T-397C polymorphic variants of ESR1 gene. The G allele (GG, AG genotypes) of ESR1 gene frequency was significantly higher (p<0,05) among group I (71,4%) comparing group II (25,7%). On other hand, among group II was significantly higher (p<0,05) the frequency of A allele (GA, AA genotype) of Cyp2D6 gene (17,1%) as compare with group I (0,05%).
Conclusion.The further investigation may help to evaluate the individual cancer risk for women with cancer family syndrome.

J11.86

Establishment And Characterization Of A Cytogenetically Complex Multiple Myeloma Case With Novel 14q Rearrangement

G. A. GIRAN[1]*, K. YARARBAS*[2]*, K. ACAR*[3]*, N. A. BAYSAL*[3]*, M. PAMUKCUOGLU*[3]*, A. TUKUN*[1]*, Y. LALELI*[1]*;*
[1]*Duzen Laboratories Group, ANKARA, Turkey,* [2]*Duzen Laboratories Group, İstanbul, Turkey,* [3]*Gazi University Faculty of Medicine, Department of Hematology, ANKARA, Turkey.*

The objective is this presentation to report the clinical and laboratory characterization of a case of multiple myeloma with complex karyotype with novel 14q rearrangement.
A 63-year-old gentleman was referred to our hospital with back pain and anemia. Laboratory values showed anemia with a hemoglobin level of 8,3 g dl^{-1}. The white blood count (WBC) was 4690 μl^{-1} and the platelet count was 238 k μl^{-1}. Serum protein electrophoresis revealed IgA lambda monoclonal gammopathy. Rest of the serum chemistries were within normal. Bone marrow aspiration revealed 72% infiltration with plasma cells. Bone marrow biopsy showed presence of CD138 antigen and cytoplasmatic lambda chains in 90% of the plasma cells. Skeletal survey showed a decrease in height of the L2 vertebral body and several lytic lesions in calvarium. He was diagnosed with Multiple Myeloma. The ISS stage was II and Salmon Durie stage was IIIA.
The cytogenetic study showed t(5;14)(q22;q32) in all mitoses examined. An abnormal cellular clone with complex karyotype was found 9 out of evaluated thirteen metaphases: 46,XY,t(5;14)(q22;q32)[4]/52,X,-Y,+5,t(5;14)(q22;q32),del(6)(q21),+del(6)(q11),+del(6)(q11),+7,-8,+9,-10,+11,der(13)add(13)(p11.2),-14,+15,+15,der(16)add(16)(q24),del(17)(p13),+18,+der(19)t(1;19)(q23;p13), der(19)t(1;19)(q23;p13),-20 [9]. Although 14q rearrangements are frequently present in MM, t(5;14)(q22;q32) was not reported before.
Recognition of aberrant features of plasma cells has a paramount role in prognostic evaluation of myeloma patients. Identification of novel translocation t(5;14)(q22;q32) in single multiple myeloma case suggesting that new rearrangements of IGH, leading to new fusion transcripts, may be involved in the malignant progression of myeloma cells by promoting their proliferation and survival. However, the prognostic significance of this rearrangement is not clear.

Single Nucleotide Polymorphisms in the Loss of Heterozygosity and Uniparental Disomy Regions in a Colorectal Cancer Patient in Saudi Arabia

A. A. alabdulrahman*, m. M. Alotaibi, M. A. Aldress, S. AlQarni, M. Alrodayyan, M. A. Aziz;*
King Abdullah International Medecal Reserch, Riyadh, Saudi Arabia.

The incidence of colorectal cancer (CRC) in Saudi Arabia is on the increase. Genetic factors specifically linked to CRC have not been investigated widely in the Saudi population. Loss of Heterozygosity (LOH) and Uniparental Disomy (UPD) are two Genetic aberrations that are associated with CRC. In this study, we searched for the presence of CRC associated single nucleotide polymorphisms (SNPs) in the regions of LOH and UPD. Out of 27 SNPs we found 5 of them in LOH/UPD regions of chromosome eight in a patients diagnosed with CRC from King Fahd National Guard Hospital, Riyadh, Saudi Arabia.
Methods: DNA from tumor (case) and non-tumor (control) tissue from 15 CRC patients excised from each patient to represent samples and controls, respectively was analyzed using the AFFYMETRIX GeneChip Cytoscan HD array.
Results: Five SNPs (rs6983267, rs7014346, rs7837328, rs10505477, rs10808555) associated with CRC were found in a single patient in the UPD and LOH regions at chromosome 8.
Conclusion: The presence of SNPs in the regions of LOH/UPD may have a causal effect in the onset of CRC. Further studies are needed to establish this relationship.

Exploring signaling pathways to identify new molecular targets for cancer therapy

M. Kaur*, L. Esau, S. Sagar, V. B. Bajic;*
King Abdullah University of Science and Technology, Computational Bioscience Research Center, Thuwal, Saudi Arabia.

It is widely accepted that cancer or other complex diseases are not caused by a single gene, rather an array of genes communicate with each other in a complex manner to determine the fate of a cell. In recent years, the research in this area has been focused on the understanding of biological pathways involved in a disease in order to develop effective drugs. In order to contribute to these efforts, we have established a work-flow in our laboratory, from initial high-throughput screening to mechanism of action level studies. It involves- *in vitro* anticancer screening focusing on cell death mechanisms, microarray gene expression analysis to identify differentially expressed genes, pathway mapping, and experimental validation of the identified pathway. The results of our study are presented here which not only led us to identify a new candidate therapeutic compound for estrogen positive breast cancer treatment but also facilitated the identification of new genes with potential role in cell death mechanisms, which may represent new molecular targets for developing anticancer therapies.

The role of cox gene in hepatocellular cancer patients

R. M. T. Issa;
Institute of Genetic Engineering and Biotechnology, Cairo, Egypt.

Cox-2 gene has an adverse effect on tumor suppressor p53,which is an apoptotic transcription factor normally found in the cytosol.Two of the metabolites of cox-2 prostaglandins A1and A2,when present in higher quantities bind to the cytosol and inhibits ability to cross into the nuclues. Aim of work,to proove the role of cox -2 gene in HCC patient.Subjects and methods,17 hepatocellular carcinoma tissue samples and twenty normal distant tumor samples,were taken from 22 patients underwent hepatectomy as a primary modality for HCC,Results:,All normal patients were cox-2 negative ,3 out of 4distant metastassis were cox -2 gene positive and 7 out of 13 were cox -2 positive,Cox-2 gene was 100% specific and 58% sensitive

Multitarget FISH assays in detecting abnormal cells in washing and bronchial biopsied lung cancer cells; a pilot study in Egyptian patients

H. F. Kayed[1], *O. M. Eid*[1], *N. A. Helmy*[2], *W. M. Ashour*[2], *N. A. Helmy*[1];
[1]*National Research Centre, Cairo, Egypt,* [2]*Chest department -Faculty of Medicine - Cairo University, Cairo, Egypt.*

Background. Lung carcinomas are associated with molecular abnormalities. We performed a pilot study to determine the feasibility of an interphase FISH assay for the detection of lung carcinoma in bronchial washing specimens and tissue biopsy. **Methods.** Twenty bronchial washing specimens were analyzed. The LAVysion multicolor probe set contains locus-specific probes to 5p15, 7p12 (*EGFR*), 8q24 (*CMYC*), and a centromeric probe to chromosome 6 was used, hTERT gene (5p15) red and control region EGR1 gene (5q31) green probe was used also. **Results.** FISH positivity in the samples of this study was 60% (12/20) for LAVysion probes and for hTERT probe 33.3 % (6 / 20) only.
Conclusions. The current study indicated that Multitarget FISH assays have shown higher sensitivity in detecting abnormal cells in washing and bronchial biopsied cells from patients with lung cancer, also, hTERT gene amplification or high copy number could be a marker for poorer prognosis in early-stage NSCLC patients.

Investigation of genomic instability in cholesteatoma tissues

Z. B. Bulut[1], *H. Acar*[1], *K. Ozturk*[2];
[1]*Selcuk University Department of Medical Genetics, Konya, Turkey,* [2]*Selcuk University Department of Otorhinolaryngology, Konya, Turkey.*

Cholesteatoma is defined as 'skin in the wrong place' that means 'the presence of squamous epithelium in middle air'. They are locally invasive and destructive lesions around bone and have high recurrence rate after the surgery. Genetic basis of cholesteatoma has not been understood yet. In this study, we searched genetic basis of cholestetaoma by using LOH (Loss of Heterozygosity) analyse including MSI (Microsatellite Instability) which has an important role in genome-wide screening. For this, microsatellite markers are used. Microsatellites are polymorphic and basically similar although they contain small differences among individuals in the field of molecular genetic that makes them appropriate to use as genetic markers. Capillary electrophoresis fragment analysis was performed by examining seven loci. Markers used were selected according to the data obtained the study including epithelial cancers in literature. MSI was observed in 6 out of 39 cases in some regions resulting in increased size of one allele. One of these six patients is recurrent. The markers of observed MSI are D6S273, D6S473, D8S261, D9S157, D9S162. In addition, we found one LOH region (D15S153) in one patient. To our knowledge, this is the first study screening of LOH for cholesteatoma. This finding indicates different genetic basis of cholesteatoma. The further study is needed to carry out the molecular basis of cholestetaoma.

The ICS (Institut Clinique de la souris) genetic engineering and model validation department: Generation of customized and read-to-use genetically engineered mice

M. Wattenhofer-Donzé*, P. André, S. Jacquot, M. Jagla, M. C. Birling, G. Pavlovic, Y. Hérault;*
Institut Clinique de la Souris, ICS, Infrastructure Nationale PHENOMIN, Illkirch, France.

The Institut Clinique de la Souris (ICS) is part of PHENOMIN the National research infrastructure that provides extensive services ranging from development of mouse models to comprehensive phenotyping.
The Genetic Engineering and Model validation Department at ICS is dedicated to the development and molecular validation of new mouse models. They can be valuable tools to better understand the molecular processes of monogenic diseases or to test drugs in vivo. We can generate duplications and deletions of defined genomic fragment (CNVs) as observed in human disease or small/large deletion or insertions, point mutations, humanizations and conditional mutations. We always work in strong interaction with the scientists and make sure to define their needs. Many publications have already arised from mice generated at ICS.
Model mice are generated either through introduction of DNA into zygotes or through injection of genetically manipulated embryonic stem cells (ESC) into blastocysts. We can either use ESC from consortium (http://www.knockoutmouse.org/) or introduce the desired mutation in our ESC. We are also able to derived ESC from your favorite mouse model if you wish to perform in cellulo experiments.
Please note that ICS phenotyping department is presented in another poster.

Exome Sequencing in Primary Chronic Myeloid Leukemia Patients

A. V. Lavrov[1,2], *S. A. Smirnikhina*[1], *E. P. Adilgereeva*[1], *V. A. Kozlov*[1,2], *E. Y. Chelysheva*[3], *O. A. Shukhov*[3], *A. G. Turkina*[3], *S. I. Kutsev*[1,4];
[1]*Research Center of Medical Genetics, Moscow, Russian Federation,* [2]*Moscow Institute of Physics and Technology, Moscow, Russian Federation,* [3]*Hematological Research Centre, Moscow, Russian Federation,* [4]*Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation.*

In chronic myeloid leukemia (CML) about 35% of patients either remain resistant or develop resistance to the most effective therapy by inhibitors of tyrosine kinase. Exome analysis is now-a-days the most powerful tool in the search for the new prognostic markers and molecular targets for individual therapy. We launched prospective study aiming to sequence exomes of leukemic cells in CML patients to find out possible exomic differences between responders and non-responders. This will help not only to find predictors to the therapeutic outcomes but also will allow to look in deep mechanisms of the disease progression which basically remain unclear. To the date there are 5 CML exomes sequenced with 20K variations found in average. About 6K of the found variants are non-synonymous. Preliminary analysis demonstrated that 123 of these nonsynonimous variants are not described in dbSNP and can potentially contribute to the pathogenesis of CML and/or resistance to the TKIs. These and new data with deep analysis of the findings will be discussed in the presentation.

J13.02

The use of genetic testing for personalized optimization of warfarin therapy in patients of the West Siberian region of Russia.

N. V. Kokh*, G. I. Lifshitz, G. A. Tsvetovsky, E. N. Voronina, M. L. Filipenko, A. A. Slepuhina;*
The Institute of Chemical Biology and Fundamental Medicine SB RAS, Novosibirsk, Russian Federation.

The aim of our study was to investigate the frequency of occurrence of CYP2C9 *2, *3 (R144S and I359L), C+1173T VKORC and G>A rs2108622 (V433M) CYP 4F2 and C>G rs 11676382 GGCX genes polymorphisms in patients of the West Siberian region of Russia, as well as to assess the contribution of these genetic markers to the change of therapeutic dosage of warfarin for this group of patients.
The study included 118 patients (mean age 51) from the West Siberian region taking warfarin more than 1 year. Effectiveness of warfarin was assessed by the International Normalized Ratio. Presence of alleles was determined

by polymerase chain reaction.
Significant differences of average daily dose of warfarin depending on the VKORC genotype were revealed: for patients with genotype CC average dose was 7,1+2,3mg, with genotype CT - 4,8+1,9mg, with genotype TT - 2,8+0,6mg (p(CC-CT)=10-6, p(CT-TT)=8*10-4, p(CC-TT)=10-9). There were not significant differences in selected doses of warfarin depending on the CYP2C9 *2 genotypes. Patients who had a „slow allele" CYP2C9*3 received low doses of warfarin (*1/*1 5.8±2.5mg and *1/*3 - 4.1±2.6mg, p=0.03). Presence of CYP2C9 *2 or *3 alleles resulted in tendency to decrease of average daily dose of warfarin based on VCORK1 genotype. Thus, genotype VKORC1 and CYP2C9*3 among other genetic markers contributes most to the titration of a therapeutic dosage of warfarin in the West Siberian population. The results of the pharmacogenetics testing on CYP2C9 and VKORC1 can predict the fluctuation range of the daily maintaining dose of warfarin.

The assessment of human plasminogen activator inhibitor - 1 (PAI-1) gene polymorphism association with deceased kidney graft initial function and survival

*V. Morozova[1], N. Kaluzina[1], J. Moisiuk[1], V. Novoseletsky[2], **V. Abramov**[3,1];*
[1]Shumakov Center for Transplantology and Artificial Organs, Moscow, Russian Federation, [2]Moscow State University, Moscow, Russian Federation, [3]Sklifosovsky Rescue Care Medicine Research Institute, Moscow, Russian Federation.

Delayed kidney graft function (DGF) is a poor prognostic sign combined with reduced graft survival.We retrospectively investigated the relationship of DGF and the deceased donor kidney graft survival with inherited polymorphism of human plasminogen activator inhibitor (PAI-1) gene in transplant recipients (n=185) and corresponding donors (n=185). Genomic DNA was isolated from frozen and stored at -50C blood or internal organ tissue fragment. PCR-Taqman technique was used to type for PAI-1 gene mutation -675 5G → 4G (Synthol, Russia). The criterion for DGF was equivalent to at least one dialysis session during the first 7 days after surgery. Binary logit model and Cox's proportional hazards model were used to assess the reliability of the effect of mutation on DGF and graft survival at 1 year, resp.Only homozygous 4G/4G PAI-1 genotype of the donor showed significant correlation with the DGF (p = 0,008) in the logit model adjusted for the transplant order, cause of death of the donor, donor age, duration of cold ischemia time of the graft, the level of panel-reactive preformed cytotoxic antibodies, compatibility for HLA class I and HLA-DR, anti-CD25 therapy, and PAI -1 genotype of the recipient. In the Cox model with the same arguments both incompatibility for HLA class I (p = 0,0009) and the 4G/4G PAI-1 genotype of the donor (p = 0,037) demonstrated significant association with the fall graft survival.Conclusion. Homozygosity of the donor, but not the recipient of cadaveric kidneys for mutation -675 4G PAI-1 gene predisposes to DGF and reduced graft survival.

The influence of A313G polymorphism in GSTP1 gene on perinatal asphyxia development and necessity of reanimation supplementation in full-term neonates

***Z. Rossokha**[1,2], S. Kyryachenko[1,2], O. Kovalova[3], V. Pochylko[3], T. Znamenskaya[4], N. Gorovenko[5,2];*
[1]Reference-centre for molecular diagnostic of Ministry of Public Health of Ukraine, Kiev, Ukraine, [2]State Institute of Genetic and Regenerative Medicine Academy of Medical Sciences, Kiev, Ukraine, [3]Ukrainian Medical Dental Academy, Poltava, Ukraine, [4]State Institution «Institute of pediatrics, obstetrics and gynecology NAMS in Ukraine», Kiev, Ukraine, [5]National medical academy of postgraduate education named after P.L. Shupik, Kiev, Ukraine.

The GSTP1gene is involved in the deactivation of free radicals, in the inflammatory response and affect the lung development. The presence of 313G polymorphic variant is changing the enzymatic activity of enzyme-isomers, which may predispose to the development of pathological conditions. The aim was to examine the relationship between the gene polymorphism and the perinatal asphyxia risk and the necessity of support in the neonatal intensive care.
Methods. We examined 70 full-term neonates with different severity of perinatal asphyxia (PA) and 71 full-term healthy neonates. The genetic analyzes were performed using PCR-RFLP. There were evaluated the frequency of mechanical ventilation and hemodynamics medical support in the neonates with PA. Statistical analysis was implemented using SPSS 16.0.
Results. We have found no differences in the frequencies of GSTP1 genotypes between two groups. The investigated polymorphic variants had also no influence on the PA severity. The presence of GG genotype did not increase the relative risk of mechanical ventilation, but the neonates with genotype GG were required the necessity of hemodynamics medical support in 50% of cases comparing with 22% of cases for the neonates with genotype AA. The maximum dose of dopamine for hemodynamic support was for neonates with AA genotype - 6,03 mg / kg / min, with GG genotype - 9,0 mcg / kg / min. The neonates with GG genotype treated significantly higher dose of dopamine.
Conclusion. The further investigation may help to optimize the medical support and dopamine dose in the neonates with PA.

The Role of Genetic Factors in the Prediction of Myocardial Infarction Complications Within One Year Follow Up

***O. A. Makeeva**[1,2], M. V. Zykov[2], E. V. Kulish[1], M. V. Golubenko[1], V. V. Kashtalap[2], I. A. Goncharova[1], O. L. Barbarash[2], V. P. Puzyrev[1];*
[1]Institute of Medical Genetics, Tomsk, Russian Federation, [2]Institute of Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation.

A sample of 165 patients with myocardial infarction (IM) with elevated ST segment has been studied to construct a prediction model for one-year period complications (recurrent nonfatal IM or cardiac death). 32 polymorphic genetic markers with confirmed role in cardiovascular disease pathogenesis were analyzed, the best model to stratify patients by risk of post-IM complications included variants rs4291 (A-240T) in the ACE gene, rs6025 (G1691A, Leiden mutation) in the F5, and rs5918 (Leu59Pro) in the IGTB3. C statistics for the genetic model was 0,75 (0,64; 0,86) p=0,001, which is comparable with characteristics of the GRACE scale for the same patients' population: 0,73 (0,61; 0,85). Thereby, analysis of a limited number of genetic markers was sufficient to create a risk prediction model for post-IM complications comparable by it characteristics to the models, which are currently in use in clinical practice. To confirm the clinical validity, the predictive model obtained in the study should be confirmed on independent samples of patients with MI.

Analysis of the associations between angiotensin-converting enzyme gene polymorphism and development of intraventricular hemorrhage in preterm infants

***O. Kovalova**[1], Y. Goncharova[1], V. Pochylko[1], Z. Rossokha[2], E. Shunko[3], T. Znamenskaya[4], N. Gorovenko[3];*
[1]Ukrainian Medical Dental Academy, Poltava, Ukraine, [2]Reference-centre for molecular diagnostic of Ministry of Public Health of Ukraine, Kiev, Ukraine, [3]National medical academy of postgraduate education named after P.L. Shupik, Kiev, Ukraine, [4]State Institution «Institute of pediatrics, obstetrics and gynecology NAMS in Ukraine», Kiev, Ukraine.

Introduction. The objective of this study was to examine the associations between angiotensin-converting enzyme (ACE) gene insertion/deletion (I/D) polymorphism and development of intraventricular hemorrhage in the preterm infants.
Material and methods. Prospective observational study included 50 preterm infants at less than 36 weeks gestation (median birthweight 1586 g, range 700-2499 g; gestation 30,8 weeks, range 27-36; 22 male) admitted to the neonatal intensive care units of children's hospitals of Poltava region. Control group consisted of healthy term infants from the same region (n=38). Both groups of patients were genotyped for the insertion/deletion polymorphism of the ACE gene. Intraventricular hemorrhage were compared in patients with II, ID, and DD genotypes of the ACE gene. Associations between different ACE genotypes and risk of intraventricular hemorrhage were analyzed.
Results. Distribution of infants in relation to the three variations of ACE gene I/D polymorphism was identical in the study (26,0 %, 54,0 % and 20,0 %) and control groups (39,5 %, 44,7 % and 15,8 %, p=0,404). Severe intraventricular hemorrhage was significantly associated with DD genotype (OR 6,938; p=0,050) while no associations with II and ID genotypes were found.
Conclusion. Results of the study confirm the potential role for genetic factors, particularly for gene variations of renin-angiotensin system, in the pa-

thogenesis of intraventricular hemorrhage.

Congenital Right Tibia Diaphysis Amputation and Bilateral Nephrolithiasis in a 6-Months-old child

M. A. SOYLEMEZ, *K. Delil, H. Simsek, A. Tafazzoli, P. Gultepe, M. Avsar, S. Ergunsu, N. Haklıgur, G. Girgin, H. Kazan, G. Koc, T. Avcılar, C. Erzik, M. jovaroq, A. I. Guney; MARMARA UNIVERSITY MEDICAL SCHOOL, ISTANBUL, Turkey.*

Objective: We report the case of a 6-Month-old boy with congenital right tibia diaphysis amputation which was nephrolithiasis of the bilateral kidney with hypercalcemia. Nephrolithiasis is a condition characterized by the formation of crystallized material in the urinary system . The occurrence of urolithiasis is most significantly influenced by metabolic disorders, hypercalcemia, urinary tract obstruction with urine stasis and urinary tract infection. Co-existence of congenital right diaphysis amputation and bilateral nephrolithiasis has not been reported previously in neonatal period.

Case Report:

A 6-month-old boy was sent to our medical genetics center with the diagnosis of Congenital right diaphysis amputation. The child was finally referred to our department for further diagnosis and treatment. There was no evidence of previous severe diseases of urinary tract. The Family history was positive for nephrolithiasis. His serum parathormon was in the normal range. However, his serum calcium and ionized calcium levels were elevated. Nevertheless, 25-OH vitamin level was normal for the patient. Renal ultrasonography showed some bilateral multiple renal micro-stones without hydronephrosis.

Conclusion: Congenital amputation of lower extremities and neonathal hypercalcemia with bilateral nephrolithiasis is not a common co-morbid disease. Early diagnosis and early treatment are essential for metabolic abnormalities of calcium. Correction and monitoring of metabolic abnormalities of calcium can be a life saving procedure.

Incidental findings in large scale sequencing studies

F. Busonero[1], *C. Sidore*[1,2], *R. Berutti*[2,3], *F. Reiner*[3], *A. Maschio*[1,4], *R. Atzeni*[3], *M. F. Urru*[5], *M. Marcelli*[5], *R. Pilu*[1], *M. Pitzalis*[1], *S. Lai*[1], *M. G. Piras*[1], *F. Deidda*[1], *H. M. Kang*[4], *A. Angius*[1,5], *D. Schlessinger*[6], *C. M. S. Jones*[3], *G. R. Abecasis*[4], *F. Cucca*[1,2], *S. Sanna*[1];
[1]*Istituto di Ricerca Genetica e Biomedica (IRGB)-CNR, Monserrato, Italy,* [2]*Dipartimento di Scienze Biomediche, Università di Sassari, Sassari, Italy,* [3]*CRS4, AGCT group, Parco tecnologico della Sardegna, Pula, Cagliari, Italy,* [4]*Center for Statistical Genetics, University of Michigan, Ann Arbor, MI, United States,* [5]*CRS4, GSP group, Parco tecnologico della Sardegna, Pula, Cagliari, Italy,* [6]*Laboratory of Genetics, NIA, Baltimore, MD, United States.*

With the increasing adoption of sequencing technologies in large scale genetic studies, there is a strong possibility of discovering clinically relevant genetic information (incidental findings) about a research participant, outside the scope of the original research objective. These findings can relate to carrier status for a heritable condition or increased susceptibility to a medical condition.

In the context of the SardiNIA Medical Sequencing Discovery Project (dbGaP Study Accession: phs000313.v3.p2), we have sequenced the whole-genome of 2,120 Sardinian individuals enrolled either in the SardiNIA project or in a parallel project on autoimmune diseases, at an average depth of ~4X. We successfully identified ~17M single nucleotide polymorphisms with an error rate of 0.2%. The draft sequences allowed us to screen for clinically relevant variants, as those responsible for mendelian diseases (such as beta-thalassemia, cystic fibrosis, hemochromatosis, thrombophilia), and those conferring high-risk for complex diseases (such as breast cancer). Interestingly, ~6% of the 2,120 samples, on average, are carriers for 5 of the 9 mendelian conditions examined. This information could be clinically relevant for their life, as simple genetic counseling for couples or as warning for late-onset diseases. Interestingly, we also observed putative risk variants for multifactorial diseases to be instead common and in disagreement with the available clinical information for the same volunteers. These analyses emphasize the need of a close collaboration with clinicians and counselors in large scale sequencing studies, as well as the need for an improved annotation of disease alleles described in literature.

J13.09

A novel desmoplakin dominant mutation responsible for Carvajal/Naxos syndrome identified by exome sequencing

S. Bardi[1], *F. Girolami*[1], *M. Benelli*[1], *G. Marseglia*[1], *C. Pescucci*[1], *B. Tomberli*[2], *F. Cecchi*[2], *I. Olivotto*[3], *F. Torricelli*[1];
[1]*Genetic Diagnostic Unit, Careggi University Hospital, Florence, Italy,* [2]*University of Florence, Department of Clinical and Experimental Medicine, Florence, Italy,* [3]*Referral Center for Myocardial Diseases, Florence, Italy.*

Naxos (OMIM#601214) and Carvajal (OMIM#605676) syndromes are rare forms of recessive Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC). We report the case of an Italian 37-year-old woman with a form of ARVC with phenotypic features overlapping Naxos/Carvajal syndrome due to a novel desmoplakin (DSP) mutation identified by Whole Exome Sequencing (WES), but with a dominant model of inheritance.

The woman was admitted to the hospital after resuscitated cardiac arrest. Clinical and instrumental evaluations showed mild biventricular systolic dysfunction, with dilated ventricles. She also has palmoplantar keratoderma and family history of sudden cardiac death. Molecular analysis was performed by WES on the Illumina HiScan SQ.

Family's pedigree showed a dominant model of inheritance. 65993 variants were individuated by bioinformatics analysis; after data filtering and integration of filtered results with patient's clinical features 4 potential mutations were selected. Only two of those variants cosegregated with the disease in the family: c.878A>T, p.Glu293Val in the DSP gene and c.626A>C, p.Tyr209Ser in the cytochrome c oxidase assembly gene (SCO2). Since the cardiomyopathy related to SCO2 gene mutations is usually associated with encephalopathy and is fatal in children, we excluded the causative role of such gene in our family. Therefore, we considered the DSP- Glu293Val variant as disease-causing and we hypothesized a modifier role for the SCO2 variant.

We identified a novel DSP gene variant associated to a dominant form of Carvajal/Naxos syndrome by Whole Exome Sequencing. This report demonstrates the utility of Next Generation Sequencing in the clinical setting for syndromic cardiomyopathies.

A discovery that ensures uniform efficiency of assays between samples and across all genome regions

C. D. Veal[1], *P. J. Freeman*[1], *K. Jacobs*[2], *O. Lancaster*[1], *S. Jamain*[3,4], *M. Leboyer*[3,4], *D. Albanes*[2], *R. R. Vaghela*[1], *I. Gut*[5], *S. Chanock*[2], *A. J. Brookes*[1];
[1]*University of Leicester, Leicester, United Kingdom,* [2]*National Cancer Institute, Bethesda, MD, United States,* [3]*INSERM U955, Créteil, France,* [4]*Université Paris Est, Créteil, France,* [5]*Centre Nacional d'Analisi Genomica, Barcelona, Spain.*

For many analytical methods the efficiency of DNA analysis varies across the genome and between samples. This tends to correlate with high C+G content in a complex way that does not explain why the direction and magnitude of effects varies between samples. We provide evidence that sequence elements that have unusually structured C+G content do not melt even when aggressive melting conditions are applied. These elements remain duplexed, thereby preventing the strands of flanking melted sequences from diffusing away from each other.

Consequently, neighboring strands, whose length will depend on the quality of the DNA (via nicking, breaks, etc), can quickly re-anneal as non-denaturing conditions are re-established. This prevents the access of oligonucleotide primers (or probes), thereby reducing amplification (or hybridization) efficiency for broad domains that we have termed 'Thermodynamically Ultra-Fastened' (TUF) regions.

This mechanism explains why some genome regions are particularly difficult to amplify and assay in many procedures, such as PCR or WGA steps of NGS and GWAS. Importantly it also explains inter-sample variability of this behavior, DNA samples of varying quality will carry more or fewer nicks and breaks, hence their intact TUF regions will have different lengths and so be differentially affected by this amplification suppression - with 'higher' quality DNAs being the most vulnerable.

A major practical consequence of this discovery is that inter-region and

inter-sample variability can be largely overcome by employing routine fragmentation methods (e.g. sonication or enzyme digestion) prior to sample amplification.

This work was funded by EC FP7 agreement 201418 (READNA)

Detection of broad range of DNA damage with Two-Dimensional Strandness-Dependent Electrophoresis (2D-SDE)

*B. Gudmundsson[1], H. G. Thormar[1,2], A. Sigurdsson[1], S. Thongthip[3], M. Steinarsdottir[4], A. Smogorzewska[3], **J. J. Jonsson**[1,4];*
[1]Univ. of Iceland, Reykjavik, Iceland, [2]BioCule Inc.,, Reykjavik, Iceland, [3]Rockefeller University, New York, NY, United States, [4]Landspitali - National University Hospital, Reykjavik, Iceland.

Two-Dimensional Strandness-Dependent Electrophoresis (2D-SDE) in manual minigels or premade microgels is a novel technique for nucleic acid analysis. In the first dimension nucleic acid fragments are separated based on length and strandness i.e. double-stranded DNA, single-stranded DNA and RNA•DNA hybrids. The nucleic acids are heat denatured before the second dimension electrophoresis and in the second dimension all fragments are single-stranded and separate only based on length.

We tested if 2D-SDE could detect various types of DNA damage *in vitro* and *in vivo*. Each sample was run in duplicate both uncut and cut with *Mbo* I which cuts both single- and double-stranded DNA. Single-stranded breaks, either nicks or gaps, were detected as horizontal streaks on 2D-SDE extending from uncut DNA molecules too large to size separate in the gel. Double-stranded breaks generated an arc in the gel. In contrast, DNA with interstrand crosslinks and bulky adducts were bent and migrated in front of that arc. Single-stranded DNA molecules, too damaged for complementary strand binding, formed a diagonal line. 2D-SDE detected DNA damage at comparable level of sensitivity to the well known comet assay. However, 2D-SDE allowed direct detection of damaged molecules and subfractions could be isolated form the gel.

2D-SDE can be used to detect many common types of DNA damage. Applications include testing quality of biosamples and efficiency of various procedures. Applications also include genotoxicity testing, chemosensitivity testing and diagnosis of genome instablity and DNA repair disorders.

Array-DASH: Dynamic microarrays for highly-sensitive and robust DNA fingerprinting, scanning, genotyping and re-sequencing in various diagnostics settings

***S. Gibson**, R. Sandhu, O. Lancaster, A. J. Brookes;*
Department of Genetics, University of Leicester, UK, Leicester, United Kingdom.

To enable widespread DNA diagnostics in myriad settings, we have developed and optimised a new, low cost, simple and universal technology. The method is termed ‚array-based dynamic allele-specific hybridisation' (array-DASH), which exploits the proven diagnostic utility of melt-curve analysis, but transfers it to the content rich format of a micro-array.

Key features include; unprecedented sensitivity (directly detects all allelic variants at 1% representation), virtually error-free mutation detection, robustness to C+G extremes and secondary structures, and the use of completely standard run conditions - serving genotyping, scanning, fingerprinting, re-sequencing, and combinations thereof.

We are now exploring the real-world utility of this system for several important applications, including prenatal testing of fetal genomes in maternal plasma, detection of emerging clonal sequences in cancer biopsies, detecting rare drug resistance variants in HIV infections, and purity testing of harvested crops. In so doing, we also aim to create a commercially available array-DASH device with inbuilt software for automated data analysis.

J14.04

A novel, generic, preimplantation genetic diagnosis (PGD) protocol applied to Cystic Fibrosis (CF) involving mutation detection through High Resolution Melting Analysis (HRMA) and simultaneous haplotype analysis through QF-PCR.

***A. Destouni**[1,2], M. Poulou[1], G. Kakourou[1], C. Vrettou[1], J. Traeger-Synodinos[1], E. Kanavakis[1,2], M. Tzetis[1];*
[1]Department of Medical Genetics, University of Athens, Athens, Greece, [2]Research Institute for the Study of Genetic and Malignant Disorders in Childhood, Athens, Greece.

CF is the most common genetic disease in Caucasians and a common indication for PGD. Due to CF's extremely heterogeneous mutation spectrum (>1800 mutations), most CF-PGD protocols reported to date, apply single-cell multiplex fluorescent PCR for segregation analysis (STR-linkage) along with p.Phe508del detection, when indicated. This approach is limiting for cases with other mutations when segregation analysis is unavailable. We report the development and successful clinical application, of a novel, generic PCR-PGD protocol to facilitate direct detection of any CFTR mutation by HRMA, and simultaneous confirmation of genotyping through STR-haplotype analysis. An optimized touch-down, multiplex PCR supports the co-amplifcation of: i). any CFTR exon-region combination using primers previously described (Montgomery et al. 2007) and ii. 6 STRs (4 intragenic and 2 extragenic). 1st PCR products were used: i. as a template for a nested PCR for HRMA and ii. to confirm the CFTR genotypes by STR haplotype analysis. Pre-clinical protocol validation involved testing 208 single isolated lymphocytes from whole blood samples of candidate PGD patients. Four clinical PGD cycles were performed, for 4 CF carrier-couples with genotype combinations as follows: p.Arg334Gln and c.489+3A>G, p.Phe508del and p.Phe508del, p.Phe508del and c.489+1G>T, p.Phe508del and p.Leu732X. 3 pregnancies were achieved and PGD genotypes were confirmed following conventional CF prenatal diagnosis after amniocentesis or trophoblast sampling.

The reported PGD method is a flexible and robust tool which facilitates direct CF genotype analysis, genotype confirmation and contamination detection in single cells, with minimal family work-up (generic) and rapid completion of PGD.

A new technology for Targeted Genome Enrichment, based upon High-Stringency Co-Operative Sequence Capture and dramatically improved amplification of synthetic oligonucleotide pools

***P. J. Freeman**, C. D. Veal, A. J. Brookes;*
The University of Leicester, Leicester, United Kingdom.

Targeted enrichment (TE) of genome sequences combined with Next Generation Sequencing (NGS) is a costly and imperfect method. It typically yields products with highly uneven representation of targeted regions regions and considerable off-target contamination.

By re-designing existing solution phase TE, we have developed a cost-effective and highly-automatable technique based on co-operative binding of oligonucleotide probes. This enables high-stringency target selection conditions, generating more specific and even sequence recovery.

A pilot application achieved a target specific enrichment factor of ~1000 fold when selecting a >200kb region, using 454 (Roche) sequencing. This was performed without repetitive element blocking. We have also designed and are now testing a novel repetitive-element blocking strategy that should

further improve performance.
A major practical and cost hurdle relevant to many TE methods is the requirement for uniform and efficient mass amplification of synthetic oligonucleotide pools. To specifically solve this problem, we designed a new, automatable and emulsion-free oligo-pool PCR procedure. This yields 2-3µg of 100% full-length, double-stranded product from ~200fg of synthesized oligo-pool sequences (e.g, comprising 99% truncated oligos and 1% full-length oligos). A simple purification step then yields >1µg of single-stranded oligo-pool material, which may be used directly in a TE reaction.
Furthermore, we applied lessons learned in optimizing oligo-pool PCRs, to improve linker-ligation methods for the production of long fragment genome libraries. This will further enhance our new TE method, with experiments now underway to determine the ideal range of fragment sizes that the technology will efficiently recover.

"Prenatal diagnosis (PND) for Cystic Fibrosis using High Resolution Melting (HRM) analysis and simultaneous haplotype analysis through QF-PCR."

M. Poulou[1], *A. Destouni*[1,2], *I. Fylaktou*[1], *G. Kakourou*[1], *E. Kanavakis*[1,2], *M. Tzetis*[1];
[1]*Department of Medical Genetics, Athens University, Athens, Greece,* [2]*Research Institute for the Study of Genetic and Malignant Disorders in Childhood, Athens, Greece.*

Cystic Fibrosis (CF) is caused by mutations of the *CFTR* gene and is the most common autosomal recessive disorder in Caucasians (carrier frequency 1 in 20) with >1800 disease causing variants. Prenatal diagnosis (PND) is offered to all CF carrier couples and includes detection of the causative mutations as well as haplotype analysis for exclusion of maternal contamination and non paternity.
High resolution melting analysis (HRM) is a validated, robust, low-cost, high throughput screening method applied in our laboratory for *CFTR* testing. Here, we report the development and retrospective evaluation of the diagnostic value of a novel multiplex HRM, genotyping and haplotyping method for CF prenatal diagnosis that overcomes the reported limitations of the HRM methodology.
Eighty study samples from 20 carrier couples referred for PND (whole blood in EDTA and CVS or amniotic fluid) were genotyped retrospectively. A multiplex 1st round PCR was optimized to co-amplify 9 *CFTR* exons along with two intragenic STRs. Haplotyping was achieved by running the 1st round PCR products on an automatic sequencer. Mutation detection was achieved by HRM analysis of a 2nd round nested PCR optimized to amplify the exon of interest.
All DNA samples (variable sources, extraction methods and unknown concentrations) were successfully amplified and genotyped by the 1st and 2nd round PCR. This generic protocol using HRM, facilitates the simultaneous analysis of DNA samples from various sources, is a robust and efficient method for CF PND and could easily be implemented for PND analysis of other genetic disorders.

Reprogramming of HDF cells to iPSc using polycistronic lentiviral vectors delivering the OSKM

M. Allahbakhshian Farsani, *M. Hashemzadeh Chaleshtori, N. Abdian, P. Ghasemi Dehkordi, A. Mirzaeian;*
Cellular and Molecular Research Center, Shahrekord University of Medical Sciences, Shahrekord, Iran, Shahrekord, Islamic Republic of Iran.

An induced pluripotent stem (iPS) cell is an adult cell that has been reprogrammed to form an artificially pluripotent stem cell. iPS cells have potential to differentiate into different cell types of body and can be generated through forced expression of specific genes in a non-pluripotent cell (typically human dermal fibroblast). The aim of the our study was the full reprogramming of human dermal fibroblast (HDF) cells into iPSCs using a single polycistronic lentiviral vectors delivering the Oct4, Sox2, Klf4, and c-Myc (OSKM) factors without extra less lentiviral integration into genome. In this study psPAX, pMD2G, and FUW plasmids were transfected into HEK-293T cell line for production lentiviral vectors containing OSKM genes. HDFs were isolated from foreskin samples and were transduced at passages 3. In this study we used only OSKM without control from tetracycline inducible lentiviral vector (rtTA). Our results show that polycistronic lentiviral vector contain OSKM genes are capable to induce full reprogrammed iPSc without transduction of extra lentiviral vector containing Tet.OP system for OSKM expression control. So we can generate iPSc with less insertional mutagenesis.

Quantitative real-time PCR technique for rapid diagnosis of TAR syndrome

V. R. Yassaee[1,2], *F. Hashemi Gorji*[1];
[1]*Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Dept. of Medical Genetic, Faculty of Medicine, Shahid Beheshti University of Medical Sciences., Tehran, Islamic Republic of Iran.*

Thrombocytopenia absent radius (TAR) Syndrome is a rare genetic disorder inherited in and with autosomal recessive fashion. Chromosomes at 1q21.1 in most individuals harbor a 200-kb deletion. RBM8A gene is located in this region. High throughput real-time PCR technique was used to develop a reliable and specific technique for rapid diagnosis of microdeletion in patient with TAR syndrome. Blood samples were collected after informed and written consent from a consanguineous family clinically diagnosed as TAR syndrome. Quantitative real-time PCR applied to measure the RBM8A gene dosage of genomic DNA from lymphocytes of tar syndrome patient and normal people, Compared to conventional cytogenetic karyotype analysis. Real-time PCR results were calculated for measuring of the RBM8A/PMP22 ratio using the 2-ΔΔCt formula in TAR syndrome to normal subjects showing 0.45 and 1.0 (95% CI), respectively. Real-time PCR technique effectively differentiates the TAR syndrome from the normal subjects. Because the RBM8A/PMP22 ratio of TAR syndrome is significantly lower than that of normal, Quantitative real-time PCR could be the first choice of method for molecular diagnosis of microdeletion in TAR syndrome rather than cytogenetic study.

New platform for real-time PCR using microchip analyzer

M. M. Nikitin[1], *N. V. Shirinekova*[2], *V. I. Larionova*[3,4,5], *M. N. Slyadnev*[1];
[1]*Lumex Ltd, St-Petersburg, Russian Federation,* [2]*St. Petersburg State Pediatric Medical University, St-Petersburg, Russian Federation,* [3]*St-Petersburg State Medical University, St-Petersburg, Russian Federation,* [4]*Turner University, St-Petersburg, Russian Federation,* [5]*North-Western State Medical University, St-Petersburg, Russian Federation.*

Nowadays a real-time polymerase chain reaction (PCR) method is a routine technique applied in various diagnostic fields. One of the most promising directions for the improvement of PCR analysis is an equipment facilities miniaturization. Indeed such miniaturization leads the laboratory diagnostics to be cost-effective and rapid.
We propose a new platform for real-time PCR with microchips containing lyophilized PCR mixtures which allow decreasing reagents consumption and reduce time of analysis. Microchips consist of silicon plate with 30 cells of 1.2 µl volume each. The inner surface of the cells is hydrophilic whereas the intercellular space is hydrophobic that helps to inject PCR mixtures inside the cells properly and reduce the risk of cross-contamination. Thermocycling and dual-channel fluorescence detection are carried out by microchip analyzer AriaDNA. To prevent sample evaporation a sealing liquid is used.
The new designed platform was used to identify some single nucleotide polymorphisms (SNPs) associated with genetic disorders and individual susceptibility to drugs. Particularly, F5 20210G/A, F2 1691G/A and MTHFR 677C/T polymorphisms in patients with vasculitis were tested. These SNPs are known to be associated with congenital thrombophilia and increase the

risk of deep vein thrombosis. With standard sample preparation protocol the analytical sensitivity was 1-10 ng/µl of genomic DNA. Single analysis (one microchip) has taken about 30 minutes. Thus encouraging assays characteristics have been obtained.
In summary, real-time PCR using microchips containing lyophilized PCR mixture provides reliable results and can be recommended for routine laboratory tests especially for screening programs.

Genetic diseases and congenital abnormalities of the children born in the families with reproductive losses (miscarriages)

B. Ginzburg;
Regional Hospital of Kaluga, Kaluga, Russian Federation.

The administration of lymphocyte therapy within complex treatment of the families with miscarriages provided successful childbearing in 92% of cases. The 8-year observation of 141 children born in the families with reproductive losses showed that those children were facing a high risk of congenital abnormalities + Down Syndrome R=2,6319 (95% CI 1,073-6,455) and autosomal dominant diseases with a more prominent gene expression in comparison with that of their parents OR=3,64(95% CI 1,23-10,81). Besides, in this group of children such rare genetic diseases as Fanconi's anemia and tuberous sclerosis were registered. Minor disorders with the frequency of 2,41 per 1 child statistically validly with the level of significance p=0,0162 on test X2 were more often registered in the children born in the families with miscarriages in comparison with the children of the control group, where the frequency of minor disorders amounted to 2,14 per one child.
Therefore we may consequently state that findings have been obtained on the accumulation of genetic diseases, congenital abnormalities and minor disorders in the generation of the families with miscarriages, which shows the increase of conditions on the border-line of "adaptive" norm or crossing its borders. Despite the fact that the children of this sampling were born «in vivo», the same problems arise in the children born «in vitro», which denotes the presence of similar biological problems in the families with low fertility.

In silico analysis of HMIP region (HBS1L-MYB intergenic region) and transcription factor identification in a region associated with fetal hemoglobin variation

***L. P. R. Venancio**, G. C. S. Carrocini, C. R. Bonini-Domingos;*
São Paulo State University - UNESP, São José do Rio Preto, Brazil.

The aim of this study was to evaluate the HMIP region, especially the portions flanking the SNP rs9399137, since this is the most significantly associated with fetal hemoglobin (Hb F) through comparative analysis of sequences (phylogenetic footprinting) based on the identification of highly conserved regions in non-coding regions from different species, indicating the possible existence of functional regions, such as transcription factors (TF). For comparative analysis were used HMIP region of *Homo sapiens*, *Pan troglodytes*, *Pongo abelli* and *Canis familiaris*, deposited in GenBank. The computational scheme for alignment and conservation analysis was based on the local alignment program BLAT and then the sequences were processed and globally aligned using the program mLAGAN. To identify FT was used rVISTA that associates the database TRANSFAC with comparative analysis of sequences. We observed the occurrence of motifs associated with embryo viability compared to normal erythropoiesis, expansion of hematopoietic stem cells and progenitor cells, acceleration of differentiation of erythroid progenitors, erythroid differentiation and control of hematopoiesis in the fetal liver, and transcription activiation of α-globin and erythroid genes. It is noteworthy here the occurrence of recognition sequences FT group SOX, which belongs SOX6, which is related to the proliferation and maturation of erythroid cells during erythropoiesis and mainly cooperates with BCL11A in silencing of gene expression γ-globin gene, affecting the levels of Hb F. Therefore, this region may be associated with the control of factors responsible for the formation and phenotypic characterization of hematopoietic stem cells in the embryo and fetus, reflecting in adulthood.

GWAS Central: A Comprehensive Aggregate-level Genome Wide Association Database

***A. J. Brookes**, C. Chrysostomou, V. L. S. Gollapudi, T. Beck, R. K. Hastings;*
University of Leicester, Leicester, United Kingdom.

Genome Wide Association Studies (GWAS) produce high-dimensionality individual and aggregate level genetic data by assaying hundreds of thousands of common Single Nucleotide Polymorphisms (SNPs) in hundreds of thousands of individuals in the search for genetic variants that may have causative effects on a disease phenotype or trait.
GWAS Central (http://www.gwascentral.org/)is a comprehensive database resource developed to enable researchers to easily visualise and search aggregate-level GWAS data in the context of genes, genome regions, phenotypes or traits [Thorisson GA *et al,* 2009, Nucleic Acids Res. 37: 797]. The database currently provides >34 million p-values for over 1,000 studies collected from public databases, outreach gathering, and direct submissions.
Key features include:
•Interactive genome browser allowing visual comparison of selected GWAS in relation to other information
•Ability to upload (not submit or share) a researcher's own GWAS p-values to compare to other GWAS studies
•Manually curated phenotype ontology annotations, assigned using MeSH and HPO, searchable via a graphical tree displays, or auto-complete text
•Nano-publications that provide key results for each study, including individual markers, phenotypes and results (<10-5) in RDF. The resulting triple store can be queried using SPARQL: http://fuseki.gwascentral.org
•A virtual machine version of the GWAS Central software, for other projects to adopt and install (e.g., GWAS India http://gcindia.igib.res.in/)
This work was funded by EC FP7 agreement 200754 (GEN2PHEN)

Identification of alternative splicing variation in RNA-seq time series data

***S. Oh**[1], S. Song[2], G. Grabowski[1];*
[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, [2]University of Cincinnati, Cincinnati, OH, United States.

Alternative splicing (AS) involves different multiple choices of splice sites to generate protein diversity. A single mRNA may code for different forms of a protein (isoform) as a result of alternative splicing, which increases the complexity of mammalian transcriptomes. Recent predictions based on deep sequencing suggest that more than 95% of human genes undergo alternative splicing, and that disruption of splicing can cause disease. Thus in order to increase our understanding of disease processes, it is essential to be able to detect alternative splicing. But no statistical methods of identifying this across time are available that would enable the new molecular techniques to assess the transcriptome. The ultimate objective of this study is to elucidate statistical methods of identifying alternative splicing in time series data. We propose fully bayesian approaches to characterize alternative splicing diversity in a variety of time course RNA-seq data and simulation sets. This methodology is based on dirichlet prior, shrinkage, and normalization method. We expect this statistical methodology to provide proof that our proposed methods will identify alternative splicing in temporal analysis. Ultimately, these methods can be used to better understand disease processes over time and to identify novel therapeutic targets by exploring variation in exon/splice expression in temporal analysis as a function of developmental stage and tissue type, so that abnormal splicing patterns can be used to help target human diseases.

Gene-scale functional impact prediction based on conservation and selection

R. Chen, *W. Yang, J. Yang;*
the University of Hong Kong, Hong Kong, Hong Kong.

Whole-genome sequencing analysis indicates that conservation and natural selection show distinctive signals between neutral and deleterious genes, making them suitable features for functional impact prediction. Approaches such as SIFT, Polyphen-2 prioritize deleterious variants on conservation and other features. We extend it to gene level and score all genes from RefGene. Another feature we include here is natural selection, which is proved to have notable stronger negative signal within genes associated with hereditary diseases. Using logistic regression and ten-fold cross validation, we estimate the probability of each gene to be deleterious. Distributions of the scores within neutral genes and disease related genes from OMIM suggest that our method can classify functional impact on gene scale well. Besides annotation on known genes, the model is also developed for prediction on novel genes.

The effect of MicroRNA-377 on methylation pattern of tumor suppressor gene in pancreatic cancer cell line

M. Azizi, *L. Teimoori-Toolabi, S. Zeinali, P. Fard Esfahani, K. Azadmanesh, M. Karimi Arzanani;*
Pasteur Institute, Tehran, Islamic Republic of Iran.

MicroRNAs (miRs) are small, noncoding RNAs that regulate expression of many genes. Recent studies suggest the role of miR in carcinogenesis. It is now well recognized that cancer is a consequence of genetic and epigenetic alterations while disruption of epigenetic mechanisms is the hallmark of cancer. Overexpressed DNA methyltransferase 1 (DNMT1) strongly contributes to silencing tumor suppressor gene in pancreatic cancer. However, the underlying mechanism of DNMT1 overexpression is still unclear. In this study, we investigated whether miR 377 is involved in the regulation of DNMT1 and aberrant patterns of methylation in two pancreatic cancer cell line (MiaPaca2). Quantitative RT-PCR was performed to check the effect of miR-377 on mRNA level of DNMT1. Upregulation of miR-377 resulted in a dramatic reduction of DNMT expression (53%, $p<0.05$). Then high resolution melt (HRM) was applied to check the effect of miR-377 on methylation pattern in promoters of tumor suppressor genes, such as BNIP3. The enforced expression of miR-377 in pancreatic cancer cell line restores normal patterns of DNA methylation (30% after 48h), induces re-expression of these methylation-silenced tumor suppressor genes (42% after 48h $p<0.05$). These findings support the role of mir-377 in epigenetic normalization of pancreatic cancer cell lines, which can be a motivation for the development of miRNA based strategies for the treatment of pancreatic cancer.

J15.07

Distribution of 5-methylcytosine and 5-hydroxymethylcytosine in metaphase chromosomes from triploid human zygotes

A. V. Tikhonov[1,2], *O. A. Efimova*[1,2], *A. A. Pendina*[2,1], *M. Krapivin*[1], *I. A. Galembo*[1], *I. D. Fedorova*[2], *A. M. Gzgzyan*[2], *T. V. Kuznetzova*[2,1], *V. S. Baranov*[1,2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*D.O.Ott's Institute of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.*

We analyzed distribution of DNA methylation marker - 5-methylcytosine (5-MeC) and active demethylation marker - 5-hydroxymethylcytosine (5-hMeC) in metaphase chromosomes from triploid human zygotes. IVF-produced triploid zygotes, discarded for uterus transfer, were enrolled in the study. All samples were donated for research with written informed consent of the patients. Zygotes were treated with 0,1% colchicines, 0.9% sodium citrate and fixed with freshly prepared 3:1 methanol:acetic acid. 5-MeC and 5-hMeC were detected by indirect immunofluorescence with anti-5-methylcytosine antibodies (Eurogentec) and anti-5-hydroxymethylcytosine antibodies (Active Motif) in QFH/AcD-banded chromosomes. Parental origin of chromosomes was determined in separately lying pronuclei on the basis of chromosome condensation type and presence of chromosome Y. Distribution of 5-MeC and 5-hMeC was analyzed in every chromosome of homologous triad.
First, distribution of 5-MeC and 5-hMeC in parental genomes demonstrated reverse patterns. In all homologues triads paternal chromosomes contained little 5-MeC, but were enriched in 5-hMeC, while maternal chromosomes were heavily methylated and contained little 5-hMeC. This shows that active demethylation involves both parental genomes, but is more intensive in paternal genome.
Second, the distribution of 5-MeC and 5-hMeC along chromosomes was not uniform and showed band-specificity. In both maternal and paternal chromosomes R- and especially T-bands were enriched in 5-MeC and 5-hMeC with 5-MeC showed less pronounced banding pattern than 5-hMeC. Constitutive heterochromatin (1q12,9q12,16q11.2,Yq12) contained neither 5-MeC nor 5-hMeC. This data suggests that active demethylation is band-specific, having the highest intensity in R- and T-bands.
Supported by RFBR, Administration of Saint-Petersburg, OPTEC grant and stipend from RF President.

ESR1 gene promoter methylation in adipose tissue

F. Guclu - Geyik[1], *T. Erginel*[2], *N. Erginel-Unaltuna*[1];
[1]*Istanbul University, Institute of Experimental Medicine, Department of Genetics, ISTANBUL, Turkey,* [2]*Istanbul Education and Research Hospital, Department of General Surgery, ISTANBUL, Turkey.*

AIM: Estrogen receptor alpha (ESR1) is a candidate gene for obesity. It was known that, obesity is formed in ESR1 knockout mice and ESR1 gene transcription decreases in obese individuals. Thus, in this study, we investigated the methylation status of ESR1 promoter in adipose tissue to sign the effect of methylation on decreased ESR1 gene transcription in obese individuals and to indicate the relationship with obesity.
METHOD: The study consisted of obese and normal 23 individuals totally. DNA and RNA are extracted from subcutaneous/omental adipose tissue. A, C, E2 and F promoter regions of ESR1 gene was analyzed by Methylation-Specific PCR.
RESULTS: As a result of the examination of ESR1 gene promoter region's methylation status in adipose tissue among obese individuals, methylation is detected as 33,3 % in promoter A and 100 % in promoter C despite no methylation in promoter F. 100 % methylation is defined in ESR1 gene E2 promoter region in adipose tissue in all groups. Although ESR1 mRNA level decreases in adipose tissue in obese individuals whose ESR1 promoter C is methylated, no significant association is detected.
CONCLUSION: In this study, methylation status of ESR1 gene promoter in adipose tissue is examined. Due to our findings, we assume that ESR1 mRNA level in adipose tissue decreases significantly depending on methylation status of ESR1 gene promoter C region in obesity. The study continues with increasing number of samples.

Methylation index as a prognostic marker in bladder cancer patients

A. Y. Babayan[1,2], *D. V. Zaletaev*[2,3], *M. V. Nemtsova*[2,3];
[1]*University Medical Center Hamburg Eppendorf, Hamburg, Germany,* [2]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [3]*Sechenov Moscow Medical Academy, Moscow, Russian Federation.*

Bladder cancer (BC) is a common malignancy worldwide. At the time point of diagnosis 70% of BCs present as superficial BC (SBC), which do not penetrate the muscle layer of the bladder. The rest 30% of cases present muscle-invasive BC (MIBC). SBC has better prognosis, though recurrences happen in 30% of cases after the primary tumor removal. MIBC has much worse prognosis and survival. Therefore it is of a prior importance to reveal possible markers of recurrences and progression of SBC into MIBC. It is proposed that methylation pattern might reflect the ability of BC to recur and/or to progress. We examined 122 tumor samples from 108 SBC patients and 14 MIBC patients. Recurrence status after 1 year was known for 39 SBC patients: 31 developed relapses, 8 did not. Genomic DNA was extracted from fresh tissue. We investigated promoter methylation of *RASSF1A, RARb, P16, p14, CDH1* using methyl-sensitive PCR. Methylation index (MI) (or mean frequency of methylation) was defined as the ratio between the numbers of methylated genes to total number of examined genes in each sample. Statistical significance was evaluated using the Mann Whitney U-test.SBC had a significantly lower extent of methylation (median MI 0.1) than MIBC (medi-

an MI 0,25) (p 0,017). Recurrent within 1 year SBCs showed median MI 0,0 while non-recurrent tumors had median MI 0,2 (p 0,047). Our results show that MI might be used as a sensitive marker for the assessment of recurrence and progression potential of SBCs.

The interactive map of NF-kappaB-dependent inflammatory molecular interactions in human

P. Zolotukhin, *E. Mashkina, K. Kovalenko;*
Southern Federal University, Rostov-on-Don, Russian Federation.

Inflammation disorders are considered nowadays to be associated with a broad range of pathologies, so making it a possible and promising target for diagnostics and therapy. Systemic understanding of molecular basis of inflammation has quantitatively and qualitatively advanced in recent years due to powerful molecular biology approaches. From this point, the novel challenge is adapting enormous amount of information for analytical and prospective purposes. Interactomic approach seems to be the most appropriate nowadays, as its idea relies on functional fusion of all cellular organization levels - from simple molecules and up to epigenome and its regulation. Considering this, we have developed (project № 14.A18.21.0199 funded by Russian Ministry of Science and Education) an interactive xml-based referenced and manually curated map of human NF-kappaB-inflammation system interactions - NFkBIM - allowing for systematization of the related most up-to-date experimental data. The map comprises more than 70 individual macromolecular factors subdivided hierarchically for logical analysis purposes, including protein, RNA, miRNA, SNP and epigenetic information fused with metabolomic effects. Much attention is paid to the description of the expression control for all the immediate participants of the system. The system of specified interactions is also integrated with two-step-neighboring higher cellular regulatory factors. NFkBIM allows for effective strategy planning and experimental design, selecting clinically significant SNPs associated with specific diseases for enhanced diagnostics purposes, and revealing feed-back and feed-forward systems for therapeutical concept development.

In silico prospection of transcription factors related to Fetal Hemoglobin regulation

G. C. S. Carrocini, *L. P. R. Venancio, C. R. Bonini-Domingos;*
Sao Paulo State University - UNESP, São José do Rio Preto, Brazil.

In adults, fetal hemoglobin (Hb F) expression comprises up to 1% of the total, suffering influence of transcription factors in its regulation. We aimed screening γ-globin genes regulatory elements by phylogenetic footprinting, in order to know the Hb F levels genetic determinants. We compared *Homo sapiens*, *Pan troglodytes*, *Macaca mulatta* and *Cebus apella* sequences, in the *National Center for Biotechnology Information*. Alignment and analysis were based on conservation programs BLAT and mLAGAN, visualized by VISTA Browser. For evaluation of the conservation was used as parameters 70% identity to at least 100 bp non-coding regions. To identify transcription factors was used rVISTA program. Among the 529 motifs of transcription factors indicated we highlight CDC5, c-MYB, CP2, BP1, KLF1, KLF11, GATA1 and GATA2. The transcription factors CP2, GATA1, GATA2 and KLF11 are direct positive regulators of Hb F, with binding sites in the promoters of the γ-globin gene. BP1, CDC5 and c-MYB act as indirect positive regulators of Hb F, from the negative regulation of β-globin gene and binding to specific sites, the -198 region of γ^G gene (chromosome 11) and *HMIP* region (chromosome 6), known to influence Hb F levels. KLF1 is a negative regulator of Hb F, act directly by interaction with the locus control region (LCR), and indirectly by the regulation of genes that silencing the γ-globin. Knowledge about the regulatory elements of Hb F can contribute in different therapeutic strategies discovery that may improve on clinical pathways when considering patients with hemoglobinopathies.

Financial support: Fapesp Process Number 2011/15570-1.

J15.12

Restriction endonuclease selection for the reduction of RRBS libraries

M. Borisova[1], *V. V. Strelnikov*[1,2], *D. V. Zaletaev*[1,2], *A. S. Tanas*[1,2];
[1]*RCMG RAMS, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.*

Reduced Representation Bisulfite Sequencing (RRBS) genomic library preparation by DNA hydrolysis with restriction endonucleases provides limitations on target sampling composition. Original RRBS protocol puts to use endonuclease MspI (methylation insensitive HpaII isoshizomer), assuming that CpG islands (CGIs) are HpaII tiny fragments. We suggest that other endonucleases might select CGIs more precisely allowing more sophisticated reduction of the RRBS libraries.

We have developed ReMark computer program (http://www.epigenetic.ru/projects/remark/) to calculate restriction endonuclease recognition site likelihood-ratio test in Markov Chain sequence models (output as "score"). The practical value of the scores calculated for selected enzymes has been estimated with the criteria of CGIs selection quality for 40-220 bp RRBS libraries.

ReMark scores and RRBS library attributes for a selected set of endonucleases.

Restriction endonuclease	MspI	HinP1I	TaqI	XmaI	AagI	NaeI	SfrI	BsePI	NotI	MauBI
Recognition site	CCGG	GCGC	CGCG	CCCGGG	CGGCCG	GCCGGC	CCGCGG	GCGCGC	GCGGCCGC	CGCGCGCG
CpG methylation sensitivity	-	+	+	-	?	+	?	+	+	+
Available RSA	+	+	+	-	-	+	-	-	+	-
library size, b.p.	70248053	40841839	15212336	3187500	1652457	1327517	1270563	977068	83604	21994
ReMark score	2.45	2.74	4.09	3.08	4.72	3.37	4.72	5.01	5.65	8.64
Library fragments overlapping CGIs, %	20	31	66	49	55	59	88	91	90	85
CGIs CpG genome coverage, %	49	42	36	7,9	5,2	4,3	6,2	5	0,4	0,1
CGIs CpGs library fraction, %	37	46	75	73	68	74	90	91	88	88
Promoter CGI library fraction, %	24	30	49	50	51	53	64	65	63	67
Exon CGI library fraction, %	14	17	27	22	29	30	32	36	38	26
Intron CGI library fraction, %	13	16	25	29	21	23	30	28	25	26
Non CGI CpGs in library, %	63	54	25	27	32	26	10	8	12	12

Higher scored endonucleases select CGIs more precisely with much smaller library sizes in spite of the fact that rare cutters omit many regions of interest. Some high-scored enzymes are methylation sensitive preventing their use for RRBS library construction. Taken that Roentgen stereophotogrammetric analysis (RSA) data is available for some, methylation insensitive mutants development may be expected.

In conclusion, ReMark software is useful for choosing endonucleases effectively selecting regions of interest for genome and epigenome research.

Prognostic significance in biochemical recurrence of prostate cancer in preoperative serum glutation S-transferase P1 gene in men following radical prostatectomy

R. Dumache[1], *S. Negru*[1], *R. Minciu*[1], *S. Putnoky*[1], *D. Ionescu*[2], *M. Puiu*[1];
[1]*Faculty of Medicine, Timisoara, Romania,* [2]*Faculty of Pharmacy, Timisoara, Romania.*

Hypermethylation of GSTP1 gene in the preoperative serum of men with localized prostate cancer(PCa) predicts early biochemical prostate specific antigen(PSA) failure , following surgical treatment. In our study we investigated the hypermethylation profile GSTP1 gene in the preoperative serum of men with clinically localized PCa who underwent radical prostatectomy, with PSA recurrence on a period of 40 months (3 years and 6 months), as a prognostic biomarker of recurrence in PCa men following radical prostatectomy.

Materials and methods:

We included a number of 77 men with clinically localized PCa, who underwent radical prostatectomy at the Urology Clinic from County Emergency Hospital Timisoara, and 38 men with negative prostate biopsy. All serum samples were collected before prostate biopsy or at least 4 months after prostate biopsy. PSA recurrence was defined as a single postoperative PSA level ≥0.2 ng/ml. To analyze the methylation status of gene GSTP1 before the surgery intervention we used the quantitative methylation-specific polymerase chain reaction(QMSP) method.

Results:

From the 77 men who underwent radical prostatectomy included in our stu-

dy, 16 (20.8 %) experienced PSA recurrence within the study period. From the 38 men with negative prostate biopsy only 4(10.6 %) presented positive GSTP1 hypermethylation
Conclusions:
Our study suggests that preoperative serum GSTP1 may be a useful prognostic biomarker for men with clinically localized PCa treated with radical prostatectomy.

Computational research in a case with t(14;17)(q32;q11.2) causing 22q11 microdeletion syndrome-like phenotype

M. Soriano[1], *N. E. De León*[2], *E. Morales*[1], *A. Castelví*[1], *L. A. Méndez*[1];
[1]*Centro Nacional de Genética Médica, Havana, Cuba,* [2]*Hospital „William Soler", Havana, Cuba.*

Abstract:
A 22q11.2 deletion syndrome was suspected in a patient with language impairment, crowded teeth, immunodeficiency, long philtrum and dismorphic features. Conventional cytogenetic analysis showed the karyotype: 46, XY, t (14;17)(q32;q11.2). This translocation has not being reported previously in a patient with a constitutional disease. Despite the association of genes presents in critical region in deletion 22q11 syndrome with the phenotype it causes is not clearly understood, recent papers show that haploinsufficiency of TBX1 can recreate many aspects of this genetic condition.
We hypothesize that the presence of genes near the breakpoints code for proteins acting in the same process that those promoting phenotype in 22q11.2 or with a similar action.
Methods: A selection of genes were collated from literature trough GoPubmed (www.gopubmed.com) with the terms "22q11.2[tiab] AND critical region[tiab] AND Genes[mesh]". Genes retrieved where compared using GeneCards (www.genecards.org) and those with high-GIFtS peak (GeneCards Inferred Functionality Score) value were selected. Also two sites were consulted for an interaction of those genes with genes located in the breakpoints: Biocarta (http://www.biocarta.com/genes/index.asp) and Biogrid (http://thebiogrid.org).
Results: No interaction where was found between genes in 22q11.2 and those in 14q32 or 17q11.2. Despite this, there are genes in 14q32 related with coronary heart disease, parathyroid secretion, thyroid hormones and immunology.
Conclusions: Genes present in 14q32 could explain in part the phenotype but additional molecular genetic testing detection of affected genes is necessary once there could be affected genes outside the breakpoints and contributing to phenotype.

Clinical implications of simultaneous promoter methylation of ERα and ERβ on sporadic breast cancers in North Indian women

S. Chattopadhyay[1], *S. Deo*[2], *N. Shukla*[2], *S. A. Husain*[1];
[1]*Jamia Millia Islamia, New Delhi, India,* [2]*All India Institute of Medical Sciences, New Delhi, India.*

DNA methylation, an epigenetic marker, has critical roles in regulation of gene activity. Aberrant promoter hypermethylation leading to gene silencing underlie altered gene expression in cancers. Estrogens play a fundamental role in the development and progression of breast cancer, activating estrogen receptors (ERs), ERα and ERβ. ERα expression level prognosticates hormonal therapy responses of patients and is perhaps the most important biomarker for determining breast cancer progression. After the discovery of ERβ, it was quite evident that the role of estrogen is far more intricate.
We have investigated the promoter methylation status of ERα and ERβ and its possible correlation with protein expression in 110 sporadic breast cancer cases from North India. Methylation-Specific Polymerase chain reaction (MSP) method was used to analyze CpG methylation of promoter region of these genes. Immunohistochemical (IHC) staining for ERα and ERβ protein was performed to correlate promoter methylation with expression.
In general, we found that ERα was methylated in 64.54% (71/110) tumors, including 51 of 61 ERα negative tumors (83.6%, *P<0.0001*). ERβ showed methylation in 52.72% (58/110) tumors, including 38 of 58 ERβ negative tumors (65.5%, *P=0.007*). In addition, we observed a strong correlation between promoter methylation of ERα and ERβ with significance of *P=0.01*. An inverse correlation was found between promoter methylation and protein expressions.
Our results show a simultaneous involvement of epigenetic regulation for ERα and ERβ, indicating that methylation pattern of these genes can be exploited as biomarkers for the prediction of breast cancer outcome.

Whole exome sequencing has enabled geneticists to explore the influence of low frequency coding variants on biomedical traits. With simple association, exonic association has the limitations of GWAS: large numbers of subjects are required. Linkage methods in families are a powerful tool to identify biomedically relevant coding variants in relatively modest collections of families especially when combined with exome chip data and conventional association analysis. African American (AA) families (45 families; 500 subjects) from the IRAS Family Study were genotyped with the Illumina Exome Beadchip resulting in 92,150 genotyped SNPs. Two-point linkage and association analysis was performed for 38 cardiovascular and metabolic traits. The most striking result was the APOE-coding variant Arg158Cys linked with apolipoprotein B(APOB) levels with a LOD=4.91 and association with APOB (P=4.4XE-19). This variant is part of the ε2 haplotype and ε2 homozygotes (1.7% haplotype frequency) have APOB levels that are 53% of normal. . When "exome-wide" results of linkage and association were summarized, numerous regions of linkage and association were observed at less striking levels of significance. Further analysis may reveal similar high impact variants. In a similar analysis of the adiponectin gene in Hispanic Americans and AAs we have identified a class of coding variants which reduce circulating adiponectin levels to <20% of normal. Different variants are observed: G45R and R55C, respectively; both 1% frequency. These studies show the power of family-based methods to identify high-impact coding variants. Extension to whole exome sequencing of the families will test whether private mutations contribute to biomedical traits.

TRAF3IP2 Gene and Systemic Lupus Erythematosus: association with disease susceptibility and pericarditis development

C. Ciccacci[1], *D. Di Fusco*[1], *C. Perricone*[2], *S. Rufini*[1], *F. Ceccarelli*[2], *G. Valesini*[2], *F. Conti*[2], *G. Novelli*[3], *P. Borgiani*[1];
[1]*University of Rome „Tor Vergata", Rome, Italy,* [2]*University of Rome „La Sapienza", Rome, Italy,* [3]*National Agency for the Evaluation of Universities and Research, ANVUR, Rome, Italy; Unit of Medical Genetics, San Pietro FBF Hospital, Rome, Italy, Rome, Italy.*

Systemic Lupus Erythematosus (SLE) is a chronic relapsing-remitting multifactorial autoimmune disease characterized by the production of a wide number of autoantibodies and the occurrence of diverse clinical phenotypes. Although genetic factors confer a predisposition to the development of the disease, only 15% of the genetic contribution is known. Recently, *TRAF3IP2* gene has been found associated with susceptibility to psoriatic arthritis and psoriasis. This gene is involved in the regulation of adaptive immunity acting as a negative regulator of humoral immunity and as a positive signalling adaptor in IL-17-mediated cellular immune responses. These evidences suggest that TRAF3IP2 gene variability could be implicated also in SLE susceptibility. We enrolled 239 consecutive SLE Italian patients and 278 healthy subjects as controls. Three *TRAF3IP2* polymorphisms were analyzed by allelic discrimination assay. A case-control association study and a genotype-phenotype correlation analysis were performed. All genotypes were in Hardy-Weinberg Equilibrium. The rs33980500 and rs13193677 resulted significantly associated with SLE susceptibility (P=0.021, OR=1.71, and P=0.046, OR=1.73, respectively). All three *TRAF3IP2* SNPs resulted associated with the development of pericarditis: in particular rs33980500 showed the strongest association (P=0.002, OR 2.59). The *TRAF3IP2* involvement was further highlighted by binary logistic regression analysis. In conclusion, our data show for the first time the contribution of *TRAF3IP2* genetic variability in SLE susceptibility, providing further suggestions that common variation in genes involved in the adaptive and innate immune

system are important in establishing SLE risk. Our study also shows that this gene may affect disease phenotype and, particularly, the occurrence of pericarditis.

Y-chromosome haplogroup analysis in the Besermyan ethnic group

S. Litvinov[1], *N. Trofimova*[1], *R. Khusainova*[1,2], *V. Akhmetova*[1], *E. Khusnutdinova*[1,2];
[1]*Institute of Biochemistry and Genetics of Ufa Science Center of Russian Academy of Sciences, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation.*

Besermyans are an ethnic group in the Volga-Ural region which speaks a language belonging to Finno-Ugric language family and which is close to Udmurt language but at the same time containing some Turkic traits. This group inhabiting North-West Udmurtia is very small and it has not been described in the terms of Y-chromosome haplogroups yet. We analyzed 53 individuals from Besermyan population using 12 Y-chromosome markers (M9, M89, YAP, M35, M130, 12f2, M170, M231, Tat, P43, M207, Page07) and found that Y-chromosome genetic pool of this ethnic group consists of haplogroups R1a1a-Page07, N1c-Tat, N1b-P43, I-M170, R1b1b-M269 and E1b1b1-M35. The majority of the Y-chromosome haplogroups in Besermyans is represented by N1c-Tat and R1a1a-Page07 lineages comprising 73,6% of all Y-chromosomes. The third leading haplogroup is N1b-P43 (13,2%) so the main share of the Y-chromosome lineages in Besermyan group is actually N-M231 (54,7%). In other words the main pattern of the Y-chromosome haplogroup distribution shows their relatedness to the Volga-Ural populations.

Application of model based approach and Bayesian networks for eye color prediction for forensic purposes

A. Zidkova[1,2], *A. Horinek*[1], *M. Korabecna*[3];
[1]*Insitute of biology and medical genetics, First faculty of medicine, Charles University in Prague, Prague, Czech Republic,* [2]*Institute of Forensic Medicine and Toxycology, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [3]*Institute of biology and medical genetics, First faculty of medicine, Charles University in Prague, Prague, Czech Republic.*

Advances both in genotyping technology and human genetics research resulted in enormous progress in field of forensic genetics. Forensic molecular phenotyping allows to narrow subset of possible suspects. Here we would like to present model based approach to create panel of SNP markers for eye color and ancestry prediction.
Population sample contained 131 unrelated individuals: 100 (76%) Caucasians, 31 (24%) Asian (Kazakhs). Samples were binned according to eye color: 47 (36%) light eye color and 84 (64%) dark eye color. Genotyping was performed using TaqMan MGB assays. All samples were analyzed using panel of 22 SNP markers selected from literature.
Data were divided into two sets: training (100 Caucasian, 31 Asian) and testing (47 Caucasian, 81 Asian). Caucasian data for testing set were obtained by genotyping, Asian data for testing set were extracted from HapMap. Firstly, SNP data of the training set were filtered using ReliefF, which minimizes risk of SNP false positive association with studied phenotype. Consequently, multifactor dimensionality reduction was performed to uncover possible epistatic regulation between studied loci. For validation of selected markers Bayesian network was constructed. Network contained ancestry determination using rs1426654 and 16891982 and eye color determination using rs12913832, rs7495174 and rs916977. Sensitivity of the model reached 0.96, specificity was 0.99. Prediction of eye color using presented Bayesian network could be useful in case of unknown remnants identification and verification of eye witness testimony. The study was supported by the grant No. I/328 of the Ministry of Industry and Trade of the Czech Republic.

Checking the hypothesis of a Balkan origin of the Armenians

L. Yepiskoposyan[1], *P. Hrechdakian*[2], *H. Simonian*[3];
[1]*Institute of Molecular Biology NAS RA, Yerevan, Armenia,* [2]*Armenian DNA Project at Family Tree DNA, Brussels, Belgium,* [3]*University of Southern California (USC), Los Angeles, Los Angeles, CA, United States.*

The origin of Armenians is a controversial subject for anthropologists, archaeologists, historians and linguists. Among several hypotheses on this point, one prevails. The ancient Greek historian Herodotus described the Armenians as Phrygian colonists because of their speech and the garments they wore. Here, we tested the Balkan version of the origin of Armenians based on the Y-chromosomal markers. We used the results of high-resolution typing (applying 50-70 SNPs) in 1171 DNA samples representing 10 Armenian geographic groups covering the whole area of the Armenian plateau and the database of the Armenian DNA project at Family Tree DNA comprising a general Armenian population. As possible signals of Greek influence the presence of the E1b1b1a1-M78 haplogroup with its major sub-branches (E1b1b1a1b-V13, E1b1b1a1a-V12 and E1b1b1a1c-V22) were considered. The frequencies of the E1b1b1a1-M78 clade in Armenians are quite low in nine out of ten geographic groups and in the general dataset, ranging from 0 to 3.8%. The highest rate (8%) of the supposed Balkan lineages is observed in a sample representing the south-eastern part of the Armenian Highland (currently north-west Iran). The mean age of this haplogroup using 14 STR markers is 14.5 ky based on evolutionary mutation rates. This value is much higher than that shown for the Greek samples which indicates that the E1b1b1a1-M78 haplogroup among south-eastern Armenians is indigenous and clearly was not introduced by back-migration from Balkan region. Thus, the patrilineal genetic structure of modern Armenians groups does not support their Balkan origin.

Molecular genetics of familial hypercholesterolemia in Petrozavodsk: known variants and new mutations

T. Y. Komarova;
Institute of Experimental Medicine, St-Petersburg, Russian Federation.

Aims. Familial hypercholesterolemia (FH) is a common single gene disorder, which leads to premature atherosclerosis and coronary artery disease. FH is mainly caused by defects in the low-density lipoprotein receptor (LDLR) gene, which lead to dysfunction of the receptor. Spectra of mutations in FH are population-specific and currently more than 1000 mutations are characterized worldwide. We aimed to investigate the spectrum of mutations in Petrozavodsk and to compare our data to recent research in St.-Petersburg.
Methods. We studied a group of 94 patients from Petrozavodsk by means of automated single-strand conformation polymorphism followed by direct PCR amplified DNA sequencing.
Results. Thirteen different mutations of LDLR gene were characterized in Petrozavodsk: c.58 G>A, c.192del10/ins8, c.195-196insT, c.618T>G, c.925-931del7, c.1194 C>T, c.1277 T>C, c.1340 C>G, c.1532 T>C, c.1686del8/insT, c.1920 C>T, c.1936 C>A, c.2191delG. Only one mutation (c.925-931del7) was earlier described in St.-Petersburg population;however, it is specific for Finland where it is common in FH patients. Six of other twelve mutations were not characterized earlier in the world.
Conclusions. Our results show that the founder effect in Petrozavodsk population is absent and the spectrum of mutations in LDLR gene is unique for Petrozavodsk.
Research was supported in part by RFBR grant 10-04-00563a.

The birth defects incidence in Russian Federation in 2000-2009

N. S. Demikova[1], *A. S. Lapina*[1], *A. J. Asanov*[2];
[1]*Research Institute of Pediatric and Child Surgery, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.*

The main aim of our long-term study of birth defects (BD) is to obtain the incidence of BD in studied populations and to analyze variations in the incidences of BD.
Material and methods. The Russian united database consists of all cases of congenital anomalies notified by regional registries including live born cases and stillbirths. We analyzed data for10-year periods (2000-2009).
Results. The total incidence of BD is 21,33 per 1000 births. The incidence of isolated congenital anomaly present in table.
Conclusions. For most defects there are no changes in incidence during 10 years and observed frequency fluctuations are random. Decreasing trends among newborn were detected for neural tube defects (anencephalus, spina bifida, encephalocele) due to effective prenatal diagnosis.

Results of Russian BD Monitoring, 2000-2009

Anomaly	Number of cases	Incidence per 1000 births
Anencephalus and similar	1481	0,24
Encephalocele	432	0,07
Spina bifida	2861	0,46
Hydrocephaly	2755	0,44
Anophthalmos/micropthalmos	115	0,02
Anotia/microtia	369	0,06
Transposition of great vessels	962	0,16
Hypoplastic left heart	451	0,07
Cleft lip with or without palate	4109	0,66
Cleft palate	2612	0,42
Esophageal atresia with/ without tracheo-esophageal fistula	1179	0,19
Anorectal atresia and stenosis	993	0,16
Diaphragmatic hernia	1127	0,18
Gastroschisis	1357	0,22
Omphalocele	802	0,13
Bilateral renal agenesis	227	0,04
Bladder exstrophy and epispadia	218	0,03
Hypospadias	7677	1,24
Limb reduction	1789	0,29
Down syndrome	6294	1,02

The FABP2 gene Ala54Thr polymorphism is associated with endurance athlete status

E. S. Nasibulina, *I. I. Ahmetov;*
Kazan State Medical University, Kazan, Russian Federation.

The intestinal fatty acid-binding protein 2 (FABP2) belongs to the family of cytoplasmatic proteins involved in the intracellular transport and metabolism of long-chain fatty acids (Albala et al., 2006). These proteins thought to participate in the uptake, intracellular metabolism, and/or transport of long-chain fatty acids. The Thr54 variant of the FABP2 gene Ala54Thr polymorphism has been shown to be associated with a two-fold greater binding affinity for the long-chain fatty acids (Baier et al.,1995, Baier et al., 1996), increased fat absorption and lipid oxidation rates (Weiss et al., 2007). Several studies have demonstrated significantly improved prolonged exercise time when high-fat diets were compared with low-fat diets. It was suggested that increasing fat intake increases endurance, perhaps by improving fat oxidation and sparing glycogen during exercise. We therefore have hypothesized that the Thr54 allele of the FABP2 gene may give some advantage to endurance-oriented athletes. In order to test this hypothesis we genotyped 290 Russian athletes and 620 controls. Genotyping was performed by PCR-RFLP. The frequencies of the Thr54 allele in groups of power-oriented athletes (n=84, 29.7 vs. 32.2%, P=0.5877), athletes with mixed (endurance and power) activity (n=88, 26.1 vs. 32.2%, P=0.1183) and a whole cohort of athletes (n=290, 32.4 vs. 32.2%, P=0.9571) were not significantly different from the controls. However, the frequency of the Thr54 allele in endurance-oriented athletes (n=118, 39.0 vs. 32.2%, P=0.0498) was significantly higher than in controls. Although more evidence is needed, one might suggest that the FABP2 gene Ala54Thr polymorphism is associated with endurance athlete status.

Genetic structure and expansion patterns of Iranian populations based on complete mitochondrial DNA variation data

M. Derenko[1], *B. Malyarchuk*[1], *A. Bahmanimehr*[2], *G. Denisova*[1], *S. Farjadian*[3], *L. Yepiskoposyan*[2];
[1]*Institute of Biological Problems of the North, Russian Academy of Sciences, Magadan, Russian Federation,* [2]*Institute of Molecular Biology, National Academy of Sciences of Armenia, Yerevan, Armenia,* [3]*Immunology Department, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran.*

Due to its pivotal geographical location and proximity to transcontinental migratory routes Iran has played a key role in subsequent migrations, both prehistoric and historic, between Africa, Asia and Europe. To shed some light on the genetic structure of the Iranian population as well as on the expansion patterns and population movements which affected this region, the complete mtDNA genomes of 352 Iranians were obtained. All Iranian populations exhibit similarly high diversity values comparable to the other groups from the Caucasus, Near East and Europe. The results of AMOVA and MDS analyses did not associate any regional and/or linguistic group of populations in the Near East/Caucasus and Iran region pointing to close genetic positions of Persians and Qashqai to each other and to Armenians, and Azerbaijanians from Iran to Georgians. By reconstructing the complete mtDNA phylogeny of haplogroups U7, R2, H13, and U3 we have found a previously unexplored, genetic connection between Iranian populations and the Arabian Peninsula, Near East and Europe, likely the result of both ancient and recent gene flow. Bayesian skyline plots (BSPs) of population size change through time show a population expansion around 40-42 kya, followed by a gradual decrease of population size up to ~24 kya. Then BSP for Persians show a continuous increase to the present, whereas the BSP for the Qashqai separates two steps (~10 kya and ~2.5 kya). This study was supported by Russian Foundation for Basic Research (11-04-00620) and by Far-East Branch of the Russian Academy of Sciences (12-III-A-06-101).

mtDNA analysis in the Volga-Ural populations.

N. V. Trofimova[1], *K. Tambets*[2], *S. Litvinov*[1], *R. I. Khusainova*[1,3], *V. L. Akhmetova*[1,3], *I. M. Khidiyatova*[1,3], *R. Villems*[2,4], *E. K. Khusnutdinova*[1,3];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Center of the Russian Academy of Sciences, UFA, Russian Federation,* [2]*Estonian Biocentre, Tartu, Estonia,* [3]*Bashkir State University, Ufa, Russian Federation,* [4]*University of Tartu, Tartu, Estonia.*

The population genetics study of the Volga-Ural region populations can be very fruitful since this region experienced different historical migrations and from the other hand there are ethnic groups that inhabit it for quite a long time.
In our study we used the method of HVS-I sequencing, RFLP analysis and mitochondrial DNA (mtDNA) complete sequencing. We have sequenced HVS-I in 1079 samples from nine ethnic groups: Tatars, Bashkirs, Chuvashes, Russians, Udmurts, Mordovians, Komis, Maris and Besermyans. For further research, we isolated samples with haplogroup H that were not identified with the RFLP analysis, and performed complete mtDNA sequencing. At this point we analyzed 18 complete sequences of haplogroup H.
We have discovered two previously not described mutations in the Udmurt population. Interestingly one of those mutations defines a new H subhaplogroup which is absent in any population except Udmurts. Another mutation defines a new subhaplogroup within haplogroup H55 and it was found in the following populations: Mari (5), Chuvash (2) and Bashkirs (2).
This study was supported by European Social Fund's Doctoral Studies and Internationalisation Programme DoRa, Program of fundamental research of the Presidium of RAS «Biodiversity and Dynamics gene pool" routine „The dynamics of gene pools», Russian Foundation for Basic Research (#11-04-00652) «Molecular phylogeography and ethnogenomics peoples of Eurasia".

PTPN22 polymorphism: associations with Type 1 Diabetes in several populations of the Russian Federation.

O. N. Ivanova, *U. V. Tishina, Y. S. Zvereva, T. L. Kuraeva;*
Endocrinological Research Centre, Moscow, Russian Federation.

After HLA and insulin gene, the next-strongest genetic association with Type 1Diabetes (T1D) is seen for the *PTPN22* gene. The *PTPN22* gene encodes a protein tyrosine phosphatase important in down-regulation of the immune response. The aim of this study is cross-ethnic group comparisons of frequencies and analysis of associations with T1D *PTPN22* single nucleotide polymorphisms (in coding part of the gene rs2476601 1858C>T R620W and in promoter region rs2488457 -1123G>C) in Bashkir, Buryat, Udmurt and Russian ethnic group of the Russian Federation. Case-control design was applied for assessment of 417 patients with T1D and 323 healthy sex and ethnos matched individuals. Allele identification was performed with RFLP or Real-Time PCR technique. Association of genetic markers with pathology was evaluated according to odds ratio index (*OR*), association was considered statistically significant when p-value<0,05). 1858T+ genotype is associated T1D in Russian(*OR*=2), Udmurt(*OR*=4) and Bashkir(*OR*=3,5) populations; -1123C+ genotype is associated with T1D in Buryat population (*OR*=2,4). Cross-ethnic comparison of frequencies of alleles showed statistically significant differences. Only in the Buryat population frequency of allele -1123G (71,3%) is much higher than the frequency of allele C. Russian population is different from other high frequency of allele 1858T (13% vs. 2,5-3,6%). It is concluded that in the Buryat ethnic group (with low incidence of T1D) diabetogenic marker is C+ genotype of rs2488457; in the Bashkir, Udmurt and Russian ethnic groups diabetogenic marker is T+ genotype of rs2476601.

Two decades of Pre-marital Screening for Beta-thalassaemia in central Iran

M. Zeinalian[1,2], *A. Moafi*[3], *M. Hashemzadeh Chaleshtori*[1];
[1]*Cellular and Molecular Research Center, Shahrekord University of Medical sciences, Shahr Kord, Islamic Republic of Iran,* [2]*Health Deputy of Isfahan University of Medical Sciences, Isfahan, Islamic Republic of Iran,* [3]*School of Mdicine, Isfahan University of Medical Sciences, Isfahan, Islamic Republic of Iran.*

Objectives: Pre-marital screening for beta-Thalassaemia, implemented for almost two decades, is one of the most important preventive screening programmes in the Iranian public health system,. We present the results of this programme between 1992-2010 in the Isfahan Province (central Iran).
Methods: Retrospective descriptive and cross-sectional study using data from the district health centers of the Isfahan Province analyzed using SPSS-19 and Excel softwares.
Results: A total of 703,082 couples were screened. Couples at risk were suspected by persisting abnormal indices (eventually after Iron therapy) and by HbA2 determination at a rate of 0.63% and 0.19% respectively and after molecular testing at 0.31% frequency.
In this way a total of 661 couples at risk have been receiving care in this period and genetic testing has been provided in 85% of the cases. The birth prevalence of severely affected children decreased from 43.7 cases per 100,000 live births in 1997 to 1.5 cases in 2010.
Conclusions: In spite of the programme's good results, shortcomings are still present in our programme that we would like to share with dedicated staff and policy makers of other countries offering premarital screening for these diseases.

Saudi Biobanks: importance, implications and opportunities.

I. ALABDULKAREEM, *M. GHAZOLI, M. Alharbi, A. ELOBEID, W. BIN YAHYA, M. ALDRESS, H. ALKHALAF, M. Aljumah;*
King Abdullah internationla medical Research Center; NGHA, Riyadh, Saudi Arabia.

Saudi Biobank (SBB) is a nationwide biorepository project recruiting blood components) Buffy coats, red blood cells; serum, plasma), tissues, and urine from 200.000 local Saudis; half of them will be healthy donors. The DNA banking services are open for NGHA hospitals and other national healthcare providers. The SBB is functioning through many teams; Medical team, Laboratory team, IT team and Ethics team.
The initial operational processes approach a total of 4,432 participants while the DNA banking possesses 3,622 aliquots through a complete automated DNA extraction/storage system. In addition, 4,852 buffy coat aliquots as backup materials and 430 cord blood units with their DNA extracts are already deposited at the biobank. Plasma and serum fractionations have yielded 732 plasma and 690 serum aliquots. The biobank laboratory serves many projects at NGHA that include HLA registry, Saudi Genome Project (SGP), ICU patients···etc. Preoperational trials and QC measurements for these fractions were carried out using AST, ALT, ALB, Bili T, Na, and K. Random selections of serum and plasma banked samples were sent to the clinical biochemistry section; consistency of measurement was seen when compared to the diagnostic samples drawn at the same day.
Next trial phase will recruit an automated high throughput blood fractionation system that automatically separates blood components and urine to be stored in the BiOS automated storage system (-80°C) and LN2.

In Search of the Origin of Haplogroup J1-P58

A. Margaryan[1], *H. Sahakyan*[1,2], *M. Haber*[3], *A. Bahmanimehr*[1], *S. Rootsi*[2], *P. Zalloua*[3], *R. Villems*[2], *L. Yepiskoposyan*[1];
[1]*Institute of Molecular Biology, Yerevan, Armenia,* [2]*University of Tartu and the Estonian Biocentre, Tartu, Estonia,* [3]*The Lebanese American University, Beirut, Lebanon.*

Y-chromosomal haplogroup J1, one of the most frequent male lineages in the Near East, is believed to have originated around 10-15 kya in Northern Mesopotamia. J1 along with R1b and J2is generally considered as a genetic marker for the Neolithic expansion, therefore the study of its origin and spread is essential for tracing back ancient human migrations and expansions from the Near-East. In this study, we report a new potential source population and geographic location for the origin of J1-P58, a major sub-clade of haplogroup J1.
Previous studies did not explore the region of Armenian Highland when investigating J1-P58 origin. For this study we have genotyped 453 Armenian samples representing eastern, central and western parts of the highland, 297 Azeri and102 Qashqai samples from Iran, as well as used already published results of different comparative data sets.
The highest J1-P58 variance was observed in the Armenian population from the central part of the highland (regions of Alashkert and Bayazet). The mean age of J1-P58 in this region based on 8 STR markers, was estimated to be the oldest among the studied populations, dating back to 19.4 ky when using the evolutionary mutation rates. It is worth mentioning that the obtained result is based on the analysis of one ethnically homogenous territorial group located in a geographically restricted region in the central part of the Armenian plateau. We believe that this approach leads to better time estimates and significantly narrows down the geographic area where J1-P58 could have originated.

HFE hemochromatosis: influence of dietary iron intakes on the phenotype of C282Y/C282Y patients

P. Saliou[1,2], *G. Le Gac*[1], *M. Mérour*[3], *A. Mercier*[3], *B. Chanu*[3], *C. Férec*[3,2,4], *V. Scotet*[2,3,4];
[1]*CHRU de Brest, Brest, France,* [2]*Inserm, Brest, France,* [3]*Etablissement Français du Sang, Brest, France,* [4]*Université de Bretagne Occidentale, Brest, France.*

Introduction: Many genetic and environmental factors are viewed to aggravate the iron overload phenotype of patients with *HFE* hemochromatosis but only few of them have been firmly confirmed. In this study, we aimed to determine the role of an iron-rich diet.
Methods: The study focused on 286 C282Y homozygous patients who were enrolled in a phlebotomy program (inclusion period: 2004-2010). Dietary intakes were assessed using an iron-rich foods frequency questionnaire. Iron parameters and the quantity of iron removed by phlebotomies (IR) were available for all patients. Potential confounding factors, such as BMI and alcohol consumption, were taking into account.
Results: Patients with iron-rich diet (n=74) and the other group (n=148) showed a similar proportion of men (58.1% vs 53.4%, p=0.50) and a similar mean age at diagnosis (48.3 vs. 50.3 y., p=0.28). The proportions of overweight patients (41.4% vs 43.6%, p=0.77) and of alcohol abusers (10.8% vs 11.0%, p=0.96) did not differ between groups. Although the median transferrin saturation coefficient was comparable between the two groups (82.0% vs 83.0%, p=0.48), patients consuming more iron had a higher degree of iron overload: higher serum ferritin concentration (749.5 vs 530.5 µg/L, p=0.06) and larger amount of iron removed (3.78 vs 3.10 g, p=0.02). These results were confirmed by multivariate linear regression analysis.
Conclusion: This study establishes a link between dietary iron intakes and the degree of iron overload in *HFE* hemochromatosis patients.

The rs3185480 SNP of the APCDD1 gene is associated with androgenic alopecia

N. Nagy[1,2,3], *K. Farkas*[3], *A. Kinyo*[2], *A. Meszes*[2], *L. Kemeny*[2,3], *M. Szell*[1,3];
[1]*University of Szeged, Dept of Medical Genetics, Szeged, Hungary,* [2]*University of Szeged, Dept of Dermatology and Allergology, Szeged, Hungary,* [3]*Dermatological Research Group of the Hungarian Academy of Sciences, Szeged, Hungary.*

Adenomatosis polyposis coli down-regulated 1 (APCDD1) gene is an inhibitor of the Wnt signaling pathway therefore it may have a role in the development of the skin appendages, moreover a mutation of this gene has been shown to be associated with a rare hair condition, hereditary hypotrichosis simplex. In this study we aimed to investigate whether SNPs of APCDD1 gene contribute to the development of androgenic alopecia. 210 patients with androgenic alopecia and 98 controls have been enrolled to the study. The genotypes of 9 SNPs in the coding region of the gene have been determined with direct sequencing. We found a significant difference in the distribution of the genotypes of the c.1781C/T, p.L476L SNP (rs3185480) of the APCDD1 gene in exon 5, causing a 3.5 and a 2.8 times increased risk for the development of androgenic alopecia for the homozygote (CI 0.933 - 13.125; Nominal Regression p=0.063) and the heterozygote carriers (CI 1.086 - 7.217; Nominal Regression p=0.033) of the alleles respectively. Regarding the possible function of the rs3185480 SNP, an in silico investigation suggested that this polymorphism is located in an exonic splicing regulatory

element thus may alter mRNA splicing. Moreover, this SNP alters the codon usage of leucine from a preferred codon (CTC) to a rare codon (CTT), which might influence the efficacy of the translation and thus the APCDD1 protein level. Currently we are working on the functional characterization of this rs3185480 APCDD1 SNP.

[1]*GenHotel-Auvergne-EA4679, Auvergne University, Clermont-Ferrand, France,* [2]*Auvergne University Hospital, Clermont-Ferrand, France,* [3]*Swiss Rheumatology Group, Geneva, Switzerland,* [4]*Pharmacy School, Auvergne University, Clermont-Ferrand, France,* [5]*GenHotel-Evry-EA3886, Evry University, Evry, France,* [6]*Lariboisière University Hospital, Assistance Publique Hôpitaux de Paris, Paris, France,* [7]*Pisa University, Pisa, Italy,* [8]*Sfax University, Sfax, Tunisia,* [9]*Grenoble University Hospital, Grenoble, France,* [10]*Geneva University Hospital, Geneva, Switzerland.*

Introduction: RA's prevalence is 0.4 % in the European population, with a sex ratio of 1:3. The monozygotic concordance rate of 12% is 3 times higher than that of same-sex dizygotic twins and the sib recurrence rate is 2-10. RA incidence in first degree relatives (FRD) is 100/100.000/year (mean age of onset at 46 years). Out of 30 RA genetics factors, 2 have been associated with genes, *HLA-DRB1* and *PTPN22*. Only one environmental factor has been definitely identified, smoking. Those factors explain about half of the increased familial risk, leaving new factors to be identified.
Aim: To set up a large European cohort of RA un-affected FDR for direct investigation of RA genetic susceptibility.
Methods: Recruitment was performed in Switzerland and France. A yearly internet health questionnaire was used, checking RA diagnosis with the Rheumatologist in charge. Yearly blood and hair samples were obtained.
Results

Characteristics at inclusion (N = 1077 since 2011)	Switzerland (N = 663)	France (N=414)
Age [years] : mean (SD)	41 (15)	48 (15)
Sex [%] : Female	73	74
Ethnicity [%]: Caucasians	93	99
RA relatives : mean (SD)	1.2 (0.5)	1.1 (0.4)

RA onset occurred in 2 Swiss participants, a 74 years old female non-smoker and a 56 years old male smoker.
Conclusion: We have set up a cohort of RA FDR, suitable for direct investigation of RA susceptibility. As 10% of the population has an increased RA risk, having a RA first or second degree relative, the cohort is extended to other family members, to search for new factors and initial biological events that could shed light on the susceptibility mechanisms.

Drug transporter and metabolic enzyme gene variants and fluvastatin adverse drug reactions in renal transplant recipients

N. Mirosevic Skvrce[1], *N. Bozina*[2], ***T. Bozina***[3], *I. Barisic*[4], *L. Zibar*[5], *L. Pejnovic*[2], *V. Macolic-Sarinic*[1];

[1]*Agency for Medicinal Products and Medical Devices, Zagreb, Croatia,* [2]*Department of Laboratory Diagnostics, University Hospital Center Zagreb, Zagreb, Croatia,* [3]*School of Medicine, University of Zagreb, Zagreb, Croatia,* [4]*Department of Internal Medicine, Division of Nephrology Arterial Hypertension and Dialysis, University Hospital Center Zagreb, Zagreb, Croatia,* [5]*Department of Internal Medicine, Clinical Hospital Osijek, Osijek, Croatia.*

Background. Statin use in transplant recipients had been hindered by concern about adverse drug reactions (ADRs). Polymorphisms in genes encoding metabolic enzymes and drug transporters could be valuable predictors of fluvastatin ADRs. Fluvastatin is substrate of CYP2C9 and drug transporters ABCB1, ABCG2 and to a lesser extent of OATP1B1 and MRP2. Methods. 52 renal transplant recipients (RTRs) that experienced fluvastatin induced ADRs and 52 control patients, were enrolled in the study. Blood samples of all participants were genotyped for *CYP2C9*2,*3; ABCG2* 421C>A; *ABCB1* 2677C>T/A, 3435C>T, 1236C>T; *SLCO1B1* 388 A>G, 521T>C; MRP2 -24C>T, 1249G>A by means of Real-Time PCR methods. Results. We found that variants of *ABCG2* 421C>A (p=0.005), *CYP2C9*3* (p=0.012) and *ABCB1* 1236C>T (p=0.05), were associated with fluvastatin ADRs. Genotypes *ABCG2* 421CA, *CYP2C9* *1/*3 and *ABCB1* 1236CC were statistically significantly more prevalent in the group of patients with adverse effects than in controls. Our results showed that polymorphism of *ABCG2* gene (OR=3.81; 95% CI=1.27-11.45) is of more importance than of *CYP2C9* (OR=2.44; 95% CI=1.05-5.71) and *ABCB1* 1236C>T (OR=2.38; 95% CI=1.04-5.47) in a subgroup of RTRs, being different from results of pharmacokinetic studies on healthy volunteers. Carriers of *CYP2C9* mutant alleles (*2, *3), who had inhibitor in their therapy, had more than six times greater odds of having adverse effects than those without inhibitor in their therapy (OR=6.59; 95% CI=1.24-35.08).
Conclusions. *ABCG2*, *CYP2C9* and *ABCB1* gene variants could be valuable predictors of fluvastatin ADRs. In real clinical settings pharmacogenetic predisposition could be of even more importance than in healthy volunteers.

Sex and ESR1 genotype may influence the response to treatment with donepezil and rivastigmine in patients with Alzheimer's disease

R. M. Corbo[1,2], *G. Gambina*[3], *E. Broggio*[4], *R. Scacchi*[2];

[1]*La Sapienza University, Rome, Italy,* [2]*CNR Institute of Molecular Biology and Pathology, Rome, Italy,* [3] *Alzheimer's Disease Center, Department of Neuroscience, University and Hospital of Verona, Verona, Italy,* [4]*Alzheimer's Disease Center, Department of Neuroscience, University and Hospital of Verona, Verona, Italy.*

Many factors could be responsible of the different response to treatment with cholinesterase inhibitors (ChEIs) donepezil and rivastigmine among late-onset sporadic Alzheimer's disease (AD) patients. Sex and the variants of the estrogen receptor α (ESR1) gene are reported to modulate the susceptibility to AD or the course of the disease.
Aim of the present study was to verify whether the two above factors could influence the response to ChEIs treatment, as there is evidence that estrogens affect cholinergic system functioning.
Two ESR1 intronic polymorphisms (PvuII, or rs2234693; XbaI, or rs9340799) were examined in 184 AD patients. 157 were treated with donepezil or rivastigmine and were compared with no treated subjects. The cognitive status was quantified using the the Mini Mental State Examination.
Females responded markedly to treatment with ChEIs, and the effects were statistically significant for donepezil and at borderline significance for rivastigmine. A significant effect of ESR1 genotypes was observed for treatment with donepezil, as treated patients carrying at least one copy of P and X alleles showed a significantly lower cognitive decline than non-carriers.
Present data seem to confirm the role of sex in AD, as women seem to be more sensitive to treatment and found to have benefits with regard to cognitive decline. ESR1 may be another gene contributing to to inter-individual variability in response to ChEIs.

Marked differences of haplotype tagging SNP distribution, linkage, and haplotype profile of APOA5 gene in Roma population samples

B. Duga[1,2], *B. I. Melegh*[1,2], *L. Jaromi*[1,2], *L. Magyari*[1,2], *K. Sumegi*[1,2], *Z. Banfai*[1,2], *K. Komlosi*[1,2], *K. Hadzsiev*[1,2], *A. Szabo*[1,2], *R. Szalai*[1,2], *E. Kovesdi*[1,2], *J. Bene*[1,2], *P. Kisfali*[1,2], *B. Melegh*[1,2];

[1]*Department of Medical Genetics, Pecs, Hungary,* [2]*Szentagothai Janos Research Centre, Pecs, Hungary.*

Polymorphisms of the apolipoprotein A5 (APOA5) gene have been found to play an important role in the development of diseases like metabolic syndrome, stroke and cardiovascular disease. We examined four major haplotype tagging variants (rs2072560 [T1259C], rs2266788 [IVS3+G476A], rs3135506 [C56G/S19W], rs662799 [T-1131C]) of the APOA5 gene in pooled DNA of healthy Roma (Romani, Gipsy) and Hungarian population samples to determine the genetic variability, the haplotype profile and linkage of APOA5. We analyzed 366 healthy Roma and 404 average Hungarian DNA samples using PCR/RFLP assay. For T-1131C, T1259C, IVS3+G476A and C56G/S19W we found elevated plasma triglyceride levels in the risk allele carriers compared to the non-carriers in both populations We found that the minor allele frequencies in Roma population were significantly higher

compared to the Hungarians (-1131C: 13.5% vs. 5.32%, IVS3+476A: 6.32% vs. 3.59%, 56G: 9.34% vs.4.70%, p<0.05), except the T1259C variant (6.69% vs. 7.55%). Furthermore, the haplotype analysis revealed significant increase of the APOA5*2, APOA5*4 in Romas (5.4 vs. 3.2; 6.3 vs. 2.0, p<0.05), while the APOA5*5 in Hungarians (0.1 vs. 4.1, p<0.05), but we did not found difference in APOA5*1 and APOA5*3. We found different linkage disequilibrium between the IVS3+G476A and C56G/S19W variants in Roma population (97%) compared to the Hungarians (42%). The data presented here show profound differences in the APOA5 genetic profiles in the Roma population, which likely has also clinical implications in respect their possible role in the development of certain diseases, taking to consideration the differences of triglyceride level changes associated with the minor alleles.

APOE E4 allele - the negative predictor of longevity

M. Zajc Petranović[1], *Ž. Tomas*[1], *T. Škarić-Jurić*[1], *J. Miličić*[1], *S. Tomek-Roksandić*[2], *N. Smolej Narančić*[1];
[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Dr. Andrija Štampar Institute of Public Health - Department of Gerontology, Zagreb, Croatia.*

The apolipoprotein E (APOE) gene is one of the rare candidate genes consistently found to be associated with the longevity. Its product, ApoE enzyme, is essential for the normal catabolism of total and LDL-cholesterol, and therefore highly correlates with the risk for the development of atherosclerotic cardiovascular disease (CVD) and dementia. We tested the association of APOE gene epsilon polymorphisms (combinations of rs429358 and rs7412) with longevity, CVD risk factors and CVD endpoints in the Croatian 80+ population (80-101 yrs; mean=88.28 yrs; N=324; 74.4% of women; 65.1% hypertensives). None of our E44 genotype carriers was older than 95 years (p=0.034), which suggested E4 being a risk allele that does not contribute to longevity. This result was confirmed by the meta-analysis of E4 allele frequencies in general population compared with 80+ yrs population: E4 allele was more frequent in younger people in all 14 tested European populations (p<0.001). In addition to meta-analysis, we found correlations between genetic and geographic distances across Europe (p<0.001).
Considering the other tested CVD risk factors, all E4 carriers had waist/hip ratio ≥0.80 (p=0.034). At the same time E2 carriers less frequently had elevated LDL-cholesterol levels (p=0.047) and diastolic blood pressure (p=0.033), in comparison with non-carriers.
Our findings confirm previously reported deleterious effect of E4 allele to the longevity.

Founder Effect of Fanconi Anemia, Complementation Group G In East Asian Using Haplotype Analysis of Korean Population

J. Park[1], *H. Chae*[2], *M. Kim*[2], *Y. Kim*[2], *N. Chung*[3], *I. Park*[4];
[1]*Samkwang Medical Laboratories, Seoul, Korea, Republic of,* [2]*Departments of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,* [3]*Departments of Pediatrics, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,* [4]*Departments of Obstetrics and Gynecology, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of.*

Fanconi anemia (FA) is a rare disorder characterized by physical abnormalities, bone marrow failure, increased risk of malignancies, and cellular hypersensitivity to DNA cross-linking agents. We previously demonstrated that founder mutations of *FANCA* and *FANCG* account for most of Korean FA like as described in Japanese FA. In this study, we performed haplotype analysis and investigated the founder effect in Korean FA-A and -G using microsatellite markers designed by Yagasaki H. The patients were 12 FA-A and 11 FA-G patients and their family members who have at least one founder mutation; c.2546delC or c.3720_3724delAAACA of *FANCA* and c.307+1G>C or c.1066C>T of *FANCG*. Haplotype analyses only revealed significantly shared haplotypes in both c.307+1G>C and c.1066C>T of *FANCG* as well as c.1589_1591delATA identified in unrelated Fanconi anemia, complementation group G (FA-G), indicating the presence of founder effects. But all FA-A patients did not share same haplotypes, suggesting that the mutation occurred independently on two different alleles and originated from different ancestors. Although *FANCA* may be a primary candidate for screening in FA patients, it is difficult to explain the founder effect in Korean and Japanese FA-A because of the diversity of the mutation profile, absence of a mutation-clustered region, and variously ethnic immigration. Haplotype analysis by means of 8 microsatellite markers spanning the *FANCG* locus indicates that c.307+1G>C (type I), c.1066C>T (type II), and c.1589_1591delATA (type III) are in complete association with distinct ancestry haplotypes.

Association of a G6PC2 gene variation with fasting plasma glucose level in elite athletes

O. N. Fedotovskaya[1], *N. D. Golberg*[1], *I. I. Ahmetov*[1,2,3];
[1]*St. Petersburg Research Institute of Physical Culture, St. Petersburg, Russian Federation,* [2]*Kazan State Medical University, Kazan, Russian Federation,* [3]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation.*

Glucose-6-phosphatase type 2 enzyme is likely to be involved in glucose-stimulated insulin secretion in pancreatic beta cells. Blood glucose levels were reduced in G6pc2 knockout mice (1). G6PC2 gene G/A polymorphism in intron 3 (rs560887) was shown to be associated with fasting plasma glucose levels, but not with type 2 diabetes risk (2). The aim of the study was to compare genotype and allele frequencies of the G6PC2 gene polymorphism in 220 elite Russian athletes and 837 non-athletic controls, and to investigate the association of the G6PC2 gene G/A polymorphism with fasting plasma glucose levels and its changes while performing physical exercise to failure in 60 elite athletes involved in cross-country skiing. Genotyping was performed by RFLP-PCR analysis. The concentration of glucose in blood serum was determined by enzymatic colorimetric method before and after step-increase load on a treadmill. Frequencies of the G6PC2*A allele (17.3 vs. 25.7%; P = 0.0003) and G6PC2*AA genotype (3.6 vs. 6.6%, P = 0.001) were significantly lower in a group of athletes compared with controls. Carriage of G6PC2*A allele was associated with significantly lower level of blood glucose in a group of cross-country skiers (P = 0.02), as well as with lower increase in blood glucose level after a step-increase load to failure (P = 0.05). These data suggest that G6PC2 gene G/A polymorphism due to its functional role might be associated with athletic performance and therefore with elite athlete status.

Association of glutathione S- transferase M1 and T1 polymorphism with male infertility and possible protective effect of P1 polymorphisms in Tunisian infertile men

m. B. G. F. cherif;
laboratory of human molecular genetics, Sfax, Tunisia.

Introduction: Genetic causes are responsible of 60% of cases of idiopathic male infertility. Polymorphisms of genes that encode Glutathione S-transferases (GSTs), a group of phase II enzymes that detoxify electrophiles, can affect the biotransformation of toxic compounds to which the male productive system is exposed. Some reports attested the association of GSTs gene polymorphisms with male infertility. In order to investigate whether there is an impact of genetic variations of GSTs on semen quality and male fertility, we studied three genetic polymorphisms in GSTT1, GSTM1 and GSTP1 in infertile men and controls from Tunisia.
Methods: Participant's were 159 men with idiopathic infertility and 102 presumed fertile men. Basic semen analysis was performed including total sperm count and concentration, motility and morphology. Genotyping of GSTM1 and GSTT1 polymorphisms were performed using the multiplex PCR. The GSTP1 Ile 105 Val polymorphism was determined using PCR-RFLP.
Results: GSTM1 null genotype (GSTM1 0/0) was significantly associated with reduced sperm count in infertile men semen (oligozoospermia) (P=.001) and GSTT1 null genotype (GSTT1 0/0) was significantly associated with low sperm motility (P=.001). However, infertile men had a higher prevalence of the wide type of GSTP1 allele (GSTP1 Ile 105) than the fertile group (80.5% and 72.54%, respectively; P=.034) and the presence of the homozygote mutant genotype (GSTP1 Val/Val) was less common in infertile men than in fertile group.
Conclusion. Our results suggest that both GSTM1 and GSTT1 gene polymorphisms have a negative impact on semen quality and are associated with male infertility in Tunisia.

NOD2/CARD15 gene in Moroccan population

n. serbati[1,2], *W. BADRE*[3], *B. DIAKITE*[1,2], *S. NADIFI*[1,2];
[1]*Department of Medical Genetics - Medical School of Casablanca, casablanca, Morocco,* [2]*CEDoc of health sciences - Medical school - University Hassan II Ain-Cock Casablanca, Casablanca, Morocco,* [3]*Department of Gastroenterology - CHU IBN ROCHD - Medical School of Casablanca, casablanca, Morocco.*

Background: IBD (Crohn's disease and Ulcerative Colitis) are chronic and multifactorial diseases of the gastrointestinal tract. Till now, their pathogenesis remains unclear. They involve innate immunity, environmental component and genetic predisposition. Polymorphisms in NOD2/CARD15 have been implicated in Crohn's disease in several ethnic groups. The purpose of our study was to assess the frequency of the three major variants of this gene (Leu1007fsinsC, Arg702Trp, and Gly908Arg) in Moroccan IBD patients and to determine a possible effect of these variants on Disease's phenotype and clinical course.
Methods: A total of 96 Moroccan unrelated IBD patients and 114 healthy controls were genotyped (PCR-RFLP method) for the three main polymorphisms.
Results: In this study, no correlation was found between NOD2/CARD15 polymorphisms and ulcerative colitis or Crohn's disease in our population. Nevertheless, 32629insC variant was associated to a structuring behaviour on CD patients.
Conclusion: These findings suggest that NOD2/CARD15 influences disease behaviour but not susceptibility to crohn's disease in Moroccan IBD patients.

Molecular characterization of the genotype of sickle cell disease patients in the state of Rio de Janeiro, Brazil

E. Belini-Junior[1], *L. S. Torres*[1], *J. V. Okumura*[1], *G. C. S. Carrocini*[1], *W. M. Barberino*[1], *R. G. Oliveira*[1], *V. U. Teixeira*[1], *D. G. H. Silva*[1], *C. L. C. Lobo*[2], *C. R. Bonini-Domingos*[1];
[1]*UNESP - Sao Paulo State University, Sao Jose do Rio Preto, Brazil,* [2]*HEMORIO - Institute of Hematology Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil.*

Sickle-cell disease (SCD) is a multisystem disease and is one of the most common severe monogenic disorders worldwide. SCD manifests itself as a chronic hemolytic disease with acute vaso-occlusive complications that require frequent hospitalizations and therefore represents a substantial burden to national healthcare systems. In Brazil, the geographical distribution of the disease is broad and in many Brazilian Blood Centers the diagnosis is made only by electrophoresis and chromatography tests. Thus, the objective of this study was to characterize the genotypes of sickle cell disease in the second state with highest frequency of SCD patients in Brazil. The study evaluated 1250 patients from Institute of Hematology - HEMORIO/ Rio de Janeiro. We performed electrophoresis in alkaline pH and acid pH, high performance liquid chromatography (HPLC) and molecular analysis using PCR-RFLP for identification hemoglobin (Hb) S and Hb D-Los Angeles and PCR-EA for identification of HbC and beta thalassemia mutations (IVS-I-110, IVS-I-6, IVS-I-1 e CD39). The genotypes found were 992 (79.4%) patients homozygous for HbS, 165 (13.2%) with HbSC disease, 73 (5.8%) with interaction HbS/beta thalassemia, 14 (1.1%) with HbSD-Los Angeles disease and 6 (0,5%) with the interaction of HbS with another unidentified Hb variant. For alleles beta thalassemia, we find 14 CD39 mutations, 14 with the IVS-I-6 mutation, 7 with IVS-110 mutation and 38 did not exhibit the four mutations assessed and require gene beta sequencing. These results show the importance of the molecular diagnosis of SCD, since the genotypic characterization assists in monitoring the disease and specific therapy for patients.

Armenian Highland as a transition corridor for the spread of Neolithic agriculturists

A. Hovhannisyan, *A. Margaryan, H. Hovhannisyan, Z. Khachatryan, A. Khudoyan, L. Yepiskoposyan;*
Institute of Molecular Biology NAS RA, Yerevan, Armenia.

The routes of Neolithic migrations from the Near East are presently intensively debated among scholars of various disciplines. Recent studies suggest that haplogroup R1b1a2-M269, which is the most common lineage in the European populations, was spread with first farmers via Anatolia to Europe during the Neolithic transition. These studies, however, did not include indigenous populations from the Armenian plateau, though it has played a key role in the ancient human migrations since early Paleolithic.
We used a total of 358 Y-chromosomal data collected in three Armenian geographic groups from eastern and western parts of the Armenian plateau and comparative datasets of various European populations to assess the genetic contribution of the region to the spread of haplogroup R1b1a2-M269 north- and westward.
The frequency of this lineage in eastern Armenian populations is higher compared with eastern European populations (including Anatolia) and lower than in Western Europe. The rate of the variance and age of the R1b1a2-M269 is the highest in western Armenian population among all datasets considered. In addition, there is a strong correlation between the genetic and geographic distances of the populations studied thus reflecting the directions of pre-Neolithic and Neolithic migrations from the Near East.
In conclusion, the southwestern area of Armenian Highland deserves to be more thoroughly examined as one of the principal transition regions for the spread of first agriculturists from Levant to Europe.

Genome-wide CNV association study with osteoarthritis in Korean

S. Moon, *M. Hwang, Y. Kim, N. Kim, Y. Kim, J. Lee, J. Lee, B. Kim;*
Korea National Instititue of Health, Cheongwon-gun, Korea, Republic of.

Osteoarthritis (OA) is a mechanical abnormality such as joints degradation. Some of causes (hereditary, metabolic, and mechanical) may lead to loss of cartilage. However, genetic studies have not identified any genes definitely conferring major risk for OA and only a small number of many genes that influence risk for OA collectively have been found to date. Copy number variations (CNVs) are quantitative structural variants including duplications and deletions. CNVs analysis is an alternative genome-wide molecular genetics approach to identify genetic aberrations underlying common complex. Given the need of more genetic information of OA and the growing implicated value of CNVs in complex disease, we performed genome-wide CNV association study in patients with OA using array comparative genomic hybridization (aCGH) method (371 cases and 467 controls).
The findings of our OA cases were compared with those in a large sample of controls. After statistical analysis, we found significant gene regions showing CNVs in patients with OA. To ensure the reliability of our CNV detection method, we experimentally validated the significant CNV using quantitative PCR (qPCR). Our data indicate that deletion of this locus is associated with OA and might be potentially important for OA.

A new approach to meta-analysis of population-specific sequencing association studies

H. Wang, *C. Hsiao, A. Hsieh, Y. Lin, C. Fann;*
Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.

Since the joint effects of the loci in genome-wide association studies (GWAS) typically explain only a small proportion of the heritability, genetic association studies require a very large sample size to achieve the desired power and minimize the detection of false associations. Meta-analysis is an effective approach to achieve higher power in GWAS by combining summary results from multiple different studies. Although large sample sizes can help guard against false-negative and false-positive results, a major potential problem is that allelic heterogeneity across populations could lead to dramatic dilution of power to detect true positive signals. Population heterogeneity is also poised to be a major concern in sequencing studies investigating the association of low-frequency and rare variants with complex traits. The effects of population heterogeneity are likely specific to particular ancestral groups. Therefore, differences in nucleotide diversity across populations become important when looking at variants in aggregate. In this study, we propose a population-differentiated test of association with quantitative or dichotomous traits, which allows for heterogeneity of allelic effects among populations. Simulations are used to demonstrate the comparison of power between proposed population-differentiated meta-analysis and traditional population combined approach. Furthermore, a real data analysis with multiethnic Prostate cancer dataset from dbGaP are used to evaluate the performance of the proposed method. Our preliminary results indicate that the proposed method has the potential to investigate the population-specific

effect for complex disease using summary data from sequencing studies in meta-analysis.

HFE gene polymorphism in Sickle Cell Disease - a way to understand the phenotypic variability

C. R. Bonini-Domingos[1], *E. Belini Junior*[1], *A. M. Mach*[2], *C. C. Lobo*[2];
[1]*UNESP, São José do Rio Preto, Brazil,* [2]*HEMORIO, Rio de Janeiro - RJ, Brazil.*

The sickle hemoglobin is a point mutation (GAG → GTG) in the *β g*lobin gene resulting in the substitution of glutamic acid by valine at position 6 of the *β* globin polypeptide chain. The multiple phenotypic expressions associated with complex genetic interactions and modifiers are not well understood. Hemochromatosis is a clinically heterogeneous condition and both genetic and environmental factors can modulate the evolution and the severity of the disease. The *HFE* gene is the more frequent gene screened in conditions that curse with iron overload, as hemoglobinopathies. Were evaluated 1256 blood samples of Sickle Cell Disease (SCD) patients from Brazil by molecular procedures. The frequency of Hb SS was 79.38%, Hb SC 13.14%, Hb S/beta thalassemia 5.89%, Hb SD 1.59% and Hb S/other variants 0.39%, that reflect the admixture of Brazilian population. The genotypic frequency of the *HFE* gene polymorphisms (C282Y, H63D and S65C) show a higher percentage of H63D heterozygotes in all Hb phenotype evaluated, mainly in Hb S/Beta Thalassemia (74.3%), Hb SS (60.6%) and Hb SC (46.7%) with significant difference (p=0.0008). The frequency of C282Y and S65C mutation were very low and without significant differences. The blood transfusion is the current treatment for SCD, and the iron overload is a consequence. The *HFE* gene profile in SCD patients improves the therapeutic strategy especially in the Brazilian multiethnic population. Identify risks of complications and understand the wide phenotypic variability of SCD will require markers of underlying processes.

Population based study of permanent teeth agenesis in Japanese

J. Machida[1], *T. Nishiyama*[2], *M. Kamamoto*[3], *S. Yamaguchi*[4], *M. Kimura*[4], *A. Shibata*[4], *K. Yamamoto*[1], *S. Makino*[1], *H. Miyachi*[4], *K. Shimozato*[4], *Y. Tokita*[5];
[1]*Toyota memorial hospital, Toyota, Aichi, Japan,* [2]*Nagoya City University Hospital, Nagoya, Japan,* [3]*Himeji Red Cross Hospital, Himeji, Japan,* [4]*Aichi-Gakuin University, Nagoya, Japan,* [5]*Aichi Human Service Center,, Kasugai, Japan.*

Permanent tooth agenesis is one of the most common developmental anomalies in humans (OMIM: #106600, #604625) and may occur independently, or as one feature of a syndrome. The nonsyndromic forms may be sporadic or familial with prevalence varying by tooth type. Nonsyndromic tooth agenesis has sometimes been divided into two types: oligodontia, defined as agenesis of six or more permanent teeth, and hypodontia, defined as agenesis of less than six teeth. The number in both cases does not include absence of third molars (wisdom teeth). The purpose of this study, which was based on a large sample of 4088 Japanese school children, was to describe the occurrence of agenesis of permanent teeth. In addition, this study described and analyzed the sibling reoccurrence ratio in 71 Japanese families with tooth agenesis.
The prevalence of hypodontia and oligodontia were 6.84%(95% CI: 6.06%; 7.68%) and 0.13%(95% CI: 0.04%; 0.30%), respectively. Sibling recurrence ratio in absence of one, two, three to five, and six or more teeth were 0.245% (95% CI: 0.138%; 0.383%), 0.250% (95% CI: 0.073%; 0.524%), and 0.222% (95% CI: 0.064%; 0.476%), and 0.438% (95% CI: 0.264%; 0.623%), respectively. This suggests severe phenotype, oligodontia fitted with an autosomal dominant inheritance, whereas mild phenotype, hypodontia is most compatible with an autosomal dominant trait with incomplete penetrance and/or polygenic inheritance. In addition, we estimated a model of missing ratio of individual tooth.

Investigation of Type 2 Diabetes susceptibility loci in the Cypriot population

C. Votsi[1], *C. Toufexis*[1], *N. Skordis*[2], *A. Antoniades*[3], *M. Karaolis*[3], *C. Pattichis*[3], *K. Christodoulou*[1];
[1]*The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,* [2]*Hospital Arch. Makarios III, Nicosia, Cyprus,* [3]*University of Cyprus, Nicosia, Cyprus.*

Type 2 diabetes (T2D) mellitus is a chronic complex multifactorial disease with a substantial contribution of genetic factors that usually occurs over the age of 40 years old. It is characterized by high blood glucose levels caused by the combination of insulin resistance and relative insulin deficiency. T2D is a serious worldwide public health problem which has reached epidemic proportions and its prevalence is increasing. The disease leads to morbidity with the life expectancy being reduced, while additional implications include premature coronary heart disease, peripheral vascular disease, renal failure, stroke and amputation. Major steps have been made in the identification of T2D susceptibility loci, both through genome-wide association (GWA) scans and meta-analysis of these scans and several genetic loci have been reported with possible association. Our study is focused on the Cypriot population. We collected a representative number of diabetic and non-diabetic blood samples, extracted DNA and created the first Cypriot T2D DNA bank. Study of nineteen already established susceptibility loci (in genes *WFS1, PPARG, TCF2, KCNJ11, TCF7L2, CDKN2A/B, CDKAL1, SLC30A8, IGF2BP2, HHEX/IDE, FTO, KCNQ1, MTNR1B, NOTCH2, CDC123/CAMK1D, ADAMTS9, THADA, TSPAN8/LGR5, JAZF1*) is underway in order to examine if they are confirmed in our population. Samples were genotyped using the TaqMan technology. Data mining and interaction testing will follow in an attempt to extract additional information regarding T2D susceptibility in our population. Study results will be presented.
Funded by CRPF (ΥΓΕΙΑ/ΔΥΓΕΙΑ/0609(BIE)/03).

J16.33

Complex analysis of association between inflammatory cytokines gene variants and essential hypertension

Y. Timasheva, *T. Nasibullin, O. E. Mustafina;*
Institute of Biochemistry and Genetics Ufa Science Centre Russian Academy of Sciences, Ufa, Russian Federation.

Essential hypertension is a common disease with severe cardiovascular complications that are the leading cause of death in the majority of developed countries in the world. The term "essential" suggests that etiology of the disease, despite the extensive research in this field, remains unknown. It is hypothesized that inflammation and endothelial dysfunction are pathophysiological processes that are underlying the disease development.
The aim of our study was to investigate an association between candidate genes, whose products are involved in inflammation, endothelial function and blood pressure control, and essential hypertension. Nine loci in *IL1RN, LTA, TNF, IL1B, IL12B, IL10, IL6, NOS3* and *AGT* genes were genotyped in the group of 480 individuals (298 patients, 192 controls). Genotyping data were analyzed using APSampler algorithm (p-values<0.05 were considered significant). We found that carrier status of *IL1B* rs16944C allele, *IL10* rs1800872A allele and *IL6* rs1800796G allele was most significantly associated with essential hypertension (P=0.0009, OR=2.00, CI: 1.30-3.06). Carriers of *IL1B* rs16944C allele and *IL10* rs1800872A allele combination were also at the increased risk of essential hypertension (P=0.001, OR=1.97, CI: 1.29-3.01). It is worth noting that the associations observed for biallelic and triallelic combinations were more pronounced than those for the same loci when analyzed separately. Our results provide an evidence for association between cytokines genetic variants and essential hypertension. IL-1B and IL-6 are potent pro-inflammatory and pro-atherogenic cytokines, and, while IL-10 exerts anti-inflammatory action, the - rs1800872A allele of *IL10* gene is known to be associated with decreased IL-10 expression.

J16.34

Structure of congenital malformations strictly accounting in the early neonatal period

M. Utsiyeva, *Z. Musabaeva, M. Zhumazhanova, L. Ainabekova, E. Moldagulova, Z. Azhetova, D. Turakbayeva;*
Center of perinatology № 1, Astana, Kazakhstan.

The birth defects were analyzed in order to study the frequency and structure of the „sentinel phenotypes" and their contribution to the early neonatal

mortality. Defects were detected in the first 6 days of life. Personalized card was filled for each patient. The diagnosis was being set in according to ICD 10. 772 diagnosed congenital defects in total, including defects „strict accountability" - 25%. The share of defects among newborns was 1.33% for the analyzed period.
Structure of congenital malformations „strict accountability": the malformations of the central nervous system (anencephaly, spinal hernia) - 9%, esophageal atresia - 3%, intestinal atresia - 2%, atresia of the anus - 3%, poly-syndactyly - 8%, reduction defects of extremities - 1%, omphalocele - 7%, gastroschisis - 2%, multiplex birth defects - 10%, Down's syndrome - 33%, other 2% chromosomal disease, cleft palate, cleft lip - 17%, achondroplasia - 3%.
Thus, study of the structure of congenital malformations will be more accurate to talk about the frequency of this disease, to monitor the dynamics of cargo of congenital disorders in the population and to take early preventive measures.

Consanguinity, endogamy and genetic disorders in Tunisia

N. Ben Halim, *N. Ben Alaya, L. Romdhane, R. Kefi, Y. Bouyacoub, I. Arfa, F. Talmoudi, K. Lasram, S. Hsouna, A. Amouri, S. Abdelhak;*
Institut Pasteur de Tunis, Tunis, Tunisia.

Background: Consanguineous marriages are common in many Arab countries including Tunisia. However, little information exists on their impact on genetic disorders in the Tunisian population. The objective of this study was to evaluate the current rate of consanguinity in Tunisia and to examine its impact on the occurrence of some specific genetic disorders.
Methods: Consanguinity profiles were retrospectively studied among 1121 Tunisian patients suffering from different monogenic autosomal recessive and dominant disorders and some complex conditions and compared to that of a healthy control sample.
Results: Consanguinity rates were 78.36% among autosomal recessive condition group, 38.04% among dominant group, 34.65% among multifactorial group and 29.80% among the control group with a first cousin union rate of 31.76%, 20.65%, 16.23% and 16.72%, respectively. The differences in consanguinity pattern were highly significant when comparing control group with recessive disorder group, but not significant compared to dominant or multifactorial groups. Consanguinity was associated with a nearly six-time increased risk to develop autosomal recessive disorders. This excess risk is proportional to the degree of consanguinity and the frequency of disease allele in the family. Furthermore, recessive disorders were associated with a very high level of regional endogamy (91.87%).
Conclusion: This study emphasizes the persistence of a high level of consanguinity in the Tunisian population (29.80%) and reveals a high impact of inbreeding and endogamy on the etiology of autosomal recessive diseases. In contrast, no significant association was found between consanguinity and complex disorders suggesting that these conditions are mainly influenced by environmental factors.

Atopic Eczema: genetic heterogeneity in European populations

R. Cascella[1], *M. Ragazzo*[1], *E. Vakirlis*[2], *D. Hashad*[3], *M. Canale*[1], *C. Strafella*[1], *C. Germani*[1], *D. Ioannides*[2], *G. Novelli*[4,5], *E. Giardina*[1];
[1]*University of Rome „Tor Vergata", Department of Biomedicine and Prevention, Rome, Italy,* [2]*Lecturer of Dermatology and Venereology, A' Department of Dermatology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [3]*Lecturer of Clinical Pathology, Faculty of Medicine, Alexandria, Egypt,* [4]*S. Pietro Fatebenefratelli Hospital, Rome, Italy,* [5]*National Agency of Evaluation of Universities and Research (ANVUR), Rome, Italy.*

Atopic dermatitis (AD), or eczema (AE), the most common chronic inflammatory skin condition, is a complex multifactorial disease. The clinical manifestations of AE vary with age of onset (infancy/childhood, adolescence and adulthood), but common symptoms are: red blotches on the body, itchy rash that can quickly develop into painful papule. AE affects almost 1-3% of people in world-wide even if its causes are not clear. Currently the background of AE is very heterogeneous; in fact apart from the gene encoding filaggrin (*FLG*), the genes causing AE are unknown. In recent years studies on several populations have found different rare mutations (R501X, 2282del4, R2447X, S3247X, 3321delA, S2554X, S2889X and S3296X) in *FLG* gene. These mutations are prevalent in north Europe and Asia (Japan, Korea and Taiwan) and have been associated with the onset of AE. Recent case/control studies carried out on populations of south Europe (Italy, Croatia and Turkey) failed to reveal variations in *FLG* gene. These results suggest that *FLG* gene should not be considered as major risk factor to populations of south Europe. In order to confirm this hypothesis, we are resequencing the entire third exon of *FLG* gene in Egyptian and Greek populations. Preliminary genotyping of R501X and 2282del4 mutations, has failed to reveal evidence of mutations in patient samples.
These preliminary data suggest that *FLG* mutations are not common in these populations. Further experiments are needed to disclose different susceptibility genes in these populations.

Increased risk of hypertensive emergencies and polymorphism of the ACE gene

A. Bonini Domingos[1], *M. A. S. Pinhel*[1], *E. Belini Junior*[2], *D. R. Silva Souza*[1], *J. F. Vilela Martin*[1];
[1]*FAMERP, São José do Rio Preto/SP, Brazil,* [2]*Ibilce/Unesp, São José do Rio Preto/SP, Brazil.*

Hypertensive crisis (HC) is characterized by a rapid, inappropriate, intense, and symptomatic blood pressure elevation. A hypertensive emergency is characterized by rapid deterioration of target-organs and poses an immediate threat to life, a situation not found in hypertensive urgency. Whereas the angiotensin-converting enzyme (ACE) plays an important role in regulating blood pressure through the renin - angiotensin - aldosterone system (RAAS), this study aim to analyze the insertion/deletion (I/D) polymorphism in the ACE gene, on HC. We collected blood samples, after consent, from 308 individuals, regardless of ethnicity and gender. 139 were normotensive individuals which compound the control group and the test group (169) with hypertensive crisis episodes, was divided into urgency (68) and emergency (101). The clinical data was obtained in the medical care. The DNA was extracted and polymorphism analysis performed by PCR. The genotypes polymorphism frequency evaluated in the control group was consistent with the Brazilian population. There no differences in gender frequencies. For the ACE genotypes there was a significant difference in the control and test group (p=0.00021). The II genotype differences were observed between control (21.58%), urgency (11.76%) and emergency (2.97%) groups (p= 0.0014). For the ID genotype the difference was in emergency (84.16%), urgency (77.94%) and control (61.15%) groups (p= 0.00021). There is a risk of emergency event associated with the D allele (Odds 5.41; p=0.02, CI:1.38-21.21). Based on these results and on the polymorphism frequency in Brazil, we consider essential to assess the gene, whereas hypertensive emergencies can be extremely harmful to individuals.

Mutation Leu40Arg of gene ITGB3 linked to mutation Leu33Pro among inhabitants of the Novosibirsk region

L. F. Mitrohina[1], *A. B. Maslennikov*[1,2], *A. R. Shorina*[1], *E. V. Maslova*[1], *Y. I. Bravve*[1];
[1]*State Novosibirsk Regional Clinical Diagnostic Center, Novosibirsk, Russian Federation,* [2]*Scientific research institute of molecular biology and biophysics of the Siberian branch of the Russian Academy of Medical Science, Novosibirsk, Russian Federation.*

The central role in realization of a primary hemostasis belongs to complex IIb/IIIa. The major mutation of gene ITGB3 - Leu33Pro, strengthening alarm functions of the given receptor and associated with development of arterial thromboses is àt the moment known. Among inhabitants of the Novosibirsk region we reveal replacement T on G in 1585 position ITGB3, leading to replacement Leu on Arg in 40 position amino acids sequences and linked to mutation Leu33Pro. In the Russian Federation Leu40Arg mutation has been given revealed earlier among inhabitants of St.-Petersburg.
At inspection of 246 healthy inhabitants of the Novosibirsk region the genital age, selected by epidemiological criteria, the Leu40Arg of ITGB3 have made frequencies of 0,0081. Thus the mutation always was in coupling with Leu33Pro and formed one of genotypes: Leu33Pro33/Leu40Arg40 or Pro33Pro33/Leu40Arg40 gene ITGB3.
Particular interest submit data received by us about authentic to higher frequency replacement T on G in 1585 position ITGB3 and genotypes Leu33-Pro33/Leu40Arg40 and Pro33Pro33/Leu40Arg40 gene ITGB3 among pati-

ents with thromboses, at children with infringement of intellectual function and in the families having reproductive problems.
The given fact confirms the importance testing mutations Leu40Arg and Leu33Pro ITGB3 at mediko-genetic consultation of families planning pregnancy.

Association of common KIBRA variants with cognitive performance in young adults

N. Maksimovic[1], *I. Novakovic*[1], *T. Stojkovic*[2], *M. Bajcetic*[3], *B. Jekic*[1], *T. Damnjanovic*[1], *L. Lukovic*[1], *E. Stefanova*[2];
[1]*Institute of Human Genetics, Faculty of Medicine,University of Belgrade, Belgrade, Serbia,* [2]*Neurology Clinic, Clinical Center of Serbia, Belgrade, Serbia,* [3]*Institute of Histology, Faculty of Medicine,University of Belgrade, Belgrade, Serbia.*

KIBRA is a cytoplasmatic protein mainly expressed in the memory related structures of the brain where it has a role in synaptic plasticity and memory formation. Several studies have linked T<C substitution in the intron 9 of KIBRA gene to episodic memory performance and Alzheimer's disease risk but results still remain controversial.
The aim of our study was to investigate the association of T<C polymorphism, mentioned above, with general cognitive abilities, working memory and episodic memory of young adults. Our study was carried out on 538 students of Faculty of Medicine, University of Belgrade (mean age 20±0.8, 66.91% women). Subjects general cognitive abilities were assessed by the Raven Standard Progressive Matrices, and working memory with the Digit Ordering task maximal span scores. Episodic memory was tested with the Rey Auditory Verbal Learning Task (RAVLT) for semantically unrelated word stimuli and with Wechsler memory scale-revised form (WMS-R) Logical Memory subtest for semantically related material.
Statistical analysis showed that TT carriers had significantly better RAVLT immediate recall scores and better RAVLT delayed recall scores but without statistical significance. No association between KIBRA genotype and general cognitive abilities, working memory nor with the results of WMS-R Logical Memory subtest have been observed.
These findings suggest that KIBRA might modulate episodic memory performance specifically in case of semantically unrelated items.

Identify LD Blocks Using biplot function method

M. Tomita[1], *K. Hayashi*[2], *K. Kurihara*[2];
[1]*Tokyo Medical and Dental University, Tokyo, Japan,* [2]*Okayama University, Okayama, Japan.*

In recent years methods of trait mapping based on theories of linkage disequilibrium analysis have been developing rapidly. In DNA sequences, domain hotspots exist at which recombinations have occurred briskly. Conversely, large domains with infrequent recombinations in which linkage disequilibrium is maintained also exist. Such a domain is called a haplotype block or LD block. Although the value of D' represents one of the disequilibrium parameters important for identifying LD blocks. We proposed that it's used biplot function and subspace method to identify LD block, based on technology developed by eigen value problem. We will show results and discussion on the day of our presentation.

First results of monitoring of health of the students - possibilities of modern genetics

O. S. Glotov[1,2,3], *I. Tarkovskaya*[1,3], *A. S. Glotov*[1,2], *V. S. Pakin*[1,3,2], *M. M. Danilova*[1], *S. Namozova*[1], *L. Shadrin*[1], *I. V. Pugacheva*[1,3], *V. S. Baranov*[1,2];
[1]*St-Petersburg State University, St-Petersburg, Russian Federation,* [2]*FSBI «The D.O.Ott Research Institute of Obstetrics and Gynecology» NWB RAMS, Saint-Petersburg, Russian Federation,* [3]*Ltd BioGlot, Saint-Petersburg, Russian Federation.*

The aim of this study was to develop a method based on genetic testing for assessing health status of students of North-West Region of Russia within 4-6 years of training in higher education institution starting with the first course. For this purpose we conducted analysis of questionnaire data, laboratory tests and more than 25 genes of „hypertension" and „fibrinolysis" systems, and others like interleukins. Before participating in the research, all participants gave their informed consent.
The polymorphisms of three genes (ACE (I/D), NOS3 (4/5), TNFA (-238G/A; -308G/A) associated with some multifactorial diseases (cardiovascular diseases, diabetes) were studied by PCR-RFLP analysis in student population of North-West region of Russia (107 people). A population group consisted of unrelated individuals of age 25-45 (59 men and 58 women) - the group 2.
Distribution of relevant polymorphisms frequencies for studied genes was similar in student group compared to the group 2. Distribution of genotypes of NOS3 gene was significantly different between women students in comparison to women of group 2 (p=0.0032, df=2) for 4/4 genotype (6.2% and 1.6%, respectively). Higher frequency of D/D (ACE) genotype was found for men in student group compared to the group 2 (D/D - 40.0% and 27.6%, respectively).
The first results allow assuming that the group of students differs from population group on the frequency of genotypes associated with cardiovascular diseases. Further monitoring of health of students, analysis of data of their laboratory tests and questionnaires, and analysis of other genes will confirm or disprove this assumption.

Genetic variance in metabolically healthy obesity

M. Nuotio[1], *J. V. van Vliet-Ostaptchouk*[2], *B. H. R. Wolffenbuttel*[2], *M. Perola*[3,1,4];
[1]*Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland,* [2]*University Medical Center Groningen, Groningen, Netherlands,* [3]*National Institute for Health and Welfare, Helsinki, Finland,* [4]*University of Tartu, Tartu, Estonia.*

Common obesity is increasingly seen as a worldwide epidemic severely threatening global well being, as it is associated to a broad range of various pathologies. Some obese individuals seem, however, to be protected or more resistant to the development of metabolic abnormalities and pathologies associated with obesity. We know these individuals as "metabolically healthy but obese" (MHO). Mechanisms underlying this protective phenotype are yet unknown.
At the population level, common obesity can be seen as a complex disease which is based on limited number of gene alleles of which each allele slightly increases the risk of obesity to emerge. Even though the relative participation of environmental and genetic factors to the emergence of obesity is rather unclear, it is probable that the occurrence of certain polymorphisms makes some individuals more prone to weight gain compared to others. It is equally probable, that genetic factors affecting healthy obesity phenotype are complex by nature. While genetics of common obesity is extensively studied, studies about genetics of metabolically healthy obesity have not been done to date.
We have characterized metabolically healthy obese individuals in ten European population based cohorts and will test an interaction between genotype and metabolically healthy obesity phenotype.
Characterization of genetic and, in future also a metabolic profile of MHO individuals can lead to the better knowledge about the pathology of obesity overall. We believe that understanding genetic and metabolic differences between healthy- and sick obesity is likely to have a great impact on the obesity research on the whole.

Background: To understand the biological evolution of Bulgarians, we need to clarify the changes of the Bulgarian gene pool over the times. This can be achieved by describing the genetic structure of the populations that inhabited Bulgarian lands in the past and comparing it with the results obtained from the study of contemporary Bulgarians.
Results: Using the most stringent criteria for ancient DNA analysis we analyzed 122 ancient samples from different regions of Bulgaria, dating from III

Millennium B.C. to VIII- X Century A.D. Preliminary results on 14 individuals (360 bp of HVS I sequence of Mitochondrial DNA) have shown that part of the ancient haplotypes are present among present-day Bulgarians, but we have also found haplotypes which are not observed in the contemporary population. Conclusion: Our results revealed discrepancies and overlaps between the ancient population and the modern Bulgarian mtDNA diversity.
Acknowledgement: This study was supported by contract № DO02-110/22 may 2009 of the Ministry of Education and Science, Bulgaria

Analysis of DFNB1-associated hearing loss in Tatar population (Russia)

N. E. Petrina, *E. I. Sharonova, T. A. Vasilyeva, N. V. Petrova, R. A. Zinchenko;*
Research Center for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

Connexins are the key components of the gap junction, which regulate various physiological and developmental processes. According to recent data, mutations in different connexin genes are associated with nonsyndromic sensorineural hearing loss (NSHL). Hearing loss is the most frequent in terms of incidence and prevalence. We conducted comprehensive medical and population genetic studies in seven regions of Tatarstan resulting in detection of 96 patients with congenital recessive deafness (Kukmorsky-18, Drozhzhanovsky-13, Buinsky-31, Atninsky - 6, Arsky - 8, Aktanyshsky - 11, Muslyumovsky - 9). Molecular genetic testing of patients DNA samples was carried out by sequencing the coding region of GJB2 gene. The frequency of the major mutation 35delG was 29,17%. The second frequent mutation was 313del14 (4,69%). The frequency of M34T mutation was 1,56%, the frequency of polymorphism V27I - 4,69%. The following mutations 299-300delAT, R165W, V153I, R127H, delV38, each was met with frequency of 0,52%, were revealed in the studied sample of patients with NSHL. A new deletion of three nucleotides (111-113delTGT), leading to a loss of one amino acid in the 38th position (delV38) was found. This mutation, 111-113delTGT, was detected in one patient with another mutant allele not yet identified. Two GJB2 mutations were detected in 8% patients, in 51% and 41% of patients one or none mutations, correspondently, were identified in GJB2 gene. Unexpectedly, screening of 35delG mutation in 710 healthy donors from three Tatar ethnographic groups showed a relatively high population frequency of 35delG mutation (1,19%). The further analysis of other connexins genes is planned.

Mutational screening for cathepsin C gene in Saudi patients with Papillon Lefevre-Syndrome

I. Alabdulkareem[1], *M. Ballow*[2], *S. ALKHENAIZAN*[3], *M. Albalwi*[2];
[1]*KAIMRC, Riyadh, Saudi Arabia,* [2]*King Abdullah internationla Research Center, Riyadh, Saudi Arabia,* [3]*King Abdulaziz Medical City, Riyadh, Saudi Arabia.*

Papillon Lefevre-Syndrome (PLS) is a rare genetic neuromuscular disease autosomal recessive disorder characterized by the development of palmar-plantar hyperkeratosis and periodontium associated with mutations in cathepsin C gene (CTSC). The disease manifestation is present during childhood characterized by severe dermal and dental manifestations.
A total of 6 families were genetically examine for the presence of CTSC gene mutation and carrier statues that included 14 PLS patients, along with their parents plus one sibling who showed no signs of PLS. Additionally, 20 healthy individuals were enrolled as study control.
The results showed that all PLS patients who participated in this study shared the same type of mutation on the CTSC gene; homozygous for c.815 G>C (p.R272P) mutation, while their parents who are first-degree cousins were all found heterozygous for the same mutation type. All control subjects in this investigation were homozygous normal.
This study is pointing into the consequence of consanguineous marriages as a major factor for increasing the risk of genetic diseases among Saudis. Additional community educational efforts should be adopted through Saudi health authorities to spread the awareness among the general population about these deformities as results of consanguinity relations.

The association of PPARD gene T294C polymorphism with endurance athlete status: a replication study

R. T. Gabbasov, *E. S. Nasibulina, I. I. Ahmetov;*
Kazan State Medical University, Kazan, Russian Federation.

Peroxisome proliferator-activated receptor delta (PPARD) regulates the genes involved in the oxidation of fatty acids, cholesterol metabolism, thermogenesis, embryogenesis, regeneration, inflammation and carcinogenesis (Furnsinn et al., 2007). The functional T294C single nucleotide polymorphism in exon 4 of the PPARD gene is located 87 nucleotides upstream of the start codon. The C allele rather than the T allele of this polymorphism has been associated with higher transcriptional activity of the PPAR-delta promoter by inducing a binding site for Sp-1 transcription factor (Skogsberg et al., 2003). It was hypothesized that the C allele is associated with increased fatty acid oxidation (endurance enhancing factor). Recently we have shown that the PPARD C allele is over-represented in Russian endurance athletes (Ahmetov et al., 2007). The aim of the study was to investigate the distribution of genotypes and the frequency of alleles of the PPARD gene in athletes (n=430) and controls (n=677) and thus replicate recent findings in independent cohorts. Genotyping was performed by PCR-RFLP. The frequencies of the C allele and CC genotypes in endurance-orientated athletes were significantly different from controls (n=106, 20.3 vs. 13.0%, P=0.0074; 6.6 vs. 3.1%, P=0.0262). Furthermore, the distribution of genotypes in athletes involved in sports games (n=114, P=0.0075) was significantly different from the controls. The distribution of genotypes and the frequencies of alleles in power-oriented athletes and a whole cohort of athletes were not different from control. Thus, we confirm that the PPARD gene T294C polymorphism is associated with endurance athlete status in Russians.

Role F2, F5, AGT, ENOS and MTHFR genes in the development of preeclampsia

A. Borovikova[1], *M. Bayanova*[1], *A. Nagimtayeva*[1], *L. Saidildina*[1], *K. Jamanaeva*[1], *G. Murzabekova*[1], *D. Turakbayeva*[2], *G. Abildinova*[1];
[1]*National Research Center Maternal and Child Health, Astana, Kazakhstan,* [2]*Center of perinatology № 1, Astana, Kazakhstan.*

Preeclampsia is one of the most frequent and complications of pregnancy. The risk of repeated development of a preeclampsia can be raised in case of a carried of some polymorphisms in genes of F2, F5, AGT, eNOS and MTHFR.
The present study might suggest roles for genes F2, F5, AGT, eNOS and MTHFR in the development of preeclampsia.
Polymorphic variants were analyzed of 142 pregnant women with preeclampsia using PCR followed by RFLP analysis.
Analysis of F2, F5, AGT, eNOS and MTHFR genes allelic variants of preeclampsia. Following genotypes have been identified: GG (3%), GA (97%) for F2 gene 20210G>A; GG (42%), GA (58%) for F5 gene 1691G>A; CC (3%), CT (76%), TT (21%) for eNOS gene 786C>T; CC (64%), CT (33%), TT (3%) for AGT gene 521C>T; CC (39%), CT (55%), TT (6%) for MTHFR gene 677C>T; AA (39%), AC (49%), CC (12%) for MTHFR gene 1298A>C.
Although the exact genes involved in development of preeclampsia are still not discovered, an important role for genes F2, F5, AGT, eNOS and MTHFR in its pathogenesis is accepted.

Genetic variation of 15 autosomal STR loci in Bulgarians

S. K. Karachanak-Yankova[1], *S. Hadjidekova*[1], *D. Nesheva*[1], *B. Rukova*[1], *O. Antonova*[1], *R. Staneva*[1], *Z. Hammoudeh*[1], *M. Kicheva*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical Faculty, Medical University, Sofia, Bulgaria, Sofia, Bulgaria,* [2]*Progene Ltd., Sofia, Bulgaria.*

Recently the understanding of the genetic variation of Bulgarians has improved in different aspects. Still, despite its forensic application and importance for inferring population structure and affinity, the autosomal STR variation in Bulgarians has not been studied. In order to fill this void we have analyzed 128 blood DNA samples from healthy, unrelated Bulgarians from across the country. They were genotyped for 15 autosomal STR loci (D8S1179, D21S11, D7S820, CSF1PO, D3S1358, TH01, D13S317, D16S539, D2S1338, D19S433, vWA, TPOX, D18S51, D5S818 and FGA). The amplification was performed using the AmpFlSTR Identifiler PCR Amplification Kit. DNA fragment analy-

sis was done on ABI 310 Genetic Analyzer and the results were processed with GeneMapperID software.
Among loci, the power of discrimination ranges from 0.835 for TPOX to 0.977 for D2S1338 and the polymorphism information content ranges from 0.65 for TPOX to 0.93 for D2S1338, which hints that D2S1338 is the most polymorphic and discriminating locus.
The combined power of exclusion for all the loci is estimated as 0,999999880570892 and the combined match probability as 5.73472982535149 x 10-18 (or 1 in 1.7 x 1017).
Our results indicate that the set of 15 STR loci we have analyzed is a useful and powerful tool not only for personal identification and parentage testing in Bulgarians but also for revealing different aspects of their genetic structure and relationships to other populations.

Common polymorphism in glutathione-S-transferase theta 1 gene and its association with dietary vitamin C in the Central-European population

*J. Vinklarek[1], **J. Novak**[1], J. A. Bienertova Vasku[1], Z. Splichal[1], F. Zlámal[1], P. Bienert[1], D. Ambrozkova[1], A. Jackowska[2], S. Havlenova[2], M. Forejt[2], I. Necesanek[1], S. Rybecka[1], R. Hezova[3], J. Dobrovolny[1], O. Slaby[3], A. Vasku[1];*
[1]Faculty of Medicine, Masaryk University, Department of Pathological Physiology, Brno, Czech Republic, [2]Faculty of Medicine, Masaryk University, Department of Preventive Medicine, Brno, Czech Republic, [3]Central European Technological Institute, Laboratory of Solid Tumours, Brno, Czech Republic.

Background: Glutathione S-transferases (GSTs) represent an important group of isoenzymes that play a pivotal role in the detoxification of carcinogens. It is also known that GSTs largely contribute to the glutathione-ascorbic acid (vitamin C) antioxidant cycle. It has been reported previously that the polymorphisms in GSTs influence the dietary intake of vitamin C. The aim of the study was to determine whether GST genotypes modify the dietary intake of vitamin C and general eating behaviour with respect to food items containing vitamin C in the Central-European population.
Material and Methods: Nonsmoking men and women [n = 764, 309 non-obese ones (78M/231F) and 455 obese ones (120M/355F)] between 16 and 80 y of age were participants in the study. The common polymorphisms in GSTM1 and GSTT1 and an Ile105Val substitution in GSTP1 were genotyped. A FFQ as well as 7-day food records were used to estimate dietary vitamin C intake and basic anthropometric parameters (% of body fat, etc.) were also measured.
Results: In the multivariate regression modelling across the whole cohort, neither GSTM1 nor GSTP1 polymorphisms expressed any prediction role for the native dietary structure (% of macronutrients) or dietary intake of vitamin C. In GSTT1 polymorphism, however, the wt allele was associated with significantly lower dietary intake of vitamin C (88.6±57.6 for males, 94.0±54.0 for females) than the del allele (109.0±85 for males, 100.4±61 for females, p = 0.04).
Discussion: In our cohort, we observed significant association of the GSTT1 polymorphism with native dietary intake of vitamin C.

Frequency of MYBPC3 gene mutations in hypertrophic cardiomyopathy patients from North-West of Iran

*L. Emrahi Govar[1], **M. Mohaddes Ardebili**[1], J. Gharesouran[1], M. Toufan Tabrizi[2];*
[1]Department of medical genetic, Faculty of medicine,Tabriz university of medical sciences, tabriz, Islamic Republic of Iran, [2]Cardiovascular research center,Tabriz university of medical sciences, tabriz, Islamic Republic of Iran.

Hypertrophic cardiomyopathy (HCM) is the most common genetic cardiovascular disease with a prevalence of 1 in 500 general populations. The disease is the major cause of sudden cardiac death in the young and morbidity in the elderly individuals. HCM is inherited as an autosomal dominant single gene disease, characterized by unexplained ventricular myocardial hypertrophy. Cmybc is a sarcomeric thick filament protein that interacts with titin, myosin and actin to regulate sarcomeric assembly. Mutations in MYBPC3 gene are one of the most frequent genetic causes of the HCM disease. The aim of the present study was to investigate the frequency and kind of MYBPC3 gene muations in the population of north-west of Iran. DNA was extracted from 42 HCM patients by salting out method after obtaining informed consent. All exons and exon-intron flanking regions of MYBPC3 gene were evaluated by PCR-SSCP assay. A cohort of 42 index patients with mean age onset of 38 including 25 familial, 10 sporadic and 8 inconclusive cases were examined. Twelve mutations (28%) were identified including three frameshift, 2-splice site, 1 nonsence and 6 missense mutations that four of them were novel. The onset mean age was 35 in patients carrying MYBPC3 mutations. In conclusion, screening of genetic variation in MYBPC3 is useful tool for management of HCM in North west of Iran population.

The association analysis of lipid metabolism gene polymorphisms with BMI, waist circumference and blood lipidogramm parameters in women

***I. V. Tarkovskaia**[1,2,3], O. S. Glotov[1,2,3], E. U. Ditkina[3], E. S. Vashukova[1,2], A. S. Glotov[1,2], I. V. Pugacheva[1,3], O. L. Belonog[3], I. V. Makhrova[3], M. V. Aseev[1], T. E. Ivashchenko[1,2], V. S. Baranov[1,2];*
[1]FSBI «The D.O.Ott Research Institute of Obstetrics and Gynecology» NWB RAMS, Saint-Petersburg, Russian Federation, [2]St-Petersburg State University, Saint-Petersburg, Russian Federation, [3]OOO «BioGlot», Saint-Petersburg, Russian Federation.

Using the PCR-RFLP method we have studied polymorphism of 36 genes involved in lipid metabolism in 212 women, residents of St. Petersburg, aged 18 to 77. We found an association of polymorphisms in several candidate genes with body mass index (BMI), waist circumference (WC) and total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C) and very low-density lipoprotein cholesterol (VLDL-C) levels. We proposed a logistic regression models for a primary assessment of these parameters in women based on corresponding genetic markers tests. We estimated the efficiency of these models on the basis of the adjusted determination coefficient (adjusted R2). The highest rates of adjusted R2 are received for the VLDL-C parameter (R2=0.101) with the smallest forecasting error (±0.21 mmol/litre) in comparison with an forecasting error of the BMI (±4.1 kg/m2), WC (±10.33 cm), TC (±0.95 mmol/litre) and the LDL-C levels (±0.83 mmol/litre). After the division of the group into premenopausal and postmenopausal women it emerged that adjusted R2 was higher in the group of postmenopausal women in comparison with the group of premenopausal women for all studied parameters: BMI (R2=0.44 and R2=0.043), WC (R2=0.38 and R2=0.098), TC (R2=0.32 and R2=0.143), LDL-C (R2=0.33 and R2=0.112), VLDL-C (R2=0.43 and R2=0.043), respectively. Our results apparently indicate higher genetic determinacy of the VLDL-C in comparison with other parameters, and also indicatethat after the menopause genes make more contribution to levels of studied parameters than environmental factors. Complimentarily, we performed Kendall's correlation analysis, which partially confirmed the association found with thelinear regression model.

Molecular characterization of deletional forms of beta-thalassemia in Antalya, Turkey

***I. Keser**[1], T. Bilgen[1], Y. Arikan[1], D. Canatan[2], A. Yesilipek[3], C. L. Harteveld[4];*
[1]Akdeniz University, Medical Faculty, Department of Medical Biology and Genetics, Antalya, Turkey, [2]AKHAV Thalassemia Center, Antalya, Turkey, Antalya, Turkey, [3]Akdeniz University, Medical Faculty, Department of Pediatric Hematology, Antalya, Turkey, [4]Leiden University Medical Center,Department of Clinical Genetics, Leiden, the Netherlands, Leiden, Netherlands.

Beta-thalassemia is the most common hemoglobinopathies with a high frequencies (13%) in Antalya. It is caused by the different types of mutations of beta-globin gene. In this study, we aimed to report the different types identified of deletional mutations and the methodological approaches to them in beta-thalassemia.
Beta-thalassemia carriers who were referred from Thalassemia Unit and AKHAV were screened by HPLC in 1171 postnatal cases in Molecular Genetic Laboratory, in this study. Following gDNA extraction, beta-globin gene was amplified by PCR, and mutations were screened by RDBH, DNA sequencing, MLPA and Gap-PCR.
Seven different types (Cod8 (-AA), Cod5 (-CT), Cod44 (-C), Cod 37/38/39 (-GACCCAG), FSC 22/23/24 (-AAGTTGG), FSC 74/75 (-C) and Turkish type inv/del) of deletional mutations were found in beta-globin gene in Antalya. Cod44 (-C) was the most common deletional mutation with frequency of

4.8%. One of the mutations is located at 5'-control region, three were on exon-1, remaining three were on the exon-2 of beta-globin gene. When the deletions of one, two and seven nucleotides were caused the HbA2 increasing, Turkish type inv/del that was detected by MLPA and Gap-PCR.increased the HbF level.
Our data showed seven different types of deletional mutations in beta-globin gene in Antalya population. No any deletional mutation on exon-3 may be an important data for the function of the gene. In conclusion, our results confirm that cases who could not be detected the mutations by classical molecular genetic tests should be screened by techniques such as MLPA and Gap-PCR for large deletions.

Association of MRAS and HNF1A gene polymorphisms and coronary artery diseases in the Tunisian population

R. Sghaier[1], *E. Chabchoub*[1], *A. Attig*[1], *H. Dridi*[1], *R. Ben Meftah*[1], *I. Boussaid*[1], *A. Boumiza*[1], *A. Achour*[1], *N. Mahfoudh*[2], *F. B. H. Slama*[1], *R. Zemni*[1];
[1]*Department of Immunogenetics, Faculty of Medicine, University of Sousse, Sousse, Tunisia,* [2]*Department of Genetics, University hospital Hedi Chekir, Sfax, Tunisia.*

Cardiovascular diseases are the leading causes of death in Tunisia and in the world. Coronary artery diseases (CADs) are complex disorders where environmental factors interact with particular genetic susceptibility background to trigger their pathogenic mechanisms.
To unravel some of the genetic aspects of these diseases, we studied the effect of MRAS and HNF1A genes on the occurrence of CADs in Tunisia since they encode proteins involved, respectively, in the cell transformation, proliferation and adhesion representing key-steps of atherosclerosis, and a transcription factor (HNF1A) in the regulation of the transcription of several genes encoding CRP, fibrin, angiotensin,...
We investigated the association of single nucleotide polymorphisms (SNPs) rs98188870 (MRAS gene) and rs2259816 (HNF1A gene) in Tunisian patients presenting a coronary artery disease compared to normal controls. Genotyping of all participating individuals was performed using mutagenically separated polymerase chain reaction.
Considering the dominant pattern of inheritance for SNP rs9818870 (MRAS gene), carriers of T allele (TT+TC) have significantly lower risk of myocardial infarction (MI) (OR= 0,59 ; 95% CI [0,36-0,95]) when compared to homozygous CC.
However, the polymorphism rs2259816 (HNF1A gene) was significantly associated with CADs, (p=0,019) since individuals carrying the A-allele are at a higher risk for CADs (OR = 1,51 ; 95% CI=[1,07-2,14]). Interestingly, the A-allele was significantly associated with a higher risk of developing CADs within non smokers.
In conclusion, in the Tunisian population the T-allele (SNP rs9818870, MRAS gene) seems to have a protective role against MI. However, A-allele (SNP rs2259816, HNF1A gene) is a risk factor for CADs.

Population carrier screening for Cystic Fibrosis: Puzzles to be solved

A. BALASSOPOULOU*, E. BOUTOU, E. E. DELAKI, T. TSANTZALI, G. KELLARIS, E. VOSKARIDOU;*
LAIKON HOSPITAL THALASSEMIA CENTER, ATHENS, Greece.

Cystic fibrosis (CF) is the second more frequent genetic disease in Greece following Thalaessemia. Carrier testing in general population is growing as an increasing number of obstetricians includes CF test in the antenatal test list.
Because of the great genetic heterogeneity the mutation detection rate ranges between 75% - 95% in different laboratories.
Carrier screening is offered to separate partners or couples planning a pregnancy, or during pregnancy. Some of them report family history, while the majority ask the test for prevention reasons only. DGGE and recently HRM analysis are used for the scanning of multiple exons and their corresponding intron boundaries of the CFTR gene. Eleven exons are scanned routinely covering about 85% of CFTR gene mutations identified in the Greek population. Carriers are offered genetic counselling and partner testing while couples at risk are offered prenatal diagnosis. The recorded results are from January 2005 to December 2012.
A total of 5500 individuals were screened and 207 carriers (3.8%) were identified. All carrier partners were screened, and subsequently 3 carrier couples were identified.
Twenty five mutations, seventeen polymorphisms and 5 novel alterations are recorded.
Intriquingly, scanning methods, in contrast to commercially available kits, may reveal novel non described gene alterations with unpredicted significance, rendering interpretation and genetic counseling rather complex. Additional questions emerge concerning the pathogenicity of alterations already referred to as mutations (F1052V, D1312G), due to their higher incidence in general population relatively to their corresponding frequency in CF chromosomes.

Population analysis of non-syndromic sensorineural deafness in Mexico: profiles of its genomic distribution.

F. Loeza-Becerra[1], *M. R. Rivera-Vega*[2], *L. M. Gonzalez-Huerta*[3], *H. Urueta-Cuellar*[3], *M. Martinez-Saucedo*[3], *P. Berruecos*[2], *S. Cuevas-Covarrubias*[2];
[1]*Secretaria de Salud, UMSNH, Mexico, D.F., Mexico,* [2]*Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico, D.F., Mexico,* [3]*Hospital General de Mexico, Mexico, D.F., Mexico.*

Mexico is a multiethnic and multicultural country. Deafness is the 2nd most common disability in some geographical regions and has predominated for more than a century. Mutations in GJB2 gene cause most cases of non-syndromic sensorineural hearing loss. In this study, 104 families were studied to determine the geographical distribution and type of causative mutations in four regions of the center-west of the country. Except for a northern region, the rest of regions were in Hardy-Weinberg equilibrium. Taking in account the Rh gene frequency and ABO, Fy and MN systems we found admixture of Amerindians (78% to 85%), Europeans (13% to 20%) and Africans (1% to 2%). Six mutations were found to be present (three transitions, two transversions and one deletion: c.250G> A, c.132G> A, c.79G> A, c.427C> T, c.91T> A and c.35DelG). The wild type frequency was 43%. Only one case showed alterations in GJB6 gene and other one showed no mutation.

GJB2 and GJB6 genes mutations associated with prelingual nonsyndromic hearing loss

C. Dragomir[1], *A. Stan*[1], *E. Severin*[2], *I. Visanoiu*[1], *L. Savu*[1];
[1]*Genetic Lab, Bucharest, Romania,* [2]*University of Medicine and Pharmacy, Bucharest, Romania.*

Introduction: The DFNB1 locus accounts for approximately 50% of congenital, severe-to-profound, autosomal recessive nonsyndromic hearing loss. Mutations in the GJB2 and GJB6 are associated with deafness at the DFNB1 locus. More than half of Caucasians with two identifiable GJB2 mutations are homozygous for the c.35delG point mutation. Approximately 2% of individuals with DFNB1 have one identifiable GJB2 mutation and one of two large deletions that include a portion of GJB6. In this respect, our aim was to use molecular testing of children at risk for confirmation of diagnosis and early intervention. Material and Methods: The study was carried out on 310 children with prelingual hearing loss. The 35delG GJB2 mutation was detected by ARMS-PCR using primers for normal and mutant alleles. We included beta-actin sequence detection as internal control. Analysis of del(GJB6-D13S1830) and del(GJB6-D13S1854) was performed by multiplex PCR. The GJB2 gene sequencing was carried out on 27 children. Results: 35delG mutation was detected in 36.12% of the 310 children tested. Homozygous status for 35delG mutation was found in 110 patients and 2 patients were heterozygous for this mutation. None of 310 children was found to have GJB6 mutations. GJB2 gene sequencing was performing for 27 children with negative results for the three mentioned mutations.The GJB2 gene sequencing revealed the recessive splice site IVS1+1G>A mutation in a homozygous status in two children.
Conclusions: Our results were in accordance with the main causes of congenital hearing loss allowing early detection and timely intervention at children with hearing impairment.

Analysis of GSTP1 and GSTA1 gene polymorphisms in Polish population using pyrosequencing.

O. Zakerska-Banaszak[1,2], *I. Sobieraj*[2], *A. Bartkowiak*[3], *A. Mikstacki*[4], *B. Tamowicz*[4], *M. Szalata*[2,3], *R. Slomski*[2,3], *M. Skrzypczak-Zielinska*[3];
[1]*The NanoBioMedical Centre, Adam Mickiewicz University, Poznan, Poland,* [2]*Department of Biochemistry and Biotechnology, University of Life Sciences, Poznan, Poland,* [3]*Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland,* [4]*Department of Anaesthesiology and Intensive Care Medicine, Poznan University of Medical Sciences, Poznan, Poland.*

Glutathione S-transferases (GSTs) are a family of enzymes that play an important role in detoxification of many hydrophobic and electrophilic compounds including drugs, xenobiotics and carcinogens by catalyzing the conjugation with reduced glutathione. *GSTA1* gene encodes a glutathione S-transferase belonging to the alpha class (α-GST), which is dominant in the liver. Product of the *GSTP1* gene is a pi class glutathione S-transferase (π-GST) also present in the liver. These proteins level measurements are used in multiple studies as a hepatotoxicity indicator of different anaesthetics, including sevoflurane. Both of genes selected for analysis are known to be highly polymorphic. Genetic variations can influence for the GST level and an individual's susceptibility of the toxicity and efficacy of drugs detoxicated in the liver, including sevoflurane.
As a first step the aim of our study was to determine the frequency distribution of nucleotide changes -52C/T (rs3957356), -69G/A (rs3957357) and -567A/C (rs4715332) in *GSTA1* promoter region and 313A/G (rs1695), 341C/T (rs1138272) in *GSTP1*, known to decrease the enzymes activity, in the Polish patients under sevoflurane anaesthesia. We analyzed DNA samples from 135 patients anaesthesized with sevoflurane using nested-PCR and pyrosequencing as a genotyping method. Allele frequencies estimated in our study for *GSTA1* gene were: 44,6% (-52T), 20,5% (-69A), 1,5% (-567C). Allele 313G and 341T in the *GSTP1* gene were identified with frequency 36% and 13% respectively. The obtained results in our study are similar to the determined in others European populations based on the literature data.

Marked differences of haplotype tagging SNP distribution, linkage, and haplotype profile of IL23 receptor gene in Roma population samples

L. Magyari[1,2], *D. Varszegi*[3], *P. Sarlos*[4], *L. Jaromi*[1,2], *J. Bene*[1], *B. Duga*[1], *K. Hadzsiev*[1], *P. Kisfali*[1,2], *K. Komlosi*[1], *E. Kovesdi*[1,2], *P. Matyas*[1], *A. Szabo*[1,2], *R. Szalai*[1,2], *B. Melegh*[1,2];
[1]*Department of Medical Genetics, University of Pecs, Pecs, Hungary,* [2]*Szentagothai Research Centre, Pecs, Hungary,* [3]*Department of Dermatology, Venereology and Oncodermatology, University of Pecs, Pecs, Hungary,* [4]*1st Department of Internal Medicine, University of Pecs, Pecs, Hungary.*

Polymorphisms of the interleukin-23 receptor (IL23R) gene have been found to play an important role in the development of several autoimmune diseases (ankylosing spondylitis, inflammatory bowel diseases, psoriasis, Sjögren syndrome, systemic lupus erythematosus). We examined five susceptible (rs10889677, rs1004819, rs2201841, rs11805303, rs11209032), one protective (rs7517847) and two neutral variants (rs7530511, rs1884444) of the IL23R gene in pooled DNA of healthy Roma (Gipsy) and Hungarian population samples. Our aim was to determine the genetic variability of the major haplotype tagging polymorphisms, and the haplotype profile of IL23R between the two groups. A total of 273 Roma cases and 253 Hungarian controls were genotyped using PCR/RFLP assay. Comparing the five susceptible conferring alleles, there were significant increase ($p < 0.05$), while in the protective alleles, there were decrease in the allele frequencies in Roma population ($p < 0.05$). One of the neutral alleles showed increase, the another one did not differ between the two groups. The haplotype analysis of the SNPs revealed fundamentally different association types of SNPs in the two groups; moreover, the frequencies of the various haplotypes also exhibited strong differences, as of ht4 and ht5 haplotypes were significantly higher, whereas the frequencies of ht2 and ht3 haplotypes were significantly lower in the Roma population than in Hungarians ($p< 0.05$). The data presented here show profound differences in the IL23R genetic profiles in the Roma population, that likely has also clinical implications in respect their possible role in the development of certain immunological diseases.

Analysis of mitochondrial mutations related to hearing loss in Brazilian patients using mass spectrometry

E. L. Sartorato, *R. M. Alves, P. M. Miranda, S. M. S. Costa;*
Universidade Estadual de Campinas, Campinas - São Paulo, Brazil.

Sensorineural hearing loss is the most common cause of sensory loss affecting at least 1 every 1000 births and presenting a diverse etiology. Among the genetic causes, mitochondrial mutations are present in about 1% of prelingual hearing loss in children, and reaching 5% in post-lingual hearing loss in the Caucasian population, thus being the second most common cause, behind only the 35delG mutation in the GJB2 gene. So far 61 mutations in mtDNA have been reported as possible causes of deafness, and the analysis of all these changes by conventional techniques such as PCR or sequencing generates a high cost and demand a very long time, so it is necessary new techniques for analyzing large amounts of data. The use of platform mass spectrometer - Sequenom, Inc. (San Diego, CA) using the technique MALDI-TOF MS (Matrix Assisted Laser Desoption Ionization-Time of Flight Mass Spectrometry) has important advantages for high-throughput analysis as the Multiplex PCR. Therefore, the objective of this study was to trace the 52 main mutations in mtDNA related with hearing loss through mass spectrometry. Our sample was consisted of 50 Brazilian patients with non-syndromic sensorineural hearing loss and 50 controls. The results have presented 11 patients with the A827G mutation, five patients with the A1555G mutation and 1 patient with G15927A and G8363A mutations. The Mass Spectrometer platform proved highly efficient for the analysis of 5200 changes simultaneously with a cost and time significantly shorter than traditional techniques.

J16.60

Study of F2, F5, MTHFR, MTR, MTRR genes in association with recurrent miscarriage

A. Nagimtayeva, *A. Borovikova, M. Bayanova, D. Zhanataeva, Z. Serikpaev, L. Saidildina, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

In order to determine the frequency of polymorphic alleles of genes F2, F5, MTHFR, MTR, MTRR in the development of miscarriage were studied the 132 women with recurrent abortions. Single nucleotide polymorphisms - C677T and 1298 A> C gene MTHFR, G1691A gene F5, G20210A gene F2, A2756G gene MTR, as well as 66 A> G MTRR gene were typed by PCR.
The frequency of homozygotes for the MTHFR C677T favorable variant - 44.1% (C / C), the frequency of heterozygotes - 55.9% (C / T). The frequency of homozygotes for the favorable variant of the gene MTHFR (1298 A> C) is 44.2% (A / A), homozygous for mutant variants - 2.9% (C / C), the frequency of heterozygotes - 52.9% (A / C).
F5 G1691A: frequency of homozygotes for the favorable variant is 58, 3% G / G), the frequency of heterozygotes - 42, 2% (G / A). Homozygous for the favorable gene variant F2 G20210A - 25% G / G, the frequency of heterozygotes was - 75% GA. MTR (A2756G): the frequency of homozygotes for the favorable variant - 13.8%, the frequency of heterozygotes was 86.2%. MTRR (66 A> G): the frequency of homozygotes for the favorable option was 13.50%, 81.1% was heterozygous, homozygotes for mutant variants amounted to - 5.4%.
In conclusion, polymorphic alleles of the gene (MTHFR 1298S, MTRR 66G) have a greater impact on the development of disease in comparison with others (MTHFR 677T, MTR 2756G) and their combination increases the risk of recurrent miscarriage.

Phenotypic features in Beta thalassemia mutations Heterozygotes from Brazil

C. R. Bonini-Domingos, G. C. S. Carrocini, ***I. F. Estevão****;*
UNESP, São José do Rio Preto-SP, Brazil.

Thalassemias occur in individuals of all ethnic backgrounds and are the most common genetic diseases worldwide. Heterozygotes for β-thalassemia are, in general, free of symptoms but have hypochromic microcytic red cells with low mean corpuscular hemoglobin (MCH) and mean corpuscular volume (MCV). In this work, 328 blood samples of β-thalassemia Heterozygotes were analyzed, by molecular procedures, to identify correlations between

hematological data and theβ-globin gene mutation. The results show the predominance (39.79%) of the CD39 mutation in the southeastern region and 78.78% of the IVS1-6 mutation in the northeastern region from Brazil. These results reflect the ethnical differences in each Brazilian region which originate mainly due to the admixture of the population. The IVS1-6 (T>C) heterozygotes, a mutation expressing a β^+ phenotype had higher MCV and MCH. A higher Hb A_2 was observed for the IVS1-1 (G>A) mutation and a higher Hb F for the CD39 mutation, both expressing β^0 phenotypes ($p<0.0001$). The data observed were different to published results of molecular thalassemia analyses in the Brazil. Hence it is very important to consider the formation of the population, the method of analysis used, the type of thalassemia, the influence of and the environment in relation to the phenotype evaluation. To establish β-Thalassemia preventive programs using the most up-to-date techniques it is important to identify the real prevalence of the mutants in each Brazilian region.

Phenotypic variability in a Hungarian family with a novel TSC1 mutation

E. Kovesdi[1,2], *K. Hadzsiev*[1,2], *K. Komlosi*[1,2], *I. Janicsek*[1,2], *J. Bene*[1,2], *L. Magyari*[1,2], *L. Jaromi*[1,2], *B. Duga*[1,2], *K. Sumegi*[1,2], *A. Szabo*[1,2], *Z. Banfai*[1,2], *B. Melegh*[1,2];
[1]*University of Pecs, Department of Medical Genetics, Pecs, Hungary,* [2]*Szentagothai Janos Research Center, Pecs, Hungary.*

Tuberous sclerosis is a multiorgan, autosomal dominant disorder, caused by mutations in the *TSC1* or *TSC2* genes. The encoded proteins-hamartin and tuberin- are involved in the control of cell migration, proliferation and differentiation. Mutation in either gene results in loss of control of cell growth and division, and therefore predispose to tumor formation. Clinical signs include non-malignant brain tumors, skin, eye, heart and kidney abnormalities. We investigated a Hungarian family, with epilepsy of various age onset, and MRI studies raising the possibility of tuberous sclerosis. While epilepsy in the grandmother started only at the age of 39 years, seizures in her younger daughter occurred at age 17; her eldest daughter is still asymptomatic at the age of 33 years. In the 5 year old boy the first seizure was seen at 15 months, his maternal uncle is treated with epilepsy since 8 month of age; the corresponding MRI alterations correspond with the severity of the symptoms seen in the male family members. Our department started molecular genetical analysis of *TSC1* and *TSC2* genes in 2012, the investigation of this family confirmed a previously non described, de novo heterozygous point mutation (c.2523 C>T) in exon 20 of *TSC1* gene leading to a premature stop codon. The mutation was detected in all examined family members even in the so far asymptomatic mother. Despite the increasing data on the pathomechanism of tuberous sclerosis, there is still little known about the genetic modifying factors influencing the broad intra-and interfamilial phenotypic variability.

Genetic polymorphisms at TNFα, TLR2, TLR4, TGFβ, CD14 and CCR2 genes in patients with lower limbs infections.

M. Zagozda[1,2], ***A. Sarnecka***[1,2], *P. Andziak*[2], *H. Galkowska*[1], *W. L. Olszewski*[3,2], *M. Durlik*[1,2];
[1]*Medical Research Center, Polish Academy of Sciences, Department of Surgical Research & Transplantology, Warsaw, Poland,* [2]*Central Clinical Hospital, Ministry of Internal Affairs, Warsaw, Poland,* [3]*Medical Research Center, Polish Academy of Sciences, Department of Human Epigenetics, Warsaw, Poland.*

Introduction: Chronic wounds are still growing challenge due to demographic changes and increased risk of artherosclerosis as well as diabetes. In innate response during bacterial infections toll like receptors, pro- and anti-inflammatory cytokines, chemokines as well as their receptors takes part. Few of them could have an essential role in the healing of pathological wounds like venous leg ulcer.
Aim of the study: The purpose of this study was to define genetic markers which could be responsible for predisposition to bacterial infections development in human lower limbs. Material and methods: The study population with serious infections (including sepsa) and with long-healing wounds consisted of 59 patients in each group and 25 patients with severe ulcers. A control group of 130 blood donors was ethnically matched to the study groups and randomly selected to comparing the study data.
The presence of polymorphic variants in six genes was investigated by PCR-RFLP method. Results: In group of serious infections we noted statistical importance of polymorphic genotypes in TNF-α
(-308G/A), TGF-β 29 codon (T/C),and TLR4 (1363C/T) genes. Group of long-healing wounds was characterized by additional importance of genotype TT in TLR2 gene (2029C/T). In the group with severe ulcers only polymorphisms of TGF-β and TLR4 genes, in described positions, were statistically significant. Conclusions: We cannot define single genetic marker responsible for occurrence of individual infection however it seems that TNF-α polymorphism is not crucial in severe ulcers and TLR2 polymorphic variant could predispose to long time of healing wound.

J16.64

Effect of estrogen receptor α PvuII and XbaI polymorphism on growth and bone mineral density in thalassemia major patients

R. Kumar[1,2], *K. Singh*[2], *S. Agarwal*[2];
[1]*Sri Aurobindo Institute of Medical Sciences, Indore, India,* [2]*Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: The etiology of bone disease in thalassemia is poorly understood. Numerous data indicate that polymorphism of estrogen receptor α (ERα) may predict lipid levels, lipid response to hormone replacement therapy (HRT), bone fracture risk, bone mineral density (BMD) and changes in BMD over time. In humans, estrogens influence many physiological processes, which include not only reproduction, cardiovascular health, bone integrity, but also cognition and behaviour.
Aim: In this study we aimed to evaluate distribution of ERα PvuII and XbaI genotypes and their effect on growth and bone mineral density in Thalassemia major patients of North India.
Material and Method: 150 β thalassemia major patients were assigned for the study. ERα PvuII and XbaI polymorphism was determined by PCR-restriction fragment length polymorphism (RFLP).
Result: PvuII genotype was distributed as follows: PP 24.5% , Pp 35.8% , pp 38.7% . Frequency of XbaI genotype was: XX 12.3% (n=13), Xx 34.9% (n=37), xx 51.9% (n=55). Four haplotypes with following frequencies were recognized: PX 17.3%, px 47.4%, Px 24.4% and pX 10.9%. We have observed significant association of PvuII digested estrogen polymorphism with low bone density at spine (P=0.010) and BMI (P=0.012) and in case of Xba I association was observed with height (P=0.001), weight (P=0.09) and BMI (P=0.007).
Conclusion: ERα gene polymorphism is probably one of the genetic factors contributing for low bone mass so it may be used as diagnostic or therapeutic marker.

Hearing impairment is one of the most common sensorineural disorders and the incidence of profound deafness is about one per 1000 at birth. The GJB2 gene mutations make the largest contribution to hereditary hearing impairment. A single nucleotide change IVS2-2A>G (NM_198999.1:c.-53-2A>G) in second intron of SLC26A5 gene has been reported in association with hearing loss. This study presents the data on the carrier frequencies of major SLC26A5 mutation c.-53-2A>G among 1310 healthy persons from 16 various populations of Eurasia: Bashkirs, Tatars, Chuvashes, Udmurts, Komi-Permyaks, and Mordvins, (Volga-Ural region of Russia), Russians, Belarusians, Ukrainians, Veps, and Karelians (East Europe), Abkhazians, Kazakhs, and Uzbeks (Central Asia), Yakuts, and Altaians (Siberia). Mutation c.-53-2A>G in heterozygous state was found in 24 subjects out of 1310 examined individuals: Belarusians (1), Ukrainians (2), Tatars (3), Chuvashes (1), Mordvins (4), Komi-Permyaks (6), Russians (3), Kazakhs (2), Abkhazians (1), Altaians (1) . Highest carrier frequency of c.-53-2A>G was revealed in Finno-Ugric populations of Mordvins (5.4%) and Komi-Permyaks (6.0%). Lower rates of this mutation were found in Slavic populations of Russians

(2.3%), Ukrainians (2.5%) and Belarusians (1.3%), and in Turkic populations of Tatars (2.5%), Chuvashes (2,6%), Kazakhs (2,5%), Altaians (1,3%) and this mutation was absent in Bashkirs, Yakuts, Uzbeks, Veps, and Karelians.
The data on the mutation c.-53-2A>G (SLC26A5) rates in studied ethnic groups can be used to investigate the prospective founder effect in origin and prevalence of this mutation in Eurasia and consequently in populations worldwide.This study was supported by RFBR grants (11-04-01221-a), (12-04-00342-a), (12-04-98520-p_vostok_a), (12-04-97004-p_povolje_a), (12-04-31230-mol_a).

Investigation of IL23R gene variants in Romanian ankylosing spondylitis patients

O. Popa[1], *E. Kriegova*[2], *L. Popa*[3], *M. Cherciu*[1], *M. Dutescu*[4], *M. Bojinca*[1], *V. Bojinca*[1], *P. Schneiderova*[2], *C. Bara*[1], *M. Petrek*[2];
[1]*University ‚Carol Davila', Faculty of Medicine, Bucharest, Romania,* [2]*Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic,* [3]*Molecular Biology Department, ‚Grigore Antipa' National Museum of Natural History, Bucharest, Romania,* [4]*National Institute of Blood Transfusion, Bucharest, Romania.*

Ankylosing spondylitis (AS) is a chronic rheumatic disease characterized by inflammation in the spine and sacroiliac joints. Interleukin 23 (IL23) is an important cytokine that acts through the signaling complex IL12Rb1-IL23R. Recent studies have reported the associations of IL23R gene single nucleotide polymorphisms (SNPs) with the risk of AS in Caucasian populations.
Objectives: The aim of this study was to investigate the association of IL23R gene SNPs with the risk of AS in Romanian population.
Methods: Nine SNPs mapping to IL23R gene (rs11805303, rs7530511, rs10489629, rs2201841, rs11465804, rs11209026=Arg381Gln, rs1343151, rs11209032, rs1495965) were genotyped in 168 consecutive AS patients and 161 healthy controls of Romanian ethnicity using the Sequenom MassARRAY platform (Sequenom, San Diego, CA) and/or TaqMan assays (Applied Biosystems, USA). Statistical analyses were performed with PLINK and Haploview softwares.
Results: We found no association between AS and individual SNPs in IL23R gene. The combined analysis of the studied SNPs revealed the association between AS and the 3-marker haplotype GCG rs11209026/rs1343151/rs11209032 (30% in patients versus 38% in controls, p=0.02, OR 0.69). The extended haplotype TTGCG rs2201841/rs11465804/rs11209026/rs1343151/rs11209032 was also significantly underrepresented in patients (24.5% versus 33.4% in controls, p=0.01, OR 0.65), thus conferring a lower risk for the disease. The prevented fraction associated with these haplotypes was 9.3% for GCG and 8.3% for TTGCG haplotype.
Conclusion: These findings confirm the contribution of IL23R gene variants to AS susceptibility in the Romanian population.
Grant support: CZ.1.05/2.1.00/01.0030, IGA_UP_ LF_2010_008 and 2013_009.

J16.67
Distribution of HIV resistance/susceptibility associated genetic markers in a healthy brazilian urban population sample

E. L. Silva, *S. F. Oliveira, M. N. K. Guimarães;*
Universidade de Brasília, Brasília, Brazil.

ABSTRACT: The Brazilian people have a peculiar history, considering the influence of Amerindian, European and African genetics. Population genetics is a powerfull instrument to better understand the formation of a people, even their susceptibility or resistance to diseases. The knowledge of human genetic variability and the analysis of the possible resistance to diseases, like the infection of human immunodeficiency virus (HIV), are as important as the study of the etiology or the biological cycles of the virus. OBJECTIVE: Evaluate genotypic distribution of a 32 base pairs deletion in the CCR5 gene, CCR5Δ32, and microsatellite markers TNFc, TNFd and TNFe, which are genetic markers associated with resistance/susceptibility to HIV, in a Brazilian healthy urban population sample. RESULTS: The frequency of the 32 base pairs deletion was 5.5%, the allele 2 of TNFc was found with a frequency of 9%, lower than previously reported in other populations in Brazil, Africa and Europe. TNFd and TNFe had the allele 3 as the most frequent and the haplotype formed by alleles TNFc *1, TNFd *3 and TNFe *3 was the most common. CONCLUSION: The frequency of the CCR5Δ32 has allowed the proposal of a gradient associated with the presence of European ancestry and corroborates the view that the population of Brasilia and also from this geographical region is a brief of the population. The description of the distribution of alleles for loci TNFc, TNFd and TNFe contributes to a better understanding of these markers, never studed before in Brasilia.

J16.68
Relation of the CD36 gene polymorphisms to the risk of nephropathy

i. samri[1], *l. bouguenouch*[1], *s. jaafour*[2], *f. moufid*[1], *t. sqalli houssaini*[2], *k. ouldim*[1];
[1]*Department of Genetics and Medical oncogenetics, Hassan II University Hospital, FEZ, Morocco,* [2]*Nephrology Department, Hassan II University Hospital, FEZ, Morocco.*

Introduction:
CD36, also called thrombospondin receptor and platelet glycoprotein IV (GPIV), is a membrane glycoprotein acting as a receptor for matrix proteins including collagen and thrombospondin. A role for CD36 in the pathogenesis of atherosclerosis, inflammation and lipid metabolism has been well-documented. However, little is known about the role of CD36 in renal diseases. Based on these data, we are currently studying the relationship between three polymorphisms of the CD36 gene and susceptibility to renal diseases in the Moroccan population.
Methods:
A population of 400 subjects from morocco are analyzed according to clinical parameters.Out of them 200 controls and 200 nephropathic patients are genotyped for three SNPs : rs1761667 (G > A), rs1527479 (A>G) using polymerase chain reaction and restriction fragment length polymorphism (PCR–RFLP) and (A>C) -178 by PCR and sequencing analysis. Statistical analysis is followed.
Results and discussion:
In patients population :
For rs1527479 (A>G), the A/G genotype was prevalent in 48.95%, the A/A was 33.33% and the G/G was 17.70%.
For rs1761667(G>A), the G/A haplotype was predominant with 45.83%, the A/A was 35.41% and the G/G was present in 18.75%.
We notice the predominace of the heterozygous and the homozygous haplotypes of this two SNP in patients population.
The sequencing of the third SNP and all controls are being studied actually.
Conclusion:
Once the study is completed, the intent of this review is to develop the concept that CD36 is a prototypic inflammatory receptor that contributes to the pathogenesis of various nephropathies.

Inherited thrombophilia and pregnancy complications in Georgian population

N. Pirtskhelani[1], *N. Kochiashvili*[1], *L. Makhaldiani*[2], *N. Pargalava*[3], *E. Gaprindashvili*[2], *K. Kartvelishvili*[1];
[1]*National Forensics Bureau/Forensic Biology (DNA) Department, Tbilisi, Georgia,* [2]*Institute of Hematology and Transfusiology, Tbilisi, Georgia,* [3]*Georgian Centre of Angiology and Vascular Surgery, Tbilisi, Georgia.*

Background: Inherited thrombophilia (Factor V Leiden (FVL G1691A), Prothrombin (PTH G20210A) and Methylenetetrahydrofolate reductase (MTHFR C677T) gene mutations, as a risk factors for pregnancy complications have gained much attention in the scientific community. Published results suggest that inherited thrombophilia plays a significant role in the development of gestational vascular complications and represents a cause of maternal and fetal morbidity and mortality.
Aim: The aim of study was to evaluate how inherited thrombophilia is associated with Gestational vascular complications in women of Georgian population.
Methods: 140 patients with gestational vascular complications and 50 healthy controls were genotyped by PCR.
Results: The presence of MTHFR homo/heterozygous forms was significantly higher in women with pregnancy complications (84.69%) than in controls (32%).
In patients homozygosity for FVL/PTH/MTHFR was found to be 0%, 0%,16.32% respectively and heterozygosity was found to be 8.16%, 4.08%, 68.37% respectively, while frequency of heterozygosity in healthy individu-

als has been reported as 0%, 0%, 32%.
Our results showed that triple heterozygous forms for FVL/PTH/MTHFR (2 cases) and double heterozygosity for FVL/MTHFR mutations (1 case) were founded in patients, while no mutations were founded in controls except heterozygous form of MTHFR.
Conclusion: The preliminary analysis indicate that investigated mutations, especially MTHFR have the significant role in increasing of risk of development of pregnancy complications in Georgian population and the future investigations in this area would be especially important.
The study has been funded by the grant FR/792/7-140/11 of Shota Rustaveli National Science Foundation of Georgia.

Association between IL28B and the response of treatment to HCV3 infection

L. M. Garrido[1,2], *L. C. Pereira*[1,2], *A. La Luna*[1,2], *A. C. S. S. Nastri*[1], *F. M. Malta*[1], *L. N. Cavalcante*[3], *A. L. D. Angelo*[3], *F. F. Souza*[4], *E. V. Martins Jr*[5], *R. L. Hayden*[5], *A. L. A. Ramos*[6], *J. Ramos*[6], *E. Rondinelli*[6], *C. A. Villela-Nogueira*[6], *A. L. C. Martinelli*[4], *A. C. Lyra*[3,7], *J. R. R. Pinho*[1,8], *H. Krieger*[1,2];
[1]*University of São Paulo, São Paulo, Brazil,* [2]*Instituto Nacional de Genética Médica Populacional, Porto Alegre, Brazil,* [3]*Federal University of Bahia, Salvador, Brazil,* [4]*University of São Paulo, Ribeirão Preto, Brazil,* [5]*Universdade Metropolitana de Santos, Santos, Brazil,* [6]*Federal University of Rio de Janeiro, Rio de Janeiro, Brazil,* [7]*Hospital São Rafael, Salvador, Brazil,* [8]*Albert Einstein Jewish Hospital, São Paulo, Brazil.*

Hepatitis C virus infection affects about 3% of world population, and about 80% of them will develop chronic active hepatitis that may evolve toward cirrhosis and hepatocellular carcinoma. Reports from several independent GWAS studies and other sources showed that some polymorphisms close to IL28B gene were strongly associated to therapeutic response to interferon based treatment, and also with spontaneous clearance of HCV. These studies indicated a strong correlation between genotypes of polymorphisms RS12979860 and RS8099917 and the outcome of the treatment with interferon in patients infected with genotypes 1 and 4 of HCV. This association was not clear with patients infected with HCV genotypes 2 or 3 due to discrepant results from different studies, although study performed with an Italian sample infected with these genotypes showed an association between polymorphism RS12979860 and therapeutic response of patients that do not achieve a rapid virologic response (no RVR). In Brazil, the genotype 3 is the second most prevalent HCV genotype with about 25-30% of reported cases. In order to verify the influence of the IL28B polymorphisms in this highly admixed population, a meta-analysis of 5 independent cohorts was conducted aiming to associate treatment outcome and the polymorphisms RS12979860 e RS8099917 genotypes. The results clearly indicated that both SNPs are associated with response, but the RS8099917 (effect $\chi 21=14.6$; heterogeneity $\chi 24=1.32$) showed a stronger association, indicating that it is a more reliable marker for HCV3 IFN therapy. Investigating the mode of KIV-2 CNV size changes at the LPA locus by SNP haplotyping of its flanking regions

A. Noureen[1], *G. Tulchiner*[1], *M. Khalifa*[2], *A. Zecha*[1], *H. Kraft*[3], *G. Utermann*[1], *K. Schmidt*[1];
[1]*Division of Human Genetics, Department of Medical Genetics, Molecular and Clinical Pharmacology, Innsbruck Medical University, Innsbruck, Austria,* [2]*Molecular Biology Lab, Zoology Department, Faculty of Science, Al-Azhar University, Cairo, Egypt,* [3]*Division of Experimental Cell Genetics, Department of Medical Genetics, Molecular and Clinical Pharmacology, Innsbruck Medical University, Innsbruck, Austria.*

The lipoprotein(a) (LPA) locus (MIM 152200) harbours a transcribed, multi-allelic copy number variation (CNV) formed by a 5.5 kb KringleIV-2 repeat (KIV-2 CNV; 1-46 copies). The actual mode of KIV-2 CNV size evolution, i.e. whether it mainly changes by mutations of +/- one KIV-2 repeat or by larger, arbitrary size changes, is unknown and currently debated.
Previously, we had identified two SNP rich regions directly flanking the KIV-2 CNV. SNP haplotyping in these regions was experimentally conducted in 20 individuals each from six world populations by segregation analysis and/or allele separation by pulsed field gel electrophoresis (PFGE) followed by re-sequencing. KIV-2 CNV size was assessed by PFGE /Southern blotting. Linkage between the SNP haplotypes and KIV-2 CNV allele size was investigated.
We observed significant linkage between the haplotypes in the two flanking regions in all populations studied, with SNP haplotypes spanning over a wide range of KIV-2 CNV sizes. These results indicate a high mutation rate for the KIV-2 CNV. Certain SNP haplotypes were restricted to CNV alleles of neighbouring sizes, indicating that the CNV does indeed mainly change by mutations of +/- one KIV-2 repeat or in small steps. However, incomplete linkage between SNP haplotypes points to crossing over events also resulting in multi-step CNV size changes.

J16.72
Incidence, trends and genetic assessment of neural tube defects

D. Stoicanescu[1], *M. Cevei*[2];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania.*

Neural tube defects represent severe congenital anomalies that result from failure of neural tube to close during early development. Given their unknown incidence in our region and complexity of the related problems, we performed an epidemiological study in newborns from Timisoara, Romania, between 2007 and 2011 and compared data with those obtained through a retrospective study, between 1989-1994. The main goals were to highlight the incidence, etiological aspects and the trend in occurrence of spina bifida and anencephaly. We found an overall incidence of 0.034‰ in 2007-2011, compared to the incidence of 1.58‰, calculated for the interval 1989-1994. In the last years there were 9 cases with spina bifida and 1 with anencephaly, compared to 51 with spina bifida and 9 with anencephaly. Studying sex ratio, the following results were obtained: females prevailed among cases with spina bifida, but the only case with anencephaly from 2007 was a male and males also prevailed in our previous study, sex ratio 2/1. 60% of the cases from the 2007-2011 study reported previous spontaneous abortions, compared to 23.33%, discussible percentages not only from the statistical point of view, but also knowing the fear of speaking about abortions, even spontaneous, in 1989 and the early 90s. Two couples had two affected children, both with spina bifida. In some cases associated anomalies were found, such as hydrocephaly or limb defects. The incidence reduction is probably due to prenatal screening and diagnosis and genetic counseling, which were not performed in our country in the early 90s.

J16.73
Frequency of Polymorphism Plasminogen Activator Inhibitor-1 (PAI-1) in Tuzla region population (Bosnia and Herzegovina): preliminary results

R. Terzic[1], *M. Pođanin*[1], *A. Karic*[1], *Z. Jerkic*[2];
[1]*University of Tuzla, Tuzla, Bosnia and Herzegovina,* [2]*University Clinical Center of Tuzla, Tuzla, Bosnia and Herzegovina.*

The -675 4G/5G polymorphism discovered in the promoter region of the PAI-1 gene causes the increased interest of PAI-1 gene polymorphism as genetic risk factor for development of venous thromboembolism. The 4G/5G insertion/deletion polymorphism is related to increased concentration of PAI -1 in plasma which is common finding in patients with deep vein thrombosis (DVT).
The aim of this study was to analyze the role of polymorphism -675 4G/5G of PAI-1 gene and increased risk of venous thrombosis in population of Tuzla region (B&H).
Genotyping of 4G/5G polymorphisms was done with polymerase chain reaction followed by simultaneous restriction of digestion with Bsl I. Compared were the frequencies of genotype of this polymorphism between 100 individuals with personal history of DVT and a control group of 100 healthy subjects without known risk factors for DVT.
The frequency of the 4G allele was 46, 99% in the group of patients with DVT and 38, 71% in the control healthy subjects, OR confidence interval [95%CI]) =1,403 (0,918-21, 45); P=0,117. Leading to the P=0,117 it did not seem to significantly influence the risk of DVT.
This study did not confirm the association the -675 4G/5G polymorphism of PAI-1 gene with DVT in Tuzla region population but it may be risk factor in combination with common genetics polymorphism associated with VTE.

Information regarding geographic structure and multiethnic distribution of clinically relevant variants in genes coding for Phase I, Phase II drug metabolizing enzymes (DMEs) and drug targets that control DME activity levels is becoming increasingly useful for improving drug therapy and explaining inter-individual and inter-ethnic differences in drug response. We evaluated the frequency distribution of most common allelic variants in three broad gene categories: CYP450 (CYP2C9, CYP2C19, CYP3A5, CYP2D6), phase II DME (GST, SULT; UGT) and drug target (TYMS and MTHFR) in the R. Macedonia using a combination of PCR/RFLP, capillary electrophoresis and Real-time PCR allelic discrimination method. The allelic frequencies are presented in Table 1. All results were in accordance with the expected genotype distributions, calculated by the Hardy-Weinberg equilibrium (P>0.05).

Table . Population frequencies of analyzed genetic variants.

Gene Group	Gene/ genetic variant	Allele frequency	
Phase I (CYP450)	CYP2C9		
	*1	0.79	
	*2[rs1799853]	0.14	
	*3[rs1057910]	0.07

Genetic differentiations of populations of Russia on genes of hereditary disorders

R. A. Zinchenko, *N. V. Petrova, E. E. Timkovskaya, T. A. Vasilieva;*
Research Center for Medical Genetics, Moscow, Russian Federation.

The medical genetics consulting should take into account patterns of genetic diversity of populations on genes of hereditary disorders (HDs). The genetic territorial diversity and differentiation of the genes of monogenic hereditary diseases (HDS) in 13 populations of Russia (7 ethnic groups: Russians from 7 regions, Maries, Udmurts, Chuvashes, Bashkirs, Tatars, Adigeans) was identified. Genetic diversity of HDs in the investigated populations was revealed more that 500 HDs. Each population was characterized by specific spectrum and prevalence of HDs. Differences was found not only in the prevalence of diseases, but the frequencies of mutations. More that 3480 healthy donors from six ethnic groups - Maries, Udmurths, Chuvashs, Tatars, Bashkirs and Russians from 3 regions of Russia were analyzed for major mutation in three genes - CFTR (Cystic fibrosis), connexine 26 gene (Deafness) and LIPH (Hypotrichosis). At least 800 chromosomes from each ethnic group with the ethnographic division were analyzed: Maries (1010 chromosomes), Udmurts (892), Chuvashes (868), Tatars (1420), Bashkirs (808) and Russians (1970). Twelve CFTR mutations (CFTRdele2,3(21kb), F508del, Idel507, 1677delTA, 2184insA, 2143delT, 2183AA>G, 2184delA, 394delTT, 3821delT, L138ins; E92K), 35delG mutation in Cx26, ΔEx 4 mutation in LIPH gene were studied. Significant differentiation in mutations frequencies between different ethnic groups was discovered between Russians and Maries, Udmurts, Chuvashs, Bashkirs. The greatest similarity of the analyzed ethnic groups on CFTR mutations and 35delG mutation in Cx26 was found between Russians and Tatars. Volga-Ural ethnic groups and Russians were found to be distinct in the frequencies of ΔEx 4 mutation in LIPH gene.

PPARα and Apo proteins target genes polymorphism, lipid and glucose metabolism parameters in children, having risk factors of the development of coronary heart disease (CHD).

A. Vasina[1], *A. Nikitina*[2], *A. Voitovich*[2], *M. Didur*[1], *V. Larionova*[1];

[1]*St.Petersburg State Pavlov University, Saint-Petersburg, Russian Federation,* [2]*The Turner Scientific and Research institute of children orthopedics Saint-Petersburg, Saint-Petersburg, Russian Federation.*

Study population: The main group consisted of 95 children and adolescents, having risk factors of cardio-vascular pathology, such as: atherogenic dyslipidemia, obesity, hypertension. The control group consisted of 55 children and adolescents of comparable age without such risk factors.

Methods: In all children cholesterol, triglycerides, HDL, LDL, glucose, insulin and C-peptide were analyzed. Molecular-genetic analysis of polymorphisms of PPARα genes and L162V PPAR α target genes (G75-A Apo A1 and C+83T Apo A1, C1131T ApoA5 and S19W Apo A5, Sst I Apo C3) was performed.

Results: In the main group 10 children and adolescents, having risk factors of CHD, had 162V allele in the heterozygous state and 1 had 162V allele in the homozygous state. In the control group only 3 children had 162V allele in the heterozygous state.

In the main group the correlation analysis of lipid and glucose metabolism parameters depending on presence or absence of 162V allele of PPARα gene was performed. In the group of children, having 162V allele of PPAR α gene, correlations between triglycerides and C peptide (0.49) and between HDL and C-peptide levels (-0.48) were found. No differences in the distribution of alleles and genotypes of studied genes were found in the main group. Comparative analysis of distribution alleles and genotypes of the PPAR α target genes (ApoA1, ApoA5, ApoC3) in the carriers of 162V allele PPARα gene and LL genotype carriers was not performed due to the small sample.

Chromosome studies in 639 Tunisian couples with repeated spontaneous abortions

A. C. Hajlaoui[1,2], *A. I. M. I. S Dimassi*[1], *A. D. M. S. A saad*[1];

[1]*ISB Monastir, Sousse, Tunisia,* [2]*Departments of Cytogenetics and Reproductive Biology and Gynaecology and Obstetrics, Farhat Hached University Teaching Hospital, Sousse, Tunisia, Sousse, Tunisia.*

Recurrent pregnancy loss (RPL) is a devastating reproductive problem. The cause is not apparent and often requires intensive and expensive laboratory investigations, despite which there is still a limited understanding of recurrent miscarriage (RM).

A retrospective study was done in couples with 2 or more fetal loss from Mai 2005 to Mai 2011. Karyotypes were performed from peripheral blood lymphocyte culture, and cytogenetic analysis was performed by using R-banding.

Among the 639 couples studied, 27 anomalies were detected (4.22%). There was no apparent relation with number of abortions. However, women were more frequently affected then men with a prevalence of 65% and 35% respectively (p<0.05). The abnormalities were 19 translocations, 7 cases of mosaicism and an inversion of chromosome 12 in one case. In 15 cases were reciprocal and in 4 were robertsonian. Most mosaicism involved the maternal X chromosome aneuploidy. When a history of normal living children, repetitive abortions, malformative syndrome or mental retardation was found in the family of one of two parents, the risk of finding chromosomal

aberrations was significantly higher.
In conclusion, parental chromosome abnormalities represent an important etiology of (RM). But, face to unknown proportion of parents who appeared chromosomally normal, we hypothesize that cryptic subtelomere rearrangements can be implicated.

The gene pool of Argyn in the context of generic structure of Kazakhs according to data on SNP-Y-Chromosome markers.

M. Zhabagin[1,2], *Z. Sabitov*[3], *I. Tazhigulova*[4], *P. Tarlykov*[5], *Y. Yusupov*[6], *K. Dibirova*[7], *P. Nymadawa*[8], *E. Balanovska*[7], *I. Zakharov*[2], *O. Balanovsky*[2,7];
[1]*Center for Life Sciences, Nazarbayev University, Astana, Kazakhstan,* [2]*Vavilov Institute of General Genetics RAS, Moscow, Russian Federation,* [3]*Gumilyov Eurasian National University, Astana, Kazakhstan,* [4]*Forensic science centre of the Ministry of Justice of the Republic of Kazakhstan, Astana, Kazakhstan,* [5]*National Center for Biotechnology of the Republic of Kazakhstan, Astana, Kazakhstan,* [6]*Institute for Humanities Research of the Republic of Bashkortostan, Ufa, Russian Federation,* [7]*Research Centre of Medical Genetics RAMS, Moscow, Russian Federation,* [8]*Mongolian Academy of Sciences, Ulaanbaatar, Mongolia.*

Study of Y-chromosome polymorphism with consideration of the genealogical structure provides information about the history and the fine structure of gene pool, and it can help identify major patterns of variation in gene pool, determination of migration routes, and genetic boundary between the relatively homogeneous gene pools.
The study was performed on the Kazakh tribe of Argyn, which are included in the three "Juz" (ethno-territorial entities of Kazakh tribes) in the „Shezhire" system of Kazakhs. The Shezhire system characterizes the tribal structure of the Kazakh people, which was the ethno-social basis of social organization. It is therefore important to examine the association of Y-chromosome variability with the genealogical structure, and clarify the relationship between biological and social kinship.
We analyzed 40 SNP and 17 STR Y-chromosomal markers. In the study, besides the descendants of Argyn (sample size N = 287), 14 tribes of Kazakhs and 12 tribes Mongolians (in all N = 2186) were analyzed. In the tribe of Argyn, twenty haplogroups were identified, among which there were one major haplogroups - G1a - P20 (71%) and three minor haplogroups R1a* - M198(xM458) (6%), C3c - M48 (5%) and C3* - M217(xM48) (3%). Other haplogroups represent less than three percent.
We calculated the genetic distances and plot multidimensional scaling, comparing the gene pools of the studied genus with other tribes of the Eurasian steppe from the frequencies of haplogroups. Tribe Argyn took on graph an isolated position, demonstrating the absence of genetic links with other Kazakh tribes.

Molecular spectrum of β-globin mutations and their linkage to β-globin gene haplotypes in North-Western Iran

S. Mansoori Derakhshan[1], *A. khorrami*[2], *A. Hosseinpour Feizi*[1], *P. Derogar*[2], *M. Niusha*[2], *M. Shekari Khaniani*[1];
[1]*Tabriz University of medical Sciences, Tabriz, Islamic Republic of Iran,* [2]*Ebne Sina Medical Genetics Lab, Tabriz, Islamic Republic of Iran.*

In β-thalassmia, a variety of mutations (>400) have been identified influencing gene transcription, translation or mRNA processing. Number of studies demonstrated a nonrandom linkage of particular RFLP haplotypes with specific β-thalassemia mutations. β-globin cluster haplotypes are a valuable tool for indirect mutation detection.
In this study, we characterised the β-thalassmia mutation spectrum using ARMS-PCR and DNA sequencing for common and non frequent mutations in Iranian Azeri subjects respectively. In addition β-globin cluster haplotypes were determined by PCR-RFLP for 35 βthal and 101 βA chromosomes.
We detected 20 different mutations in the 105 chromosomes. IVSII-1(G>A) (30.47%), was the most frequent mutation followed by IVSI-110 (G>A) (16.19%), and CD8 (-AA), CD8/9(G) both (7.6%).
We determined the haplotypes belonging to 35 βthal and 101 βA chromosomes. Haplotype I was found to be the most common haplotype in both normal (25.74%) and mutant (20%) chromosomes, as is the case in the Mediterranean region. The subsequent common haplotype associated with mutant chromosomes was haplotype IV in 5 (17.14%) and IX, V in 11(10.89%) normal chromosomes. It is found that the highest observed heterozygosity was related to HindIII Gγ, Hind II 5'ψß of all polymorphic sites with a value of 48% whereas the highest expected heterozygosity was for HindIII Gγ, HindII ε with a value of 50%. These two markers (HindIII Gγ, HindII ε) have the highest PIC, 0.37. In this study for 20 out of 26 couples at-risk of having a child with major β-thalassmia, prenatal detection of β-thalassemia mutations accomplished successfully by ß-cluster haplotyping.

The association of AGTR2 gene polymorphism with athlete status and body composition

L. J. Mustafina[1,2], *M. M. Mustafina*[2], *G. N. Khafizova*[1], *R. R. Almetova*[1], *R. R. Mudarisova*[1], *E. S. Nasibulina*[2], *N. V. Rilova*[1], *I. I. Ahmetov*[1,2];
[1]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation,* [2]*Kazan State Medical University, Kazan, Russian Federation.*

The angiotensin II type 2 receptor (encoded by AGTR2 gene in the X chromosome) by mediating the effect of the angiotensin II play an important role in the development of muscle fibers (Johnston et al. 2011). The CC genotype of the C3123A (rs11091046) polymorphism of the AGTR2 gene located within the 3-untranslated region of exon 3 have been reported to be associated with increased proportion of slow-twitch (fatigue resistant) muscle fibers (Ahmetov et al. 2006). The aim of present study was to investigate the association between the C3123A polymorphism of the AGTR2 gene, athlete status and body composition in Russians. Two hundred and five Russian athletes (51 females and 154 males) from different sporting disciplines were involved in the study. AGTR2 genotype and allele frequencies were compared to 159 controls (85 females and 74 males). Body composition parameters were assessed by bioelectrical impedance analyzer Tanita MC 980 (Japan) in 79 athletes (16 females and 63 males). We found that the frequency of the AGTR2 C allele was significantly higher in endurance-oriented male athletes compared to controls (62.3 vs 43.2%; P=0.0001). Similarly, the frequency of the AGTR2 C allele was significantly higher in female cross-country skiers compared to female controls (83.3 vs 50.6%; P = 0.036). Furthermore, CC genotype was associated with higher relative muscle mass in female athletes (P=0.0268). In conclusion, we have shown that the C3123A polymorphism of the AGTR2 gene is associated with endurance athlete status and body composition in Russians.

Polygenic profile of Russian power athletes

I. I. Ahmetov[1], *A. M. Druzhevskaya*[2], *A. M. Hakimullina*[2], *I. V. Astratenkova*[2], *O. N. Fedotovskaya*[2], *A. A. Arkhipova*[3], *E. S. Nasibulina*[3], *L. J. Mustafina*[1], *R. T. Gabbasov*[3], *N. D. Golberg*[2], *S. H. Day*[4], *A. G. Williams*[4];
[1]*Volga Region State Academy of Physical Culture, Sport and tourism, Kazan, Russian Federation,* [2]*St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation,* [3]*Kazan State Medical University, Kazan, Russian Federation,* [4]*Manchester Metropolitan University, Crewe, United Kingdom.*

Power performance is a complex phenotype, subject to the influence of both environmental and genetic factors. The aim of the present study was to investigate the associations of multiple common gene polymorphisms (involved in anaerobic glycolysis, glucose, insulin and lipid metabolism, and regulation of muscle fiber type composition) with power athlete status. The study involved 1161 Russian athletes (272 endurance athletes, 462 athletes with mixed endurance/power activity, 427 power athletes) and 934 controls. ACE I/D, ACTN3 R577X, HIF1A P582S, PPARA intron 7 G/C and PPARG P12A gene polymorphisms were determined by PCR-RLFP. To assess the combined impact of all 5 gene polymorphisms, all athletes were classified according to the number of 'power' alleles they possessed. We also determined a „total genotype score" (TGS, from the accumulated combination of the 5 polymorphisms, with a maximum value of „100" for the theoretically optimal polygenic score) in athletes and controls. The proportion of subjects with a high (4-8) number of 'power' alleles was greater in elite power athletes compared to controls (50.0% vs. 34.1%, P=0.0049). Furthermore, the mean TGS was significantly higher in elite power athletes (35.9 (15.8) vs. 30.2 (12.8); P=0.0003) compared with controls, whereas it did not differ between endurance athletes and controls (P=0.906), nor between athletes

with mixed activity and controls (P=0.995). These data suggest that the likelihood of becoming an elite power athlete depends on the carriage of a high number of power-related alleles.

The monitoring of the congenital malformations and inheritable disorders in population of the Kazakhstan

R. Nazyrova, *L. Nazarova, A. Nagimtayeva, M. Bayanova, B. Kamaliyeva, A. Borovikova, D. Samatkyzy, A. Vibe, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

In order to monitor the frequency and the spectra of congenital malformations and inheritance disorders the computerized database was developed which consist of several blocs: the private data, the anamnesis, the objective status, and the results of examination. Diagnosis was detected in according to ICD (International Classification of Diseases).
The database contains information about 2005 cases of patients and the fetuses with congenital malformations and inheritance disorders with predominance of the congenital malformations according EUROCAT. The frequency of congenital malformations makes 49% of all cases. The most frequent cases represent the neural tube defects in 157 (18%), the multiple malformations in 132 (15%) cases, congenital malformations of urinary and genital in 122 (14%) cases, the congenital heart defects in 112 (14%) cases, the malformations of digestive system in 103 (12%) cases.
The chromosomal abnormalities were detected in 428 (26%) cases. The diagnosis of chromosomal abnormalities was confirmed by cytogenetic and molecular cytogenetic methods. The genetic registrar contains information about 250 fetuses with chromosomal abnormalities revealed by prenatal invasive diagnostics. The aneuploidy and the structural chromosomal abnormalities were diagnosed by cytogenetic research.
The monogenic pathology was discovered in 452 (26%) cases. The molecular genetic tests (RFLP, MLPA, mass spectrometry and fluorimetry) were applied for diagnostics. The autosomal dominant diseases were detected in 35% cases, the recessive diseases in 50% cases, X liked diseases in 15% cases.

Peculiarities of *HLA-G* polymorphism in St. Petersburg population (North-West of Russia)

A. P. Alenichev[1], *Y. A. Nasykhova*[2], *T. E. Ivaschenko*[2], *V. S. Baranov*[1];
[1]*St. Petersburg State University, St. Petersburg, Russian Federation,* [2]*Institute of Obstetrics & Gynecology, St. Petersburg, Russian Federation.*

HLA-G is a key gene involved in the maintaining of the maternal-fetal tolerance during pregnancy. Less-polymorphic than the majority of *HLA* genes, *HLA-G* being expressed by extracellular trophoblast is involved in silencing of the maternal immune response, thus some *HLA-G* alleles could negatively effect on the fetal development. In our study 116 healthy individuals were genotyped for *14bp ins/del* in exon 8, *-725G>C* and for 6 other most frequent alleles G**0101-G*0106*. Frequencies of 14b.p. *del* and *ins* alleles were 59% and 41% respectively. Hardy-Weinberg distribution was not affected (χ^2=0,22; p>0,05). Genotype *-725G/G* was not found, rates of *-725C* and *-725G* alleles were 87% and 13% respectively, thus observed frequencies deviate significantly from those expected according to the Hardy-Weinberg ratio (χ^2=15,82; p=0,0001). Absence of this genotype could be explained by evolutionary pressure due to allele *-725G is* associated with increasing miscarriage rates. Frequency of Alleles *G*0101, G*0102, G*0103, G0104 and G*0105* were 89%, 1%, 2%, 6.5% and 2 % respectively. *G*0106* allele was not detected. Our data are significantly different from studies in other populations (p= 0.005, p= 0.001), it might be treated as a specific trait of St. Petersburg population.

J16.84

FGB and FV genes polymorphism and their association with longevity

V. V. Erdman, *T. R. Nasibullin, I. A. Tuktarova, D. D. Karimov, O. E. Mustafina;*
Institute of Biochemistry and Genetics, Ufa, Russian Federation.

Changes of hemostasis parameters are traced with age. Genetic background, which determinant protection of organism in conditions of hypercoagulability, may be predisposed to increase of lifespan and promote human longevity. Our objective was to estimate alleles and genotypes frequencies dynamic of FGB (rs1800790) and FV (rs2269648) genes with age. Gene polymorphism was analyzed by PCR-RFLP. There was composed group of 1520 unrelated individuals, from 1 to 109 years, ethnic Tatars (Russia). For comparison of age groups was used Fisher's two-tailed exact test (P<0.05 was considered significant). In aged and senile groups, in compare with middle-age I group, FGB*A/*G genotype frequency was higher and FGB*G/*G genotype frequency was lower. Frequencies of FGB*G/*G genotype and FGB*G allele differed between senile individuals, in one hand, and middle-age II persons, on the other. Among senile and long-lived male FGB*A/*G genotype frequency was higher, than in middle-age I group; FGB*G/*G genotype frequency was lower in group of long-livers than in middle-age I individuals. Using logistic regression analysis (SPSS18.0) there was established that FV*C/*C genotype frequency was an increase in age from 45 until 81 years (p=0.037, OR=1.015) in total group and also in age from 55 until 82 years (p=0.045, OR=1.027) among female. As well, within male in age from 25 years FGB*A/*G genotype frequency was rise (p=0.008, OR=1.011), FGB*G/*G genotype frequency was reduce (p=0.009, OR=0.990). Thus, received results suggests that rs2269648 polymorphism of FV gene, probably, is associated with achievement of senile age and rs1800790 polymorphism of FGB gene- with attainment of longevity status.

Molecular heterogeneity of familial hypercholesterolemia in Russia

M. Y. Mandelshtam[1,2], *A. B. Maslennikov*[3,4];
[1]*Institute for Experimental Medicine, St.Petersburg, Russian Federation,* [2]*St.Petersburg State University, St.Petersburg, Russian Federation,* [3]*State Novosibirsk Regional Clinical Diagnostic Center, Novosibirsk, Russian Federation,* [4]*Scientific research institute of molecular biology and biophysics of the Siberian branch of the Russian Academy of Medical Science, Novosibirsk, Russian Federation.*

Background: Familial hypercholesterolemia is a common monogenic disorder usually caused by mutations in the low density lipoprotein (LDL) receptor gene and leading to premature atherosclerosis development.
Aim of the study: To evaluate variability of the LDL receptor gene mutation spectra in different regions of Russia.
Results:

Region	Number of FH-causing mutations/Mutations common with St.Petersburg	Number of mutations specific for Russian subregion/Mutations common with other countries of the world
St.Petersburg	33/33	18/15
Moscow	17/2	14/3
Novosibirsk	21/5	10/11
Petrozavodsk	13/2	7/6

Conclusion: High variability of mutation spectra in different regions of Russia argues against strong founder effect in Russian population. Mutation carriers have high level of blood cholesterol and increased risk of coronary heart disease.

Association of single nucleotide polymorphism in *ERCC6* gene with indivuduals including dental materials

E. ARSLAN[1,2], *B. Ozkubat*[1,2], *A. Unverdi Eldeniz*[1,3];
[1]*Selçuk University, Konya, Turkey,* [2]*Department of Biology, Faculty of Science, Selcuk University, 42031, Konya, Turkey,* [3]*Department of Endodontics, Faculty of Dentistry, Selcuk University, 42031, Konya, Turkey.*

The aim of this study was to investigate the role of excision repair cross-complementing group 6 (*ERCC6)* gene polymorphisms, which has very rare been reported to be associated with indivuduals including dental materials. A variety of materials are used for filling and the bonding of restoration materials to the tooth cavity. Particularly, amalgam is known for its toxicity potential as it releases mercury and shown to be genotoxic as well. The defects in the DNA repair gene *ERCC6* is thought to play a role in the development of malignancy in humans. The association of *ERCC6* codon 399 polymorphism were compared between the individuals having at least one or more amal-

gam fillings together with composite fillings or crowns with control group; individuals who does not contain any dental material in the oral cavity with RFLP-PCR method. We found that frequency of the *ERCC6* codon 399 genotypes (G/A, A/A) is rates 20% in control groups and 45% in indivuduals including dental materials. Our results showed that the heterozygous and homozygous A allele of the *ERCC6* codon 399 may be associated with dental materials and a useful marker for primary prevention in oral cancer.

Genetic risk factors of bronchial asthma in the Buryat population, Russia

B. T. Batozhargalova[1], *N. V. Petrova*[2], *E. E. Timkovskaya*[2], *T. A. Vasilyeva*[2], *R. A. Zinchenko*[2], *Y. L. Mizernitskiy*[1];
[1]*Research Institute of Pediatrics and Children's Surgery, The Ministry of healthcare and social deve, Moscow, Russian Federation,* [2]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Asthma is one of the most frequent chronic disease due to the interactions between many genetic and environmental factors. Several candidate genes have been implicated in the development of asthma. The prevalence of polymorphisms in these genes can vary considerably by ethnicity, so the importance of specific polymorphisms may be very different in different ethnic groups. We assessed whether polymorphisms in *FCER2*, *ADRB2*, *NOS2*, *NOS3*, *GSTM1*, *TNFA* and *GSDMB* genes are associated with asthma in Agin Buryat schoolchildren. Agin Buryat is an ethnogeographic group of Buryats inhabiting the Agin Buryat Autonomous Region of Zabaykalsky Kray, Russia. 68 schollchildren with asthma and 100 healthy control individuals were included in the survey. The significant association of rs7216389 polymorphism in *GSDMB* gene and VNTR polymorphism in exon 4 of *NOS3* gene with development of bronchial asthma is confirmed in children group of the Buryat population. The frequency of allele T of rs7216389 *GSDMB* polymorphism was significantly higher in patients than in control group (0.788 vs 0.580; p=0.00011). Odd rates were 2.66 [CI95% 1.59- 4.39] for rs7216389 T allele. The homozygous rs7216389 T/T genotype may be a risk factor for BA (OR=6.55 [CI95% 3.30-12.99]; $p=3\times10^{-8}$). The frequency of allele 4 in VNTR polymorphism of *NOS3* gene in Buryat patients with BA was 0,103, in healthy control - 0.045 (p=0.04), OR=2.44 [CI95% 1.02-5.80]. The risk of BA was significantly higher in persons carried allele 4 of *NOS3* gene (genotypes 4/4 and 4/5) than in homozygotes for allele 5 (OR=2.72 [CI95% 1.06-6.97]; p=0.030).

Correlation between cardiovascular gene polymorphisms and functional capacities of the students

A. S. Glotov[1,2], *M. M. Danilova*[1], *V. S. Pakin*[1,2], *O. S. Glotov*[1,2], *E. S. Vashukova*[1,2], *R. V. Kurilov*[1], *I. V. Tarkovskaya*[1], *T. I. Baranova*[1], *A. D. Minigalin*[1], *S. S. Namozova*[1], *L. V. Shadrin*[1], *Y. P. Milyutina*[3], *V. S. Baranov*[1,2];
[1]*Saint-Petersburg State University, St.-Petersburg, Russian Federation,* [2]*The D.O.Ott Research Institute of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation,* [3]*The D.O.Ott Research Institute of Obstetrics and Gynecology, St.-Petersburg, Russian Federation.*

Associations of genes polymorphisms with different parameters of cardiovascular system are well-known. The goal of the study was to disclose feasible correlation between genetic factors participating in regulation of metabolic processes with relevant indicators of cardiovascular system state in students.
The polymorphisms of *NOS3* (5/4), *AGT* (Met235Thr), *ACE* (I/D), *AGTR1* (1166A>C), *AGTR2* (3123C>A), *BDKRB2* (-58T>C), *REN* (-83G>A), *F5* (1691G>A), *PAI1* (5G>4G), *ITGB3* (1565 T>C), *F2* (20210G>A), *F1* (455G>A), *MTHFR* (677C>T), *ADRB2* (48A>G,
81C>G), *PPARA* (2528G>C), *PPARD* (294T>C), *PPARG (*Pro12Ala), *UCP2* (Ala55Val), *UCP3* (-55C>T), *PPP3R1* (5I/5D) were studied in students (N=170). Gene's polymorphisms were determined by PCR-RFLP and PCR-biochip methods. Assessment of the cardiovascular system state included: the concentration of fibrinogen and homocysteine in serum, blood pressure, volume of blood, stroke volume of blood and others. Correlation between genotypes and parameters was determined by the Pearson correlation.
Strong positive relationship was proved between stroke volumes and minute blood volume and T/T genotype of *AGT* (r<0,63; p<0,01) or C/C of *ITGB3* (r<0,8; p<0,01). Correlation between body surface area index and T/T genotype of *AGT* (r=0,66; p<0,005), diastolic and average arterial pressures and G/G of *ADRB2* (r<0,51; p<0,05), average arterial pressure and 4G/4G of *PAI1* (r=0,75; p<0,05), total peripheral resistance and M/M of *AGT* and T/T of *GP3A* (r=0,69; p<0,005 and r=0,77; p<0,01) was assessed.
Our data confirm clear cut genotype contribution in functional capacity of cardiovascular system. Combined analysis of more representative cohorts of the samples is now in progress.
The work was supported by Saint-Petersburg State University grant (№1.38.79.2012).

Genetic aspects of essential hypertension

S. NASSSEREDDINE[1], *F. KORCHI*[2], *Y. KASSOG*[1], *R. HABBAL*[2], *S. NADIFI*[1];
[1]*Laboratory of Genetics and Molecular Pathology, Faculty of Medicine and Pahrmacie casablanca Morocco, casablanca, Morocco,* [2]*Department of Cardiology University Hospital Casablanca Morocco, casablanca, Morocco.*

Cardiovascular diseases are the leading cause of premature death in the worldwide adults. Overall prevalence of hypertension in Morocco is there about 33.6% being a real public health issue.
Causes of elevated peripheral resistance are certainly multiple and involve several types of factors: vascular endothelial factors involving sympathetic stimulation and the renin angiotensin aldosterone system (RAAS).
Several candidate genes that encode for proteins involved in the pathophysiology of hypertension have been studied, to highlight a link between polymorphisms of these genes and the level of blood pressure.
Our study focused on 132 patients enrolled in the department of Cardiology of the University Hospital of Casablanca Ibn Rushd. Our population was stratified according to cardiovascular risk (CVR) and in which we studied the genetic variability of two genes namely the MTHFR gene (C677T) involved in vascular factors and ACE gene (I / D) which is part of renin angiotensin aldosterone system.
According to the RRS, we found 35% of our population (sex combined) respectively having a medium risk and high risk, while 29.2% were low risk, by ethnicity, we found that whites have low risk with a percentage of 19.40%.
Concerning the genetic study, we found an allelic frequency (D) of the gene ACE about 67.74% and allele frequency (T) around 29.5% of the gene MTHFR and are related with a high cardiovascular risk.

The study of monogenic hereditary dermatosis in the Rostov region (Russia)

E. Degtereva[1], *N. Vetrova*[1], *S. Amelina*[1], *R. Zinchenko*[2];
[1]*Scientific Research Institute of Biology „Southern Federal University", Rostov-on-Don, Russian Federation,* [2]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

In the literature, more than 200 different genodermatosis or hereditary dermatosis (HD) were described. Genodermatosis can be divided into isolated (violation of only bodies of the skin) and syndromal (a combination of disorders of the skin to other organs and systems). At HD affected different systems of skin covers: skin, hair, nails, glands. The main group of HD up monogenic autosomal dominant disease (AD), less common autosomal recessive (AR) dermatosis, and a small part are of X-linked, dermatitis. Information on the prevalence of HD in different countries is few and hard to compare with each other because of differences in the approach to data acquisition. Hereditary dermatosis in the population 12 districts of the Rostov region was studies (surveyed 497460 people). A basic group was made by AD diseases: ichthyosis vulgaris (prevalence 1:6140 people), neurofibromatosis, type 1 (1:12133), keratosis palmoplantaris (1:19900), epidermolytic palmoplantar keratoderma (1: 124365), monilethrix (1:22611), multiple lipomatosis (1:33164), tuberous sclerosis (1:62182), epidermolysis bullosa simplex, Koebner type (1:124365), LEOPARD syndrome (1:62182), and met rarely alopecia, Von Hippel-Lindau syndrome, ectrodactyly with ectodermal dysplasia, and cleft lip/palate syndrome. The AR diseases were presented: congenital ichthyosiform erythroderma, epidermolysis bullosa dystrophica, Hallopeau-Siemens type, keratosis palmoplantaris with periodontopathia, albinism oculocutaneous, acrodermatitis enteropathica. The X-linked diseases were presented: X-linked ichthyosis and Christ-Siemens-Touraine syndrome. Total prevalence of HD was 5.97±0.35/10000 people (5.07-AD,

0.38-AR and 0.64-X-linked). We examined the patient with monilethrix by means of molecular genetic tests. We detect previously known mutation in 7 exon of the hHb6 gene.

Search of the prevalence of recurrent mutation R138Q NPHS2 gene in steroid-resistant nephrotic syndrome among Moroccan patients.

L. Boualla[1,2], *S. Chafai Elalaoui*[1], *N. Oulhiane*[3], *H. Ait Ouamar*[3], *A. SEFIANI*[1,2];
[1]*Institut National d'Hygiène, RABAT, Morocco,* [2]*le centre de génomique humaine, Faculté de médecine et de Pharmacie, Rabat, Austria,* [3]*Service Pédiatrie IV Hôpital d'Enfants C.H.U Ibn Sina, RABAT, Morocco.*

Familial idiopathic steroid-resistant nephrotic syndrome is characterized by a nephrotic syndrome with often early onset. Prevalence in the general population is unknown. The nephrotic syndrome is defined by severe proteinuria with low serum albumin and possible edemas.This disease is rare but severe as it usually progresses to end-stage renal failure. Steroid-resistant idiopathic nephrotic syndrome does not respond to cortico therapy or immunosuppressors and progresses to terminal renal insufficiency. Recurrence after transplantation is exceptional. Several causative mutations have recently been identified. Among these, mutations in the *NPHS2* gene (chromosome 1q25-q31 and encoding podocine) have been found to be involved in autosomal recessive forms of the disease. Mutations in the podocine gene have also been detected in later-onset forms and in apparently sporadic forms (10 to 30% of the cases depending on the series). The R138Q mutation has been reported as recurrent mutation in patients with steroid-resistant nephrotic syndrome, especiallly familial cases.

Objective: Search by targeted sequencing the recurrent mutation R138Q in the NPHS2 gene in Moroccan patients with steroid-resistant nephrotic syndrome.
Determine the prevalence of this mutation in Moroccan patients with steroid-resistant nephrotic syndrome with the aim to propose as a first-line diagnostic strategy in this disease.
Provide genetic counseling to families and allow early treatment of children, to improve the prognosis of this condition.

Materials and methods:

- Recruitment of patients with familial steroid-resistant nephrotic syndrome or sporadic cases with consanguinity,
- Search of the mutation R138Q NPHS2 gene by molecular biology techniques.

Analysis of eight polymorphic nuclear genome DNA loci in Tatar population

N. V. Petrova, *E. E. Timkovskaya, T. A. Vasilyeva, R. Zinchenko;*
Research Center for Medical Genetics, Moscow, Russian Federation.

Population genetic survey of the indigenious populations of the Tatarstan Republic (Russian Federarion) belonged to the three Tatar ethnographic groups: Kazan (Arskiy, Atninskiy districts) and Mishary (Buinskiy, Drojjanovskiy districts) and Teptyary (Muslimovskiy, Aktanishskiy districts), was carried out. DNA samples of 675 individuals were examined at eight polymorphic DNA loci of nuclear genome, diallelic: *CCR5 (del32)*, *ACE (del/ins)*, *DATI (del/ins)*, *NOS3 (VNTR)*, and polyallelic: *THOI (STR)*, *FABP2 (STR)*, *CFTR (IVS6aGATT)*, *PAH (VNTR)*. Allele and genotype frequency distributions, indexes of heterozygosity (H_s) and intrapopulation differences ($F_{ST)}$ were obtained for each subpopulation (district) as well as for the ethnic group overall. Analysis of allele's frequency of autosomal DNA markers in Tatar subpopulations shows considerable genetic differentiation between them. The highest level of genetic diversity in diallelic system was established at locus *ACE (del/ins)*, H_{obs}=0,4359, in multiallelic system - at locus *THOI (STR)*, H_{obs}=0,7950. The index of mean heterozygosity is 0,4665. The index of mean intrapopulation differentiation (F_{ST}) was 0,0260. The highest level of intrapopulation differentiation was revealed at locus *FABP2* (F_{ST}=0,1129), the lowest one - at locus *ACE* (F_{ST}=0,0039). The analysis of dendrograms, based on correlations between the matrix of genetic distances, and multidimentional scaling analysis prompted us to conclude that subpopulations of Kazan and Mishary Tatars are genetically closer to each other than subpopulation of Teptyary Tatars. Analysis of genetic distances between populations of the Volga-Ural region shows that the population of Tatars joins the cluster of Udmurts and Bashkirs, where as Mari and Chuvash populations form distinct cluster.

A genome -wide survey of copy number variations in population of Lithuania

Ž. Čiuladaitė, *J. Kasnauskienė, Š. Germanas, A. Jakaitienė, V. Kučinskas;*
Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

Background: Copy-number variation (CNV) is the most prevalent type of structural variation in the human genome, and contributes significantly to genetic heterogeneity. The extent of CNV and its frequency in different ethnic populations is still largely unknown. Population studies and reference databases for control and disease-associated samples are required to provide an information resource about CNVs frequencies and their relative contribution to phenotypic outcomes.**Objective**: The accessment of CNVs frequencies and distribution in population of Lithuania. **Methods:** A healthy cohort from population of Lithuanian (n=150) were genotyped using the *Agilent* 400K microarray.**Results:** We detected 1073 CNVRs encompassing 166 Mb and accounting for 5.1% of the human genome. The median size of CNVRs was 65 kb (range 20 - 5200 kb). Copy number losses were 1.4 times more frequent than copy number gains. 87% (969 out of 1073) of these CNVRs were common. In this study we found four common CNVRs that were not reported CNV in database of genomic variants (DGV). Interestingly, in Lithuania population 53% (72 out of 137) of rare CNVRs are well known from previously studies. 47% (65 out of 137) of rare CNVRs were novel and not present in the Database of Genomic Variants (DGV).**Conclusion:** In this study the spectrum and frequencies of identified CNVRs supplemented the knowledge of genome peculiarity of Lithuanian population and will be valuable resources for studying human genome diversity and its association with disease.

Genetic dissection of ascending aorta diameter: microsatellites and SNPs linkage analyses in an isolated population of Cilento.

R. SORICE, *D. Ruggiero, T. Nutile, S. Nappo, M. Aversano, M. Ciullo;*
Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Naples, Italy.

The ascending aorta is the most vulnerable segment of the aorta. In fact, this segment faces the entire cardiac output volume coming from the left ventricle, since it receives little support from surrounding tissue and no arteries branch from it. The weakening of the aortic wall and loss of elasticity could produce a dilatation and degenerate into a dissection and rupture, becoming a potentially life-threatening disease.
So far, the genetic contribution underlying the ascending aorta diameter (AAD) variability remains unknown. Through echocardiography, we evaluated the AAD in an isolated population from Cilento area in South Italy (N=1,435). The estimation of heritability was of 0.43. Sex, age, BMI and blood pressure were used as covariates. To identify the loci influencing the AAD variability we performed a genome-wide linkage analysis with a regression-based approach using 1122 microsatellites. A significant maximum LOD score of 5.96 was detected on chromosome 4q25. To confirm this results, a linkage analysis using a SNP map was performed. Applying the MASEL method, a subset of SNPs highly informative and with a minimum linkage disequilibrium was selected on chromosome 4. A maximum LOD score of 3.2 was detected in the same region identified with the microsatellites confirming the involvement of the 4q25 region in the ADD variability. Moreover, the SNP analysis allowed us to refine the linkage region from 7.9 to a 6.7 Mb. In this work, for the first time, we found a strong linkage signal on chromosome 4q25 linked to AAD in an isolated population of Cilento.

Assessment of detection of proviral DNA and RT (MET 184 VAL) gene resistance mutation in HIV-1 identified by polymerase chain reaction and restriction fragment digestion assay

R. Shrestha;
Sri Ramachandra Medical college and Research Institute, Chennai, India.

ABSTRACT

Proviral DNA and ART (Antiretroviral Therapy) resistance forms a corner stone of a short chemotherapy course for post-exposure prophylaxis. The aim of this study was to rapidly identify the proviral DNA and screen M184V

ART (Antiretroviral) resistance mutation in HIV-1 reverse transcriptase by using PCR-RFLP (Polymerase Chain Reaction- Restriction Fragment Length Polymorphism).The male patient's outnumbered female. Among 13 male subject 2(15.4%) were proviral DNA positive and 11(84.6%) were proviral negative. Among 2 female subject 1(50.0%) were proviral DNA positive and 1(50.0%) were proviral negative. RFDA (Restriction Fragment Digestion Assay) were performed using restriction enzymes CViAII allowing determination, on Agarose gel electrophoresis, of 184M wild-type (ATG) or 184V mutant (GTG) strains. All isolates were only digested by CViAII restriction enzyme and confirmed as wild type. No mutation was detected in the analyzed sample. In summary. Potent antiretroviral therapies suppress cell-free plasma viral RNA levels below the limit of current assay detection necessitate other complementary approaches for assessing viral burden, such as quantification of cell associated proviral DNA. Therefore, it is recommended to use this technique for the diagnosis of Drug Resistance Mutation in HIV-1 patients and the response of ART for their Better Health Care.

Keywords: HIV/AIDS, HAART, Drug resistance, mutation, env gene, RT gene, PCR, RFDA.

Screening for Fragile X syndrome in females: A molecular approach in a Brazilian Public Genetic Service routine

P. M. Fritsch, *J. F. Mazzeu, M. S. Cordoba, H. P. N. Safatle, R. Pratesi, B. Lima, C. Martins de Sá, Í. Ferrari;*
Universidade de Brasília, Brasília, Brazil.

ABSTRACT: Fragile X syndrome (FXS) is caused by the expansion of trinucleotide repeat citosin-guanin-guanin $(CGG)_n$ in the 5´untraslated region (UTR) in exon 1 on *FMR1* gene on X chromosome. OBJECTIVE: Implement a molecular screening methodology for SXF on females in a Brazilian Public Genetic Service in the aim to reduce the necessity to use Southern Bloting. METHODS: Sixty-three females tested by PCR-ssp, when resulted inconclusive were tested on PCR-*fam* by capillary electrophoresis. RESULT: It was possible to determinate a final result in 31.75% of females tested by PCR-ssp, 68.25% resulted inconclusive. On PCR-*fam*, 74.42% resulted in heterozygosis, 4.65% presenting gray-zones and 20,93% of all was homozygosis. CONCLUSION: The techniques show efficiently identification of homozygosis and heterozygosis females, reducing of 85,71% of the necessity to apply SB to give a final diagnostic on FXS in females.

The relationship between BRCA2 mutation risk and pedigree size

V. Stefansdottir[1,2], *O. T. Johannsson*[3], *C. Chapman*[4], *L. Tryggvadottir*[5,6], *H. Skirton*[7], *H. Tulinius*[8], *J. J. Jonsson*[9,2,8];
[1]*Landspitali – National University Hospital, Reykjavik, Iceland,* [2]*Department of Biochemistry and Molecular Biology, Faculty of Medicine, University of Iceland, Reykjavik, Iceland,* [3]*Dept. of Medical Oncology, Landspitali - National University Hospital, Reykjavik, Iceland,* [4]*West Midlands Regional Genetics Unit, Women Hospital NHS Trust, Birmingham, Birmingham, United Kingdom,* [5]*Icelandic Cancer Registry, Reykjavik, Iceland,* [6]*Faculty of Medicine, University of Iceland, Reykjavik, Iceland,* [7]*Faculty of Health, Education and Society, Plymouth Univ., Plymouth, United Kingdom,* [8]*The Genetical Committee of the University of Iceland, Reykjavik, Iceland,* [9]*Department of Genetics and Molecular Medicine, Landspitali – National University Hospital, Reykjavik, Iceland.*

Introduction. Genetic counselling for HBOC in Iceland uses a population-based electronic genealogy database and cancer registry, ClinicalPedigree and Boadicea risk assessment programs. All mutations in Iceland are rare except c.771_775del5c in the BRCA2 gene (prevalence 0.6%). This unique situation makes it possible to study the relationship between pedigree-size and accuracy of risk assessment.

Materials and methods. 340 individuals (136 probands) received cancer genetic counselling during 2009-2011 at Landspitali. Two electronic pedigrees were obtained for each counselee, one for each family side. After exclusions, calculations for the relevant side were carried out for 102 individuals. Included were 12 belonging to previously known BRCA2 families. From this group, 82 probands had BRCA2 mutation testing.

Results and Discussion. On average, the pedigrees sides included 260 individuals (range 21 to 1288). Of 82 tested, 20 had BRCA2 and 1 BRCA1 mutation. Nine were sent for full mutation screening with no new mutation found. Truncation of pedigrees to 3° relatives included 43.4 (8 to 139), 2° relatives 22.8 (5 to 63) and 1° relatives 8.7 (3 to 17). The average BRCA2 mutation likelihood score for BRCA2 positive individuals in Boadicea with 3° truncations was 0.2280 (range 0.0063 to 0.7426). Average score for non-tested individuals was 0.0165 (0.0010 to 0.0897). Average score for further analyses was 0.1759 (0.0131 to 0.3871). By using ≥10% as a cut off for increased risk, the sensitivity for BRCA2 mutation increased with pedigree size, i.e. for 1° truncation the sensitivity was 45%, for 2° truncation 55% and for 3° truncations 70%.

Microarray Comparative Genomic Hybridization analysis (array-CGH) as a diagnostic tool for the investigation of patients with autism or autistic spectrum disorders

V. Oikonomakis[1], *M. Tzetis*[1], *K. Kosma*[1], *A. Syrmou*[1], *K. Giannikou*[1,2], *H. Fryssira*[1], *E. Kanavakis*[1], *S. Kitsiou-Tzeli*[1];
[1]*Department of Medical Genetics, Medical School, University of Athens, Athens, Greece,* [2]*Alexander S. Onassis Public Benefit Foundation, Athens, Greece.*

Aim: Autism or autistic spectrum disorders (ASD) are a lifelong neurodevelopmental disorder and α few cases of chromosomal abnormalities are found by conventional cytogenetic techniques, while the microarray Comparative Genomic Hybridization analysis (array-CGH) allows the identification of submicroscopic genomic rearrangements. This study describes the application of array-CGH, as a diagnostic tool for the investigation of patients with autism or ASD.

Materials- Methods: During the last 4 years, 88/480 patients were studied with autism or ASD of unknown aetiology but with normal previous conventional karyotype and other genetic tests. High resolution 4X180K and 1x244K Agilent arrays were used in the study (>170.000 and > 236.000 probes respectively, average resolution of 8.9 Kb).

Results: Submicroscopic genomic rearrangements (CNVs), ranging in size from 0.08 to19.01 Mb were detected in 51/88 (58%), some of which also presented: seizures (8/51), hypotonia (1/51), obesity (2/51), mental retardation (9/51), hearing loss (1/51) and dysmorphic features (2 / 51). CNVs detected were in loci at high risk for autism: 2q37.2, 2p16.3, 5p15.32p14.3, 7p22.3, 10q26.3, 12q24.22q24.3, 15q11.2q11.3, 16p11.2, 18q22.3q23, 21q22.3, Xq21.31. Genes associated with autism or ASD which were identified included: NRXN1, SHANK3, DOCK8, ZNF92, ASMT, HSFX1, KCNH7, CHRFAM7A, CHRNA7, KCND2, CNTNAP3, MAOA, MAOB, STS, VCX.

Conclusions: In patients with autism or ASD and non-syndromic phenotype, array CGH analysis is mandatory to detect possible submicroscopic chromosomal abnormalities. For the family, positive results of array-CGH, provides comprehensive genetic counseling, which includes determining the patient's prognosis and planning antenatal diagnosis in subsequent pregnancies.

Genetic counseling for patients with intellectual disability in IRAN

S. Arzhangi[1], *N. Nikzat*[1], *M. Mohseni*[1], *H. Najmabadi*[2], *K. Kahrizi*[1];
[1]*Genetics Research Center, USWR, Tehran, Islamic Republic of Iran,* [2]*Genetics Research Center,USWR, Tehran, Islamic Republic of Iran.*

Intellectual disability (ID) is an unresolved health care problem worldwide and an enormous socio-economic burden. Our goal for genetic counseling was providing reliable data for the best decision in families which suffering ID.

Over last10 years total of 985 Iranian families with ID have been referred to Genetics Research Center of USWR. After obtaining informed consent form, completing clinical profile was performed. As a primary investigation, karyotyping, fragile X testing and metabolic screening have been performed.

From 985 families, a total of 859(87.2%) had autosomal recessive pattern of inheritance, 32(3.2%) with autosomal dominant, 94(9.5%) with X-linked recessive pattern. Two hundred forty (24.3%) out of 985 families were associated with microcephaly of whom 56 families MCPH genes have been detected. A total of 46(4.6%) families identified with fragile X syndrome. In 18(1.8%) cases different types of chromosomal abnormalities have been detected and 36(3.65%) families were positive for metabolic disorders. In 27(2.7%) families different known ID syndromes has been detected and 68(6.9%) families had mutations in recently identified genes responsible for hereditary ID.

Genetic counseling is helpful for families by providing information about recurrence risk, carrier detection and offering prenatal diagnosis for future

pregnancies. Therefore genetic counseling is a suitable method for reducing the prevalence of ID in each population.

Unusual splicing mutations in patients with neurofibromatosis type 1

M. Nemethova[1], *A. Bolcekova*[2], *D. Ilencikova*[2], *S. Pozgayova*[2], *L. Kadasi*[1,3], *A. Zatkova*[1];
[1]*Laboratory of Genetics, Institute of Molecular Physiology and Genetics, Bratislava, Slovakia,* [2]*2nd Department of Pediatrics, Comenius University Medical School University and Children´s Hospital, Bratislava, Slovakia,* [3]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.*

Neurofibromatosis type 1 (NF1) is an autosomal dominant disorder caused by inactivating mutations within the NF1 gene. Protein product of NF1, neurobibromin, is a negative regulator of Ras proto onkogen. In Slovak population we identified 85 NF1 gene mutations. 14 of them (16,5%) represent splicing defects, that were easily uncovered thanks to the sequencing of cDNA prepared from a total RNA extracted from the patients' cultivated lymphocytes. Consequently, by sequencing of affected exon on gDNA level individual nucleotide changes causing such incorrect splicing were described. In 9 cases (64,3%) these mutations involved consensus splicing regulatory sequences, in remaining 5 patients (35,7%) non-typical splicing pathogenic variants were uncovered. In one of them skipping of exon 29 or 29 and 30 was caused by short genomic deletion including part of intron 28 and exon 29 that eliminated acceptor splice site. In another case a single nucleotide substitution in intron 9 created new splice site, leading into insertion of last 17 nucleotides of intron 9 into transcript. Another 3 mutations were single nucleotide substitutions affecting exons 7, 10b and 24 that would normally be described as missense mutations, however, cDNA sequencing uncovered their splicing defects. Prediction program HSF (Human Splicing Finder) indicates in all of them activation of cryptic splice sites. Three of the unusual splicing mutations are novel, whereas two missense mutations causing skipping of exon 24 and partial deletion of exon 10b have already been described. Our work confirms the advantage of using RNA based method for NF1 gene mutation detection.

Molecular genetic analysis in Russian families with neurofibromatosis type 2

T. A. Vasilyeva[1], *L. A. Bessonova*[1], *V. N. Shimansky*[2], *N. V. Petrova*[1], *R. A. Zinchenko*[1];
[1]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*Burdenko Neurosurgery Institute, Moscow, Russian Federation.*

¬¬Neurofibromatosis type 2 (NF2) is an autosomal dominant disease (prevalence around 1 in 60,000), that is caused by inactivating mutations of the NF2 gene localized on chromosome 22q12.2. NF2 is characterized by the development of schwannomas (the most typical feature is bilateral vestibular schwannomas), meningiomas, spinal tumors, peripheral nerve tumors, ocular abnormalities. Previous studies have stated that half of NF2 patients have no family history and have de novo mutations in the NF2 gene, 25-33% of these new cases are mosaic with the mutation only detected in tumour and not in lymphocyte DNA. We describe NF2 gene molecular diagnosis in 15 individuals from 13 families from Russia with (7) or without (8) family history of NF2, mostly patients of Burdenko Neurosurgery Institute (Moscow) after surgery vestibular shwannoma removing. We have screened lymphocytes and tumor DNA samples for germ line and somatic mutations in NF2 gene. Mutation analysis was performed by direct sequencing using 17 primers pairs covering the coding sequences and their intron-exon junctions and MLPA (MRC Holland). Overall, we found 16 mutations in 15 patients (as in lymphocytes and in tumors): one large deletion (including exon 4), two duplications (one includs the regeon promotor-exon 4 and the other one is duplication of 11-17 exons) and 13 point mutations (4 of which have been described by other authors: R196X, R198X, R57X, Y153X). The remaining 9 point mutations are not announced in HGMD: S87X, Q121X, V219M, c.241-3C>T, Y266D, K278X, K284X, R335W, E378X. This is the first survey of NF2 in Russia.

The first Iranian patient affected with Oguchi disease

H. Aryan[1], *D. Farhud*[2], *M. Sanati*[3], *S. Sahahzadeh-Fazeli*[1], *T. Monshizadeh-Samiei*[1];
[1]*Fazeli-Sanati genetic laboratory, Tehran, Islamic Republic of Iran,* [2]*Tehran university, Tehran, Islamic Republic of Iran,* [3]*Fazeli-Sanati genetic laboratory, National institute for genetic engineering and biotechnology, Tehran, Islamic Republic of Iran.*

Oguchi disease is characterized by congenital static night blindness and diffuse yellow or gray coloration of the fundus. After 2 or 3 hours in total darkness, the normal color of the fundus returns.
Based on mutations in two genes, namely, the arrestin (also called S-antigen, *SAG*) and rhodopsin kinase (also called G-protein-dependent receptor kinase 1, *GRK1*), the disease is classified as type 1 or type 2, respectively.
A 38-year-old boy with bilateral eye pain and headache on reading and non-progressive blurring of distance and near vision, especially in the dark, was referred by a neurologist.
To identify the genetic cause of the disease in the patient, blood samples were collected by venipuncture in EDTA vacutainer tube from the patient and the available family members. The samples were stored at 4 °C till DNA isolation was performed. Oguchi disease candidate gene analysis was performed in the family by sequencing *both SAG and GRK1 gene.*
The PCR products were sequenced with the 3710 Applied Biosystems, ABI. Carrier screening of the identified mutation in the family was also performed with sequence analysis of exon 4 in all family members. Sequencing analysis showed a homozygote deletion C, in codon 96 (in exon 4). Parents of patients were heterozygote for mentioned deletion as well.
In conclusion, we have identified the first deletion mutation in the *SAG* gene in a patient with Oguchi type 1 disease in IRAN.

Ambiguous genitalia in newborns - clinical variability due to rare genetic causes

E. Kurvinen, *R. Zordania, K. Joost;*
Department of Genetics, United Laboratories,Tartu University Hospital, Tallinn, Estonia.

Disorders of sexual development (DSD) are among the most fascinating conditions encountered by clinicians. The ability to diagnose these disorders soon after birth is very important clinical issue with its different aspects relating to diagnosis, treatment and sex of rearing. The causes to DSD are frequently related to effects of sex hormones- congenital adrenal hyperplasia (21-hydroxylase deficiency) and androgen insensitivity syndrome are most widely recognised. Rare causes of DSD include other forms of congenital adrenal hyperplasia (CAH), chromosomal abnormalities including mosaic karyotypes and genetic syndromes where ambiguous genitalia is one of the presenting symptoms.
The aim of this study is to describe the rare genetic causes of DSD in the patients with ambiguous genitalia presenting in newborns.
Materials and methods. Patients referred to the genetic consultation due to ambiguous genitalia in the region of Northern Estonia are described.
Results. During 2007-2012 four babies were consulted as newborns due to ambiguous genitalia in neonatal period. Mosaic karyotypes were diagnosed in 2 patients: Down-Ullrich-Turner (DUT) syndrome (fibroblast karyotype 45,X (66%), 47,XY,+21 (34%)) and mosaic Turner syndrome (fibroblast karyotype 45,X[48]/46,XY[53]) were diagnosed. 17-α-hydroxylase deficiency, a rare form of CAH was diagnosed in a girl with 46,XY karyotype and Smith-Lemli-Opitz syndrome was diagnosed in a dysmorphic child with the karyotype 46,XY.
Conclusion. Wide range investigations including hormonal, metabolic and genetic studies are necessary to establish the cause of ambiguous genitalia. Identifying the underlying cause of is necessary for the individual prognosis and genetic counselling of the family.

Patient with chronic pancreatitis and polycystic kidney disease

G. Nagyová[1], *E. Hegyi*[1], *D. Ilenčíková*[1], *I. Čierna*[1], *A. Krajčiová*[1], *L. Vavrová*[2], *M. Konečný*[2], *L. Kovács*[2];
[1]*2nd Department of Pediatrics, Comenius University Medical School and University Children´s Hospital, Bratislava, Slovakia,* [2]*Department of Clinical Genetics, St. Elizabeth Cancer Institute, Bratislava, Slovakia.*

Introduction: The major ethiological factor for recurrent acute pancreatitis/chronic pancreatitis (RAP/CP) in adults is the excessive alcohol consumption. Among children anatomical anomalies of pancreas and biliary

tract and genetic factors seem to be crucial.
Autosomal dominant polycystic kidney disease (ADPKD) is the most frequent hereditary renal disease, leading to terminal renal failure of around the fifth decade. *PKD1* and *PKD2* genes are responsible for its clinical manifestation. ADPKD is usually asymptomatic during childhood.
Case report: A 10-years-old girl with acute exacerbation of chronic pancreatitis (2nd attack) was admitted to the hospital. Ethiologic causes including autoimmune, metabolic, infectious, drug and systemic were excluded. The MRCP was performed and structural anomalies were ruled out, but multiple cysts in both kidneys were the accidental finding.
Family history was negative for CP, but positive for ADPKD. Hence unexplained CP in the girl, molecular-genetic analysis of 4 genes associated with CP (*PRSS1, SPINK1, CFTR, CTRC*) was performed. The homozygous c.180C>T mutation of *CTRC* gene was confirmed. The linkage analysis of ADPKD genes validated the presence of the risk haplotype and carriage of germ line mutation in *PKD1* gene.
Conclusion: We present a girl with two genetically determined disorders. The CP is in this case caused by the homozygous c.180C>T mutation of *CTRC* gene. It increases the risk of CP about 10-fold and is associated with early-onset RAP/CP.
The risk genotype of ADPKD with *PKD1* gene involvement expects more severe course of the disease, consequently requires early management to prevent complications.

J18.10
One month exercise training effect on body composition and muscular performance in young cystic fibrosis patients

*A. M. Rusu[1], **B. Almajan-Guta**[2], C. Avram[1], O. O. Cluci[3];*
[1]West University of Timisoara, Romania, Timisoara, Roman, Romania, [2]University "Politehnica" Timisoara, Romania, Timisoara, Romania, [3]Special Care Center "Speranta", Timisoara, Roman, Romania.

Aim: To evaluate the effectiveness of one month intervention programme on body composition and muscular performance in young cystic fibrosis patients.
Material and Methods: We performed a one month prospective study, on 19 cystic fibrosis patients, aged between 6 and 12 years old. According to their availability to spend a period of 4 weeks at the Romanian National Cystic Fibrosis Center, patients were divided in 2 groups. Intervention group (10 patients-accepted to remain in the hospital for the entire period of intervention) performed intensive exercise training and received specific diet and nutritional counselling; and Control group (9 patients) who returned home after receiving nutritional and exercise training advices. Patients were evaluated, at baseline and at the end of the intervention period in regard to body composition (using a four-paired electrode bioimpedance device - InBody 720) and muscular performance of the lower limbs (using Myotest system).
Results: At the end of the study we observed a significant increase of skeletal muscle mass (from 19.90±7.27 to 21.82±7.45, p= 0.0003), explosive power of the lower limbs (from 19.23±2.28 to 21.89±1.87, p< 0.0001) and force of the lower limbs (from 19.77±2.72 to 20.81±2.95, p< 0.0001) in the intervention group. One month intervention did not influence significantly the patients in the Control group.
Conclusions: A one month in-patient intervention programme based on intensive exercise training associated with proper nutrition significantly improves the body composition and muscular performance in cystic fibrosis patients.

J18.11
Should we offer preimplantation genetic screening to women with advanced maternal age?

***Z. Demir**[1], E. C. Tuysuz[1], O. F. Bayrak[1], G. Yildirim[2], C. Ficicioglu[2], A. Kuskucu[1];*
[1]Yeditepe University Medical School, Department of Medical Genetics, Istanbul, Turkey, [2]Yeditepe University Medical School, Department of Gynecology & Obstetrics, Istanbul, Turkey.

Chromosome abnormalities increase with advanced maternal age (AMA). This leads to an enhanced risk to have an offspring with aneuploidy and miscarriages.
Interventions for prenatal diagnostic purposes and spontaneous miscarriages due to aneuploidy following IVF can be often disappointing for the women in advanced age. Preimplantation genetic screening (PGS) a variant of preimplantation genetic diagnosis, screens for frequent numerical chromosomal abnormalities that are observed in miscarriages and widely recommended in AMA cases to select euploid embryos.
In this study, we analysed aneuploidy rates of 45 spontaneous miscarriage materials from women with AMA. 15 of these cases were IVF pregnancies. 20 of 45 cases revealed chromosomal abnormalities (44.4 %) and all of them were aneuploidy including trisomy 4, 13, 15, 16, 18, 21 and 22. 12 of 30 AMA cases (40 %) and 8 of 15 (%53.3) IVF+AMA pregnancies revealed aneuploidy.
These results supported the hypothesis offering PGS to women in advanced age for selection of euploid embryos would increase reproductive success.
PGS is routinely offered in many IVF centers by the way the low quantity and quality of oocytes after ovarian stimulation, which is closely related to the ovarian reserve, is still a problem. For this reason, we suggest if the response to the ovarian stimulation is enough we can offer PGS to the women in advanced age.

Renal Disease's Genetic Counseling- a Must for an Affected Family

***I. E. Jurca- Simina**[1,2], M. Puiu[1,2], M. Gafencu[1,2];*
[1]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [2]"Louis Turcanu" Emergencies Hospital for Children, Timisoara, Romania.

Introduction: genetic counseling represents a challenge in families with socio-economic problems, even in countries with a properly preventive medicine. We present a local family case report aiming to analyze how a precocious correct diagnose and a proper family counseling may improve the quality of life and requires a low grade of society's resources giving hope for severely affected family.
Methods: family tree, antecedents' analysis, the onset, diagnoses or suspicions of disease, genetic counseling.
Results: studying the family, it revealed 5 persons with inherited renal disease: 5 years old boy, 16 years old girl, 18 years old young woman, their mother and their grandmother. All children have no other brothers or sisters; their mother has 2 healthy sisters. All the members of the family that have the disease presented a precocious onset, with a progressive glomerulonephritis, the adult ones being on dialysis. They had a restricted access on medical information and they weren't investigated of an inherited renal disease till now. They have renal biopsy for a proper diagnosis in these days and we start a suitable genetic counseling for their family potential offspring. Our counseling started with genetic consult and psychological sessions, individual and with all family members.
Conclusions: After 10 years of dialysis (grandmother) and 5 - mother, this family receives now a good medical care but with a difficult management of their genetic disease, without a global viewing of their pathology.The correct diagnose followed by a proper counseling is their chance to improve next generation future and life.

J18.13
A Novel mutation in POLH gene in Tunisian families with a severe phenotype of XP-V

***N. LAROUSSI**[1], O. MESSAOUD[1], M. BEN REKAYA[1], H. AZAIEZ[1], M. ZGHAL[2], M. JONES[1,2], A. AMOURI[1], M. S. BOUBAKER[1], H. YACOUB[1], B. FAZAA[1,2], S. ABDELHAK[1];*
[1]Université Tunis El Manar, Tunis, 1068, Institut Pasteur de Tunis, Laboratoire de Génomique Biomédicale et Oncogénétique, LR11IPT05, Tunis, Tunisia, [2]Dermatology Department, Charles Nicolle Hospital, Tunis, Tunisia.

Xeroderma pigmentosum (XP) is a genetically heterogeneous autosomal recessive disorder with seven complementation groups and an additional variant form, XP-V, that is characterized by late onset of skin symptoms and absence of neurological abnormalities.
In the present study, we report on the molecular investigation of three patients belonging to two Tunisian unrelated families and manifesting severe phenotype. Homozygosity by descent analysis was carried out using two microsatellite markers: D6S1582 and D6S271. Haplotype analysis showed homozygous haplotype for all patients that share a common allele for D6S271 marker. Mutations were screened by direct sequencing of exons 5, 9, 10 and 11 of *POLH* gene. Results showed a new splice site mutation c.660+1G>A at the donor site of intron 5. Bioinformatic tools revealed abolition of the donor splice site. Assessment of mRNA by RT-PCR analysis showed total ab-

sence of *POLH* mRNA in all patients. Absence of mRNA could be explained by the involvement of the Nonsense Mediated Decay mechanism, responsible for the aberrant mRNA degradation and thus leading to the severe phenotype of XP-V patients.
In conclusion, molecular investigation allows identification of the genetic basis of the severe form of XP-V in Tunisian population. This will enable families to beneficiate from genetic counseling.

Parent's attitude towards prenatal diagnosis and termination of the pregnancy could be influenced by other factors rather than by the severity of the condition

A. A. Al-Sulaiman;
King Faisal Spcialist Hospital RC, Riyadh, Saudi Arabia.

Objective: The aim of this study is to inevstiagete whether the severity of a particular condition alone influences parents attidues toward prenatal diaganosis (PND) and termination of pregnancy (TOP) or are there other factors involoved? Additionally, we aim to find similarity and different views toward PND and TOP for 29 conditions (variable severeities) compared to thalasseimia (severe condition).
Methods: A questionnaire which mainly focuses on parent's attitude toward PND and TOP for 30 different hypothetical scenarios for a series of genetic, non-genetic and non-medical conditions were completed by 400 Saudi parents. Results were compared and scored and parents comments were noted. Additionally, cross tabulation of thalassemia, considered the most severe and had most favorable PND and TOP, against the 29 other conditions were carried out to find similarities and different views toward TOP and PND.
Results: We found that parents' attitudes towards PND and TOP for thalassemia are significantly associated with their attitudes in relation to all of the other conditions (Fisher's exact P<0.01 in all cases). Some parent's attitudes toward TOP were clearly influenced by their religious-beliefs, others by cultural-values and some by the impact on their quality of life regardless of the severity of the condition.
Conclusion: Saudi Parents attitudes toward TOP and PND are not always influenced by the severity of the condition, but religious-beliefs, cultural-values and impact on parent's quality of life also play a role.

J18.15
Genetic counselling and epigenetics

R. Dragotoiu;
Medical and Pharmacy University, Bucuresti, Romania.

When providing genetic counselling to a patient or a couple it is important to choose the most relevant and objective information and to assure its understanding. Only then the patient's future decisions are well-grounded.
The aim of this study was to discover the opinion of students regarding the influence of epigenetics on genetic counselling.
For this purpose 154 students of the Medical and Pharmacy University „Carol Davila" in Bucharest were asked to write their opinions in a two page essay. The first year medical students had learned in seminars and lectures about genetic counselling and epigenetics. In the essay entitled „Genetic counselling and epigenetics", it was specified that they had to address whether or not the new discoveries impede genetic counselling. The essay was part of their final evaluation in Medical Genetics.
Students' views at the end of the first academic term are reviewed, discussed and the most frequent opinions are summarized. They viewed as irreplaceable the followings: determining the risk of occurrence or recurrence of a disease, preimplantation and prenatal diagnosis, the use of predictive genetic testing, as well as the ongoing genomic research, which increases our understanding of how diseases are caused and progress.
As a conclusion, all students highlighted the importance of genetic counselling in present day medicine and the need to integrate all new data in a genetic consultation. So epigenetics can only be an essential tool in the management of inherited disorders shaping accordingly the genetic counselling.

J18.16
Dynamic prenatal screening in the I and the II trimesters of pregnancy

D. T. Tursunova, *A. K. Yuldasheva, Z. G. Khvan, F. K. Odinaeva;*
Tajik scientific research institute of obstetrics and gynecology and perinatology, Dushanbe, Tajikistan.

Combined screening in the 1st and 2nd trimesters of pregnancy, comparative analysis.
309 women 9-13 and 16-22 weeks of pregnancy are surveyed using noninvasive and invasive screening methods. The research methodology included undertaking ultrasonic screening; identification of the serum markers of-HCGβ and PAPP-A in the I trimester; human chorionic gonadotropin (hCG), Alpha Fetoprotein and Estriol - in the II trimester; computer analysis with application of the Life Cycle programs in the I trimester and PRISCA-in the II trimester; invasive methods of prenatal diagnostics.
At dynamic control in the I trimester of pregnancy from 47 (15,2%) women in the group of risk 9 (19,1%) fetuses were diagnosed with the Down syndrome (5), Edwards (3) and Patau (1). In the II trimester in the group of risk of 64 (20,7%) women no fetus were found with the chromosomal pathology i.e. all changes of a karyotype were established in the I trimester.
All chromosomal pathology cases were diagnosed in the I trimester of pregnancy. Therefore, based on the results of the analysis, the advantages of inspection in early times of pregnancy were identified.
The screening programs should be predominantly applied in the I trimester to identify pregnant women of risk group. When low risk is identified, inspection in dynamics is inexpedient. Noninvasive screening in the II trimester should be carried out only in the absence of risks in early periods of pregnancy. At high risks it is necessary to decide carrying out invasive methods of prenatal diagnostics in the I trimester of pregnancy.

Childhood obesity and the MC4R gene: Necessity for early genetic testing

R. Subramaniam;
MGM University of Health Sciences, Mumbai, India.

According to a survey conducted be the WHO, globally around 170 million children (< 18 years) are estimated to be overweight.
Mutations in the MC4R (melanocortin-4 receptor gene) are the most common genetic cause of obesity. The *MC4R* gene codes for a protein that is primarily expressed in the brain and encoded by a single exon on 18q22. Mutations in this gene are associated with obesity in an autosomal-dominant fashion. In a study, the MC4R mutation accounted for 5.8% of the 500 morbidly obese children who participated. Symptoms accompanying MC4R-related early onset obesity are also seen with other types of obesity and may become apparent only over extended periods of time. Therefore, MC4R-related early onset obesity cannot be diagnosed via symptomatic clinical diagnosis. Genetic testing allows a diagnosis of MC4R-related early onset obesity at any age**. Genetic testing can also identify carriers of obesity-associated mutations.** Studies in cell culture have indicated that the functionality of a normal MC4R protein is not affected by presence of a mutated receptor protein in the same cell .Therefore, increased stimulation of the remaining healthy MC4R protein with specific drugs may be able to compensate for the loss of function in the mutated receptor. Early detection of this mutation shall help start treatment immediately. Also preventive measures such as dietary control can be immediately incorporated, thus reducing levels of obesity and bringing down the risk of associated disorders such as Diabetes and cardiovascular disorders.

Comprehensive Phenotyping of Mouse Models

M. Champy;
IGBMC, illkirch, France.

The Institut Clinique de la Souris (ICS) is a technology platform that provides a comprehensive set of highly specialized mouse services to scientists from academia and industry. The ICS combines the capacity of generating mutant mice on a large scale with a high-throughput and comprehensive phenotypic analysis of mice. The ICS phenotyping platforms are adapted for the study of genetically engineered mouse models, as well as for pharmacological and toxicological studies, allowing better understanding of human diseases and their underlying physiological and pathological basis. The ICS

has successfully assembled a comprehensive phenotyping platform on 5 following core units: 1) Clinical chemistry laboratory covers biochemistry, hematology, coagulation, immunology, endocrinology exploration. 2) Metabolic exploration service is set up to explore energy balance including body composition, glucose homeostasis, and energy expenditure, as well as the skeletomuscular and the uro-genital systems, and the gastro-intestinal tract. 3) Cardiovascular and respiratory exploration including tests to analyze the cardiac function and anatomy, as well as the respiratory system such as in asthma models. 4) Behavior and nervous system. This core has developed a comprehensive tests battery to evaluate: general CNS function, affective behaviors (anxiety, depression), cognitive function, sensory thresholds and analgesia, as well as the sensory systems (visual and auditory functions). 5) Histology and pathology. This service provides a comprehensive histological and histopathological analysis of mutant and control mice, as well as embryology studies. The assays performed by each core unit will be presented, as well as validated flow schemes for applications in therapeutic areas.

Molecular and genetic aspects of the regulation of lipid metabolism in individuals with different levels of fitness

L. Kayumova, *E. Vorobieva, V. Gorbunova;*
Bashkir State Pedagogical University from after M. Akmulla, Ufa, Russian Federation.

In recent years, increased interest in the study of lipid metabolism in the adaptation to the effects of physical activity and its nature in athletes of different specialization and different levels of fitness. Long-term adaptation of athletes to physical activity of varying intensity accompanied by specific changes in the structure of the lipid metabolism.
Important role in the regulation of metabolism of triglyceride-rich lipoproteins and HDL genes belong, which is part of a gene cluster A1/C3/A4/A5 apolipoproteins, of which we have studied polymorphic variants of two genes - apolipoprotein A-I APOA-I (rs 1799837, A-75G) and gene apolipopotein C-III APOC-III (rs 76353203, C3238G), located on chromosome 11 (11q23 and 11q23.3, respectively).
The material for the study is based on 456 DNA samples of healthy individuals. Determining the level of the major lipid profile (total cholesterol, triglycerides, low density lipoprotein, high density lipoprotein) was performed by standard enzymatic methods. Analysis of polymorphic DNA loci APOA-I, APOC-III was performed by PCR-RFLP.
Univariate analysis of variance revealed a significant effect of genotype APOA-I A/A (F=4,967; p=0,028) at a lower concentration of triglycerides, and genotype APOA-I A/G (F=7,862; p=0,006) to increase the concentration of triglycerides.
A comparative analysis showed a group of individuals practicing significant increase genotype APOA-I A/A (p=0,0151; χ2=5,9795) and a decrease in genotype APOA-I A/G (p=0,0112; χ2=6,5579).
During the haplotype analysis in a group of individuals practicing found a significant increase in the haplotype G/C (p=0,0006; χ2=17,5365) and a decrease in the haplotype A/G (p=0,0348; χ2=4,4642; OR=1,6186).

Monosomy 1p36 case with left ventricular „noncompaction“ and right ventricular rhabdomyoma

H. Gurkan[1], *S. Gokalp*[2], *H. Tozkir*[1], *G. Sari*[1], *U. Vatansever Ozbek*[3];
[1]*Trakya University,Faculty of Medicine, Department of Medical Genetics, Edirne, Turkey,* [2]*Trakya University,Faculty of Medicine, Department of Pediatric Cardiology, Edirne, Turkey,* [3]*Trakya University,Faculty of Medicine, Department of Pediatry, Edirne, Turkey.*

Monosomy 1p36 syndrome is characterized by many different dysmorphic features including large and late-closing anterior fontanelle, microcephaly, brachycephaly, deep-set eyes, depressed nasal bridge and a pointed nose and jaw structure. LVNC syndrome has been reported as associated with 1p36 deletion in pediatric population. On 31/05/2012, the patient, genetically unrelated three-year married couple's first baby, was born by caesarean section at 38 weeks. They applied to our clinic with complaints as fetal rhabdomyoma, left ventricular „noncompaction“, VSD, PDA. Large forehead, open and large anterior fontanelle with front starting point, flat and broad bridge of the nose, straight eyebrows, short palpebral fissures, narrow and slanted, both ear curved inward and helix, small corners of the mouth, bevel-down, long philtrum, high narrow palate, pointed chin, telangiectasia/hemangioma inside the thumb of the right hand, inner palmar of the left hand, hypopigmented macules on the right axillary region, the lower-right quadrant of the abdomen and lumbar region, open sinus on sacrococcygeal region, second fingers of both feet were top placement. 46, XX chromosome structure was determined according to the chromosome analysis of patient's peripheral blood sample with G-banding technique. Heterozygous 1p36.32-36.33 microdeletion was detected by the mental retardation panel of MLPA analysis method. 60 cells were examined by the method of FISH for the verification and 1p36 deletion was detected in all cells This case has importance because this is the first case of LVNC-monosomy 1p36 syndrome shown in Turkish population and different from recent studies with the presence of hypopigmented macules.

Perceptions of physicians on pharmacogenetics in Abant Izzet Baysal University, Medical Faculty, Turkey

Z. Ozunal[1], ***S. Duzenli***[2], *A. Arslan*[2], *R. Bayram*[1], *A. Gepdiremen*[1];
[1]*Abant Izzet Baysal University Medical Faculty, Dept. of Pharmacology, Bolu, Turkey,*
[2]*Abant Izzet Baysal University Medical Faculty, Dept. of Medical Genetics, Bolu, Turkey.*

Abant Izzet Baysal University (AIBU) Medical Faculty pharmacogenetics testing laboratory is recently established. To inform the availability and recent pharmacogenetics knowledge, two seminars are given to the total of 106 hospital attendees. After the availability of pharmacogenetic testing, we evaluated physicians' perceptions on pharmacogenetic testing and its implementation.
The survey was performed among 35 academic medical staff in the faculty and 35 recently graduated medical faculty students. The results were calculated with the EpiInfo statistics software using the χ2-test.
According to this survey performed at AIBU Medical Faculty, 2.9% of the responding academic medical staff (AMS) was trained for pharmacogenetics at undergraduate level, while 20% of recently graduated medical faculty students (GMS) declared the same. Belief in the influence of genotypes on drug response was as 91.4% and 100% of AMS and GMS, respectively. Relatively fewer AMS (31.4%), than GMS (25.7%) reported that they felt adequately informed about the availability of genetic testing and its application. Test results of the two groups were statistically significant (p<0.001).
In this survey we can conclude that there is a remarkable difference in the knowledge, approach and proceeding on pharmacogenetics between academic medical staff and recently graduated students. The cause of the difference can be speculated as experience or curriculum differences. Additionally, we can follow up, that this particular issue is now taught in faculties. To complete, one can postulate, that with the availability of pharmacogenetic clinic implementation knowledge and more education, future adopters will rise.

Rapid detection of fetal aneuploidies by Quantitative Fluorence PCR (QF-PCR) in prenatal dioagnosis

T. Tufan[1], *A. Pazarbasi*[1], *M. A. Erkoc*[1], *G. Comertpay*[1], *S. K. Sel*[1], *F. T. Ozgunen*[2], *M. B. Yilmaz*[1], *S. Buyukkurt*[2], *N. S. Ilgaz*[1], *L. Ozpak*[1], *I. N. Uslu*[1], *P. Pazarci*[1], *D. Alptekin*[1], *C. Evruke*[2], *H. U. Luleyap*[1];
[1]*Cukurova University, Medical Faculty, Department of Medical Biology and Genetics, Adana, Turkey,* [2]*Cukurova University, Medical Faculty, Department of Obstedrics and Gynecology, Adana, Turkey.*

Purpose to investigate which STR markers are better for prenatal diagnosis and the frequency of euplodies and aneuploidies in prenatal diagnosis of pregnant subjects in Cukurova, Adana region. QF-PCR, a novel technique, which is fast and reliable, is employed to detect aneuploidies (13,18, 21, X, Y) without the need of time consuming culturing process. QF-PCR can detect 5 different chromosome aneuploidies with 98.6% accuracy. Methods, 1804 amniotic fluid samples of pregnant subjects, who were referred to molecular biology section of our department, were analyzed with QF-PCR technique employing 35 STR markers for detecting chromosomes 13, 18, 21, X and Y aneuploidies. Results we detected 152 subjects (8,42%) out of 1804 with aneuploidies or euploidies. The average age of pregnant subjects was 32 (varies between 14 and 49). Abnormal karyotypes detected were as follows: 47,XX,+21 (34.87%, 53/151); 47,XY,+21 (40.13%, 61/151); 47,XX,+13 (0.66%, 1/151); 47,XY,+13 (1.32%, 2/151); 47,XX+18 (7.89%, 12/151); 47,XY+18 (5.93%, 9/151), 47,XXX (1.32%, 2/151); 69,XXX (1.32%, 2/151); 45,X (6.58%, 10/151). Conclusions QF-PCR can be regarded as an alternative method of conventional cytogenetic analysis since it is rapid and reliable, however in most cases it is required to be supported or validated with conventional cytogenetic karyotyping.

Coexistence of Townes-Brocks syndrome and Albinism in a case

K. Nadir, *S. Çelik, S. Çitli, T. Çora;*
Selçuk University, Selçuklu Medical Faculty,The Department of Medical Genetics, Konya, Turkey.

Townes-Brocks syndrome (TBS) is a rare genetic disorder. The most common features of this syndrome are anal atresia, abnormally shaped ears, and hand malformations that most often affect the thumb. TBS syndrome is caused by mutations in a SALL1 gene. This gene is located chromosome 16q12.1.2 Albinism is one of the archetypal inborn errors of metabolism described by Archibald Garrod, with a frequency of around 1:20.000. It is usually defined as a congenital hypopigmentation of the skin, hair, or eyes. There are a large number of genes responsible for the occurrence of albinism .One of this gene is The melanocortin 1 receptor gene (16q24.3).
Our patient is male child who his age is 9 months. He has an obstruction of the anal opening (imperforate anus), low and simple ears, ear tag, simian line, short palpebral fissure. The patient's mother and father were not consanguineous. We performed a cytogenetic analysis and the other laboratuary analysis. We have found that patient`s chromosome 16 has anormal structure. The patient was evaluated as TBS after we performed a cytogenetic analysis and the other laboratuary analysis. However, he has a congenital hypopigmentation of the skin, hair and eye. This new situation was evaluated as Albinism because his mother has albinism. Therefore, we thought that our patient is both Townes-Brocks syndrome and albinism. In addition, further research will be beneficial because the localization of these two genes which are responsible for the disease is closely.

PhD, MD

M. L. Sprincean[1,2], *E. Halabudenco*[1], *N. Barbova*[1,2], *A. Mişina*[1], *T. Samoilenco*[1];
[1]*Institute of Research of Healthcare of Mother and Child, Chisinau, Moldova, Republic of,* [2]*State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of.*

Background: peculiarities of clinical manifestations and cytogenetic features are analyzed in Turner syndrome, which is a gonosomal abnormality characterized by a loss of X chromosome (total or partial) with or without mosaics.
Materials and methods: A group of 68 children with Turner syndrome was investigated during medical genetic counseling in the study.
Results: The most characteristic features of patients with Turner syndrome are: short stature - 97%, incomplete sexual maturation 95%, cubitus valgus - 48%, pterygium colli - 44%, short neck - 42%, palatine arch - 37%, multiple nevus - 23%, lymphedema - 24%, nail dysplasia - 13%, scoliosis - 12%. The frequency of cytogenetic variants of Turner Syndrome: 1. homogeneous form or X monosomy: 45 X - 53% of cases; 2. mosaic form: 45, X/46 XX, 45, X/46, XY - 11.8% cases; 3. structural abnormalities of X chromosome: 46, xix, 46, X delX, 46, X dicX, 46, XRX - 17.6% cases; 4. mosaicism with structural abnormalities of X chromosome: 46, XX/46XiX/45, X - 2.9% of cases and other chromosome: 46, XY - 14.7% cases.
Conclusions: Peculiarities of phenotype manifestations in girls with Turner syndrome induce the diagnosis in the early neonatal period, however up to 60% of patients are not diagnosed during early childhood because of lack of complaints of family and the late visits to geneticist. Karyotype in Turner syndrome is highly variable and different, in 53% of cases being the homogeneous form or X monosomy - 45, X.

A Case Report: 46, XX, ins (3, 1) (q22; q25qter) karyotype in dizygotic twin sisters

R. U. Akkoyunlu, *K. E. Gümüslü, S. Eren, B. Doğruoğlu, D. Sünnetçi, N. Çine, H. Savli, E. Özsu, F. Çizmecioğlu;*
Kocaeli University Health Sciences, Kocaeli

İnsertion is a chromosome abnormality that is due to a nonreciprocal type of translocation in which a segment is removed from one chromosome and then inserted into a broken region of a nonhomologous chromosome. This can happen due to unequal crossover during meiosis. Although, chromosomal insertions are considered as balanced chromosomal abnormalities, they can be hazardous if the affected region is in an exon. We present the case reports of 13 years old female s. Both patients were presented with short stature, pubertas tardas, dysmorphic features and mild mental retardation. Classic cytogenetic G banded karyotype analysis performed on peripheral blood samples demonstrated a 46,xx, ins (3, 1)(q22;q25qter) in both Twin A and Twin B. Abnormal karyotype ins (3, 1)(q22;q25qter) is rarely reported in the literature. The phenotypic effects of this karyotype is not fully described. The affected loci after insertion may contain genes associated with growth, cognitive ability and sexual development. We suggest that performing advanced molecular techniques will assist in determining the affected genes and their roles in phenotype-genotype relationship.

Phenotype variability in pericentric inversion of chromosome 9 - case series

A. Chirita-Emandi, *S. Dumitriu, C. Popa, S. Arghirescu, M. Puiu;*
University of Medicine &Pharmacy, Timisoara, Roumania, Timisoara, Romania.

Background: Inherited pericentric inversion of chromosome 9 - inv(9)(p11-q13) is relatively commonly found in humans (1-4%), generally without apparent phenotypic alterations. However, the inv(9)(p11-q13) was also found to be associated with congenital malformations and certain cancers.
Aim: We aim to examine the relation between the inv(9)(p11-q13) and the various phenotype it is associated with in a series of 5 cases.
Methods: We present 4 boys, aged 7 months, 2 years, 4 years and 13 years, respectively and a five years old girl. The patients were examined and also had blood work alongside cytogenetic studies.
Results: We found various phenotypes ranging from facial dysmorphism (2 cases), delayed milestones (2 cases), micropenis and cryptorchidism (2 cases), mild growth retardation (1 case), atacsia (1 case). Mothers of two of the boys also presented the inversion. Interestingly, we also found the duplication 16q12.2q2 in one boy presenting facial dysmorphism.
Conclusion: The phenotype associated with pericentric inversion of chromosome 9 is extremely variable; consequently, further studies analyzing each breakpoint region of inv (9), using mo¬lecular cytogenetics are needed to understand the disease association.

J18.27

Karyotype and SRY gene analysis in patients with phenotype and genotype incompatibility

E. Akbas, *Z. Mert Altintas, H. Senli;*
Mersin University - Faculty of Medicine, Mersin, Turkey.

The major factor in creation of the gender is the SRY gene on chromosome Y. SRY gene neighbors the pseodoautosomal region 1 *(PAR1)* crossing over region on the short arm of the chromosome Y. Rarely the SRY gene on the Y chromosome may pass to the X chromosome via erroneous crossing over. In this case, if the gamete carrying the X chromosome that received the SRY gene is inseminated, only male phenotype individual is created in XX genotype. In case the gamete carrying the Y chromosome that has lost the SRY gene is inseminated, only female phenotype individual is created with XY genotype. SRY genes of only females with 46,XY genotype and 45,X/46,XY mosaic individuals with genotype-phenotype incompatibility, that is detected as a result of the chromosome analysis carried out in our cytogenetic laboratory, are studied in the present study. Standard chromosomal analysis was performed by using giemsa-trypsin (GTG) banding. The SRY gene was amplified by polymerase chain reaction (PCR).
SRY is positive only in 46,XY genotype female phenotype patients. However, it gives rise to the thought that it may be caused by other factors such as noncreation of male phenotype, inactivity of the SRY gene, androgynous receptor dysfunction or 5 α-reductase deficiencies. Although SRY gene is available in 45,X/46,XY mosaic cases, it is insufficient in creation of male phenotype since the band level is thin in ratio proportional to the level of mosaic. Turner phenotype is emerged due to the excess number of Turner genotype cell ratio.

J18.28

Chromosome 15 alterations implicated in Silver-Russell Syndrome

A. Dobrescu, *S. Dumitriu, A. Chirita-Emandi, C. Borza, M. Puiu;*
University of Medicine &Pharmacy, Victor Babes, Timisoara, Romania.

Background and aims: Silver-Russell Syndrome (SRS) is a clinically and genetically heterogeneous disorder. Most frequently the 7 and 11chromosomes are involved, other chromosomes considered as candidate loci for SRS are 1, 8, 15, 17, 18 and X.
We aim to present a case with classic Silver Russell syndrome phenotype with chromosome 15 alterations.
Methods: The infant was comprehensively examined trough clinical, lab work, imagistic and genetic studies.
Results: An 8 month old female infant with intrauterine growth retardation, severe hydramnios and single umbilical artery, born at 33 weeks of gestation, weighing 1200 grams (below 2 standard deviations), presented slow weight gain during the first 6 months of life (average 362 grames /month). She displayed a classical Silver Russell syndrome phenotype. The infant had delayed bone age (corresponding to 1-2 months of age). The patient's karyotype was 46,XX,dup(15)(pter-q22::q22-qter), the mother had normal karyotype, while the father's karyotype was 46,XY,1qh+ without phenotypical alterations. She has now started growth hormone treatment.
Conclusions: The patient shows a typical phenotype although the association between chromosome 15 alterations and Silver Russell Syndrome is rarely mentioned in specialized literature. This confirms that this phenotypic syndrome is genetically heterogeneous.
The case needs molecular cytogenetic investigations leading to a more detailed description of chromosomal rearrangements for both parents and patient.

Genetics counseling in a case of Kabuki syndrome

D. Capatina[1], *G. Cozaru*[1,2];
[1]*Constanţa County Emergency Hospital, Constanta, Romania,* [2]*Andrei Saguna University of Constanta, Constanta, Romania.*

Kabuki syndrome (KS) is a rare disorder and has an estimated frequency of 1 in 32,000.
This paper reports the case of an 5-year-old male with KS who has the various features typical of the disease: hypotonia and postnatal growth deficiency, characteristics face (long palpebral fissures, ectropium of the lateral third of the lower eyelids, arching eyebrows with sparse lateral halves, depressed nasal tip, large and prominent ears, micrognathia, mid-facial hypoplasia, dental abnormalities), moderate mental retardation, distinctive behavioural features and learning difficulties, urogenital abnormalities (congenital inguinal hernia, ectopic testis), short stature and skeletal abnormality.
The etiology of the syndrome is unknown and is thought to be possibly due to sporadic mutation with no familial history. There is no prenatal screening, genetic test or consensual diagnostic criteria to confirm this condition. The patients are diagnosed according to the recognizable facial features. The identification of the basis of genetic diseases is essential to provide an accurate genetic counseling and to ensure proper disease prevention. In this case is difficult to estimate the risk of parent's patient having another child with KS.
The prognosis of survival to adulthood is relatively good as KS is not typically associated with severe medical complications.

D. Capatina: None. **G. Cozaru:** None.

Distribution of trisomies in 96 cases of trisomic spontaneous abortions

J. Jovanovic Privrodski, *I. Kavecan, M. Kolarski, D. Radovanov, M. Obrenovic;*
Institute for Children and Youth Health Care Vojvodina, Novi Sad, Serbia.

In thirteen years period, from 1999 to 2011, i<<<<<<<n Genetic Centre in Novi Sad, Serbia were analyzed 759 spontaneous abortions and we detected 96 trisomic karyotypes. The most frequent trisomies were: 18.75% Edwards syndrome (N= 18/96), 16.67% trisomy of
chromosome 15 (N=16/96), 13.54% Daun syndrome (N=13/96); 12.5% Patau syndrome (N=12/96); 9.37% trisomy of chromosome 22 (N=9/96); 14.58% trisomy of chromosome 16 (N=14/96); 3.12% trisomy of chromosome 9 (N=3/96); 3.12% trisomy of chromosome 14 (N=3/96); 8.33% others (N=8/96). Trisomies were predominantly detected in first trimester from 9th to 12th week of gestation (83%).
Cytogenetic abnormalities are one of most important cause of spontaneous abortions. Genetic counseling provide information that may be helpful for subsequent pregnancies.

Mosaic trisomy 9 in a girl with mental retardation and dysmorphic syndrome

I. Bradinova[1], *R. Vazharova*[1], *V. Bojinova*[2], *A. Savov*[3];
[1]*National Genetic Laboratory, UHOG „Maichin dom", Sofia, Bulgaria,* [2]*USBALNP „Saint Naum", Sofia, Bulgaria,* [3]*National Genetic Laboratory, UHOG, Sofia, Bulgaria.*

Trisomy 9 is an uncommon chromosome abnormality that may be seen in a mosaic or non-mosaic state. As complete trisomy 9 is often lethal to the fetus, individuals affected by this disorder commonly display mosaicism, harboring a mixture of cells in which some cells contain the normal two copies of chromosome 9, while other cells contain a third copy of chromosome 9. Associated symptoms and findings may vary greatly in range and severity and include intrauterine growth retardation; mental retardation; congenital heart defects; distinctive craniofacial abnormalities; musculoskeletal, genital, kidney , and/or additional physical abnormalities.
We present the case of a 10 yrs old female patient born from the first pregnancy of a healthy couple with normal birth weight and length. The girl had found psychomotor retardation, abnormal behavior, truncal obesity, joint hypermobility and dysmorphic features (broad-based nose with bulbous tip , high arched palate, short palpebral fissures, microretrognatia, tapering fingers). The performed brain imaging did not find any structural brain anomalies. The routine cytogenetic test detected mosaic trysomy 9 (47,XX,+9[3]/46,XX[21]).
Mental retardation and non specific dysmorphism are leading clinical features in our patient. The wide phenotypic range in trisomy 9 mosaic syndrome is likely to explain by the percentage of trisomic cells in different tissues. Routine cytogenetic investigation remains important test in individuals with mental retardation and/or dysmorphic features. A large number of cells is needed in order to obtain a correct karyotype diagnosis in mosaic patients. Correct diagnosis is essential to define the prognosis and provide accurate genetic counseling.

A Genetic approach to understand the rare Liddle syndrome in India

B. A. R. S. Nath[1], *D. Thaniga*[2], *G. Natarajan*[2], *R. Saraswathy*[1];
[1]*VIT University, Vellore, India,* [2]*Madras Medical College, Chennai, India.*

Genetic analysis of the rare syndrome, Liddle syndrome is carried out for understanding its etiology. It is reported in fewer than 30 families (or isolated cases) worldwide. It is known to be autosomal dominantly inherited and presented with hypertension and low plasma renin activity, metabolic alkalosis due to hypokalemia caused by elevated levels of sodium ions and loss of potassium from the renal tubule. Till now this syndrome has been identified by the biochemical parameters only and to the best of our knowledge no cytogenetic analysis has been carried out. In this study the proband was confirmed by the biochemical parameters. In addition, all the family members (n=7) were subjected to genetic analysis. The cytogenetic analysis included the chromosome aberration assay (CA) and cytokinesis block micronuclei assay (CBMN Cyt assay). The molecular analysis included the mutation study for the genes SCNN1B and SCNN1G exon 13. The frequency of CAs was significantly higher in the proband (0.18±0.43) than the other family members and controls (0.005±0.0085). In CBMN Cyt assay, the frequencies of micronuclei, nucleoplasmic bridges and nuclear buds were significantly higher than in the family members and controls. To the best of our knowledge this is the first study involving Genetic analysis of Liddle Syndrome and family members. This will help in understanding the etiology of this disease and affecteds in the family. This kind of study will be useful in genetic counseling for an early intervention.

Bend it like Beckham! The ethics of genetically testing children for athletic potential.

C. Silvia;
King's College London, London, United Kingdom.

In this paper I analyse the use of direct-to-consumer (DTC) genetic tests[1], sometimes coupled with more traditional methods of talent scouting such as intensive summer camps[2], to assess a child's predisposition to athletic performance. The recent boom of DTC-genetic tests, aimed at measuring children's athletic potential, is the latest wave in the "pre-professionalization" of children that has characterized, especially but not exclusively, the US in the last twenty years.[3] In this paper I discuss the scientific evidence at the basis of the DTC-genetic tests and challenge their predictive ability. I then discuss how the parental use of DTC-genetic tests impact on the children's right to an open future, and on their developing sense of autonomy and of self-determination. I argue that the use of DTC-genetic tests to allegedly 'measure' children's athletic potential is ethically problematic as it trumps the right-in-trust of children to an open future favouring a too broad interpretation of parental reproductive and child-rearing freedom. I conclude tht DTC-genetic tests to scout children's potential should be seen as a 'wake up' call for other problematic parental attitudes aimed at scouting and developing children's precocious talents, be they in sports or elsewhere.

Reduced telomere length in placentas during pregnancies complicated by intrauterine growth restriction

J. Toutain[1], *M. Carlotti*[2], *E. Chevret*[2], *D. Cappellen*[2], *F. Pelluard*[3], *J. Merlio*[2], *J. Horovitz*[4], *D. Lacombe*[1,5], *R. Saura*[1];

[1]*CHU Bordeaux, Génétique médicale, Bordeaux, France,* [2]*Univ. Bordeaux, Histologie et pathologie moléculaire des tumeurs, Bordeaux, France,* [3]*CHU Bordeaux, Anatomo-pathologie, Bordeaux, France,* [4]*CHU Bordeaux, Gynécologie-obstétrique et médecine fœtale, Bordeaux, France,* [5]*Univ. Bordeaux, Maladies Rares: Génétique et Métabolisme (MRGM), Bordeaux, France.*

Objectives: Recent studies have shown that telomere length was significantly reduced in placentas collected at delivery from pregnancies complicated by intrauterine growth restriction (IUGR) secondary to placental insufficiency. Placental telomere length measurement during ongoing pregnancies complicated by IUGR has never been reported. *Methods:* In our center, late chorionic villus samplings were performed between 18 and 37 weeks of amenorrhea in 24 subjects with severe IUGR (cases) and in 28 subjects with other indications for prenatal diagnosis (controls). Placental insufficiency was assessed by histo-pathological examination. Relative measurement of telomere length was carried out prospectively by quantitative Fluorescent *In Situ* Hybridization (FISH) using Peptide Nucleic Acid probes on interphase nuclei obtained from long-term cultured villi and with an automated epifluorescent microscope. A quantitative Polymerase Chain Reaction (Q-PCR) technique was performed to confirm the quantitative FISH results. The number of copies of gene loci encoding the RNA template (*hTERC*) and the catalytic subunit (*hTERT*) of the enzyme complex telomerase were also estimated in these placentas by FISH. *Results:* Mean fluorescence intensity of telomere probes estimated by quantitative FISH was significantly less for cases compared to controls ($p<0.001$). This result indicated that mean telomere length was significantly reduced in placentas during pregnancies complicated by IUGR. Reduced telomere length was confirmed by the Q-PCR technique. No copy number variation of the *hTERC* and *hTERT* loci was noticed for cases, or for controls. *Conclusion:* This study clearly demonstrates a reduction of placental telomere length in ongoing pregnancies complicated by severe IUGR secondary to placental insufficiency.

J19.03

Preimplantation Genetic Diagnosis (PGD) for beta-thalassaemia and sideroblastic anaemia, combined with HLA-typing, employing three different technologies for single cell genotyping: fragment analysis, nested real-time PCR and nested high-resolution melting (HRM) analysis.

G. Kakourou[1], *A. Destouni*[2], *C. Vrettou*[1], *M. Poulou*[1], *J. Traeger-Synodinos*[1], *E. Kanavakis*[1,2];

[1]*University of Athens, Department of Medical Genetics, "Aghia Sophia" Children's Hospital, Athens, Gr, Athens, Greece,* [2]*Research Institute for the Study of Genetic and Malignant Disorders in Childhood, „Aghia Sophia" Children's Hospital, Athens, Greece.*

PGD with HLA-matching to select histo-compatible siblings to facilitate curative haematopoeitic stem-cell transplant (HSCT) is widely applied. We describe a rare case, where HLA-PGD was performed to exclude two familial single-gene disorders (SGDs). The couple were heterozygous for different beta-thalassaemia mutations as well as an identical sideroblastic-anaemia mutation.Their daughter, affected with sideroblastic-anaemia, was programmed to have HSCT. We optimized a one-step-multiplex-fluorescent-touchdown-PCR protocol for the simultaneous amplification of 19 genetic regions: the *HBB*-gene mutated regions (c.118C>T and c.25-26delAA), four linked-short tandem-repeats (STRs) in chr11p15.4 (4-138kb upstream and downstream of *HBB*), the *SLC25A38* gene mutation (c.726C>T), two linked-STRs in chr3p22.1 (208-245kb upstream-downstream of *SLC25A38*), plus eleven STRs for HLA-haplotyping (chr6p22.1-21.3). This was followed by nested real-time PCR and high-resolution melting (HRM) for direct mutation detection and analysis of all STRs on a genetic analyzer for indirect genotyping and HLA-haplotyping. The protocol was validated following PGD guidelines and successfully performed in a clinical cycle. A single blastomere was biopsied from each of 19 day-3 embryos and sent for genetic analysis. One blastomere failed to amplify at all loci. From the remaining 18 embryos, diagnosis was as follows:for beta-thalassaemia, 15/18 were unaffected, 2/18 affected and 1/18 showed only normal maternal alleles.For sideroblastic-anaemia: 9/18 were unaffected, 7/18 affected, 2/18 inconclusive.Two embryos were HLA-compatible, 14/18 not compatible, 2/18 inconclusive. One HLA-compatible embryo was also unaffected for both SGDs and transferred, however a pregnancy was not achieved.The couple plans a second cycle. The novel methodological PGD-approach described here is fast, accurate, clinically-validated and has a low cost.

J19.04

Prenatal molecular cytogenetic analysis should be performed on mesenchymal core rather than on cytotrophoblast cells

R. Saura[1], *J. Horovitz*[2], *F. Pelluard*[3], *D. Lacombe*[1,4], *J. Toutain*[1];

[1]*CHU Bordeaux, Génétique médicale, Bordeaux, France,* [2]*CHU Bordeaux, Gynécologie-obstétrique et médecine fœtale, Bordeaux, France,* [3]*CHU Bordeaux, Anatomo-pathologie, Bordeaux, France,* [4]*Univ. Bordeaux, Maladies Rares: Génétique et Métabolisme (MRGM), Bordeaux, France.*

Objectives: To examine the reliability of interphase FISH analysis of the main aneuploidies performed on mesenchymal core when prenatal diagnosis was performed on pregnant women with first-trimester fetal abnormalities on ultrasound. *Methods:* 386 first trimester prenatal examinations were investigated from chorionic villus samplings for increased nuchal translucencies or other fetal ultrasound abnormalities. Interphase Fluorescence *In Situ* Hybridization (FISH) for the main aneuploidies (trisomies 13, 18, 21 and gonosomal aneuploidies) was performed on the mesenchymal core of villi. Molecular cytogenetic results were always complemented by conventional cytogenetic results on long-term cultured villi (LTC-villi). Short term cultured villi (STC-villi) preparations were retrospectively performed only when a chromosomal abnormality was observed with interphase FISH and/or LTC-villi. *Results:* 88 chromosomal abnormalities (88/386 = 22.8% of first-trimester diagnoses) which could discuss subsequent abortions were observed after LTC-villi preparations. All cases possibly detectable by interphase FISH were detected. Thus, 85 aneuploidies (85/386 = 22.0% of first-trimester diagnoses; 85/88 = 96.6% of chromosomal abnormalities) were detected by interphase FISH, allowing early abortion by curettage before week 14 amenorrhea. No discrepancy occurred between interphase FISH and LTC-villi results for the aneuploidies studied. Three false-negative results (3/386 = 0.77% of first-trimester diagnoses; 3/88 = 3.41% of chromosomal abnormalities) were observed with STC-villi. *Conclusion:* We observed a high rate of false-negative results on cytotrophoblast cells. Conversely, interphase FISH of the main aneuploidies on the mesenchymal core provided rapid and reliable results. We therefore postulate that prenatal molecular cytogenetic analysis should be performed on mesenchymal core rather than on cytotrophoblast cells.

J19.05

The Interaction of 3.7kb alpha-globin gene triplication with beta-globin gene mutations in Iranian population

S. Farashi, *N. Bayat, N. Faramarzi Garous, M. Montajabi Niyat, M. Ashki, S. Vakili, I. Hashem, V. Hadavi, A. Azarkeivan, H. Najmabadi;*
Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran.

The 3.7kb triplicated α-globin gene has been found in most populations. It results from unequal crossover between misalignmented homologous segments in the α-globin gene cluster during meiosis. The pathophysiology and clinical severity of ß-thalassemia (ß-thal) are associated with the degree of α-chain imbalance. The excess of α-globin chains plays an important role in the pathophysiology of ß-thal. When heterozygous/homozygous ß-thal coexists with alpha gene numerical alteration, the clinical and hematological phenotype is affected, showing a decrease (-α/) or increase (ααα/) in thalassemia carriers' anemia.
The coexistence of α-globin gene triplication (ααα/) consider as an important modulator of the severity of ß-thal, exacerbating the phenotypic severity of ß-thal by causing more globin chain imbalance.This type of phenotype modification has rarely been observed and reported in Iranian population. Here, we report co-inheritance of triple α-globin gene arrangement and heterozygous/homozygous ß-thal in 21 cases presenting thalassemia intermedia/major phenotype. Some of these patients consider as having mild intermedia phenotype, they need no transfusion, some receive blood occasionally in their time life (for example on delivery time) but some of them are dependent to regular blood transfusion (once every 20 to 40 days). Our study focus on the importance of detecting 3.7kb triplicated α-globin gene in genotype/phenotype prediction in Iranian thal patients.

Chromosome polymorphic variants in infertility and their effect on ongoing pregnancy rates

R. Morales[1], *B. Lledo*[1], *J. A. Ortiz*[1], *J. Ten*[2], *J. Llacer*[2], *R. Bernabeu*[2];
[1]*INSTITUTO BERNABEU BIOTECH, Alicante, Spain,* [2]*INSTITUTO BERNABEU, Alicante, Spain.*

INTRODUCTION: Polymorphic variants on chromosomes were considered normal without clinical significance, however previous studies have reported that incidence of these variants is higher in infertile patients. The aim of this study was investigate the correlation of chromosome polymorphic variants with infertile phenotype and its effect in IVF cycles outcome.
MATERIAL AND METHODS: We considered a total of 1551 cytogenetic studies involving infertile patients (n=866) and oocyte/sperm donors for the control group (n=685). Rate of aneuploid spermatozoa were evaluated using FISH in 145 infertile men. Outcome of IVF cycles were analyzed in 259 patients. RPL was defined as two or more miscarriages.
RESULTS: A statistically significant increase in the frequency of chromosome variants was observed in infertile patients (16.9% study group, 24.1% in RPL patients vs 12.8% controls; p<0.05). Significant differences were observed in rate of aneuploid spermatozoa between infertile men with and without polymorphisms (37,7% vs 16,3%; p<0.05). In the IVF cycles analyzed, biochemical and clinical miscarriage rates were higher in the group of patients without RPL carrying of polymorphisms compared with patients carrying of normal karyotype (35.6% vs 22.7% for biochemical miscarriage and 20.7% vs 9.8% for clinical miscarriage).
DISCUSSION: Higher frequencies of chromosomal variations are present in infertile patients compared with fertile population. Moreover, the presence of these variants is higher among patients with repeated pregnancy loss (RPL). Men carrying polymorphisms have a higher incidence of sperm aneuploidies. Moreover, the patients without RPL undergoing an infertility treatment have a higher incidence of miscarriage when are carriers of polymorphisms.

Correlation of 5-hydroxymethylcytosine-positive spermatozoa frequency in ejaculate with DNA integrity and head morphology

I. A. Galembo[1], *A. A. Pendina*[2,1], *O. A. Efimova*[2,1], *E. M. Shilnikova*[2,1], *I. D. Fedorova*[2], *A. V. Tikhonov*[1], *M. Mazilina*[1], *T. V. Kuznetzova*[2,1], *A. M. Gzgzyan*[2], *V. S. Baranov*[2,1];
[1]*Saint-Petersburg state university, Saint-Petersburg, Russian Federation,* [2]*D.O. Ott's Institute of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.*

Male gametes quality is essential for fertilization capacity and subsequent pre- and postimplantation embryogenesis. DNA integrity and correct chromatin epigenetic status are necessary for appropriate gamete function. Recently a new epigenetic marker was discovered - 5-hydroxymethylcytosine, which is a product of 5-methylcytosine oxidation by TET proteins.
We assessed correlation between rate of spermatozoa with fragmented DNA and rate of spermatozoa with hydroxymethylated DNA. Study group consisted of 3 sperm donors and 17 patients of IVF clinic. Semen analysis was performed according to WHO criteria. Sperm morphology was assessed using strict Kruger's criteria. Preparations were made from sperm samples fixed with ethanol:acetic acid (3:1). Spermatozoa with fragmented DNA were detected by TUNEL (CellDeath Detection kit, Roche). The rate of spermatozoa with fragmented DNA varied from 0,10% to 20,78% (n=2000 for each patient). The rate of spermatozoa with 5-hydroxymethylcytosine was evaluated after immunostaining of preparations with anti-5-hydroxymethylcytosine polyclonal antibodies (ActiveMotif). The rate of 5-hydroxymethylcytosine-positive spermatozoa in ejaculate of different patients ranged from 0,06% to 13,89% (n=5000 for each patient). The direct linear correlation between sperm DNA fragmentation and hydroxymethylation was found (r=0,40; P=0,048). Moreover the negative correlation was found between sperm DNA hydroxymethylation and the frequency of spermatozoa with morphologically normal head (r=-0,53; P=0,021).
Thus,the frequency of 5-hydroxymethylcytosine-positive spermatozoa is associated with markers of semen quality-DNA integrity and morphology of spermatozoa. This suggests that the rate of hydroxymethylated spermatozoa could be used as a new marker of semen quality.
Supported by RFBR, Administration of Saint-Petersburg,OPTEC grant and stipend from RF President

Assessment of genetic variations of DPY19L2 and DYDC1 in men with total globozoospermia

M. Sabbagian[1], *S. Yazdani Khah*[1], *M. Totonchi*[2], *A. Amiri Yekta*[2], *H. Hoseinifar*[1], *T. Modarresi*[1];
[1]*Department of Andrology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR,, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR,, Tehran, Islamic Republic of Iran.*

Background: Globozoospermia is a rare and severe type of teratozoospermia, characterized by round-headed spermatozoa lacking an acrosome. The pathogenesis of this anomaly is still unclear but genetic factors are likely to be involved. Recently, it has been shown that DPY19L2 deletion can be found in a vast majority of, but not all, globozoospermic patients, suggesting that probably other genes associated with the disorder. DYDC1 plays a crucial role during acrosome biogenesis and it is of particular interest in this context because of phenotypes in the null mutant mice that are very similar to human globozoospermia. The objective of this study was Assessment of genetic variations of DPY19L2 and DYDC1 in men with total globozoospermia.
Methods: 15 total globozoospermic men and 30 men with normal spermogram referred to Royan fertility and infertility Centre were included in the study. DPY19L2 deletion was assessed in men with total globozoospermia and noromozoospermic controls by performing both PCR of two exons and a long-range PCR across the deletion and then, sequenced the entire coding region of DYDC1 in the patients without DPY19l2 deletion.
Results: Our results showed that 73.3% of the patients (n=11) have DPY19L2 homozygous deletion. We did not find mutation in the coding regains of DYDC1 in other patients (n=4).
Conclusion: This study confirms that DPY19L2 is the major gene responsible for globozoospermia in Iranian men and also seems that there is no relationship between DYDC1 and globozoospermia in human.

Genetic analysis of gonadal disorders of sex development (46, XY DSD) by cytogenetic and molecular methods

J. Tavakkoly-Bazzaz[1], *A. Shojaei*[1], *P. Derakhshandeh-Peykar*[1], *R. Ebrahimzadeh-Vesal*[1], *M. Razzaghy-Azar*[2], *F. Behjati*[3];
[1]*Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Pediatric Endocrinology and*

Metabolism, Aliasghar Children Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran, [3]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran.

Among disorders of sex development (DSD) which result from abnormalities during gonadal determination and differentiation, there are especially rare forms such as 46, XY gonadal dysgenesis with mutations in SRY, NR5A1, DHH, DAX1 and WNT4 genes. Mutations of known genes are responsible for only a few percentages of these disorders and there are probably some other potential genes or loci that play a role in sexual disorders that are waiting for further analysis.
We recruited patients that were clinically suspicious for 46, XY gonadal dysgenesis. Cytogenetic analysis as well as the direct sequencing of the SRY, NR5A1and DHH genes was performed for all cases. MLPA technique was used to detect deletions and duplications in DAX1 and WNT4 genes and subsequent imbalances were confirmed by real time PCR. Additionally, other potential loci were investigated by whole genome Array CGH method.
One new chromosomal rearrangement and SRY deletion was found in one and five patients, respectively. Two heterozygous partial deletion and duplication were present in NR5A1 and WNT4 genes. Array CGH results confirmed the chromosomal rearrangement data and one partial deletion were detected in the SOX2OT gene.
Autosomal chromosome abnormalities could play a role in DSD. SRY gene deletion has a significant role in DSD and has a similar incidence in our patients compared with other reports. Del/dup mutations found to be more common than point mutations in our patients and might be preferred to check Del/dup mutations prior to point mutations. SOX2OT might have a potential role in gonadal dysgenesis.

Oligonucleotide-based array CGH analysis of blighted ovums

***A. A. Kashevarova**, N. A. Skryabin, T. V. Nikitina, I. N. Lebedev;*
Institute of Medical Genetics, Russian Academy of Medical Sciences, Tomsk, Russian Federation.

Approximately half of first trimester miscarriages have abnormal karyotype according to conventional karyotyping. However, some additional cases of pregnancy loss may be caused by non-visible submicroscopic chromosomal rearrangements. The role of microdeletions/microduplications is even more expected for blighted ovum (empty fetal sac) - the most severe form of miscarriage. We were aimed to search for unbalanced chromosomal aberrations and genes essential for proper embryo development in 10 blighted ovums specimens using SurePrint G3 Human CGH+SNP 4×180K Microarray Kit (Agilent Technologies, USA). All specimens were shown to have normal karyotype by conventional karyotyping. Three to eighteen unbalanced aberrations were detected in each of 10 miscarriages (altogether 95 CNVs). The size of aberrations varied from 726 bp to 26 Mbp. Using Gene Ontology enrichment analysis and visualization toolkit (GOrilla) for complex CNVs analysis we found that genes of gamma-aminobutyric acid signaling pathway were significantly represented in the CNVs affected genomic regions in blighted ovums ($p<0.00001$). It is unexpected because this pathway is essential for the central nervous system development and functioning. But taking into consideration that the number of genes normally expressed in the brain is the greatest in comparison with other tissues and that it is the brain which controls a variety of processes within the organism our funding is of particular interest. After benign CNVs were excluded using Database of Genomic Variants, the analysis of the remaining dataset showed the prevalence of DNA-dependent transcription factors group ($p<0.001$). This study was supported by grants of Federal Program N 8276 and 8720.

Importance of Preimplantation Genetic Screening (PGS) in the reduction of multiple pregnancies in *in vitro* fertilization (IVF) cycles

***A. Vereczkey**[1], Z. Kósa[1], S. Sávay[1], M. Csenki[1], L. Nánássy[1], B. Dudás[1], Z. Dömötör[2], D. Debreceni[2];*
[1]Versys Clinics Human Reproduction Institute, Budapest, Hungary, [2]Reprogenex Gene Diagnostic Laboratory, Budapest, Hungary.

In general, the live birth rate of assisted reproduction techniques (ART) ranges about 20% worldwide, while the rate of clinical pregnancies varies between 25-45%. One of the most recent achievements of the continuously improving techniques of assisted reproduction is preimplantation genetic testing, which serves to genetically analyze the embryos prior to their transfer into the uterus. Several randomized controlled trials analysed the outcome of embryo transfer upon the application of the newly introduced preimplantation genetics methods and verified already a significant increase in clinical pregnancy rates (60-79 %) and a major decrease in miscarriage rates (3.4-6.9 %). Furthermore, frequent genetic disorders (such as Down syndrome, Patau syndrome etc.) can be selected before embryo implantation, thus their prevalence could be decreased.
One of the major scopes of preimplantation genetic screening is however the reduction of multiple pregnancy rates in *in vitro* fertilization (IVF) cycles. The proportion of multiple pregnancies in IVF is 20-60% based on the data of several international studies; in Hungary the average rate of multiple pregnancies is 24.9% (10-54%).
The preimplantation genetic screening with microarray comparative genomic hybridization (aCGH) technique was first applied in Hungary at the Versys Clinics, Human Reproduction Institute. We have analyzed more than 430 embryos and had more than 100 embryos transferred since 2011. PGS provides the possibility of selecting and transferring only euploid embryos, therefore can we perform mostly single embryo transfers (SET). Here we present about the strategy of decreasing multiple pregnancy rate with SET following preimplantation genetic screening.

Early diagnosis of a boy with adrenoleukodystrophy due to the ABCD1 gene mutation and prenatal genetic diagnosis of his sibling for bone marrow transplantation.

***Y. Saglam**[1], M. Ortanc[1], H. Karadayı[1], K. Ulucan[2], O. Baltaci[1];*
[1]Goztepe Medical Park Hospital, Department of Medical Genetics, Istanbul, Turkey, [2]Üsküdar University, Faculty of Engineering and Natural Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey.

Introduction: Adrenoleukodystrophy is an X-linked disorder (X-ALD) which is due to the mutations in the *ABCD1* gene. These mutations result in the defect of peroxisomal beta oxidation and leading to the accumulation of saturated very long chain fatty acids (VLCFA) in body tissues. The clinical menifestations of the disorder occur primarily in the adrenal cortex, the myelin of the central nervous system, and the Leydig cells of the testes. In this report, we analyzed the *ABCD1* gene of a boy whose uncle died because of the same disease.
Material- Method: The patient was diagnosed as X- ALD due to high serum amounts of VLCFA together with pristanic and phytanic acids. PCR- sequencing methodology was used in order to confirm the disease and identify *ABCD1* gene mutations. Amplification of the whole coding regions including exonic- intronic boundaries were assessed by using spesific primers and sequenced directly (ABI Prism 3100 Genetic Analyzer).
Results: Sequencing process revealed that the examined boy carries c.G1202A (p.R401A) mutation in the *ABCD1* gene and his hemizygous mother has the same mutation as heterozygous and therefore, she is carrier.
Discussion: In addition to biochemical analysis, genetic testing is required in determining the correct diagnosis to genetic diseases. *ABCD1* genetic analysis revealed that the boy is X- ALD and needs a bone marrow transplantation. Prenatal genetic diagnosis was assessed for HLA identical baby and his mother is pregnant for his sibling.

Investigating autosomal recessive gene defects in severe oligospermic and azoospermic infertile men

***G. Girgin**[1], A. A. Özdemir[2], G. Koç[1], B. B. Türköver[3], C. Akbal[4], A. I. Güney[1];*
[1]Marmara University, Department of Medical Biology and Genetics, Istanbul, Turkey, [2]Zeynep Kamil Women's and Children's Hospital, Department of Urology, Istanbul, Turkey, [3]Zeynep Kamil Women's and Children's Hospital, Department of Genetics, Istanbul, Turkey, [4]Marmara University, Department of Urology, Istanbul, Turkey.

Infertility is a serious public health issue and studies show out of every 100 couples, 15 are infertile. Furthermore; 50% of these infertile couples suffer from male factor infertility. Although many factors on sperm structure and functions have been investigated including environmental factors, ethiologies of many infertility cases are yet to be enlightened. From the genetic point of view, chromosome abnormalities and genetic mutations are important causes of male infertility. The aim of this study is to detect autosomal

recessive genetic mutations in oligospermic and azoospermic infertile men. Patients included in the study were required to fill special survey forms not only to exclude environmental factors, but also to choose patients with consanguineous marriages or patients with at least 2 infertile people in their family. Blood samples of 20 Turkish men; 6 of whom were azospermic, and 14 severe oligospermic, were evaluated using array technology. Several genes in the "Spermatogenesis-associated protein" SPATA family, "Sperm-associated antigen" (SPAG1, SPAG4, SPAG5, SPAG8, SPAG9, SPAG11A / SPAG11B, SPAG16) genes, "Sperm acrosome-associated protein" (SPACA3, SPACA4) genes, as well as a few other genes known to play roles in spermatogenesis were found to be defective. These results will guide physicians in genetic consultation and in choosing the best assisted reproductive therapy.

About 46,XY DSD: A rare mutation of the ligand-binding domain of the AR protein in three Tunisian sisters with complete androgen insensitivity syndrome

N. B. ABDELMOULA[1], *R. Louati*[1], *M. Zenker*[2], *T. Rebai*[1];
[1]*Medical University, Sfax, Tunisia,* [2]*Institute of Human Genetics University Hospital Magdeburg, Magdeburg, Germany.*

The androgen insensitivity syndrome (AIS) is an X-linked recessive disorder in which affected males have female external genitalia, female breast development, blind vagina, absent uterus and female adnexa, and abdominal or inguinal testes, despite a normal male 46,XY karyotype. Mutations in the androgen receptor (AR) gene cause the AIS by impairing androgen-dependent male sexual differentiation to varying degrees. Thus they are associated with a variety of phenotypes, ranging from CAIS to PAIS or men with infertility. Through AR gene mutations Database (http://androgendb.mcgill.ca), AR gene mutations reported until 2012 overtake 1000.
Here we report a rare AR mutation in three Tunisian sisters presenting with all of the characteristics of CAIS. This Tunisian consanguineous family from Sfax town is composed of three daughters suffering from primary amenorrhea and one healthy son. DNA analysis was carried out by direct sequencing of PCR-amplified exonic fragments of the AR gene. A c.3474C>T substitution in exon 6 of the AR gene leading to a missense mutation p.(Arg787*) in the ligand-binding domain (LBD) of the AR protein, was confirmed in the three sisters as well as in their mother who was heterozygous for the mutation.
This mutation resulted in a truncated form of the receptor including a major part of the C-terminal LBD which is not only involved in binding to androgen, but also involved in binding of coactivator proteins and dimerization.
This mutation is a rare variant associated with CAIS and was described only three times. Furthermore, it was described in association with prostate cancer twice.

The outcome of prenatal diagnostics in pregnancies with increased risk for chromosomal abnormalities

O. Miljanovic[1], *M. Bulatovic*[1], *T. Ostojic*[1], *S. Raspopovic*[2], *D. Likic*[3], *T. Dakic*[1], *S. Teofilova*[1];
[1]*Centre for medical genetic and immunology, Clinical centre of Montenegro, Podgorica, Montenegro,* [2]*Gynecology and Obstetric Clinic, Clinical Centre of Montenegro, Podgorica, Montenegro, Podgorica, Montenegro,* [3]*Institute for public health of Montenegro, Podgorica, Montenegro, Podgorica, Montenegro.*

Chromosomal abnormalities (HA) still remain a remarkable challenge, with prenatal detection and pregnancy termination, as the most effective negative eugenic method. The aim of this study was to evaluate the outcome of 10 years invasive prenatal diagnostics (2002-2012yr). A total of 3227 pregnant woman with increased risk to fetal HA were referred to pre-testing genetic counseling. Invasive prenatal diagnostics was provided for all (2747 amniocenteses and 181 chordocenteses), except 229 (9%) women, who refused the indicated diagnostics. Fetal karyotype was analyzed using GTG banding method. The fetal loss after invasive prenatal diagnostic was 0.27%, all after amniocentesis.
Advanced maternal age was the most frequently recognized risk factor for fetal HA (58%), followed by abnormal ultrasound findings, abnormal maternal serum screening and parental balanced translocations. Abnormal karyotypes were ascertained in 76 (2.6%) of all performed cytogenetic analyses. Aneuploidies were the most frequent HA (83%), predominantly trisomy 21 (49%), and followed by trisomy 18 (21%), gonosomal trisomias/monosomy X (11%, 8% respectively), trisomy 13 (6%), and others (5%). Unbalanced structural aberrations were found in 13 (17%) fetuses, as "de novo" event or resulted from parents' reciprocal/Robertsonian translocation. Balanced structural rearrangements and polymorphisms were found in additional 31 (1%) of all fetal karyotypes, and pregnancies were continued. After comprehensive and detailed genetic counseling, an option for pregnancy termination was offered in all cases of fetal abnormal karyotipe (except XYY status), and was accepted in 96%. Gonosomal aneuplodies presented a particular challenge for genetic counselor, requesting more delicate counseling, including covering some ethical issues.

Prenatally diagnosed case of mosaic trisomy 13 associated with Currarino triad

A. Vičić[1], *B. Mišković*[1], *P. Korać*[2,3], *D. Jandrić*[1], *F. Stipoljev*[1];
[1]*Clinical Hospital „Sveti Duh", Zagreb, Croatia,* [2]*University Hospital „Merkur", Zagreb, Croatia,* [3]*Faculty of Science, University of Zagreb, Zagreb, Croatia.*

Currarino triad, also known as Currarino syndrome, is a complex of congenital caudal anomalies characterized by anorectal malformation, sacral bone abnormality and presacral mass. Currarino syndrome was first described in 1981, however its genetic basis still remains unclear. Although, mutations in the *HLXB9* gene were found in almost all cases of familial Currarino syndrome, they are present in less than 30% of patients with sporadic Currarino syndrome. To date, only few reports on genetic causes in cases of sporadic Currarino syndrome have been published.
Herein, we present prenatally detected case of Currarino triad associated with mosaic trisomy 13. A 32-year-old woman, G1P0, was referred to our hospital because of suspected fetal urogenital anomalies. Ultrasonic examination at 20 weeks gestation showed sacral bone defect, low presacral unechogenic mass of irregular shape, bilateral hydronephrosis, megaureters and urinary bladder with hypertrophied bladder wall and "keyhole sign". Amniocentesis was performed, and cytogenetic analysis revealed a female karyotype with 89% of trisomic cells. Parents elected to terminate the pregnancy, and pathological examination showed imperforate anus, kidneys with markedly dilated renal pelvis, distended urinary bladder, and cystic mass histologically identified as immature teratoma. The sacral bone was undeveloped and coccygeal was missing. Trisomy 13 mosaicism was confirmed in cultured skin fibroblasts and fetal cord blood lymphocytes.
Since our case is the fifth report on association of trisomy 13 and Currarino triad, it supports the idea that trisomy 13 in mosaic form could be involved in etiopathogenesis of sporadic cases of Currarino triad complex.

Fanconi anemia (FA) is a rare genetic disorder characterized by variable congenital anomalies, progressive bone marrow failure, and high predisposition to acute leukemia.
This study describes successful molecular diagnosis and subsequent prenatal diagnosis of FA in a Tunisian consanguineous family.
The index case, was an 8-year-old girl with typical clinical features of FA and born to first-cousins healthy parents. Physical examination of the younger sister has shown skeletal anomalies. Thus, the diagnosis of FA was suspected. According to sensitivity to MMC, the index case and the younger sister were diagnosed as FA. The parents requested prenatal diagnosis during the actual pregnancy.
Genotyping analysis using four markers flanking the FANCA gene was carried out using DNA from parents, the unaffected older sister, the affected younger sister and foetal DNA obtained from amniotic fluid at a gestational age of 16 weeks. Multiplex ligation-dependent probe amplification (MLPA) was performed in order to confirm cytogenetic and genotyping results. Haplotype analysis showed that the affected members present the founder haplotype at a homozygous state whereas the fetus shows a different haplotype likely segregating with the normal alleles. These results were confirmed by MLPA analysis that revealed a total deletion of exon 15 for the affected

child while this mutation was absent in the fetus showing that he is unaffected and is not at risk of developing FA.
The present study is the first report of molecular testing that was successfully applied for prenatal diagnosis of FA in Tunisia and in North Africa.

Revealing genetic reasons for fetal death by combining new and old methodology: three different cases

K. Piippo[1], *K. Kiiski*[1], *K. Jairus*[2], *O. Kostina*[2], *H. Kokkonen*[3], *M. Mäntymaa*[4], *R. Salonen*[5], *N. Horelli-Kuitunen*[1];
[1]*United Medix Laboratories Ltd., Helsinki, Finland,* [2]*Nova Vita Klinik AS, Tallinn, Estonia,* [3]*Nordlab, Oulu, Finland,* [4]*Kymenlaakso Central Hospital, Kotka, Finland,* [5]*Norio Centre, Rinnekoti Foundation, Helsinki, Finland.*

Fetal death can occur for different reasons in any gestational age. The reason behind fetal death is important to resolve for information of the parents and estimation of recurrence risk. We report three cases where different methods were combined to unravel the genetic reason behind fetal death or abnormality.
Case 1: a monochorial twin pregnancy where both fetuses died in utero h23+5. Prenatal BoBs (PNBoBs) from placental sample showed a duplication of the chromosomal region 15q11. Genomic microarray analysis (GMA) showed trisomy 15. Karyotype of cultured cells was 47,XX,+15[1]/46,XX[8]. Thus, a mosaic trisomy 15 was detected in the placenta.
Case 2: a monochorial twin pregnancy where fetus B died in utero h36+5. A skin sample was studied by PNBoBs that showed a duplication of the region 22q11. Karyotype was unavailable due to absent cell growth. GMA confirmed a 2,8 Mb duplication of 22q11.21. Also, dup(22)(q11.21) was shown in peripheral blood of twin sister by PNBoBs.
Case 3: an abnormal karyotype 46,XX,?i(18q) in amniotic fluid sample (NT:4,39; T18-risk: 1:68). The pregnancy was terminated. GMA from fetal skin sample showed duplication of 18q12.1-18qtel and deletion of 18p11.32-18ptel while cell culture failed. Mother had an abnormal karyotype 46,XX,inv(18)(p11.32q12.1). Thus the fetus had inherited der(18) rising from inversion chromosome 18 from the mother. She has increased risk for unbalanced chromosome rearrangement also in future pregnancies.
To conclude, PNBoBs and GMA are valuable methods in revealing genetic reasons for fetal death or abnormality especially when cell culture is not successful, and in detecting submicroscopic aberrations.

First trimester screening - beyond trisomy 21, 18 and 13.

V. Curtisova*, I. Dhaifalah, J. Hyjanek;*
Department of Human Genetics and Fetal Medicine, Fakultní nemocnice Olomouc, Olomouc, Czech Republic.

First trimester screening is primarily used to establish the risk for trisomy 21, 18 and 13 in a fetus. If the risk exceeds an agreed threshold an invasive procedure is recommended and the karyotype of the fetus is ascertained. During the screening procedure and subsequent karyotyping other abnormalities apart from trisomy 21, 13 and 18 can be diagnosed. We reviewed all cases of first trimester screening performed in our department in 2010 and 2011; in total 5690 women were tested. Abnormal findings were encountered in 65 fetuses (1 in 87) - trisomy 21 and 18 (no trisomy 13 was found) in twenty three fetuses (35.4%) and other abnormalities (other chromosomal abnormalities, congenital abnormalities without abnormal karyotype, or NT above 3.5 mm without abnormal karyotype or other congenital abnormality) in forty two fetuses (64.6%). Trisomy 21 and 18 represented just over a third of abnormal findings encountered during the first trimester screening.

Men with LOC203413 minor T allele have an increased risk for impaired spermatogenesis

P. Noveski[1], *M. Mirchevska*[1], *T. Plaseski*[2], *B. Peterlin*[3], *D. Plaseska-Karanfilska*[1];
[1]*Macedonian Academy of Sciences and Arts, Research Center for Genetic Engineering and Biotechnology „Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Clinic of Endocrinology and Metabolic Disorders, Faculty of Medicine, Skopje, Macedonia, The Former Yugoslav Republic of,* [3]*Institute of Medical Genetics, University Medical Center Ljubljana, Ljubljana, Slovenia.*

Association studies have shown that a number of gene polymorphisms modulate the efficiency of spermatogenesis. Previously, we have investigated the association of male infertility with nine single nucleotide polymorphisms (SNPs) in eight different genes: FASLG, JMJDIA, LOC203413, TEX15, BRDT, OR2W3, INSR and TAS2R38 among two ethnic groups from the R. Macedonia. This study showed an association of rs5911500 in LOC203413, rs3088232 in BRDT and rs11204546 in OR2W3 gene with azoospermia and/or oligozoospermia in Macedonian and/or Albanian males. Here, we present an association study of the nine SNPs in 242 infertile men (82 azoospermic and 160 oligozoospermic) and 116 fertile men from Slovenia. The methodology included multiplex PCR/SNaPshot analysis, followed by capillary electrophoresis on ABI3130 Genetic Analyzer. Only two SNPs were found in association with male infertility among Slovenian men with borderline statistical significance; rs34605051 in JMJDIA gene was associated under the dominanat model, while rs2059807 in INSR gene showed an association under the recessive model. Although the difference was not statistically significant, the LOC203413 minor T allele was found with higher frequency among infertile Slovenian men (22.7%) when compared to the fertile controls (17.2%). When all three populations (Macedonian, Albanian and Slovenian) were analyzed together, statistically significant association was observed for the rs5911500 in LOC203413 (OR 1.73, 95% CI 1.14-2.62; p=0.0090) with male infertility. In conclusion, the association study of a total of 644 infertile men with azoospermia and oligozoospermia from three different ethnic populations shows that men with LOC203413 minor T allele have an increased risk for impaired spermatogenesis.

Does inbreeding lead to decreased Tunisian human fertility?

W. Hammami[1], *O. Kilani*[1], *W. Ayed*[1], *M. Ben Khelifa*[1], *N. Ben Halim*[2], *S. Abdelhak*[2], *A. AMOURI*[1];
[1]*Cytogenetics Department and Laboratory of Biomedical Genomics and Oncogenetics, Institut Pasteur de Tunis, Tunis, Tunisia,* [2]*Laboratory of Biomedical Genomics and Oncogenetics, Institut Pasteur de Tunis, Tunis, Tunisia.*

Although a high proportion of marriages in Tunisia are consanguineous there are very few reports about the association between consanguinity and fertility.
In the present study, one hundred and four infertile male patients and 100 fertile male attending the department of Cytogenetics of the Pasteur Institute of Tunis were asked if they are born from consanguineous parents and if they are married to close biological relatives.
Infertile patients were more likely than controls to report first-degree (parental) and second-degree (grandparental) consanguinity. Men with azoospermia and severe oligospermia showed high rates of both consanguinity and family clustering.
This study demonstrated a significant association between consanguinity and family clustering of male factor infertility cases, suggesting a strong genetic component.

Mutational analysis of MED12 exon 2 in uterine leiomyoma in patients from North-West of Russia

N. S. Osinovskaya[1], *T. E. Ivashchenko*[1], *V. F. Bezhenar*[1], *A. K. Dolinskiy*[1], *I. U. Sultanov*[1], *V. S. Baranov*[1], *S. A. Gembovskaya*[2], *E. P. Hoffman*[2], *A. A. Tscypurdeeva*[1];
[1]*Ott's Institute of Obstetrics & Gynecology, Russian Academy for Medical Sciences, St.Petersburg, Russian Federation,* [2]*Research Center for Genetic Medicine Children's National Medical Center 111 Michigan Ave NW Washington DC 20010, Washington, DC, United States.*

Uterine leiomyomas arise from smooth muscle tissue in majority of women at the age of 45. MED12, encodes the 12th subunit of the Mediator complex, implicated in transcriptional regulation. The mutations in exon 2 of MED12 gene were identified in 70% of sporadic uterine leiomyomas. The mutation hot spot affected an evolutionary conserved region of the MED12 protein. DNA samples of 25 tumours from 15 patients with uterine leiomyoma from North-West of Russia have been analyzed by sequencing of exon 2 in MED12 gene. MED12 mutations were identified in 62% cases (16/25) with almost half of them (27%) were mutations in codon 44 of MED12 gene. Seven leio-

myomas (27%) displayed an exonic insertion-deletion mutation, one (4%) was represented by missens mutation in codon 36 and one (4%)- by somatic intronic T to A mutation eight base pairs upstream of the splice exon 2 acceptor site. No exon 2 mutations of MED12 were found in DNA samples isolated from the peripheral blood of the same patients thus proving somatic origin of MED12 mutations. The finding of two different mutations in the same leiomyoma tissues registered in two cases favors the origin of these mutations after separation of myoma cell clones. Our data are in line with other studies, proving substantial impact of exon 2 MED12 gene mutations in the origin and development of leiomyomas. Regular origin of these mutations in specific locus of particular gene and its actual contribution into molecular pathogenesis of leiomyoma remains obscure and requires further studies.

Noninvasive screening method for fetal gender determination in pregnancies at risk for Duchenne muscular dystrophy

A. M. Stan[1,2], *C. Dragomir*[1], *E. Severin*[2], *M. Badila*[1], *D. Tudor*[1], *I. Rujan*[1], *I. Visanoiu*[1], *A. Ratiu*[1,3], *D. Stefanescu*[1], *L. Savu*[1];
[1]*Genetic Lab S.R.L., Bucharest, Romania,* [2]*University of Medicine and Pharmacy, Bucharest, Romania,* [3]*Faculty of Biology, University of Bucharest, Bucharest, Romania.*

Introduction: The fetal sex determination at an early gestational age is of most importance for pregnant women carrying an X-linked recessive chromosomal abnormality. The identification of a male fetus indicates hemizygosity for the X chromosome and thus potential diseases such us Duchenne muscular dystrophy. Our aim was to demonstrate the applicability of the noninvasive fetal (NIPD) gender screening procedure in clinical practice of pregnancies at risk for Duchenne muscular dystrophy.
Materials and Methods: We applied a method based on PCR and high-resolution capillary electrophoresis for fetal gender determination from maternal plasma aiming two Y specific sequences - SRY and DYS14. Two pregnant women with extended deletion in the DMD gene were tested noninvasively. For prenatal DMD gene analysis we used the SALSA MLPA kit P034-A2/P035-A2 DMD/BECKER (MRC Holland).
Results: This NIPD protocol for fetal gender determination was applied in two cases with long histories regarding the DMD gene heritability. In the first case, the pregnant woman was a heterozygous carrier for the exons 51-55 deletion and in the second case for the exons 30-43. The NIPD gender screening showed a female fetus in the first case and we eliminate de invasive sampling procedure. For the second case we detected a male fetus, the invasive DMD gene test was performed and the result was negative for the 30-43 deletion.
Conclusion: The pregnancy management in the case of DMD-carrier mothers can be improved by this NIPD screening approach for fetal gender determination.

Preimplantation genetic diagnosis (PGD) for sixteen translocation carriers by FISH and clinical outcomes

Z. Yilmaz Celik[1], *B. Haydardedeoglu*[2], *H. B. Zeyneloglu*[2], *F. I. Sahin*[1];
[1]*Baskent University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey,* [2]*Baskent University Faculty of Medicine Department of Obstetrics and Gynecology, Ankara, Turkey.*

The incidence of balanced chromosome abnormalities including mostly reciprocal or Robertsonian translocations is approximately 4-5% in couples with recurrent miscarriage. Genetically unbalanced gametes can be produced through meiotic segregation in these couples. Pre-implantation genetic diagnosis (PGD) provides the detection of chromosomal abnormalities and their exclusion before embryo transfer in assisted reproductive techniques. In this study, we reviewed 24 cycles of PGD in 16 couples with balanced translocations (5 Robertsonian, 11 Reciprocal) and analyzed pregnancy outcomes and the meiotic segregation mode of gametes of the translocation carriers using fluorescent in situ hybridization (FISH). PGD couples had either one or two blastomeres biopsied from all embryos with ≥7 blastomeres on day 3 post oocyte collection. These blastomeres were assessed for the specific chromosome rearrangement using FISH. Clinical outcomes were assessed retrospectively. We found that 34 of 117 embryos (29.05%) were normal or balanced. Five couples had no normal or balanced embryos and transfer process were cancelled. Twelve clinical pregnancies (50%), including four spontaneous abortions (33.3%) and one ectopic pregnancy were established. Four pregnancies resulted in healthy babies with normal or balanced karyotypes, others are being followed. Our results suggested that specific probes of part of translocation chromosomes used for PGD beneficial for translocation carrier couples by reducing the risk of miscarriage and avoiding a pregnancy with an unbalanced form of the translocation. Besides these advantages, this method is technically limited for the detection of other potential chromosome anomalies at the same time.

Prenatal genetic diagnosis of a case whose sibling is a CRLF1 related Crisponi syndrome

Y. Saglam[1], *M. Aydogan*[2], *K. Ulucan*[3], *H. Karadayı*[1], ***M. Ortanc***[1];
[1]*Goztepe Medical Park Hospital, Department of Medical Genetics, Istanbul, Turkey,* [2]*Medipol Hospital, Department of Orthopedics, Istanbul, Turkey,* [3]*Üsküdar University, Faculty of Engineering and Natural Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey.*

Introduction: Crisponi sydrome (CS; 601378), is caused by homozygous or compound heterozygous mutation in the cytokine receptor- like 1 (CRLF1) gene (604237) that is located on chromosome 19p12. CS is inherited in an autosomal recessive manner and characterized with busted sucking and swallowing resulting in poor feeding that drives individuals to medical intervention during neonatal life. In this study, we report a girl with CS, whose mother is pregnant to a prenatally genetic diagnosed embryo.
Material- Methods: *CRLF1* mutation analyzes were assessed in the effected girl and in her parents who have consanguinity. Peripheral blood samples were used as DNA sources, QIAamp DNA Blood Mini Kit was used for extraction. 9 of the exons, including intronic boundaries, were amplified and sequenced directly (ABI Prism 3100 Genetic Analyzer).
Results: We detected a homozygous duplication, c.713dupC, leading a asparagine to alanine substitution (p.P239Afsx92) in exon 5 of the girl. Her parents had the same duplication as heterozygous.
Discussion: *CRLF1* gene is accepted as an causative factor for CS. Scoliosis was the additional menifestation of the disease in our patient. To date, there are not adequate number of studies reporting c.713dupC homozygous mutation in CS patients. Her mother is pregnant to her sibling, who was prenetally screened and now mother has a healhy pregnancy. As a conclusion, we suggest to analyse *CRLF1* gene for genetic counselling or for preimplantation genetic diagnosis for releated diseases.

Evidence for association of the rs605059 polymorphism of the HSD17B1 gene with recurrent spontaneous abortions

K. Lamnissou[1], *P. Ntostis*[1], *K. Agiannitopoulos*[1], *K. Pantos*[2];
[1]*Dept of Genetics & Biotechnology, University of Athens, Athens, Greece,* [2]*Genesis Athens, In Vitro Fertilization Clinic, Athens, Greece.*

Objective: Estrogen production and levels of circulating estrogen are markedly increased during pregnancy. The HSD17B1 gene product, enzyme 17β-hydroxysteroid dehydrogenase type 1, mainly regulates the biological activity of specific steroid hormones by catalyzing their conversion. We investigated whether the rs605059 polymorphism of the HSD17B1 gene is related to an increased risk of recurrent spontaneous abortions (RSA).
Material and Methods: The study group consisted of 138 women with three or more unexplained spontaneous abortions, before the 20th week of gestation, while 140 women with at least two live births served as controls. All individuals were Greeks. For genotyping the subjects we used the PCR- RFLP method.
Results: The observed frequencies for AA, GA and GG genotypes were 0.18, 0.52, 0.30, respectively, for the patient group and 0.32, 0.49, 0.19, respectively, for the control group. The A allele frequencies were 0.45 and 0.57 for the patient and control group, respectively, while the G allele frequencies were 0.55 and 0.43 for the patient and control group, respectively. Statistical analysis of these results revealed significant differences in genotype and allele frequencies between the patient and control group.
Conclusions: The rs605059 polymorphism of the HSD17B1 gene has

been found to be strongly associated with RSA. Thus the G allele of this polymorphism could be considered as a risk factor for RSA in our population.

Combined QF-PCR and subtelomere MLPA molecular analysis for the detection of chromosomal abnormalities in early spontaneous miscarriages

G. Bozhinovski[1], *I. Maleva*[1], *K. Kubelka*[2], *D. Plaseska-Karanfilska*[1];
[1]*Macedonian Academy of Sciences and Arts, Research Centre for Genetic Engineering and Biotechnology "Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Private Hospital "Adzibadem-Sistina", Skopje, R. Macedonia, Skopje, Macedonia, The Former Yugoslav Republic of.*

A miscarriage affects 10-15% of all clinically recognized pregnancies. Chromosomal abnormalities are the underlying cause in 40-50% of the miscarriages. The vast majority of the chromosomal abnormalities are numerical aberrations, of which trisomies are the most common, followed by polyploidies and monosomies. Conventional karyotyping is hampered by the high rate of culture failures and maternal cell contamination. Several studies have shown that molecular approach is an efficient and cost-effective diagnostic testing strategy for miscarriage products. The aim of this study was to evaluate the usefulness of a molecular strategy, involving quantitative fluorescent polymerase chain reaction (QF-PCR) and subtelomere multiplex ligation probe amplification (MLPA) for the detection of chromosomal abnormalities in early spontaneous miscarriages. The multiplex QF-PCR, including 17 STR markers on the chromosomes 13, 18, 21, X and Y was performed by in-house method, while MLPA was performed with commercial kits from MRC Holland (P036 and P070). A total of 86 spontaneous miscarriage product samples were studied. QF-PCR results showed that ten miscarriage samples (11.62%) were contaminated with maternal tissue. Chromosomal abnormality was detected in 38 samples (50%). The most frequent abnormality was trisomy 16 (37.84%), followed by Turner syndrome, trisomy 22 and trisomy 14 (10.81% each), trisomy 21 (8.11%), trisomy 18 (5.41%), trisomy 4, trisomy 7, trisomy 8, trisomy 10, trisomy 15, monosomy 21 and triploidy (2.70% each). No chromosomal abnormality was detected among 33 control artificial abortion samples. We conclude that QF-PCR and subtelomere MLPA is a suitable strategy for routine chromosome analysis of spontaneous miscarriages.

A Unique Case: Prenatal Diagnosis Of Paternal UPD (18)

O. Ozer, *A. Koc, C. Gezer, A. Ekin, S. Kurtulmus;*
Tepecik Training and Research Hospital, Izmir, Turkey.

Uniparental disomy (UPD) is a genetic condition which describes inheritance of two homologue chromosomes/chromosome pairs from a single parent. Aberrant dosage of genes regulated by genomic imprinting and homozygosity of a recessive mutation are most important issues as a consequence of UPD. This atypical pattern of inheritance could be detected by newly developed technologies such as STR analysis. We report a patient which was referred to our department for prenatal diagnosis because of abnormal biochemical screening test results. QF-PCR test were performed from amniotic fluid samples for rapid aneuploidy screening. There was no numerical abnormality for 13, 21 and sex chromosomes. Although, all screening markers for chromosome 18 were uninformative. We used FISH test to exclude monosomy 18 and test results were compatible with disomy 18. Parental QF-PCR analysis was showed paternal UPD (18). Chromosome analysis from amniotic fluid was revealed normal karyotype. Results were discussed with family in several genetic counseling sections and they decided to continue pregnancy. The child, who has been followed up until the first year, is healthy and normal. According to our knowledge, this is the first prenatal case with paternal UPD (18). Detection of findings with unknown significance in prenatal diagnosis complicates the management of pregnancy. We believed that our case and diagnostic algorithm would be important and guiding for further management of such complex cases.

AZFc partial deletions are commonly associated with Y-chromosome N-haplogroup and R1a1-haplotypes among infertile men from Ukraine

H. Makukh[1], *M. Tyrkus*[1], *V. Cherepanin*[2], *S. Gavrulushun*[3], *O. Hnateyko*[1];
[1]*State institution "Institute of Hereditary Pathology of Academy of Medical Science of Ukraine", Lviv, Ukraine,* [2]*Prycarpatian Center of Human Reproductions, Ivano-Frankivsk, Ukraine,* [3]*Lviv regional center of reproductive health of the population, Lviv, Ukraine.*

The relationship between Y-chromosome haplotypes with diversity and historic-ethnographical aspects as well association with the some conditions has been extensively studied. Heterogeneous phenotypes are associated with partial AZFc deletion and their role as a risk factor for impaired sperm production is unsettled because of controversial data for different populations. The purpose of the study to analyze Y chromosome haplotypes pattern in cohorts of fertile and infertile men of Ukrainian origin with and without AZFc partial deletions

Among 350 males with idiopathic spermatogenesis disturbance 28 (8.0%) were detected to have different types of AZFc partial deletions but in no one among control group (0/100) ($p<0.01$). 19 different Y chromosome haplotypes were identified among studied groups of Ukrainian men. The most frequent are R1a1 (18%), R1a1a (18%) and I2a (19%). Over 50% of males from both studied groups belong to haplogroup R. The Y-chromosome haplotypes were differentiated depending on the presence and the type of Y-chromosome AZFc partial deletions. The accessory haplogroup N was established only in patients with b2/b3 AZFc partial deletions. In contrast, 8 out of 10 men (80%) with gr/gr partial deletions belonged to haplotype R1a1, which was not identified among fertile males of control group. These results point to the following association: haplogroup N increases the risk of b2/b3 partial deletions (OR=11.05, 95% CI: 1.21-101.2, p=0.019), and the presence of R1a1 haplotype increases the risk of gr/gr partial deletion of AZFc region (OR = 20.09, 95% CI: 2.44 - 165.57, p=0.0004).

Complex chromosomal rearrangements in a patient with oligozoospermia and Charcot-Marie-Tooth disease

G. J. Braathen[1,2,3], *V. Haugan*[2], *A. G. F. Helland*[2], *K. O. Clausen*[2];
[1]*Faculty Division Akershus University Hospital, Oslo, Norway,* [2]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway,* [3]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway.*

BackgroundComplex chromosomal rearrangements (CCR) occurring in phenotypically normal persons are rare, about 255 cases have been reported. Most familial cases have a normal phenotype with apparently balanced rearrangements while de novo cases usually are unbalanced or apparently balanced but with associated multiple anomalies as well as mental retardation. **Method**A couple with fertility problems was investigated. He had oligozoospermia and Charcot-Marie-Tooth disease.

ResultsChromosomal analysis and fluorescence in situ hybridization with whole chromosome paint revealed that he had apparently balanced translocation between chromosome 2, 7 and 14. Array comparative genomic hybridization was normal.

ConclusionTo our knowledge, this is a new case of CCR identified in the human population and the first time a CCR is identified in a patient with CMT.

"High Risk" maternal serum screen and adverse pregnancy outcome

K. Godbole, *A. Kulkarni, M. Moghe, G. Godbole, A. Kanade, A. Wakankar, P. Kulkarni;*
Deenanath Mangeshkar Hospital, Pune, India.

Aim: To compare adverse obstetric (PIH and oligohydramnios) and neonatal outcomes (prematurity, low birth weight, NICU admission) in women screened "high risk" or "low risk" for chromosomal aneuploidy by maternal serum screening and to find association between individual serum marker (PAPP-A, beta hCG (measured in the 1st trimester), AFP, UE3 and beta hCG (measured in the 2nd trimester) and adverse obstetric and/or neonatal outcome.

Methods: Records of delivered women who underwent maternal serum screening (1st trimester or second trimester) for chromosomal aneuploidy were studied retrospectively. Women undergoing invasive procedure wit-

hout fetal chromosome anomaly were grouped as "High risk" (n=111) while others were grouped as "low risk" (n=157).
Results: "High risk" women were older compared to the controls (31.5+ 4.7 & 29.1+ 3.9 yrs respectively, p<0.005) but did not differ significantly for parity. They experienced high risk for PIH [OR=2.15 (CI: 1.05-4.41)], oligohydramnios [OR=4.07 (CI: 1.70-9.75)] and prematurity [OR= 2.05 (CI: 1.10-3.83)] as well as LBW [OR= 2.12 (CI: 1.12- 4.01)] as compared with 'low risk' women, after adjusting for age. Birth weight was positively correlated with PAPP-A (r=0.274, p<0.05) and inversely with free beta hCG measured in the 1st trimester (r= -0.243, p<0.05) while the second trimester beta hCG was inversely associated with oligohydramnios (r=-0.30, p<0.05) and birth weight (r=-.0.24, p<0.05) after controlling for age.
Conclusion: It might be worth following all women with "high risk" screen for early detection and timely intervention to avoid obstetric and neonatal complications.

J19.32
Preimplantation genetic testing of balanced translocation by haplotyping analysis in Gennet.

***I. Soldatova**, L. Krautová, M. Hejtmánková, M. Brandejská, J. Míka, D. Stejskal, M. Putzová;*
GENNET, Prague, Czech Republic.

In 2012, we first performed pre-case haplotyping (PGH) and subsequent preimplantation genetic diagnosis (PGD) of embryos in family with balanced structural aberration of chromosomes 13 and 21. We present atypical case in which affected embryos may not be unambiguously determined by cytogenetic analysis using standard FISH probes due to hybridisation problems.
In presented case, male partner was carrier of *de-novo* balanced structural aberration t(13;21)(q14.1;q22.1). Pre-case haplotyping (PGH) was concluded, based on analyses of STR markers located on the long arms of chromosome 13 and 21, in both partners and mother of the male partner.
During the IVF cycle haplotyping technique by multiplex PCR was used on products of multiple displacement amplification (MDA) from one blastomere biopsied from the cleavage-stage embryo on the day 3. In rare cases of ambiguous result from the blastomere, analysis may be repeated from trophectoderm and embryo is still managed to be transferred on the day 5.
During the PGD analysis we excluded from transfer embryos, carrying either trisomy, or monosomy of tested parts of chromosome 13 or 21. IVF cycle with PGD was performed in January 2013: 7 COCs were retrieved, 4 blastomeres were biopsied, 2 embryos were diagnosed as at low risk and 1 embryo was transferred on the day 5.
Haplotyping analysis using STR markers is technique suitable for indirect PGD testing of monogenic diseases, but can be used also for PGD of structural aberrations, when FISH approach cannot be applied. Confirmed pregnancy is currently on-going.

Complex fetoplacental rearrangement : discrepancies between array-CGH and FISH results

***C. Rooryck-Thambo**[1,2], N. Houcinat[2], F. Pelluard[3], S. Moutton[2], M. Vuillaume[1,2], D. Cailley[2], J. Horovitz[4], T. Jérôme[2], R. Saura[2];*
[1]Université Bordeaux Segalen, Laboratoire Maladies Rares: Génétique et Métabolisme (MRGM), Bordeaux, France, [2]Génétique médicale,Hôpital Pellegrin, Bordeaux, France, [3]Anatomopathologie - foetopathologie, Hôpital Pellegrin, Bordeaux, France, [4]Gynécologie-obstétrique et médecine fœtale ,Hôpital Pellegrin, Bordeaux, France.

We report the case of a 22-year-old woman, G1P0, who underwent prenatal diagnosis in our fetal medicine center for severe intrauterine growth restriction with decreased fetal movements and tinny lower limbs muscles.
Late chorionic villi sample was realized at 34 weeks of amenorrhea (WA). Conventional karyotyping on cultured placental villi revealed no abnormality. Array-CGH identified a complex 1p36 rearrangement, consisting of a terminal deletion of 14.6Mb, composed by a contiguous mosaic (~70%) 1p36.33p36.23 deletion (6.7Mb), a mosaic (~45%) 1p36.23p36.21 deletion (7.8Mb) and a non-mosaic 1p36.21 deletion (405kb). To confirm these results, FISH techniques were applied using two different probes targeting 1p36.33 locus. Unexpectedly, they showed 2 copies of this locus. Since 1p36.33 deletion was not confirmed, amniotic fluid was sampled at 36 WA. Array-CGH on amniocytes revealed the same non-mosaic 1p36.21 deletion as in the villi and identified a non-mosaic duplication, reciprocal to the 7.8Mb deleted region in the villi. Otherwise, no terminal 1p36.33 deletion was found in amniocytes by array-CGH.
Specific FISH analyses confirmed the presence of the non-mosaic 1p36.21 deletion in both amniocytes and villi. They also confirmed the presence of the 1p36.23p36.21 duplication in amniocytes, and surprisingly showed this duplication in the villi instead of the expected mosaic deletion. The terminal 1p36.33 deletion remained not confirmed.
Pregnancy termination was proposed, based on the ultrasound anomalies and array-CGH results. Indeed, despite discrepancies between FISH and array-CGH results, a complex rearrangement of the 1p36 region was highly suspected. The exact nature of this rearrangement is still to be determined.

IL-6 gene promoter polymorphisms: Genetic susceptibility to recurrent pregnancy loss

***N. Bozkurt**[1], O. Ates[1], N. Karakuş[1], F. Demirturk[2], O. Gunal[3], T. Aysal[2], M. C. Nacar[2];*
[1]Gaziosmanpasa University Faculty of Medical Department of Medical Biology, TOKAT, Turkey, [2]Gaziosmanpasa University Faculty of Medical Department of Obstetrics and Gynecology, TOKAT, Turkey, [3]Gaziosmanpasa University Faculty of Medical Department of Infectious Diseases and Clinical Microbiology, TOKAT, Turkey.

Recurrent pregnancy loss (RPL) is defined as three or more pregnancy losses before 20 weeks. RPL is a multifactorial condition with several etiologic factors including genetic abnormalities of the parents, anatomical, endocrinological, hematologic and immunologic abnormalities, infections, nutritional and environmental factors. The causes of pregnancy loss in about half of the women with RPL even after extensive investigations remain unknown. We analyzed IL-6 -174 G/C, -572 G/C, -597 G/A, -1363 G/T, -2954 G/C promoter region polymorphisms in 113 RPL patients and 113 healthy subjects by using polymerase chain reaction (PCR)-based restriction fragment length polymorphism (RFLP) assay. The -174G/C genotypic and -174C allelic frequency and the -2954G/C genotypic and -2954C allelic frequency of IL-6 was higher in RPL patients than healthy controls and significant association was found between RPL and -174G/C, -2954G/C polymorphisms (P: <0.0001, OR: 0.28, 95% CI: 0.15-0.51, P: <0.034, OR: 0.16, 95% CI: 0.01-1.12 respectively). We found remarkably similar frequencies in RPL patients compared with controls for IL-6 -572G/C,-597G/A and -1363G/T genotypes/alleles and no association was observed between RPL and these polymorphisms. Our study supported that IL-6 -174G/C and -2954G/C polymorphisms are associated with increased risk of RPL in Turkish patients.

J19.35
Search for NLRP7 mutations in first trimester missed abortions with multiple methylation changes in imprinted genes

***M. V. Lepshin**, E. A. Sazhenova, I. N. Lebedev;*
Institute of Medical Genetics, Siberian Branch of Russian Academy of Medical Science, Tomsk, Russian Federation.

NLRP7 gene has been identified as the gene involved in biparental hydatidiform moles (BiCHM) and associated with multiple loss of imprinting (LOI) of the maternal allele. Previously, we report about multiple epimutations affected from 4 to 12 imprinted genes in placental tissues of first trimester missed abortions (Sazhenova et. al., 2012). It is possible that BiCHM and miscarriage have common pathogenetic mechanisms of the epigenetic regulation. To investigate whether the *NLRP7* mutations might cause a miscarriage with LOI we sequenced this gene in the placental tissues of 11 first trimester missed abortions with previously detected hypo- or hypermethylation of multiple imprinted loci. We found nine *NLRP7* genetic variants. Seven of them had already been described in the Ensembl or INFEVERS databases in women with BiCHM and normal reproductive outcomes. In this study, we report the two new homozygous genetic variants c.1405delC and c.1444delC in the embryo with multiple LOI. This embryo had hypomethylation in imprinted genes *PEG10*, *KCNQ1*, *WT1*, *ZNF215* and hypermethylation in *INS*, *PWCR1*, *GABRA5*. These imprinted genes participate in apoptosis and cell differentiation (*PEG10*, *WT1*, *INS*), cell proliferation and growth (*INS, WT1*), reproduction (*WT1*), transport (*GABRA5*, *INS*) and cell cycle (*INS*). It is notable, that epimutations of all these genes, except *PEG10*, were confined by chorion cytotrophoblast or extraembryonic mesoderm indicating its postzygotic but not germinative origin. These findings provide new insights

into the etiology of miscarriages and associated abnormalities of genomic imprinting. Further studies are needed to evaluate the role of *NLRP7* mutations in early pregnancy losses.

SRY- negative 46, XX male with complete virilization and infertility as the main anomaly

***s. jallad**, m. basly, s. b jemaa, m. chibani, r. rachdi;*
laboratory of human reproductive biology- military hospital- tunis, tunis, Tunisia.

Introduction : the 46, xx male syndrome is a rare cause of male infertility and a rare form of sex reversal with complex mechanisms leading to a large clinical features. We report a case of man with a normal male phenotype who presented for exploration of infertility and was found to be 46, xx male without SRY gene in the x chromosome.
Case report : A 34 year old man was referred to our institution because of history of primary infertility in whom repeated seminal analysis showed complete azoospermia. Physical examination showed normal phenotype exept bilateral gynaecomastia. Penis size and testes volume were normal. Serum LH, FSH and prolactin were normal but testosterone serum concentration was under the limit of normal range (1.98ng/ml). The testicular biopsy revealed germinal cell aplasia and fewer leydig cells without sertoli cells anomalies. karyotype analysis showed 46, xx chromosome complement without evidence of mosaicism in peripheral blood cells. Polymerase chain reaction analysis and fluorescence in situ hubridization were performed in lynphocyte culture and also confirm the absence of Y chromosome sequences including any detectable SRY gene.
Conclusion : This case presented here is a rare SRY negative, xx male with testicular differenciation, complete virilization and to our knowledge, it is the third case reported of diagnosed during investigations of infertility. This finding suggests that other genes downstream from SRY not yet identified, play an important role in sex determination such as the presence of mutations of an autosomal or x-chromosomal gene.

Identification of IVS-I (-1) (G>C) or Hb Monroe as a first report on the beta- globin gene with a beta thalassemia minor phenotype in South of Iran

***M. Hamid**[1,2], G. Shariati[3,2], A. Saberi[3,2], B. Kaikhaei[3], H. Galehdari[3,2], M. Mohammadi[2];*
[1]Pasteur Institute of Iran, Tehran, Islamic Republic of Iran, [2]Narges Medical Genetics & PND Laboratory, Ahvaz, Islamic Republic of Iran, [3]Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran.

β-Thalassemia (β-thal) syndrome, is one of the most frequent hereditary diseases in the Mediterranean region, comprising about 280 mutations. We described the first report of IVS-I (-1), codon 30 (G>C)or Hb Monroe in five individuals from four unrealated families in Khuzestan province. PCR followed by sequencing of the beta-globin gene confirmed the presence of Hb Monroe in the heterozygous form which causes β0-thalassemia due to missplicing in the course of mRNA processing. This mutation has described in individuals originated from Arabic and Behbahani origins, Ahvaz city, Southern of Iran. The knowledge of the β-globin variants present in the Iranian population is essential for the molecular diagnosis and prevention of hemoglobinopathies.

Altered intra-nuclear organization of heterochromatin of chromosome 1 in interphase nuclei of patients with endometriosis by 3D-FISH

***R. Mikelsaar**[1], H. Paves[2];*
[1]Department of Human Biology and Genetics, Institute of Biomedicine, University of Tartu, Tartu, Estonia, [2]Department of Gene Technology, Tallinn University of Technology, Tallinn, Estonia.

Chromatin structure and spatial arrangement of genomic regions, including heterochromatin in interphase nuclei are important in the gene expression and genome function. Variations in heterochromatic segments are usually considered as normal ones without any direct harmful phenotypic effect. However, it is already known that changes in heterochromatin structure and organization in interphase nuclei are associated with two disorders, Roberts and ICF syndrome.
We report for the first time: 1) two females with endometriosis, who have decrease in length of heterochromatin on the long arm of chromosome 1 (1qh-) revealed on peripheral lymphocyte cultures by GTG and CBG banding methods, and 2) the influence of 1qh- on the intra-nuclear organization revealed by 3D-fluorescence in situ hybridization (3D-FISH) on interphase nuclei of these two patients and two healthy control women. Endometriosis is a common, gynaecological disease characterized by the presence of uterine endometrial tissue outside of the uterus. Its causal mechanisms are not fully understood. Our results of 3D-FISH showed statistically significant changes in sizes of volumes of hybridization D1Z1 signals (DNA probe for 1q12) and their relocation to the periphery in interphase nuclei of patients compared with controls. Thus, our results give new insights into the chromosome alterations in metaphase cells and spatial intra-nuclear organization of heterochromatin of chromosome 1 in interphase nuclei of endometriosis patients. We suggest that observed changes in the structure and location of heterochromatin of chromosome 1 in interphase nuclei have major role in the pathogenesis of endometriosis due to altered intra-nuclear architecture and genome function.

Chorionic Villi Sampling: Cytogenetic, Molecular and Clinical Findings in the Western part of Romania

***C. GUG**[1,2], C. Muresan[3], B. Muresan[4], F. Dorneanu[5], T. Cioata[6], V. Dumitrascu[7], D. Vlad[7], R. Mihaescu[8];*
[1]Dept. Microscopic Morphology, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [2]Private Medical Practice and Genetics Laboratory Dr. Cristina Gug, Timişoara, Romania, [3]Dept.Obstetric Gynecology, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [4]Dept. Fetal Medicine, Privat "President" Hospital Timisoara, Romania, Timisoara, Romania, [5]Dept. Fetal Medicine, Privat "President" Hospital, Timisoara, Romania, [6]Dept. Fetal Medicine, Privat "Athenat" Hospital, Timisoara, Romania, [7]"Victor Babes", University of Medicine and Pharmacy, Timisoara, Romania, [8]"Victor Babes", University of Medicine and Pharmacy Timişoara, Timisoara, Romania.

First-trimester chorionic villus sampling (CVS) was performed on a number of 80 pregnancies in the last 2 years. The test used in all cases was chromosomal analysis from mesenchymal cells belonging to long-term cultures combined with the Quantitative Fluorescent Polymerase Chain Reaction (QF-PCR) for the most common chromosomal aneuploidies. The main reasons for sampling were the presence of fetal malformations at ultrasound examination (42,10%), the biochemical risk (33,33%) and the maternal age (26,25%). Abnormal laboratory findings resulted in 10 terminations of pregnancy (12,5%). We have detected 4 fetuses with trisomy 21, 2 with trisomy 18, one with trisomy 13 in robertsonian translocation, one with mosaic X monosomy, one with double monosomy (-18,-19) and one with maternal duplication dup(1q12-14). In addition four unexpected balanced chromosome rearrangements were detected: two fetuses with maternal 9 inversion and two with paternal balanced translocation t(2;18)(q36;q21) and "de novo" t(1q;Xq),t(1p;Xp). There were no false negative findings. False-positive cytogenetic findings occurred in 2 cases, comprising with mosaicism confined to the trophoblast: 1 case with trisomy 16 in the CVS karyotype, presenting normal karyotype when amniocentesis was performed and a tripleX case that resulted after a QF-PCR test, turning out to be a 45,X/46,XX karyotype when amniocentesis was performed. Another discrepancy that arose was by fault of maternal contamination: a false XX/XY mosaicism which amniocentesis proved to be a normal 46,XY karyotype. QF-PCR has proven to be rapid (24-48h), relatively inexpensive, efficient in detecting major numerical abnormalities, reliable complementary diagnostic method alongside fetal karyotyping resulted from long-term cultures.

Identification of a novel mutation in the AR gene in a Tunisian Family with Complete Androgen Insensivity Syndrome in the daughter and with Primative Ovarian Failure in the mother

***B. Ben Rhouma**[1], N. Belguith[1,2], F. Abdelhedi[1,2], M. M. Feki[3], M. Kesentini[1,2], K. Chabeene[4], H. Kamoun[1,2], F. Fakhfakh[1];*
[1]Molecular Human Genetics Laboratory, Faculty of medicine of Sfax, Sfax, Tunisia, [2]Department of Medical Genetics , Hedi Chaker Hospital, Sfax, Tunisia, [3]Department of Endocrinology , Hedi Chaker Hospital, Sfax, Tunisia, [4]Department of Maternity and Geneco-Obstetrics, Hedi Chaker Hospital, Sfax, Tunisia.

The Androgen Insensitivity Syndrome (AIS) is a frequent etiology of 46, XY Disorders of Sexual Development and is caused by mutations in the Androgen Receptor (AR) gene, mapped to chromosome Xq11-12, the AR encodes the AR protein, which binds both testosterone (T) and dihydrotestosterone and acts as a transcriptional factor involved in the expression of genes responsible for the development of male sexual characteristics. The Complete AIS (CAIS) is characterized by external female genitalia, absence of Mullerian structures, a blind-ending vagina and a developed breast in patients with 46, XY karyotype formula.

We studied a female Tunisian patient diagnosed with CAIS at the puberty age. A novel mutation c.3162C >T leading to p.P683S was identified in the patient and in a heterozygous state in patient' mother. Using multiple alignments, we noticed that the Proline residue is conserved and the 3D modeling showed that the mutated AR conformation may be alerted. As previous reports of AR knockout mice model and Indian women with AR gene mutations showed POF (Premature Ovarian Failure) phenotype, the novel mutation p.P683S could be among the genetic causes of POF observed in the patient'mother.

As a conclusion, the novel mutation p.P683S is the first mutation to be described in a mother with POF and the daughter with CAIS; it substantiated the implication of the AR gene in the POF among 46, XX females subjects and in the Androgen Insensibility Syndrome in 46, XY patients.

Complex chromosomal rearrangement involving chromosome 2,5 and 10 in a fertile male: meiotic segregation and interchromosomal effects

A. G. Zamani, *E. Tuncez, A. Acar, M. S. Yildirim;*
Necmettin Erbakan University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey.

Complex chromosomal rearrangements (CCRs) are defined as rare structural abnormalities. They involve between more than two chromosome breaks and exchanges of chromosomal segments.CCRs are usually associated with male infertility as a result of the disruption of spermatogenesis due to complex meiotic configurations and the production of chromosomally abnormal sperm.

Here, we describe a rare case of an apparently balanced karyotype of 46,XY, t(2;5;10)(q21;p15.3;q22.1) in a fertile male. The couple admitted to our clinic because of recurrent spontaneous abortions. They had four abortions and a healthy 6-year-old son whose karyotype was normal. Parental karyotypes of our patient were normal,too. Thus it was assumed to be a de novo case. In general, most familial cases have a normal phenotype with apparently balanced rearrangements. In contrast, half of de novo CCRs are unbalanced, and remaining half are apparently balanced but associated with multiple structural anomalies as well as mental retardation.

Sperm fluorescence in situ hybridization (FISH) analysis was performed on each of the involved chromosomes to determine the patterns of segregation. FISH was also performed on chromosome 13, 18, 21, X and Y to determine any interchromosomal effect. An array-CGH analysis was planned. Findings of the patient are discussed and compared with literature.

A patient with a Diamond-Blackfan Anemia-1due toa mutation in ribosomal protein S19 gene and prenatal genetic diagnosis for bone marrow transplantation.

Y. Saglam[1], A. Yesilipek[2], ***H. Karadayı***[1]*, M. Ortanc[1], N. Akaltan[3], K. Ulucan[4];*
[1]Goztepe Medical Park Hospital, Department of Medical Genetics, Istanbul, Turkey, [2]Goztepe Medical Park Hospital, Department of BMT Unit, Istanbul, Turkey, [3]Goztepe Medical Park Hospital, Department of IVF Unit, Istanbul, Turkey, [4]Üsküdar University, Faculty of Engineering and Natural Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey.

Introduction: Diamond-Blackfan anemia-1 (DBA1, MIM 105650) is a rare, mostly autozomal dominantly inherited condition characterized by congenital erythroid aplasia that usually presents in infancy. One of the candidate gene responsible for the condition is ribosomal protein S19 gene (RPS19, MIM 603474). In this case study, we report a girl with DBA1 and anaylzes of RPS19 gene in her family.

Material- Method: DNAs from the individuals enrolled in the study was extracted by using QIAamp DNA Blood Mini Kit from 8 ml perpheral blood. All coding regions and exonic- intronic regions were amplified and sequenced directly for mutation detection.

Results: The patient had a heterozygous mutation in its *RPS19*, c. 185G>A transition in exon 4, which leads a arginine to glutamine substitution, p.R185Q. We detected no mutation in her healty sibling and parents fort he same gene analysis. **Discussion:** *DBA1* has severe effects during the neonatal life and needs bone marrow transplantation for the effective treatment. In this case, we present a mutation in *RPS19* in agirl, and screened candidate embryonic cells for the detected mutation and nearby markers, and HLA, as well in the terms of appropriate embryo transfer. Mother is not pregnant now but the process is still going on for the treatment of the girl.

Non-immune hydrops fetalis: a prospective study of cases

C. A. Moreno[1]*, T. Kanazawa[1], R. Barini[1], M. L. Nomura[1], K. C. Andrade[1], C. P. Gomes[1], J. K. Heinrich[1], C. L. Campanholo[1], R. Giugliani[2], M. Burin[2], D. P. Cavalcanti[1];*
[1]State University of Campinas, Campinas, Brazil, [2]Federal University of Rio Grande do Sul, Porto Alegre, Brazil.

Non-immune hydrops fetalis (NIHF) is caused by a heterogeneous group of conditions and the investigation of cases constitutes a diagnostic challenge. This study aimed to evaluate prospective and systematically a series of NIHF cases from an expanded investigation protocol and review the frequency of inborn errors of metabolism in the published series of NIHF. During the period (2010-2011), 53 individuals with NIHF were evaluated. A clinical-etiological or pathogenic diagnosis was reached in 46 (86.8%) cases. The main diagnostic groups were chromosomal abnormalities (17 - 32.1%), syndromic (8 - 15%), isolated cardiovascular anomaly and congenital infection (4 - 7.5% each one). Metabolic disease was identified in three (5.7%) cases, being all due to lysosomal storage disorder (LSD). Seven (13.2%) cases were classified as idiopathic - unknown cause after wide investigation (three cases) and incomplete evaluation (four cases). The hydrops was identified in prenatal period in most cases (48 - 90.5%), and despite the poor prognosis commonly associated to NIHF, three (5.7%) cases had spontaneous and complete resolution of the hydrops during pregnancy. The overall mortality was 75.5%. The IEM frequency in the present study (5.7%) is higher than that usually reported in the literature, justifying the inclusion of a systematic approach of these conditions in NIHF. IEM investigation, however, should be performed after exclusion of the more common causes, i.e., chromosomal abnormalities, isolated cardiovascular anomaly, congenital infections. Furthermore, considering that placental examination and skeletal evaluation may be suggestive of LSD, these exams should not be neglected in the NIHF investigation.

Investigation of Interleukin 4 Gene -590 C>T Polymorphism and Distribution of Genotypes in Preeclampsia and Normal Pregnancies

L. Özpak*, A. Pazarbaşı, M. Kasap, N. Keser, S. K. Sel, M. B. Yılmaz, S. Ilgaz, G. Cömertpay, T. Tufan;*
Çukurova University, Adana, Turkey.

Preeclampsia is a complex disease of pregnancy with both feto-placental and maternal factors contributing to its pathogenesis. Although the cause of this disease is uncertain, imbalance between pro-and antiinflammatory cytokines has been implicated in the pathogenesis of preeclampsia. Functional single nucleotide polymorphisms (SNPs) of interleukin (IL)-4 -590 (C>T), was examined by polymerase chain reaction-restriction fragment length polymorphism to identify their merit as genetic markers for preeclampsia. The study cohort was a group of 128 woman with preeclampsia and 85 healthy pregnant woman subjects from the general turkish population. Among controls, the IL-4 Ava II genotypes of C/C, C/T, and T/T were observed in 74.1%, 24.7%, and 1.2% , respectively, whereas the C/C, C/T, and T/T genotypes were observed in 69.5%, 26.6%, and 3.9% of case patients, respectively. There was not significant difference in terms of genotype (p=0.456) frequencies of IL-4 gene -590 polymorphism. Polymorphisms of IL-4 gene in the immune system pathway was not associated significantly with preeclampsia risk.

Child outcome following mid - trimester amniocentesis: respiratory health and sleep habits

D. Serapinas[1,2], *G. Pečiulyte*[3], *R. Sakalauskas*[1];
[1]*Department of Pulmonology and Imunology, Lithuanian University of Health Sciences, Kaunas, Lithuania, Kaunas, Lithuania,* [2]*Mykolas Romeris university, Vilnius, Lithuania,* [3]*Department of Family Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania, Kaunas, Lithuania.*

OBJECTIVE. The aim of the study was to determine the incidence of respiratory problems and sleep disturbances (sleep habit, sleep scheduling and sleep maintenance) in babies born after second trimester amniocentesis. It is first Lithuanian study analysing child outcome following mid - trimester amniocentesis for sleep and respiratory health.
METHODS. Analysis was performed with 3 years babies of mothers who had undergone second trimester amniocentesis (n = 50) for fetal karyotyping because of advanced maternal age or family history of chromosomal abnormality. Data were compared with children whose mothers (n=47) declined the test (control group).
RESULTS. Amniocentesis was associated with a significantly higher incidence of child sleep disturbances: 30 child (60%), comparing with control group 11 child (23.4%) (P = 0.001). Although there was no significant difference in the frequency of acute respiratory infections rate, stridor, apnea, we observed that 7 children (14%) had asthma in postamniocentesis group, while in control group asthma was diagnosed only for 1 child (2,1%) (P = 0.06).
CONCLUSIONS. Second trimester amniocentesis does not appear to compromise child lung function development however amniocentesis may impair postnatal sleep habits.

Prenatal screening for Aneuploidies in Iranian families using QF-PCR

P. Rostami, *S. Valizadegan, R. Najafi, M. Mahdizadeh, M. Ghalandari, G. Esmaeilnia, S. Khalili, H. Imanian, S. Almadani, F. Afrouzan, S. Keyvani, R. Heydari, A. Kariminejad, R. Kariminejad, H. Najmabadi;*
karimnejad-najmabadi genetic lab, tehran, Islamic Republic of Iran.

Quantitative fluorescence polymerase chain reaction (QF-PCR) has been introduced in a number of genetic laboratories as an inexpensive, rapid and reliable method for prenatal recognition of aneuploidy in chromosomes 13, 18, 21, X and Y. We have investigated the efficacy of QF-PCR for the prenatal recognition of common aneuploidies and compared our findings with cytogenetic results in Iran.
Total of 1747 prenatal samples (1720 amniotic fluid and 27 chorionic villous samples) were analyzed by QF-PCR using several selected STR markers together with amelogenin.
Results were compared with those obtained by conventional cytogenetic analysis. We could detect 55 numerical abnormalities in our subject by QF-PCR. Concordant QF-PCR and karyotype results were obtained in 1716 (98.22%) of the samples. An abnormal karyotype associated with adverse clinical outcome undetected by QF-PCR was found in 0.5% of samples.
Using QF-PCR alone we were able to detect abnormalities in 98.56% of all referred families, however, the karyotyping results improved the detection rate to 99.60% in the referred cases.
In countries where large scale conventional cytogenetic is hampered by its high cost and lack of technical expertise, QF-PCR may be used as the first line of screening for detection of chromosomal abnormalities. In addition, karyotyping will also recommended for all prenatal cases to increase the power of detection. We also recommend for all the families that are seeking prenatal diagnosis of single gene disorders, additional aneuploidies screening to be added to their work up.

A complex fetal chromosomal aneuploidy due to maternal translocation t(1;9)

T. Zorjanova, *E. Kurvinen, A. Tiidema, T. Mölter-Väär, R. Zordania;*
Tartu University Hospital, United Laboratories, Department of Genetics, Tallinn, Estonia.

Introduction: Chromosomal abnormalities- aneuploidy and structural anomalies are frequently associated with fetal malformations and postnatally mental retardation.
Aim was to present a case history of a complex fetal trisomy of 9q21.33-pter and 1q42-qter diagnosed antenatally. According to cytogenetical to molecular-genetical investigations this abnormality had maternal original.
Materials and methods: The family was consulted by clinical geneticist and antenatal invasive investigations were performed due to fetal abnormalities detected by ultrasound (US): brain anomaly and soft fetal US markers of possible chromosomal disease which was indication for fetal chromosomal analysis. There had been one early miscarriage in this family previously. Fetal G-banding was performed using the trypsin-Giemsa staining technique. At least 20 metaphases were analysed. Fetal karyotype was abnormal : 47,XX,+add(9)(q22). Parental cytogenetical investigation showed, that father had a normal man`s chromosomal finding, mother had a karyotype 46,XX,t(1;9)(q42;q21.33).To clarify the possible etiology of this change submicroscopical chromosomal analysis by HumanCytoSNP-12 array was performed. A pathological fetal result was achieved: arr[hg19] 1q42.12-q44(226,350,383-249,138,233)x3,2q13(110,859,672-110,982,530)x1,9p24.3-q21.33(1-88,226,038)x3.The final fetal karyotype was 47,XX,+der(9)t(1;9)(q42;q21.33)mat.Genetic counselling to the family was performed and the family decided to terminate the pregnancy. Pathological investigation of the fetus is presented.
Conclusion: Using different cytogenetical methods allowed us to verify fetal kayotype. A complex aneuploidy was associated with fetal anomalies and may play a role in the etiology of the miscarriage in this family. Clinical, laboratory and pathological data are presented and genetic counselling problems of this kind of complicated families are discussed.

A case of confined placental mosaicism for trisomy 21 and fetus with abnormal ultrasound findings

R. RAYNOVA[1], *I. Bradinova*[1], *R. Vazharova*[1], *V. Dimitrova*[2], *K. Vladimirova*[1], *A. Savov*[1];
[1]*National Genetic Laboratory,University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria,* [2]*Department of Fetal Medicine, University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.*

Confined placental mosaicism (CPM) is found in 2% of the diagnostic chorion villus sampling (CVS). Clinically CPM may be associated with a spectrum of fetal manifestations ranging from normal pregnancy outcome to intrauterine death of a chromosomally normal fetus or intrauterine growth restriction (IUGR). Chromosome specific mosaicism could be responsible for suboptimal placental function and associated pregnancy complications.
Here we report a case of CPM for trisomy 21 detected by QF-PCR on 13 gw CVS. A 27-years old pregnant woman was referred for prenatal diagnosis with an increased nuchal translucency (5.3mm), hypoplastic nasal bone and calculated high risk for trisomy 21 (1:5) from the maternal serum screening; free bCG =5.8 MoM.
QF-PCR analysis was performed with Aneufast (Molgentix SL, Barcelona, Spain) and analyzed on ABI 3130xl. Two of the markers located on chromosome 21 showed ratios consistent with a trisomic condition, the other three markers were normal. The family opted for termination of the pregnancy due to poor prognosis. Chorionic villi and fetal tissue from the terminated pregnancy were analyzed by QF-PCR. The results from the villi were concordant with those from the CVS. The QF-PCR profile of the fetus was normal. Long term culture of the chorion showed normal male karyotype.
Based on these results, a low level placental mosaicism type I - confined to the trophoblast could be considered. In addition, an array CGH analysis is planned to be performed.

CYP21A2 gene analysis in Congenital Adrenal Hyperplasia patients from Bashkortostan Republic of Russia

A. A. Rakhimkulova[1], *V. L. Akhmetova*[1], *I. R. Gilyazova*[1], *O. A. Malievsky*[2], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Centre of RAS, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency is the most common inherited defect of adrenal steroid biosynthesis.
The molecular genetic analysis of the CYP21A2 gene was performed in 126 CAH patients from Bashkortostan Republic of Russia. Our study showed that the gene deletions/large gene conversions were present in 27.7% of unrelated alleles. The most frequent point mutations I2splice and R356W

occurred in 13.5% and 11.1%, respectively. Other mutations, I172N, Q318X, V281L and P30L were rare (4.8%, 4%, 2.4% and 1.2%, respectively). Mutations R426C and delIle384 were identified in only 0.4% of alleles.
Furthermore, the clusters of mutations on one chromosome Q318X+R356W (5%), I172N+Q318X (1%), delA2orLGC+V281L (1%), I2splice+P453S (0.4%) were found in CYP21A2 gene in 8 CAH patients.
In one patient with simple virilizing form we identified the insertion of one nucleotide in exon7 of CYP21A2 gene. The frameshift mutation F307+1 nt was found in a heterozygous state with I172N mutation.
Moreover, the analysis of CYP21A2 gene detected several polymorphic variants. The frequency of alleles T of rs6462 (c.289+9C>T), rs6449 (c.289+67C>T) and S374S was40.5%, 22.5% and 11.3%, respectively. The allele A of rs6474 (R307K) was found in 40.5% of unrelated alleles.
Thus, studying of molecular-genetic nature of CAH represents the doubtless scientific and practical importance in respect of use of the received data for differential diagnostics of its various forms, medical and genetic consultation and prenatal diagnostics.

J19.50
Small supernumerary marker chromosomes (sSMC) detected prenatally

T. V. Zolotukhina, *N. V. Shilova, E. V. Judina, M. E. Minzhenkova, Y. O. Kozlova;*
Research Centre for Medical Genetics of RAMS, Moscow, Russian Federation.

The restriction of the GTG-analysis at identification of small supernumerary marker chromosomes (sSMCs) represent a big problem in prenatal diagnosis. FISH-method with different DNA-probes allows to identify chromosomal origin of sSMCs and to ascertain if they include the euchromatic segments in order to estimate of fetal genetic risk. The FISH-analysis was carried out on a AxioImagerM1 (Zeiss) with Isis software (MetaSystems) and DNA probes: CEP15/LSI D15S11, wcp 13, 14, 15, 21, 22, LSI TUPLE I/ARSA (Abbott, Vysis). Also the multicolor FISH techniques were used. Four cases of autosomal sSMCs were found at GTG-analysis on fetal lymphocytes. In cases 1and 2 bisatellite sSMCs were derived from chromosome 15 (inv dup 15) of parental and maternal origin respectively containing only heterochromatic segments (15pter-q11.1). In case 3 sSMC was detected as inv dup 22(q11.1) de novo with wcp 22 and TUPLE/ARSA DNA-probes (Abbott, Vysis). Ultrasound examination of these fetuses was normal and pregnancies ended with normal childbirth. In case 4 two sSMCs were found in fetus with severe intrauterine growth retardation. Multicolor FISH (cen-mFISH, mFISH, mBAND) was used and the origin of these sSMCs was established: both sSMCs appeared as ring chromosomes 5 and 20 respectively. The fetal karyotype was defined as 48,XY, +r(5) (p13.2q11.2), +r(20) (p11.1q12) dn, there is a partial trisomy on (5) (p13.2→q11.2) and a partial trisomy on (20) (p11.1→q12). Interpretation of sSMCs origin and euchromatin involvement are a big clinical problem since it is difficult to establish connection between of these chromosomes presence and fetal anomalies.

J19.51
Two cases of insertional translocations in patients with reproductive disorders

I. Timofeeva, *E. Markova, N. Zotova, N. Kazmina, N. Makhalova, A. Novoseltseva, M. Zaitseva, N. Keosyan, A. Svetlakov;*
Krasnoyarsk Center for Reproductive Medicine, Krasnoyarsk, Russian Federation.

Insertional translocations (ITs) are rare chromosomal rearrangements. Correct definition of IT is critical for preimplantation genetic diagnosis (PGD) and prenatal diagnosis.
In our practice there were 2 cases with ITs in 6500 karyotypes.
In the first case a couple was infertile. Analysis of GTG-banded male's chromosomes demonstrated a reciprocal translocation 46,XY,t(1;4)(p32;q21). During genetic counseling the couple refused PGD. In vitro fertilization (IVF) cycle was performed. Prenatal diagnosis detected a derivative chromosome 1 in a fetus karyotype. Unbalanced IT was established by whole chromosome painting (WCP) for chromosome 4, and the fetus was aborted. Reanalysis of male's karyotype using WCP demonstrated the balanced IT - 46,XY,ins(1;4)(p32;q22q28?). IT regions were detected through high-resolution banding. Locus specific probe LSI 4q22 validated IT. Individual FISH (fluorescent in situ hybridization) probes were composed for PGD. A pregnancy was not obtained in the second treatment cycle IVF/PGD.
The second case was a couple with two healthy daughters and four cases of miscarriages. Analysis of male's karyotype detected a reciprocal translocation - 46,XY,t(2;3)(p23;p21),1qh+. For PGD set-up we used centromeric and telomeric FISH probes, but the reciprocal translocation was not confirmed. WCP for chromosome 2 identified balanced IT - (2;3)(p23;p22p24?). Genetic counseling was carried out. The couple is suggesting the PGD cycle.
According to these cases we consider that identification of ITs by GTG-banding is complicated, and needs additional cytogenetic techniques.

J19.52
The role of IL-6, IL-8, and IL-10 gene polymorphisms in the pathogenesis of recurrent pregnancy loss

A. Kucherenko[1,2], *R. Gulkovskyi*[1,2], *I. Vorobiova*[3], *N. Rudakova*[3], *K. Khazhilenko*[4], *L. Livshits*[1];
[1]*Institute of Molecular Biology and Genetics of National Academy of Sciences of Ukraine, Kyiv, Ukraine,* [2]*Taras Shevchenko National University of Kyiv, Educational and Scientific Centre „Institute of Biology", Kyiv, Ukraine,* [3]*SI "Institute of Pediatrics, Obstetrics and Gynecology of NAMS of Ukraine", Kyiv, Ukraine,* [4]*"ISIDA" clinic, Kyiv, Ukraine.*

The maternal immune system is crucial for pregnancy establishment and maintenance. IL-6, IL-8 and IL-10 are key regulators of immune response in gestational tissues. Fluctuations of abovementioned cytokine levels are controlled by regulatory elements in promoter or intron regions of respective genes and are critical for pregnancy tolerance.
The study aimed to evaluate the role of *IL6* gene -174G/C, *IL8* gene -781C/T, *IL10* gene -592 C/A and -1082G/A variants in recurrent pregnancy loss (RPL) pathogenesis. Study material - genomic DNA extracted from peripheral blood of unrelated individuals from Ukrainian population. Case group (60 women with history of RPL) and control group (106 healthy women, who have given birth to at least one child conceived in natural way) were genotyped by a PCR based RFLP assay. Statistical analysis was performed using OpenEpi statistical package.
There was no significant difference in *IL6* -174G/C genotype and allele frequencies between case and control groups. Frequency of *IL8* -781T allele carriers was significantly higher (p<0,05; OR=1,866; CI95%: 1,073-3,244) in RPL group (0,716) comparing to control (0,576). Frequencies of *IL10* -592A and -1082A allele carriers were higher (p<0,05) in group with RPL (0,484 and 0,825 respectively) comparing to control (0,34 and 0,764). Odds ratio calculation showed association of both these variants with RPL (OR=1,8; CI95%: 1,062-3,116 and OR=2,16; CI95%: 1,07-4,362 respectively).
Obtained results suggest that *IL8* gene -781T, *IL10* gene -592A and -1082A alleles are associated with RPL risk in Ukrainian population.

A new case of pregnancy with X homogenous monosomy in a patient with Turner syndrome

E. Gorduza[1], *V. Martiniuc*[2], *M. Gramescu*[1], *C. Bujoran*[3], *M. Diaconu*[2], *L. Caba*[1], *E. Braha*[1], *R. Popescu*[1], *L. Butnariu*[1], *D. Nemescu*[1];
[1]*"Grigore T. Popa" University of Medicine and Pharmacy Iasi, 700115 Iasi, Romania,* [2]*"Cuza Voda" Obstetric and Gynecology Hospital Iasi, 700115 Iasi, Romania,* [3]*"Sf. Maria" Children Hospital Iasi, 700115 Iasi, Romania.*

Monosomy X affects 1/2,500 girls and it generates the Turner syndrome (TS), characterized by: short stature, primary amenorrhea, deficit of sexualisation and sterility. The studies of TS indicated that 90% of patients have lack of pubertal development and primary amenorrhea. The normal puberty is more frequent in mosaic X monosomy, 10-15% of these having menarche, but usually they present a secondary amenorrhea. The pregnancy in TS patients is a rare situation, associated with a high risk for chromosomal abnormalities. Before introduction of IVF techniques was cited <150 pregnancies in TS. 10% of pregnancies in mosaic X monosomy patients presented an X monosomy. We present a case of 45,X/46,XX women, 22 years old, that have a pregnancy finished by spontaneous abortion in 10 weeks of gestation. The patient was diagnosed with TS during childhood, but not received therapy with GH or estro-progesterone. She developed a spontaneous puberty and has regulated menstrual cycles. The women have 143 cm and 40 kg, and she was directed to our service by obstetrician in 5 weeks of pregnancy, confirmed by level of β-hCG. Unfortunately, a second echographic examination of embryo (10 weeks) attested a cystic hygroma and the stop of vital activities. The obstetrician decided to produce an abortion, and he took a sample of chorionic tissue. We analysed the embryonic tissue by FISH and we also harvested the cells. Both analysis confirmed the presence of 45,X monosomy.

Our case indicates the importance of prenatal genetic analysis in all pregnancies at patients with TS.

Hb Ahvaz [α-83 (F4), Leu>Arg], a new hemoglobin variant of the α2-globin gene

*M. Hamid[1,2], **G. Shariati**[3,2], A. Saberi[3,2], H. Galehdari[3,2], B. Kaikhaei[3], M. Mohammadi -Anaei[2];*
[1]Pasteur Institute of Iran, Tehran, Islamic Republic of Iran, [2]Narges Medical Genetics & PND Laboratory, Ahvaz, Islamic Republic of Iran, [3]Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran.

In general, α- globin variants result from point mutations in α1 or α2 globin genes leading to abnormal α-chain hemoglobins . Alpha thalassemia is also common in Iran and the most frequent lesion reported so far is the -α3.7 mutation. We report a novel mutation in the α2-globin gene, codon 83 (T>G), detected in two members of two unrelated families from Khuzestan province, South of Iran, which we named Hb Ahvaz. This mutation detected by cellulose acetate electrophoresis and characterized by molecular studies. Hb Ahvaz seems to be no responsible for hematological abnormalities in the carriers but with Alpha zero thalassaemia defects it might induce severe clinical symptoms.

Comparison of multiplex ligation-dependent probe amplification (MLPA) technique and routine karyotype method in diagnosis of common chromosomal aneuploidies

*M. Omrani[1], S. Saleh Gargari[2], **F. Azizi**[1], N. Safavi Naini[1];*
[1]Department of Medical Genetics, Faculty of Medicine, Shahid Beheshti University of Medical Sciences,, Tehran, Islamic Republic of Iran, [2]Feto-Maternal Unit, Mahdiyeh Hospital,No. 16, Fadaieaneslam Street, Shoush Avenue, Tehran, Islamic Republic of Iran.

Introduction: The major aneuploidies diagnosed prenatally involve the autosomes 13, 18, 21, and sex chromosomes X and Y. Improvements in non-invasive screening methods for detection of common aneuploidies have radically changed the indications for prenatal diagnosis over the last decade. Using Multiplex ligation-dependent probe amplification (MLPA) technique instead of traditional culture method, allows for quick, easily automated multiplex testing of these aneuploidies in one polymerase chain reaction.
Material and Methods: Chromosome copy numbers were determined by analyzing size and peak area for each MLPA probe. Cytogenetic culture was attempted too. Results were confirmed by quantitative fluorescent-PCR (QF-PCR).
Results: In this blind study, MLPA with P095-A2 aneuploidy probe mixes was performed on 55 amniotic fluid (AF) and 10 control samples. The mean age of pregnant women was about 33 years old. Using this technique, one case with 45, X monosomy diagnosed. There were no false-positive results. In all conclusive tests, the MLPA results were concordant with cytogenetic and qf-PCR findings.
Discussion and Conclusion: The experiment demonstrates that MLPA can provide a rapid and accurate clinical method for prenatal identification of chromosome aneuploidies with 100% sensitivity and 100% specificity.

Cytogenetic survey of 270 Iranian females with premature ovarian failure.

*A. Mohseni Meybodi[1], T. Madani[2], S. Zari Moradi[1], N. Almadani[1], H. Gourabi[1], **H. Kalantari**[1];*
[1]Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for reproductive, Tehran, Islamic Republic of Iran, [2]Endocrinology and Female Infertility Department at Reproductive biomedicine Research Center, Royan Institute for Reproductive biomedicine, ACECR,, Tehran, Islamic Republic of Iran.

Menopause normally occurs in women during their late 40s or early 50s. However, in almost 1% of cases, it occurs before age 40 called "premature ovarian failure". It known as an enigmatic and heterogeneous disorder, with poorly understood etiology. The importance of chromosomal abnormalities in the aetiology of premature ovarian failure (POF) is well-known but in many cases POF still remains idiopathic. To date, several studies have attempted to clarify association between type of chromosomal abnormality and incidence of disease.
The aim of this study was to investigate the frequency and type of chromosomal abnormalities in Iranian POF patients to assess the efficacy of cytogenetic screening for them. We investigated the frequency and type of chromosomal aberrations in Iranian females, diagnosed with idiopathic POF. Standard cytogenetic analysis was carried out in a total of 270 patients. Karyotype analysis of these patients revealed that 240 (88.88%) patients had normal female karyotype and 30 (11.11%) patients had abnormal karyotypes. The abnormal karyotypes included sex reverse SRY negative (7 Cases), X chromosome mosaicism (10 cases), abnormal X chromosomes (7 cases), abnormal autosomes (4 cases), and X-autosome translocation (4 cases).
It is clear that, if the diagnosis of POF made after complete follicular depletion, the infertility of patients with POF would not be restored, so, early diagnosis by genetic investigation may instead lead to the advice of early conception or oocyte harvesting and preservation. Chromosomal studies thus provide valuable clinical information for reproductive management and genetic counseling

The presence of one trisomic diallelic marker of a fetus for D21S1411 with normal karyotype

***D. Alptekin**[1], A. Pazarbasi[1], H. U. Luleyap[1], M. A. Erkoc[1], M. B. Yilmaz[1], G. Comertpay[1], T. Tufan[1], S. K. Sel[1], S. Buyukkurt[2], O. Demirhan[1];*
[1]Cukurova University, Medical Faculty, Department of Medical Biology and Genetics, Adana, Turkey, [2]Cukurova University, Medical Faculty, Department of Obstetrics and Gynecology, Adana, Turkey.

Introduction: The purpose of this study was to evaluate the results of a Chorionic Villus Sample (CVS) with QF-PCR and conventional cytogenetic methods.
Methods: In this study, a CVS was obtained from pregnant women with positive maternal serum screening, attending to the Cukurova University, Department of Obstetrics and Gynecology outpatient clinic. QF-PCR was used for trisomy detection. Karyotypes of the fetus and the family were performed with standard GTG banding procedure.
Results: Except D21S1411, all markers of fetus were informative and normal. D21S1411 was at trisomic diallelic form. QF-PCR was used for identification of the parental origin of the trisomic diallelic marker of the fetus for D21S1411. The father had the one allelic form for D21S1411 marker. Chromosome analysis confirmed that all cells of CVS had 46,XX karyotype. Karyotypes of the parents also were normal.
Conclusion: Trisomic diallelic form of D21S141 was found as polymorphism in some populations. It could be a polymorphism but chromosome 21 of the fetus should be investigated with a powerful molecular technique. Although assessment of a normal or trisomic copy number is concluded when at least two informative markers were detected for the chromosome of interest we want to investigate the genes of this region of the fetus with high throughput sequencing technique. The pathological QF-PCR results require additional cytogenetic analysis that is still regarded as gold standards in order to clarify the underlying chromosomal rearrangement.

J19.58

The microdeletions of Y chromosome and chromosomal abnormalities at idiopathic infertility

***B. Kamaliyeva**, D. Zhumazhanova, A. Pshenbaev, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

Cytogenetic and molecular genetic studies were performed in order to identify the genetic causes of idiopathic infertility in men of reproductive age.
The material of the study were peripheral blood 203 men with a history of reproductive disorders (59% astenoteratozoospermia, oligoastenoteratozoospermia in 29% and azoospermia in 12% in cases).
Cytogenetic and molecular genetic studies were carried out. Cytogenetics differentially stained chromosomes, derived from 72-hour culture of peripheral blood lymphocytes was performed to identify numerical and structural chromosomal abnormalities.
Genomic DNA was extracted by the standard method. Multiplex polymerase chain reaction was performed using Taq-polymerase. The nine of STS-mar-

kers specifying of AZF-locus were used. The results of amplification reaction were evaluated by electrophoresis in 7% PAAG.
Normal karyotype - 46, XY was diagnosed in 176 cases. The 27 cases (10%) showed chromosomal abnormalities. The Klinefelter's syndrome (47, XXY) was determined in 74%, the disomy of Y chromosome (47, XYY) - 11% and the structural abnormality - 45,XY,der(14,15)(q10;q10); 46,XY,inv(9)(p11q13); 46,XY,t(X;21)(q21;q12); 46,X,t(Y;1)(q12;q21.1) in 15%.
The 91 men with normal karyotype were carried out molecular genetics investigations. The 11 patients had deletions of AZF locus such as AZFa in the 10%, AZFb in the 10%, AZFa+b in the 10%, AZFc in the 70%.
The obtaining results showed the genetics causes of idiopathic infertility and the tactics of IVF / ICSI program.

Maternal biochemical screening as an approach for genetic prevention - the experience of the Laboratory in Medical Genetics, University hospital "St.Marina " - Varna, Bulgaria

M. Hachmeriyan[1], *L. Angelova*[1], *M. Stojanova*[1], *D. Konstantinova*[1], *B. Yakov*[2], *R. Vazharova*[3];
[1]*Univercity Hospital St. Marina, Varna, Bulgaria,* [2]*Maichin Dom Hospital, Varna, Bulgaria,* [3]*National Genetic Laboratory, Sofia, Bulgaria.*

Objective: Performance of eight year experience on prenatal screening for Down syndrome.
Methods: The Laboratory in medical genetics was the 2nd laboratory which started the prenatal biochemical screening for risk estimation of Down syndrome and neural tube defects in 2005.
Pregnant women underwent screening in second trimester (ST2) - 15-19+3 gestational week using serum AFP and free beta-hCG biochemical markers. At the end of 2009 first trimester test was implemented (11-13+6 gestational weeks). The combined screening test (CST1) was based on US measurements of NT (nuchal translucency) and NB (nasal bones) supplemented by biochemical markers of serum free beta-hCG, PAPP-A.
Results: The test was performed on 17348 pregnant women: 12968 by ST2 test (10903 at the age < 36 and 2065 at the age > 36) and 4380 - in the first trimester (3561 at the age < 36 and 719 at the age > 36). High risk for a chromosome disorder was found by ST2 test in 1095*:* 649 <36 and 448 >36. The more sensitive CST1 detected 33 and 60 women respectively to the age groups. For the eight year period prenatal diagnostic tests by DNA and cytogenetic analyses were performed. Among pregnancies tested for chromosomal diseases variety of abnormalities were found. Additional ultrasonographic scan confirmed the biochemical risk for a serious Neural Tube / Abdomainal Wall defects.
Conclusions: Based on screening and diagnostic results we comment on the sensitivity, limitations and the stepwise sequential testing way of achieving a high performance of screening.

Chromosomal rearrangement in Xq and CNVs in Xp in a Turkish patient with premature ovarian failure

C. G. Ekmekci[1], *E. Gumuslu*[2], *F. Aybar*[1], *S. G. Temel*[3,4], *M. Yesil*[1], *C. Beyazyurek*[1], *S. Kahraman*[1];
[1]*Istanbul Memorial Hospital, Assisted Reproductive Technologies and Reproductive Genetics Center, Istanbul, Turkey,* [2]*University of Kocaeli, Faculty of Medicine, Department of Medical Genetics, Kocaeli, Turkey,* [3]*University of Uludag, Faculty of Medicine, Department of Histology & Embryology, Bursa, Turkey,* [4]*Near East University, Department of Histology & Embryology, Lefkosia, Cyprus.*

Premature ovarian failure (POF) is defined as amenorrhoea for more than 6 months, occurring before the age of 40, with a FSH level higher than 40mIU/ml and hypoestrogenism accounts for about 10% of all female infertility. Furthermore abnormalities of the X chromosome are associated with POF. Here we describe 30 year old woman who referred to our IVF clinic because of infertility and secondary amenorrhoea. She reported normal pubertal timing and progression, with menarche at age 13 years. At age 16 years, she experienced oligomenorrhea therefore she was placed on oral contraceptive pills for cycle regulation. At age 20 years although the oral contraseptive pills usage, she experienced amenorrhea. Baseline laboratory evaluation included day 3 FSH 113 mIU/ml, estradiol <20 pg/ml. She was diagnosed as POF. Analysing of her and available family members karyotype revealed that she had a karyotype of 46,XX, t(3,X) (p21.1,q22.3) and the translocation was de nova. Involvement of the gene disruption in the breakpoint of the X chromosome rearrangement can be cause of the POF clinic, therefore aCGH was performed. Data analysis revealed no major chromosomal alterations. The comparison with the literature data showed 2 CNV's significantly associated with the POF phenotype that overlapped with CNV's found in our case in Xp22.31 and Xp22.33. However in our patient these overlapping CNV's were smaller and include gene in one CNV. Although the particular overlapping was found, further studies are required to asses whether there really is an association between these CNV's and the POF phenotype.

Prenatal diagnosis and DNA analysis case of thrombocytopenia-absent-radius (TAR) syndrome from Russia

T. V. Fedotova[1], *A. Stepanova*[2], *V. P. Fedotov*[1], *A. V. Polyakov*[2];
[1]*1 Regional Clinical Hospital, Voronezh, Russian Federation,* [2]*2 Research Center forMedical Genetics, Moscow, Russian Federation.*

Thrombocytopenia, aplasia of the radial (TAR) syndrome - a rare form of multiple birth defects with bilateral aplasia of the radius and the development of thrombocytopenia, an inherited autosomal recessive (MIM 274000). Most of the TAR-syndrome caused by a rare deletion in the 200-kb region 1q21.1, RBM8A related gene on one chromosome, and low-frequency noncoding single nucleotide polymorphisms (SNP) in RBM8A to another.
We report a case of prenatal diagnosis of TAR syndrome is not consanguine family at young parents. Sonography of the fetus at 32 weeks of pregnancy established bilateral aplasia of the radius while maintaining thumb, radial deviation of the hands. Upper limbs dramatically shortened by shortening and forearm strain, small-fetal gestation. The presence of thumb on both sides allowed excluding Holt-Oram syndrome and Fanconi anemia.
Birth 37 weeks of gestation by cesarean section, the weight 2460, is long 48 cm, half female. On examination, the child says: radial deviation of the hands, (thumbs saved), hemorrhagic rash on the skin of the trunk and extremities, gastric bleeding, thrombocytopenia (platelet counts are the 8000 to 45 000). X-ray confirmed aplasia radius and ulna shortening.
The child has been found by MLPA-analysis of gene RBM8A SNP rs139428292 G/A in the homo/ hemizygous state. DNA analysis allows early prenatal diagnosis in the family.

Prenatal diagnosis and molecular genetic analysis of isochoromosome 18 at amniocentesis

M. SAKA GUVENC, *H. Onay, A. Durmaz, B. Durmaz, O. Cogulu, F. Ozkinay;*
Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey.

A quantitative fluorescence polymerase chain reaction (QF-PCR) technique based on the determination of triple-dose chromosome-specific short tandem repeats (STR) has been recently developed for the prenatal diagnosis of numerical abnormalities of chromosomes 21, 18, 13 and X and Y. Specific 5 STR markers for chromosome 13,18 ,21 and sex chromosomes are used. If the patients have at least two trisomic markers for a spesific chromosome, result is detected as trisomy. A 32-year-old woman was referred to Ege University Medical Genetics Department due to abnormal prenatal USG finding (NT=6.8 mm). Amniocentesis was performed at the 16 week of gestation. The trisomy of 3 STR markers (D18S386 , D18S390 and D18S535) localized on the long arm of the chromosome 18 was detected whereas D18S391 marker located on the short arm of the chromosome 18 was found to be normal in the fetus. The pick areas rates for the markers mentioned above were 1:1.63,1:1.66, 1:2.1 and 1:1, respectively. QF-PCR analysis of parents was normal. Cytogenetic analysis of cultured amniocytes revealed a karyotype of 46,XX,i(18)(q10) in fetus. Pregnancy was terminated by the approval of the ethics committee. This report emphasizes the efficiency of QF-PCR in structural chromosomal abnormalities besides numerical abnormalities.

Associations between SNPs IL-10 and IFN-γ, level this cytokines in women and idiopathic recurrent pregnancy loss

K. Sosnina[1], *O. Terpylyak*[1], *D. Zastavna*[1], *M. Malachynska*[2], *G. Sylvester*[2], *V. Boretskyy*[2];
[1]*Institute of Hereditary Pathology, NAMS of Ukraine, Lviv, Ukraine,* [2]*Lviv regional center of reproductive health, Lviv, Ukraine.*

Successful pregnancy is dependent on maintaining a fine balance between Th1 and Th2 immunity. Taking into consideration the discussion of IL-10 and IFN-γ SNP influence on the level of their expression the aim of our research is to investigate the genetic polymorphisms of IL-10 and IFN-γ associated with cytokine levels in women with RPL in comparison with the blood levels of IL-10 and IFN-γ in these women. Methods: DNA extraction from peripheral blood cells, PCR, agarose gel electrophoresis, ELISA. Results: 225 women with RPL and 290 reproductively healthy women have been observed. The analysis of distribution of IL-10 SNP-1082G/A, -592C/A, -819C/T genotypes has shown the significantly higher 1082GG-genotype (P<0.01) and 592CC, 819 CC-genotypes (P<0.05) frequency in the group of women with RPL in comparison with the control group. The increasing of risk of RPL up to 4 times with 1082GG-genotype (OR=3.43;CI: 1.72-6.84) and 592CC, 819 CC-genotypes, (OR=3.87;CI: 1.23-12.20) has been established. Significantly lower IFN-γ +875AA genotype frequency (P<0.05) and significantly higher T allele frequency (P=0.01) has been shown in the group of women with RPL in comparison with the control group. The presence of +875TA or +875TT genotypes in women are associated with 3-fold increased risk of RPL (OR=3.15;CI: 1.18-8.36). Determining the level of IL-10 and IFN-γ in the serum showed the significantly higher of IFN-γ level in women with RPL (P<0.05) in comparison with the control group. Conclusions: IL-10 and IFN-γ influence on fetus development and their genetic regulation is a key to the development of a successful pregnancy.

J19.64

Correlation between sperm DNA fragmentation and sperm head morphology

E. Shilnikova[1], *M. Mazilina*[1], *I. Fedorova*[2], *A. Gzgzyan*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*Ott's Institution of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.*

Conventional semen analysis evaluating sperm concentration, motility and morphology are widely used to assess man's reproductive potential giving no information about sperm DNA characteristics. Among different sperm genome abnormalities DNA fragmentation is one of the most frequent especially in infertile patients. Sperm DNA damage is closely associated with embryo development, implantation, pregnancy outcome and the health of offspring conceived both naturally and by assisted reproductive technologies.

The aim of this study was to establish the correlation between sperm DNA fragmentation and some morphological forms.

Sperm DNA fragmentation and head morphology were assessed in semen samples from 70 patients with reduced fertility and 12 sperm donors. The following morphological forms were highlighted: normal, with small pathology, bulb, amorphous and vacuolated. 300 sperm heads per sample were analyzed. The method used to assess sperm DNA fragmentation was the terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay. 2000 spermatozoa per sample were evaluated.

The direct linear correlation between the frequency of the spermatozoa with fragmented DNA and vacuolated sperm heads was found (r=0,55; P<0,05). DNA fragmentation rate was not associated with the prevalence of bulb or amorphous sperm heads.

Sperm head vacuoles are related to increased sperm DNA fragmentation rate. Therefore, vacuolated sperm heads may be a predictive mark of sperm DNA fragmentation. Such correlations may be useful tool for improving the choosing of the most competence gamete for fertilization.

Supported by Carl Zeiss, Administration of Saint-Petersburg and RFBR

Birth of healthy twin from hemophilia A carrier after transferring single zygote, a PGD case report

S. Zeinali[1,2], *P. Fouladi*[2], *S. Amanpour*[3], *F. Ramezanzadeh*[3], *H. Bagherian*[2];
[1]*Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*Kawsar Human Genetics Research Center, Tehran, Islamic Republic of Iran,* [3]*Vali-e-Asr Reproductive Health Research Center, TUMS, Tehran, Islamic Republic of Iran.*

An obligate hemophilia carrier mother had come to our center requesting PGD to have a healthy boy. We identified several STRs linked to the F8 gene and subsequently designed primers. We then used these STRs and five other X-chromosome specific STRs as well as amelogenin region for diagnostic purpose. The mother went through routine IVF procedure and mature oocytes well collected and each was microinjected with a single sperm. In day 3 a single blastomere was collected from each embryo and multiples STRs were performed. From eight embryos a single unaffected male and two unaffected female embryos were obtained. The mother insisted in only transferring a single male embryo. Pregnancy was obtained and later solography revealed twin pregnancy. Fetuses were tested at 11th week gestation and the twin was diagnosed unaffected identical male twin. The pregnancy ended up to term in June 2011 and both boys are healthy. This is the first report of PGD for hemophilia in Iran.

Clinical and cytogenetic correlation in primary amenorrhea: retrospective study on 493 patients

L. I. Butnariu[1,2], *L. Caba*[2], *M. Panzaru*[1,3], *C. Rusu*[1,4], *M. Gramescu*[2], *E. Gorduza*[5];
[1]*Sf. Maria Children's Hospital, Iasi, Romania,* [2]*University of Medicine and Pharmacy „Gr. T. Popa", Iasi, Romania,* [3]*University of Medicine and Pharmacy „Gr. T. Popa, Iasi, Romania,* [4]*University of Medicine and Pharmacy „ Gr. T .Popa", Iasi, Romania,* [5]*University of Medicine and Pharmacy „ Gr. T. Popa", Iasi, Romania.*

Primary amenorrhea (PA, absence of menarche) have many causes including hypothalamic and pituitary disorders, gonadal dysgenesis and uterovaginal malformations.

We performed a retrospective study, with the purpose of establishing the frequency and the type of chromosomal abnormalities, in 493 patients with PA who were clinically and cytogenetically evaluated (1985-2009) in Iaşi Medical Genetics Center.

The X chromatin test, used as a screening test, was abnormal in 201 cases (40.8%) and normal in 292 cases (59.2%). The karyotype was normal in 224 cases (45.43%) and abnormal in 269 (54.56%) patients; the most frequent abnormality detected was X chromosome monosomy, homogeneous (137 cases - 27.78%) or mosaic (80 cases - 16.22%). Other 22 cases (4.46%) had X chromosome structural unbalanced abnormalities (homogeneous or in mosaic). One particular group, represented by 23 patients with PA, had a Y chromosome cell line and the final diagnosis was: pure gonadal dysgenesis (8 cases), CAIS (6 cases), mixed gonadal dysgenesis (4 cases) and true hermaphroditism (5 cases). Other 7 patients presented X trisomy (4 cases) and structural chromosomal abnormalities (3 cases).

Our results were similar with other reported studies and attest the importance of cytogenetic investigations in the etiologic diagnosis of amenorrhea.

Infertility is appreciated as a problem across all societies and affects about 10%-15% of couples. Half of these cases are due to male factors. Male infertility is a heterogeneous disorder, with various genetic and environmental factors. We here report a 30-year-old Iranian male with both primary infertility and skeletal abnormalities. His parents are non consanguineous with no family history of male factor infertility. The clinical signs were azoospermia with sertoli cell only syndrome, short stature, short hands, and brachydactyly. Routine chromosome analysis using standard GTG banding technique revealed 46,X,-Y,+mar. FISH technique confirmed that the marker chromosome was originated from Yp; accordingly, this deletion included the whole AZF region along with growth-control gene (GCY). By the way, MLPA analysis using subtelomeric kits showed a microdeletion of Short stature

homeobox (SHOX) gene, a pseudoautosomal gene in PAR1 of the Y chromosome. This is the first report concurrently indicating the presence of male infertility and short stature in a patient, who suffers from Yq deletion, including AZF region and the GCY gene and also SHOX haploinsufficiency. We hope this case report will facilitate genetic counseling when male infertility is associated with skeletal abnormalities.

J19.68

Peculiarities of prenatal diagnosis of cystic fibrosis in Republic of Moldova.

N. I. Barbova, *V. V. Egorov, N. D. Sirocova;*
National Center of Human Reproduction and Medical Genetics, Chisinau, Moldova, Republic of.

Cystic fibrosis (CF) remains important medical and social problem in Moldova, due to difficulties with diagnosis, treatment and social support. As a result of investigation in framefork of international scientific project, was revealed fact what mutations which are important in development of CF in Moldova, are: F508del (58,84%), 2789+5G>A (1,7%), G542X (1,36%). N1303 (1,36%.), 2184insA (1,36%), and 30% mutations of *CFTR* gene remains unidentified.
Aims - analysis of effectiveness of prenatal DNA diagnosis in families with high level of CF.
We observed 58 families with high risk of CF. Since 2001 to 2012 years within 20 families children were born: in 10 of families were used prenatal diagnosis. In Moldova we can made molecular diagnosis of five mutations in *CFTR* gene. In four cases the diagnosis was done jointly with our colleagues from France, Ukraine and Russia. Were studied 11 samples of DNA derived from amniocytes or chorion villi.
During the period of study by results of prenatal diagnosis of CF 8 pregnancies from 11 in 10 families were saved (in 2 fetuses mutations of *CFTR* gene were not detected, and in 6 fetuses were detected mutations, one in each case). In these cases in 100% of cases were prevented CF in newborns. In 10 families where parents refused from prenatal diagnosis were 10 children, 6 of them (60%) suffered from CF.
Conclusion. A prenatal diagnosis within the framework of international cooperation is an effective method of preventing of CF in families with high risk from Republic of Moldova.

FMR1 Premutation and Premature Ovarian Failure

A. Eslami[1], *U. Asadpour*[2], *Z. Ghezelayagh*[2], *M. Totonchi*[2], *T. Madani*[2], *S. Zari Moradi*[2], *H. Gourabi*[2], *A. Mohseni Meybodi*[2];
[1]*Department of Biology, Science and Research Branch, Islamic Azad university, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, ROYAN Institute for reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran.*

Background: Premature ovarian failure (POF) is a common cause of infertility. It is a hypergonadotropic ovarian deficiency with primary or secondary amenorrhoea affecting 1% of women before the age of 40. The Known causes of POF include iatrogenic agents, autoimmune disorder, exposure to environmental toxicants and genetic causes. Among the latter, POF can be associated with abnormalities affecting X chromosome such as premutation in *FMR1* gene (50- 200 CGG repeats).
Objective: We investigated of the *FMR1* premutation prevalence in women with POF.
Material &Method: This study included 90 women with POF reffered to Royan Institute. 11 women were excluded after finding X chromosomal mosaics and abnormal karyotype. 30 women with proved fertility and normal hormonal profile enrolled as the control group.
DNA was extracted from the blood samples by salting out method under the informed consent of patients. The repeated trinucleotide sequence was amplified by Hot Start PCR and was run on 4% agarose gel over night. Different DNA bands were purified from the gel and the number of trinucleotide repeats were determined by sequencing.
Result: 13 (16 %) of 79 women with POF had *FMR1* premutation, meanwhile none of the women in control group had *FMR1* premutation.
Conclusion: According to our results, determining the number of CGG repeats in *FMR1* gene can be used as a diagnostic method in the susceptible individuals. Thus, earlier screening of the *FMR1* premutation may help them to choose between oocyte freezing or earlier pregnancy.

Coexistence of SMN1 deletion and duplication in unrelated cases

Z. Sharifi[1], ***M. S. Fallah***[1], *R. Moghaddam*[1], *N. Khazaei*[1], *H. Bagherian*[1], *A. Sarhadi*[1], *M. Masoudifar*[2], *S. Zeinali*[1,3];
[1]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [2]*Dr Zeinali's Medical Genetics Lab, Tehran, Islamic Republic of Iran,* [3]*Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.*

Spinal muscular atrophy (SMA) is the second most common autosomal recessive genetic disorder. About 95% of cases are characterized by homozygous deletion of exon 7 in SMN1 gene. Here we report an unusual presentation of SMA in cases that was referred to Dr. Zeinali Medical Genetic Lab.
SMA molecular diagnosis for cases with clinical impression of SMA was performed using specific MLPA kit P021B1, MRC-Holland. DNA was extracted and qualified. MLPA was performed according to the standard protocol including hybridization, ligation and amplification. PCR product was separated using ABI-3130 genetic analyzer. Raw data were analyzed by Gene Marker V1.95.
Through analysis of those referred to our Lab, we found 3 unrelated families with a deletion in one parent and normal MLPA pattern in another parent (i.e. two copy of SMN1 gene). Paternity and/or maternity were tested and confirmed. Pedigree analysis showed several consanguinity marriages in previous generations. Further investigation of the family and pedigree analysis showed that normal parents have received both deletion and duplication from their parents. So they had 2 copies of SMN1 gene in one chromosome (duplication) and no copy in another one. This feature couldn't be identified from normal cases by MLPA technique.
In spite of high prevalence of deletion in SMN gene, co-existence of a duplication in a normal people with family history of an affected child should be considered. Further investigation of other family members is recommended.

A case of a fetus with non-acrocentric sSMC

M. Komnenić[1], *B. Petrović*[1], *O. Stojković*[2], *O. Lekić-Miladinović*[1];
[1]*Cilinical for ginecology and obstetrics, Clinical centre of Serbia, Belgrade, Serbia,* [2]*Institute of Forensic Medicine University of Belgrade, Belgrade, Serbia.*

We report a case of a fetus in thirty week of gestation having small supernumerary non-acrocentric marker chromosome (sSMC) wich was found after amniocenetesis and then confirmed by cordocentesis. Prenatal diagnostic was performed because mother was thirtyseven years old, but on ultrasound examination there were no abnormalities of fetus. Fetal karyotype was 47, XX+sSMC [63]/46, XX [37]. We also done an aneuploidy screening QF-PCR from fetal blood, showing one trialelic trisomic marker for chromosome 21 (D2S1411, for region 21q22.3). We performed chromosome analysis from peripheral blood of parents and normal karyotypies appeared. We did QF - PCR analysis for chromosome 21 from parents' DNA and for both of them, normal markers were found. Literature data are showing us that 70% of non-acrocentric sSMC do not have phenotype exspression, while 30% might have different clinical appearances. After genetic counseling parents decided to keep the pregnancy. In our case, phenotype of the newborn was normal, although it is believed that this marker (D2S1411, for region 21q22.3) is one of the most informative markers for the phenotype of Down syndrome.

Diagnosis and implication of structural chromosomal anomalies prenatally detected - our experience

S. Farcas[1], *C. D. Crişan*[2], *N. Andreeascu*[1], *M. Stoian*[1], *E. Bernard*[2], *A. Motoc*[3], *M. Puiu*[1];
[1]*University of Medicine &Pharmacy Victor Babes, Department of Microscopic Morphology, Genetics, Timisoara, Romania,* [2]*University of Medicine &Pharmacy Victor Babes, Department of Obstetrics and Gynecology, Timisoara, Romania,* [3]*University of Medicine &Pharmacy Victor Babes, 3Department of Anatomy and Embryology, Timisoara, Romania.*

Introduction Since 70s when it was first used, till now new techniques for

screening and diagnosis of fetal chromosomal aberrations were introduced. Using the new screening tests that can select the pregnancies at risk, many syndromes can be identified before birth by performing prenatal diagnosis.
Material and method. We present here our experience in regard to the genetic diagnosis and counseling offered for pregnancies in which structural chromosomal aberrations were found. The study lot is formed by 528 prenatal samples of amniotic fluid and chorionic villi, received by our laboratory from 2006 through October 2012 for cytogenetic diagnosis.
Results. By using conventional citogenetic investigation accompain in some cases by FISH technique a total number of 21 structural chromosomal anomalies and polymorphic variants were identified in the study lot. The chromsomal aberrations identified included several deletions and microdeletions, situations with abnormal long p arm of acrocentric chromosomes, duplications, reciprocal translocations, inversions, additions, Robertsonian translocation associating trisomy 13, one 9q heteromorphism and one complex chromosome rearrangement.
Conclusion. An accurate characterization of the fetal chromosomal defects has implications in the couple decision regarding the continuing of the pregnancy or elective abortion and brings important information for the future reproductive options. Currently the prenatal genetic diagnosis can benefit from the advances of the molecular techniques that are very useful for the accurate characterization of the chromosomal anomalies. The genetic counseling, corroborating the cytogenetic information with the ultrasound abnormal findings, where present, and the results of the molecular investigations are essential for the pregnancy management.

J19.73
X chromosome inactivation in Klinefelter syndrome and 46,XX testicular DSD

V. B. Chernykh, *E. A. Bliznetz, A. L. Chukhrova, O. P. Ryzhkova, L. F. Kurilo, A. V. Polyakov; Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

We analyzed X-chromosome inactivation (XCI) in 50 Klinefelter syndrome (KS) and 15 46,XX testicular DSD patients. Chromosome analysis was performed on peripheral lymphocytes using GTG-technique. The Y-chromosome was analyzed by mPCR for SRY, AMELX/Y, ZFX/Y loci and 21 Y-specific STS markers. XCI pattern was determined by the identification of methylated (inactive) CAGn allele in exon 1 of the androgen receptor (AR) gene using methylation-sensitive restriction enzyme *Hpa*II. KS patients presented following karyotypes: 47,XXY, n=42; 48,XXXY, n=1; 48,XXYY, n=1; 47,XXY,t(3;8)(q23;p21), n=1; 47,XY,+der(X), n=1; mos46,XY/47,XXY, n=3, mos46,XX/47,XXY, n=1. No 'classic' AZF deletion was found; partial AZFc, deletion (b2/b3, n=3; gr/gr, n==2) were detected in 10% KS patients. Two of 15 (13.3%) 46,XX males were SRY-negative individuals with complete (n=1) or incomplete (n=1) masculinization. SRY+XX-males presented complete masculinization and a 46,XX karyotype (n=12), one SRY-positive patient had XX-sex reversal with Robertsonian translocation, 45,XX,der(13;14)(q10;q10). Breakpoints in the Yp11.2 locus were localized in all SRY-positive 46,XX patients. No significant difference in CAGn length between the groups was found. Also, no preference of X-inactivation toward the short and/or long AR-allele was revealed. XCI failed to evaluate in 21 KS patients and one SRY-XX-male that was homozygous for AR-CAGn allele. Skewed XCI (≥80%) was detected in 20% XX-males and 6.9% KS patients presented heterozygosity for AR-CAGn allele. Extremely skewed X-inactivation (ratio ≥90%/10%) was found only in 2 46,XX males (one SRY+ patient with complete masculinization and one SRY- patient with incomplete masculinization). Obtained data indicate that skewed XCI occurs in 46,XX-males more often that in KS patients.

J19.74
Cytogenetic and molecular analysis of complex Y chromosome mosaicsm

E. G. Okuneva, *V. B. Chernykh, E. A. Kalashnikova, Y. O. Kozlova, M. E. Minzhenkova, N. V. Shilova, T. V. Zolotukhina, O. P. Ryzhkova, A. L. Chukhrova, A. V. Polyakov; Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

We report on newborn patient with sexual differentiation abnormality and complex Y chromosome mosaicism. The patient's mother was referred to invasive prenatal diagnosis due to cardio-vascular abnormalities detected by ultrasonography and elevated hHG. Non-mosaic 45,X karyotype was revealed by conventional chromosome analysis. FISH with DXZ1 and DYZ3 probes allowed to detect a mosaicism 45,X(72%)/46,XY(9%)/47,XYY(19%) in amniotic cells.
At the birth, following features were revealed: intrauterine dwarfism, micrognatia, high nasal bridge, ventricular septal defect. Genitalia ambiguous with penoscrotal hypospadias and bilateral cryptorchidism were prominent. The gonads were not found in the scrotum and inguinal canals. Ultrasonography demonstrated the presence of vagina, but not uterus.
Postnatal chromosome analysis was performed on cultured blood lymphocytes using GTG-staining. FISH with DXZ1, DYZ1, DYZ3 and LSI SRY probes was done on metaphase chromosomes and interphase nuclei of peripheral lymphocytes and interphase nuclei of buccal smears. Molecular analysis was performed on DNA extracted from peripheral lymphocytes with QF-PCR and mPCR for SRY, AMELX/Y, ZFX/Y, TAFL, 4SH loci and 20 Y-specific STS markers.
Postnatal chromosome analysis shown 45,X karyotype, but FISH results confirmed the presence of complex Y chromosome mosaicism: X(73.8%)/X,idic(Y)(p11.3)(13.8%)/XY(6.6%)/XY,idic(Y)(p11.3)(4%)X,idic(Y)(p11.3),idic(Y)(p11.3)(1.8%) and X(56%)/X,idic(Y)(p11.3)(26%)/XY(16%)/X,idic(Y)(p11.3),idic(Y)(p11.3)(2%) in peripheral lymphocytes and buccal smears, respectively.
QF-PCR analysis demonstrated the ratio X:Y signals approximately as 70%:30%. PCR amplification was positive for Y-chromosome loci, excluding sY1192. Detected 'b2/b3' deletion, partial AZFc region microdeletion of Y chromosome, presented in all Y-bearing cell lines. Yp breakpoint was localized distally to SRY locus in Pseudoautosomal region 1 that is characterized for idicYq chromosomes.

Clinical expression of de novo 18(q-) syndrome in a child with multiple congenital malformations

S. Mandal[1], *B. B. Ganguly*[1], *N. N. Kadam*[2]; [1]*MGM Centre for Genetic Research & Diagnosis, Navi Mumbai, India,* [2]*Paediatric Department, MGM Institute of Health Sciences, Navi Mumbai, India.*

Congenital malformations in children are generally manifestations of numerical or structural alterations at chromosomal level. Numerical alterations are mostly the result of meiotic non-disjunction and structural aberrations are inherited from parents in balance or unbalance form. De novo structural abnormalities are less common; however, cause severe congenital malformations and multiple systemic defects in children. We report one 18 month old boy born to non-consanguineous healthy parents as the second child at one month pre-term with 1.2 kg birth weight. Prominent malformations, including cleft lip and palate, hypertelorism, protruding tongue, micropenis, hypotonia, atopic dermatitis and bilateral overlapped and depressed mid toe. Pediatric echo cardiography detected congenital heart disease with malaligned VSD, absent pulmonary valve and moderate pulmonary stenosis. The child could follow light when it was close to face and could not respond to sound. Conventional karyotyping detected constitutive abnormality with 46,XY,del(18q21). Parental karyotyping confirmed de novo origin of the deletion. At this age, the child had severely delayed milestones and mental retardation. This child could not hold head and didn't have social smile. Distal deletion in 18(q) is a rare disorder with an epidemiological index of 1 in every 40,000 live birth; however, it is the second most common syndrome involving chromosome 18. The mother had continuous vomiting and swelling of hands and legs till delivery and that could have been considered significant for counseling and prenatal karyotyping for prevention of this rare de novo chromosomal aberration. Prenatal karyotyping is an established cost-effective measure of taking care of chromosomal aberrations.

J19.76
Sperm DNA fragmentation rate among patients with reduced fertility

M. Mazilina[1], *E. Shilnikova*[1], *I. Fedorova*[2], *A. Gzgzyan*[2]; [1]*Saint Petersburg State University, Saint Petersburg, Russian Federation,* [2]*Ott's Institution of obstetrics and gynecology, Saint Petersburg, Russian Federation.*

Conventional semen parameters are widely used to assess man's reproductive potential. But they give us an incomplete picture of men's reproductive health. Information about sperm DNA integrity impacting on early embryo-

nic development also is very important. Sperm DNA integrity assessment is not a routine diagnostic, and specific mark seen performing standard spermogram are required to assign patients for DNA fragmentation assay.
The aim of this study was to determine sperm DNA fragmentation rate in men with reduced fertility.
Semen samples were collected from 58 men with reduced reproductive potential and from 12 sperm donors as a control. Semen analysis was performed according to WHO criteria. All patients were divided into four groups: normozoospermic, teratozoospermic, patients with reduced motility alone or in combination with reduced concentration. The method used to assess sperm DNA fragmentation was the terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay. 2000 spermatozoa per sample were evaluated.
The DNA fragmentation rate in normozoospermic group (0,54±0,69) was equal to DNA fragmentation rate in control group (0,25±0,14) (P=0,14). Increased sperm DNA fragmentation rate was observed in teratozoospermic men (0,88±0,41). There was a statistically significant difference between DNA fragmentation rate in teratozoospermic group compare to control (P<0,05). No difference was found between mean DNA fragmentation rate in group with reduced motility alone or in combination with reduced concentration, so sperm DNA fragmentation has no effect on sperm motility.
On the foregoing in case of teratozoospermia sperm DNA fragmentation assessment should be recommended.
Supported by Carl Zeiss, Administration of Saint-Petersburg and RFBR

Genetic service as a part of Assisted Reproductive Technology - experiences of Center of Reproductive Medicine (Belarus)

S. Zoukovskaya, *N. Rumiantsava, L. Savenko, H. Abramchik, L. Shamgina, K. Mosse, K. Mosse;*
Center of Reproductive Medicine, Minsk, Belarus.

Genetic factors cause infertility, spontaneous abortions, repeated IVF failures, fetal abnormalities. At present, genetic service (GS) is a necessary part of Assisted Reproductive Technologies (ART). We present a model that includes combination of ART and GS in Center of Reproductive Medicine (CRM). Results. ART programs include insemination, IVF, IVF+ICSI, testicular biopsy, cryopreservation of sperm, oocytes, embryos, blastocysts. Effectiveness is 49.2%. Genetic investigations, included in practice of CRM since 2005, are expanding every year. GS provides: 1) Counseling (~850 per year) of infertile couples for outcome prognoses, persons with malformations, monogenic, chromosomal pathology; 2) Cytogenetic studies (2005-2012 years): 1.4% rearrangements were detected among 7116 karyotypes (numerical, structural aberrations, markers); 3) Molecular testing (2010-2012 years, 2152 patients) for: deletions of AZF region Y (22/423=5.4%), mutation 1691G>A Leiden (33/1209=2.7%), mutations dF508, CFTR2,3del, 2184insA of CFTR gene (10/448=2.2%), polymorphism G20210A of F2-protrombine gene (18/1209=1.5%), polymorphism 677T/T of MTHFR gene (114/1209=9.4%); 4) Prenatal diagnostics (2005-2012years) provides: combined screening in 1-2 trimesters (3344 pregnant women); counseling of pregnant with advanced age (25.6%), calculated risk for combined screening ≤1:360 (12,6% pregnant), parental balanced rearrangements, fetus abnormalities in need of fetus examination (karyotype, DNA). Reduction of affected fetuses in multiple pregnancies (18). Pre-implantation diagnostics of aneuploidies, monogenic diseases using polar body, FISH, DNA markers and sex-linked diseases detection using free fetal DNA in maternal plasma was started. Conclusion. Combination of above-mentioned methods in reduces loss of time for necessary examinations, increases efficiency of ART, which is confirmed by the birth of 5200 healthy children.

Chromosomal Abnormalities Identified at Prenatal Diagnosis

A. Pazarbasi[1], *E. Tunç*[1], *D. Alptekin*[1], *U. Luleyap*[1], *O. Demirhan*[1], *N. Tanriverdi*[1], *F. T. Özgunen*[2], *N. Inandiklioglu*[1], *C. Evruke*[2], *L. Özpak*[1], *S. Büyükkurt*[2], *T. Tufan*[1], *I. N. Uslu*[1], *S. N. Ilgaz*[1], *G. Cömertpay*[1];
[1]*Çukurova University, Faculty of Medicine, Department of Medical Biology and Genetics, Adana, Turkey,* [2]*Çukurova University, Faculty of Medicine, Department of Obstetrics and Gynecology, Adana, Turkey.*

Purpose: Amniocentesis is a very crucial diagnostic procedure for preventing the birth of genetically defective fetuses in order to decrease the prevalence of genetic diseases in populations.
Methods: The karyotyping of 5861 fetuses was carried out in our department during the years of 2000-2013 from the samples of amniotic fluids which were sent from departments of Gynecology and Obstetrics of Balcali Hospital and other regional hospitals.
Results: Among 5861 fetuses that were karyotyped; 2989 fetuses were males and 2872 fetuses were females and 351 (5.98%) fetuses had various chromosomal abnormalities. The mean age of pregnant women having fetuses with chromosomal abnormalities was found to be 33 years of age which suggest that fetal chromosomal abnormalities were associated with maternal age. Numerical chromosomal abnormalities predominated the structural chromosomal abnormalities (65% and 33%). Both numerical and structural chromosomal aberrations were observed in 9 (2%) of all abnormal cases. The numerical chromosomal abnormalities with an incidence of 28.5% trisomy 21, 11.4% trisomy 18, 7% monosomy X, 4% trisomy 13, 3.4% triploidy, 3% Klinefelter Syndrome, 1.1% trisomy X, 0.9% XYY Syndrome, 5.7% mosaics and the others represented the remaining. The frequent structural abnormalities were 7.7% 46,XX/XY, inv(9)(p11;q13) and 6% 46,XX/XY, inv(9)(p11;q12) in all abnormalities.
Conclusions: Corollary to literature and our findings revealed that the advanced maternal age and certain environmental factors can increase the risk of fetal chromosomal abnormalities. Fetal chromosomal abnormalities representing 5.98% in our study group is crucial and underlines the importance of prenatal diagnosis for healthier pregnancies.

Cell-free fetal DNA in maternal blood using for noninvasive prenatal diagnostics of RHD gene

G. Abildinova[1], *B. Kamaliyeva*[1], *V. Zvyaginceva*[2], *M. Bayanova*[1];
[1]*National Research Center Maternal and Child Health, Astana, Kazakhstan,* [2]*Medical University „ Astana", Astana, Kazakhstan.*

Noninvasive determination of RHD gene using cell-free fetal DNA was detected in 98 rhesus negative women in the 1nd and 2nd trimester of pregnancy.
To identify fetal DNA in maternal blood approach based on polymerase chain reaction (PCR) with fluorescence detection of PCR RT was used. Regions of exon 7 of RHD gene were subjected to amplification.
Material for molecular genetics study was total DNA extracted from the plasma of pregnant women with Rh negative blood factor. Pregnant women were of different nationalities and parity women. Determination of the Rh factor in the fetus was done in consisted steps.
Among 98 RhD-negative women the results from 43 samples diagnosed Rh negative factor and 55 cases - Rh-positive factor.
The analysis took into account the position of the curves of fluorescence amplification curve relative to the curve of positive control (PC). Indirect indicator of the quality of procedures for the allocation and taken for analysis is the value of the threshold cycle between the curves of RNase-P and PC.
The difference should be no more than 2-3 of the cycle. The big difference (5 cycles or more) means serious loss of DNA during isolation leading to a decrease in the number of fetal DNA in the reaction mixture less than the detection limit of the test system and can lead to the possibility of false-negative results.
Thus the minimum allocation to guarantee correct operation of the diagnostic kit and reliable results is approximately one milliliter of plasma, recommended - 2 milliliters.

Prenatal genetic diagnosis in cystic fibrosis

L. Pop[1], *I. Ciuca*[1], *L. Tamas*[2], *Z. L. Pop*[3], *I. Popa*[1];
[1]*Pediatric II Department, Timisoara, Romania,* [2]*Biochemistry Department, UMF V Babes, Timisoara, Romania,* [3]*Obstretics and Gynecology Department, UMF V Babes, Timisoara, Romania.*

Background and aim: Our goal was to detect CFTR mutations in fetal genomic DNA isolated from amniotic fluid collected by classic amniocentesis and early amniocentesis. **Methods**: Ten couples where selected for performing prenatal diagnosis. Molecular diagnostic was performed on Genomic DNA isolated from venous blood samples collected on EDTA from both parents and on amniotic fluid samples collected by classic amniocentesis (16th week

of pregnancy) and by early amniocentesis (13th week of pregnancy) . For detection of CFTR mutations we used the Elucigene CF29 kit. **Results** showed: 6 couples with negative genetic test, 3 with heterozygote for one of next mutation (DF508, G542X, 621+1 G-T), and one of them affected DF508/621+1 G-T). **Conclusion.** Prenatal diagnosis can be performed on samples of amniotic fluid collected by normal amniocentesis or by early amniocentesis however, due to the greater risks for pregnancy and fetus of this early procedure and because the volume of collected amniotic fluid is reduced . Also, for an accurate renatal diagnosis in mucoviscidosis it is required to have a good sampling technique for the amniotic fluid. Mutation detection by ARMS-PCR with Elucigene CF29 is applicable only to those couples in which at least one of the parents is a carrier of the ΔF508 mutation, or when both parents carry different CFTR mutations, other than ΔF508, because the kit can differentiate between the condition of heterozygote (carrier of a mutation) and homozygote (diseased) only in the case of ΔF508 mutation.

Pseudomosaicism in several cases of amniocentesis

L. Neagu, *S. Grigore, D. Albu;*
Life Memorial Hospital, Bucharest, Romania.

Introduction: Our study is based on a work of three years of amniocentesis.
It is known that sometimes the cultured cells develop subtle changes from original cells.
The presence of chromosomally abnormal cells in a single culture of amniocytes with only normal cells in all other cultures is considered to represent pseudomosaicism since the fetus is usually found to have a normal karyotype.
We have three cases of structural abnormality of chromosomes and ten cases of numerical chromosomal modifications.
For each case, three primary cultures were set up using Falcon flasks, Amniomax medium and classic GTG bands.
The first case was represented by a pregnant woman of 36 years old reffered for amniocentesis because a positive triple test; fetal karyotype revealed a normal 46,XX in two flasks, while in one flask was found a deletion on the long arm of chromosome X.
The second case was a 39 years old pregnant woman of 16 weeks pregnancy. The fetal karyotype was normal 46,XX but in one flask was found an inversion on 11 chromosome and one cell with a deletion on long arm on 10 chromosome.
The third case was a pregnant woman of 19 weeks of pregnancy with fetal karyotype 46,XY in two flasks and in one flask few metaphases revealed t(4;22) (p14;q11.2).
Conclusion : Later on, for a correct diagnosis, amniocentesis was repeated and in all cases fetal karyotypes were found to be normal.

Genetic basis of recurrent miscarriage in Kazakh population

G. S. Svyatova, *G. M. Berezina, A. R. Aimbetova, D. N. Salimbaeva;*
The Scientific Center of the obstetrics, gynecology and perinatology, Almaty, Kazakhstan.

The recurrent miscarriage (RM) of pregnancy has a multifactor background as a results from interactions between environmental factors and functionally weak alleles of many susceptibility loci across the genome. The aim of this research was to determine the contribution of some genotypes of genes of RM predisposition in Kazakh population.
The polymorphisms of genes of coagulation system FV и FII, ITGB3, FGB, PLANH1; folate metabolism MTHFR, MTRR, MTR; II phase of detoxification system - GSTM1, GSTT1, GSTP1; lipid metabolism ApoC, ApoE; endothelial dysfunction eNOS3 and ACE genes were detected.
Molecular genetic and clinical laboratory assays were carried out in a group of 200 women with 2 and more spontaneous early abortions in anamnesis and 150 women with normal reproductive function. All were Kazakhs.
The most important contribution in RM was determined for unfavorable genotypes of FII и FV coagulation factors, carriers of which increase the risk of RM (OR) in 4-18 times, antiphospholipid syndrome (APS) in 5 times. The carriage of 677TT and 1298CC genotypes (MTHFR), 66GG (MTRR) and 2756GG (MTR) increase risk of RM in 2.5-8.3 times. The carriage of 3 unfavorable GST genotypes decrease the activity of antioxidant enzymes and increases the risk of RM (OR) in 2.3 to 12.2 times.
We observed the significant genetic input of functionally weak genotypes in RM, APS in Kazakh population. The algorithm of prognosis, preconceive prophylaxis of RM were worked out, which reduced to 2.5 times the frequency of RM for Kazakhs.

Still Births and Foetal Genetic Defects causing Recurrent Miscarriages in couples

N. J. Jain[1], *K. Gomes*[1], *N. Patil*[1], *S. Salvi*[1], *B. Ganguly*[2];
[1]*Padmashree Dr D Y Patil University, Navi Mumbai, India,* [2]*MGM Centre for Genetic Research and Diagnosis, Navi Mumbai, India.*

Recurrent pregnancy loss (RPL), defined as two or more miscarriages of fewer than 20 weeks of gestation, affects up to 5% of couples trying to establish a family, whereas still birth is the intrauterine foetal death (IUFD) at 20 weeks of gestation or greater. These abnormalities are caused by errors in the number or structure of chromosomes. Some chromosomal abnormalities result in miscarriage or stillbirth. However, clinicians and patients find it particularly frustrating that no convincing aetiology is identified in at least 50% of cases. This report describes known and suspected causes of recurrent miscarriages and stillbirth including genetic abnormalities, maternal and paternal age, infectious diseases, environmental toxins, obesity, infertility, and a variety of medical conditions in the mother, etc. The aim of this study is to detect the cause of foetal wastage and assess the frequency and nature of chromosomal abnormalities that contribute to the occurrence of foetal wastage in couples. Karyotype analysis of the abortus tissue was performed by our cytogenetic laboratory using standard G-banding techniques. Metaphase chromosome preparations from the amniotic fluid samples were also made according to standard cytogenetic protocols and studied. Chromosomal abnormalities were reported according to the current international standard nomenclature (ISCN). In almost 50% of the cases, the miscarriages were due to chromosomal abnormalities in the embryo. A common type of chromosomal abnormality is trisomy 21, affecting approximately 1 in 800 babies. This report helps to describe the cytological abnormalities and correlate the recurrent abnormalities in a given population.

Screening of chromosomal aberrations in infertility work-up

B. B. Ganguly[1], *G. Khastgir*[2];
[1]*Genetics Center, Navi Mumbai, India,* [2]*BIRTH Fertility Clinic, Kolkata, India.*

Infertility is a serious societal concern for women for not being able to give birth to a child. Always priority is given to perform a series of investigations for the woman since she carries the pregnancy. Gynecologists advise karyotyping for the couple; however, generally the family decides to consider the woman for the test first, and the male partner agrees when wife's karyotype comes normal. Karyotypic configurations of the partners have been found as one of the major issues leading to reproductive failure. We report chromosomal status of 223 couples having history of primary infertility or recurrent first trimester miscarriage. Peripheral blood samples were collected from 446 partners and cultured in serum and phytohemagglutinin supplemented RPMI 1640 medium for 72 hours at 37_0C. Mitotic cells were collected following standard colcemid-hypotonic-fixative protocol. A total of 11150 G-banded metaphases were analysed with the help of IKAROS imaging software (MetaSystems, Germany). Five cells were classified in karyotypic form as per ISCN nomenclature. Chromosomal abnormalities, including small Y (30%), long Y (2.24%) and inv(Y) (1.34%) were recorded exclusively in Y chromosome in 34% male partners. Other constitutive aberrations, including t(2;7), t(6;20), t(3;6), t(1;7), t(17;20), t(3;4), inv(9) and del(9q), inv(7), XX/XXX mosaicism and XY female were present in 2.69% with an equal ratio in males and females. Small Y could be the result of microdeletion in AZF factor and warrants seriously for considering a molecular test for every infertile male partner. Thus, in general, karyotyping of the couples should invariably be included in infertility management.

The possibilities of prenatal DNA diagnostics of complex chromosome pathology using fluorescent quantitative PCR analysis

T. Asadchuk, *L. Padliashchuk;*
Scientific-Practical Center "Mother and Child", Minsk, Belarus.

The most frequent cause of congenital human pathology are numerical ab-

normalities of chromosomes (aneuploidies). For diagnostics of numerical abnormalities of human chromosomes there was developed a quantitative multiplex PCR analysis based on the simultaneous testing of 15 microsatellite markers of chromosomes 13, 18, 21, X, Y.
We analyzed 200 DNA samples from fetuses having the high risk of chromosomal pathology. DNA was extracted from the amniotic fluid cells or cell culture of chorionic villus. Numerical abnormalities of human chromosomes were detected in 19 cases (9.5%). Diagnosis determined by DNA analysis was confirmed by karyotyping in all the cases. Revealed pathology included trisomy of chromosome 21 (8 fetuses - 4%), trisomy of chromosome 18 (5 fetuses - 2.5%), trisomy of chromosome 13 (1 fetus - 0.5%), triploidy (3 fetuses - 1.5%), mosaic form of chromosome X monosomy (1 fetus - 0.5%, karyotype 45,X[50]/46,XY[5]). Molecular-genetic study has also identified an unusual pathology (1 fetus - 0.5%) with three chromosomes 13 and 21 and two chromosomes 18 and X. Cytogenetic study determined karyotype 67,XX,-18[14]/47,XX,+18[1] with mosaicism both of triploidy and trisomy simultaneously. The proband's parents were examined with the help of DNA analysis, and it was found out that the extra set in triploid clone was of paternal origin.
Only a comprehensive study including DNA-analysis and a cytogenetic analysis allows to determine the karyotype and the abnormality formation mechanism in a complex chromosome pathology.

Complex chromosome rearrangement, t(1;21;4) in an azoospermic male

E. Ivanovska[1], *M. Vasilevska*[1], *S. Lazarevski*[1], *G. Dimeska*[2];
[1]*Clinical Hospital Acibadem-Sistina, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Faculty of natural sciences and mathematics, Skopje, Macedonia, The Former Yugoslav Republic of.*

Complex chromosome rearrangements (CCRs) are very rare structural aberrations in human population involving at least three chromosomes with three or more chromosomal breakpoints. Most of the males with CCRs have shown infertility problems and there have been several such reports in the literature of CCRs in males with oligozoospermia or azoospermia. Here we report 54 years old male with normal phenotype who was diagnosed with azoospermia, during routine infertility examinations including clinical history, spermiogram and blood hormone levels. The testicular biopsy which was later performed confirmed the diagnosis showing spermatogenic arrest at the spermatocyte level on histology. Karyotype analysis with standard GTG- banding on peripheral lymphocytes was then performed and revealed a 46, XY, t(1;21;4) (q21; q22; p15) chromosome complement. The cytogenetic investigations showed a complex chromosomal rearrangement involving firstly a translocation between the long arm of chromosome 1 and the long arm of chromosome 21, secondly a translocation between the long arm of the same chromosome 21 and the short arm of chromosome 4 and third a translocation between the short arm of the same chromosome 4 and the long arm of chromosome 1.
We conclude that the complexity of CCRs might affect the severity of spermatogenetic impairment, thus azoospermia of our patient can be explained with apoptosis of produced genetic imbalanced spermatocytes.

High Incidence of Chromosomal Aberrations in Couples with Reproductive Failure in Canakkale

F. Silan[1], *S. Yalcintepe*[1], *D. Uysal*[1], *A. Uludag*[1], *E. Cosar*[2], *A. N. Cakir Gungor*[2], *O. Ozdemir*[1];
[1]*Canakkale On Sekiz Mart University, School of Medicine, Department of Medical Genetics, Canakkale, Turkey,* [2]*Canakkale On Sekiz Mart University, School of Medicine, Department of Obstetrics and Gynecology, Canakkale, Turkey.*

Numerical and structural abnormalities of chromosomes may be the reasons of infertility and recurrent pregnancy losses (RPL). Patients should include karyotyping of both parents for chromosomal aberrations. Mainly balanced rearrangements are common in couples with reproductive disorders.
In Canakkale On Sekiz Mart University, School of Medicine, Department of Medical Genetics, Cytogenetic Laboratory, from 94 couples diagnosed as infertility and 118 couples diagnosed as recurrent pregnancy loss- total 424 patients- chromosome analysis was done with heparinized peripheral blood samples by applying the G-banding who referred to Clinic of Obstetrics and Gynecology and Clinic of Medical Genetics between May 2011-November 2012.
In RPL group, there was no numerical anomalies but there was 4.26 % balanced structural chromosomal abnormality. There were structural abnormalities in 9 patients: 46,XY,inv(11)(p13q11), 46,XX,inv(11)(p13q11) (no consanguineous marriage), 46,XY,ins(9;22)(9pter-q12::22q11.1-q13.33::9q12-9qter), 46,XX,9qh+ in 2 patients, 46,XY,inv(9)(p11q13), 46,XY,t(4;6)(q13.1;qter)(4pter-4q13;6pter-6qter::4q13-4qter), 46,XX,t(8;12)(p22;p12.3), 46,X,t(X;2)(q27;p25).
In infertility group numerical chromosomal anomaly was 3.72 %, balanced structural chromosomal anomaly was 4.26 %. Our results were 6 numerical and 8 structural abnormalities: 45,X in 3 patients, 47,XXY in 2 patients, 46,X,i(X)(qter-->q10:q10-->qter), mos46,X,i(X)(qter-->q10:q10>qter)[14/45,X[7, mos47,XXY[33/46,XY[17, 46,XX,robt(13;14) in 2 patients, 46,XY,robt(13;14), 46XY,t(1;2)(p36;p14-->16)pat, 46,XY,t(3;8)(q21;q24) and 46,XY,inv(9)(p11q13). In a couple with a history of two failed IVF and first degree cousin marriage, it was detected robt(13;14) in both wife and husband.
Genetic counseling was given to couples about possible outcomes of pregnancies, having healthy children, prenatal diagnosis and preimplantation genetic diagnosis.

A mosaic Klinefelter Syndrome variant identified with amniocentesis

H. Ü. Lüleyap[1], *A. Pazarbaşı*[1], *F. T. Özgünen*[2], *S. T. Bozdoğan*[3], *S. Büyükkurt*[2], *D. Alptekin*[1];
[1]*Cukurova University, Medical Faculty, Department of Medical Biology and Genetics, Adana, Turkey,* [2]*Cukurova University, Medical Faculty, Department of Obstetrics and Gynecology, Adana, Turkey,* [3]*Department of Medical Genetics, Numune Research and Education Hospital, Adana, Turkey.*

Purpose: In 80% of the cases, the karyotype in Klinefelter syndrome is 47 XXY. Remaining 20% chromosomal variants including mosaicism is seen. Here we report a 32-year-old pregnant woman referred to our laboratory due to abnormal sonographic finding.
Methods: The karyotyping and QF-PCR of the fetus was carried out in our department from the sample of amniotic fluid which was sent from department of Gynecology and Obstetrics of Balcali Hospital. This fetus is the sixth pregnancy of consanguineous Turkish parents, after one mol pregnancy, one intrauterine death at last trimester, two female and one male birth. A standart GTG banding procedure was performed on fetal cells and peripheral blood cell of the family. Quantitative fluorescent PCR was used for trisomy detection.
Results: Chromosome analysis of amniotic fluid from two culture flask revealed mos 46,XY[21] / 48,XXXY[6] karyotype. The parents and fetus were normal with QF-PCR analysis. Omphalocele was detected by USG at the fetus as a different feature from Klinefelter syndrome.
Conclusions: A mosaic Klinefelter syndrome variant is compared with other reported cases of the literature and the follow-up of prenatally diagnosed mosaic Klinefelter variant is discussed. Due to presence of omphalocele, this case should be investigated for another abnormality.

Association of MTHFR, MTR, MTRR polymorphism with the risk of pregnancy loss: a study on a Russian population

O. V. Kochetova, *T. V. Viktorova;*
Institute of Biochemistry and Genetics Ufa scientific centre, Ufa, Russian Federation.

The objective of study is the genetic association between methylenetetrahydrofolate reductase (MTHFR c.665C>T и c.1286A>C), methyltetrahydrofolate homocysteine methyltransferase (MTR c.2756A>G), 5-methylenetetrahydrofolate-homocysteine methyltransferase reductase (MTRR c.66A>G) polymorphism and recurrent pregnancy loss among women with petrochemical toxic substances. It as done prospective case-control study. A total of 159 recurrent pregnancy loss female workers at the petrochemical plant and 150 healthy control female workers with successful pregnancy were analyzed.
Genotyping was done by tetraprimer ARMS-PCR. Age and professional exposition adjusted odds ratios were calculated by logistic regression analysis. All surveyed women were Russian.
The frequency of rare allele polymorphism MTHFR c.1286A>C among women with recurrent pregnancy loss was 42%, among healthy control 31%. We found that presence of rare allele „C" polymorphism c.1286A> C and heterozygous and rare homozygous genotypes significantly increased the

risk of recurrent pregnancy loss. Association was identified polymorphism c.1286A> C MTHFR gene to the risk of fetal loss in women for the „CC" genotype (OR=2.61 (CI 95% 1.23-5.53); p=0.038) and for the allele „C" OR=1.52 (CI 95% 1.07-2.18); p=0.02. The association of haplotype TC gene MTHFR (c.667C> T and c.1286A> C) with the development of fetal loss (OR = 1.96 (CI 95% 1.05 - 3.68); p = 0.037).
No significant association in MTHFR (c.665C>T) и MTR (c.2756A>G), MTRR (c.66A>G) genotype frequency was observed for the recurrent pregnancy loss.
Conclusion: Our results confirm that polymorphisms in the MTHFR gene are associated with recurrent pregnancy loss susceptibility.

Mosaic trisomy 22 after in vitro fertilization

I. I. Kavecan, *J. Jovanovic Privrodski, M. Obrenovic, M. Kolarski, D. Radovanov;*
Institute for Children and Youth Health Care Vojvodina, Novi Sad, Serbia.

We report a case of mosaic trisomy 22 after in vitro fertilization (IVF). Assisted reproductive treatment was done in a 36 years old, healthy female with history of sterility because of oligoasthenospermia in her husband, 39 old year male. This was a first pregnancy of noncounsanguinous couple after first IVF.
Biochemical screening was done in 12th week of gestation (gw): free beta hCG was 10.15 MoM, PAPP was 1.17 MoM. Expert ultrasound in 12th GW revealed nuchal transluceny 1.5 mm and crown rump length 69.7mm without pathological findings or congenital anomalies. Expert ultrasound in 17th gw revealed intrauterine growth retardation and in 20th gw, complex heart congenital anomalies, pulmonary atresia and ventricular septal defect were seen. Amniocentesis was done in 18th gw and finding was: 46, $XY_{[15]}$ /47,XY,+$22_{[15]}$, mosaic trisomy 22 (G-banding technique, 30 metaphases). Couple was informed about cytogenetical findings by genetic counselor and pregnancy was terminated. In next pregnancy, also after IVF, amniocentesis was performed in 16 gw and result wasnormal male karyotype. This case emphasizes the importance of genetic counseling and preimplantation diagnostics.

GAPDHS gene polymorphism in asthenozoospermic men with dysplasia of the sperm fibrous sheath

S. Khayat, *E. E. Bragina, L. F. Kurilo;*
Research Centre for Medical Genetics of Russian Academy of Medical Sciences, Moscow, Russian Federation.

Dysplasia of the sperm fibrous sheath is a genetic sperm defect, characterized by dysplastic development of the axonemal and periaxonemal cytoskeleton. Most of the glycolytic enzymes are localised in principal piece of the sperm tail and the sperm-specific isoform of glyceraldehyde-3-phosphate dehydrogenase is tightly associated with the sperm fibrous sheath is an essential enzyme for glycolysis.
In order to investigate possible *GAPDHS* alterations semen samples from 5 asthenozoospermic men with dysplasia of the fibrous sheath and 5 sperm donors were collected. DNA was extracted from each semen sample. Analysis on the possible *GAPDHS* alterations was performed by PCR amplification and sequencing.
Single nucleotide polymorphism rs29381 (660-22 G>A) of *GAPDHS* was revealed in all analyzed samples from asthenozoospermic men with dysplasia of the fibrous sheath, whereas DNA samples extracted from donated sperm correspond to reference *GAPDHS* sequence.
Further studies are currently ongoing in order to validate these findings.

Investigation of relationship between the risk of Down syndrome and 844ins 68 polymorphism of the cystathionine β-synthase gene

D. Neagos, *L. Bohiltea, R. Cretu;*
Genetic Departament, U.M.F. Carol Davila, Bucharest, Romania.

Introduction: Human cystathionine β-synthase is a hemoprotein which catalyzes the condensation of Hcy and serine to form cystathionine The gene encoding cystathionine synthase (CBS) has been localized in chromosome 21 (21q22.3) in a region correlated with Down syndrome phenotype. The aim of the present study was to investigate the effect of 844ins 68 polymorphism in cystathionine β-synthase gene as a maternal risk factor for DS.
Materials and methods: The study was performed on a total number of 72 women split in two groups: one group of 26 women who gave birth to at least 1 DS baby and the other group comprises 46 women, who gave birth only to healthy children.
Human genomic DNA was isolated from peripheral blood samples with peqGOLD blood DNA mini kit. The common CBS polymorphism that causes an insertion of 68 bp at the 844 position was identified using the method PCR.
Results: The frequencies of CBS 844ins68 genotypes, (ins-/ins-, ins+/ins-) among mothers with DS children were 84.6 and 15.4%, respectively. The corresponding frequencies among controls were 91.3 and 8.7%, respectively. There were no significant differences, in genotype frequencies between the two groups (OR 1.91; 95% CI 0.44 - 8.38 P 0.39) and there were no subjects identified with homozygous genotype ins+/ins+ .
Conclusions: Allele frequencies for CBS 844ins68 polymorphism do not point to the association between this particular polymorphism and DS phenotype. Therefore, CBS 844ins68 the polymorphism is not a maternal risk factor for DS.

J19.93
Repair and cell cycle control systems' genes analysis for miscarriage

K. Kutsyn, *K. Kovalenko, E. Mashkina, T. Shkurat;*
Southern Federal University, Rostov-on-Don, Russian Federation.

According to current conception miscarriage or spontaneous abortion is the multifactorial disorder. Most spontaneous abortions are occur during the first trimester (from 50 to 70 %). Genetic component of miscarriage multifactorial etiology is much diversified and involves many functional groups of genes which in combination with lifestyles and environmental factors lead to spontaneous abortion development. The goal of our work was to investigation of repair (APEX1, ERCC2 (XPD)) and cell cycle control system (CHEK2) gene variants in blood cells and chorion tissues from women with physiological and miscarriage pregnancies using allele-specific PCR assays. The following polymorphic variants were tested: APEX1 Asp148Glu, ERCC2 Lys751Gln, 2 1100delC. The difference was not between controls and spontaneous abortion groups during analysis of the blood samples genotype and alleles frequency. During analysis of the chorionic samples significant difference in genotype and gene variant frequency for 1100delC polymorphism of 2 gene was determined between controls and undeveloped pregnancy group. The frequency decreasing of normal homozygotes for ERCC2 and 2 polymorphisms and increasing of part of Gln/Gln and del/del occurs in the spontaneous abortion group in comparison with controls. Also significant differences in ERCC2 Lys751Gln and 1100delC 2 gene variants frequency were revealed between control and undeveloped pregnancy groups. Our results suggest that the presence of the polymorphic variants of repair system genes in the genotype lead to the spontaneous abortion susceptibility. This work was supported by the RFBR (project № 12-04-31408).

Validation of a commercially available mRNA reprogramming method for iPS cell generation.

I. Varela[1], *A. Karagiannidou*[1], *M. Tzetis*[2], *V. Oikonomakis*[2], *E. Petrakou*[1], *M. Theodosaki*[1], *E. Kanavakis*[2], *E. Goussetis*[1];
[1]*Stem Cell Transplant Unit, Aghia Sophia Children's Hospital, Athens, Greece,*
[2]*Department of Medical Genetics, University of Athens Medical School, Athens, Greece.*

Since the pioneer work of Takahashi and Yamanaka in 2006, many methods have been reported on the generation of induced pluripotent stem (iPS) cells. Most protocols rely on viral vector-mediated transduction of reprogramming genes involving random insertions of exogenous sequences into the genome with insertional mutagenesis being a serious concern. Recently, a non-integrating system has been reported to efficiently reprogram human BJ foreskin fibroblasts using synthetic mRNA trancripts encoding the Yamanaka factors. The mRNA method requires the use of irradiated human newborn foreskin fibroblasts (NuFF) as feeder cells. We evaluated the commercially available mRNA reprogramming system (Stemgent) on human adult skin fibroblasts (ASF) using human BJ foreskin fibroblasts as positive control. For the required feeder cells, we used either irradiated NuFF or human fetal skin fibroblasts. Five mRNA encoding reprogramming factors (Oct4, Klf4, Sox2, Lin28, c-Myc) were delivered to the target cells via a lipid-based vehicle (RNAiMAX, Invitrogen). Transfection efficiency for both ASF and BJ cells was about 50% positive cells. For the BJ culture, colonies began

to appear as early as 10 days demonstrating a reprogramming efficiency of 1.45%. For the ASF experiment, colonies began to emerge by day 17 with an iPSC conversion efficiency of 0.1%. Transcriptional expressions of Nanog, Oct3/4, Sox2 and Rex1 confirmed the pluripotency of the colonies. In our hands, we obtained iPS-colonies only when using NuFF feeder layer. Our results demonstrate that this mRNA method can efficiently reprogram fibroblasts and it must be further investigated if it is applicable to other cell types.

J20.02

Mesenchymal derivatives of genetically unstable human embryonic stem cells (hESCs) also show genetic alterations but undergo senescence in culture as do bone marrow derived mesenchymal stem cells.

A. Karagiannidou[1], *I. Varela*[1], *M. Tzetis*[2], *K. Giannikou*[2], *E. Petrakou*[1], *M. Theodosaki*[1], *E. Goussetis*[1], *E. Kanavakis*[2];
[1]*Stem Cell Transplant Unit, Aghia Sophia Children's Hospital, Athens, Greece,*
[2]*Department of Medical Genetics, Medical School, University of Athens, Athens, Greece.*

Cultured hESCs usually reveal at their undifferentiated stage genomic instability that renders them inappropriate for the application of cell therapy. However, it is not yet clear whether genetic or epigenetic alterations occuring in the pluripotent cells during culture, would exhibit any effect on the growth potential of the specific differentiated derivatives. We report that hESC lines HUES-7 and -9 carrying genetic alterations, produce *in vitro* mesenchymal stem cells (hESC-MSCs) which show progressive growth arrest and enter senescence after 12 and 15 passages, respectively. No difference was observed in their proliferative potential compared to bone marrow derived MSCs. Comparative genomic hybridization analysis (a-CGH) of hESCs and hESC-MSC revealed a significant overlap in chromosomal alterations (Table) suggesting that genetically altered hESCs are not selected out during differentiation. Our findings suggest that hESC-MSC despite their genomic instability, exhibit an *in vitro* growth pattern of normal MSCs and not that of transformed cells not acquiring selective *in vitro* growth advantage.

Isodicentric Y chromosomes in Egyptian patients with Disorders of Sex Development (DSD)

M. K. Mekkawy;
National Research Center, Cairo, Egypt.

Isodicentric chromosome formation is the most common structural abnormality of the Y chromosome. As dicentrics are mitotically unstable, they are subsequently lost during cell division resulting in mosaicism with a 45,X cell line.
This study reports six patients with variable signs of disorders of sex development (DSD) including ambiguous genitalia, short stature, primary amenorrhea and male infertility with azoospermia.
Cytogenetic studies showed the presence of a sex chromosome marker in all patients; associated with a 45,X cell line in five of them. FISH technique was used to determine the structure and the breakage sites of the markers that all proved to be isodicentric Y chromosomes.
Three patients, were found to have similar breakpoints: idic Y(qter→ p11.32:: p11.32→ qter), two of them presented with ambiguous genitalia and were found to have ovotesticular DSD, while the third presented with short stature and hypomelanosis of Ito.
One female patient presenting with primary amenorrhea, Turner manifestations and ambiguous genitalia revealed the breakpoint: idic Y (pter→q11.1::q11.1→pter). The same breakpoint was detected in a male with azoospermia but in non-mosaic form.
An infant with ambiguous genitalia and mixed gonadal dysgenesis had the breakpoint at Yq11.2: idic Y(pter→q11.2::q11.2→pter).
SRY signals were detected in all patients.
Sequencing of the *SRY* gene was carried out for three patients with normal results.
This study emphasizes the importance of FISH analysis in the diagnosis of patients with DSD as well as the establishment of the relationship between phenotype and karyotype.

Promyelocytic leukemia (PML) expression during mouse embryonic stem cells (mESCs) neural differentiation indicates a role for PML nuclear bodies (PML-NBs) in cellular pluripotency than neural differentiation

K. Karbalaie[1,2], *S. Vallian*[1], *H. Baharvand*[3], *M. Nasr-Esfahani*[2];
[1]*Isfahan University, Isfahan, Islamic Republic of Iran,* [2]*Royan Institute, Isfahan, Islamic Republic of Iran,* [3]*Royan Institute, Tehran, Islamic Republic of Iran.*

Promyelocytic leukemia nuclear bodies (PML-NBs) have been known as one of the major cellular features, containing several proteins which are involved in cell growth and differentiation. Promyelocytic leukemia protein (PML) is one of the major proteins in the PML-NBs. In somatic cells there are numerous PML-NBs while in human embryonic stem cells (hESCs) there are few large PML-NB structures with two different "rod" and "rosette" morphologies and different contents. In hESCs prior to or concomitant with the onset of differentiation, different PML-NB structures form and the nuclear size increases. This results in alteration in cell state, pluripotency and self-renewal property. In addition, an antiproliferative activity has been reported for PML. This operates either directly or indirectly by means of interaction with the neural differentiation machinery. This suggested a role yet to be known for PML in neural differentiation and nervous system development. To understand the actual role of PML, the expression pattern of this protein was investigated in embryonic stem cells (mESCs) at different stages of neural differentiation. Our data, for the first time, showed that PML protein expression decreased in neural precursor cells relative to ESCs, but this expression slightly reappeared in neural cells. These data suggested that the PML expression may have a more important role in cellular pluripotency than neural differentiation.

Inherited mosaic 16p11.2 microduplication in patient with cognitive impairment

S. Kemeny[1,2], *C. Pebrel-Richard*[1,2], *E. Pierre-Eymard*[1,2], *A. Tchirkov*[1,2], *C. Francannet*[3], *P. Vago*[1,2];
[1]*CHU Estaing, Cytogénétique Médicale, Clermont-Ferrand, France,* [2]*ERTICa, Univ Clermont 1, UFR Médecine, Clermont-Ferrand, France,* [3]*CHU Estaing, Génétique Médicale, Clermont-Ferrand, France.*

Gene copy number variations (CNVs) at the 16p11.2 locus have been associated with cognitive disorders including autism (deletions), schizophrenia (duplication) and more recently with severe obesity and being underweight. Even if these chromosomal imbalances were de novo in the majority of cases, some of them were inherited from a parent to a child in an autosomal dominant manner. Chromosomal abnormalities can be homogeneous or in mosaic form. Mosaicism is the presence in an individual of more than one genetically distinct cell line developed from one zygote. Mosaicism can be

observed in both somatic and germ line cells and assumes that individual could transmit the specific affected cell line to his or her offspring homogeneously.
We report clinical, cytogenetic and molecular investigations of a 14 years-old girl with cognitive impairment and mildly dysmorphic appearance. We carried out detailed clinical phenotyping of this patient and investigated the genetic basis using Agilent 180K array comparative genomic hybridization (array-CGH).
We identified by array-CGH and confirmed by Fluorescence In Situ Hybridization a mosaic 16p11.2 microduplication. Family investigations reveal the same abnormality in the mother, also in mosaic form. Most cases of inherited mosaic chromosomal abnormalities represented supernumerary markers, and only few cases of inherited mosaic interstitial microduplications have been described.

Report of a child with a pure de novo 17p13.2pter duplication localized to the terminal region of the short arm of chromosome 14

M. Krajewska-Walasek[1], *M. Kucharczyk*[1], *D. Gieruszczak-Białek*[1,2], *M. Kugaudo*[1,3], *A. Cieślikowska*[1], *M. Pelc*[1], *A. Jezela-Stanek*[1], *A. Gutkowska*[1];
[1]*The Children's Memorial Health Institute, Warsaw, Poland,* [2]*Department of Pediatrics, Medical University of Warsaw, Warsaw, Poland,* [3]*Department of Child and Adolescent Psychiatry, The Medical University of Warsaw, Warsaw, Poland.*

Chromosomal duplications including 17p13.3 has been recently defined as a new distinctive syndrome (MIM#613215) with several diagnosed patients. Some variation is known to occur in the breakpoints of the duplicated region and consequently in the genes content as well. This variation is reflected by the slight variability in phenotype. When the duplication includes all four genes strongly correlated with the phenotype (*PAFAH1B1*, *RPA1*, *CRK*, *YWHAE*), clinical picture seems to be complex. Most of these aberrations are relatively small interstitial duplications and only 4 involved terminal regions.
Here, we report on another, fifth patient, a 4-year-old girl with a pure *de novo* subtelomeric duplication 17p13.2pter identified by MLPA. This finding was confirmed and further characterized by FISH and aCGH studies. As it turned out a 5.77 Mb duplicated region of 17p13.2pter is resided on the non-deleted terminal region of chromosome 14p and involves all genes important for defining the phenotype.
Our patient with moderate psychomotor delay presents all facial features described so far in duplication 17p13.3 comprising marked hypotonic and long face, downslanting palpebral fissures, low-set ears, small nose with round tip and small mouth. In addition, unilateral palmar transversal crease and oculocutaneous albinism are present.
Our case indicates that the facial features observed in individuals with psychomotor delay and *de novo* duplication encompassing the whole 17p13.3 region are specific enough to allow delineating of a clinically recognizable phenotype.
The study was supported by MNiSW Grant No. 0605/B/P01/2009/37. Acquiring of the Roche NimbleGen microarray platform was co-financed by ERDF project POIG.02.01.00-14-059/09.

J20.07
Characterization of 42 small supernumerary marker chromosomes by FISH methods

N. V. Shilova, *M. E. Minzhenkova, Z. G. Markova, Y. O. Kozlova, V. G. Antonenko, T. G. Tsvetkova, T. V. Zolotukhina;*
Federal State Budgetary Institution «Research centre for medical genetics» under the Russian Academy of Medical Sciences, Moscow, Russian Federation.

We report 42 cases with small supernumerary marker chromosomes (sSMCs) that were not identified unambiguously by conventional chromosome-banding alone. In order to determine the origin of sSMCs, we used a variety of FISH methods with different DNA-probes as well as multicolor FISH techniques (mFISH, mBAND, cen-mFISH). A total of 12 sSMCs (28,6%) originated from chromosome 15: inv dup(15)(q11.1) markers were detected in 9 cases (1 mosaic) with normal phenotype; inv dup(15)(q13) sSMCs , contained PWS/AS critical region– in 3 cases with abnormal phenotype. sSMCs derived from chromosome 22 were detected in 13 cases (31%): inv dup(22)(q11.1) markers were detected in 8 cases (2 mosaic) with normal phenotype; inv dup(22)(q11.2) – in 3 cases (2 mosaic) (cat eye syndrome); der(22)t(11;22)(q23;q11.2) – in 1 case (Emanuel syndrome); inv dup (22)(:p11.1→qter)– in 1 case. sSMC originating from chromosome 21 - inv dup(21)(q11.1) was detected in one case. sSMCs as the product of 3:1 segregation of a reciprocal translocation were characterized in 2 cases. sSMCs associated with Pallister-Killian syndrome were detected in 3cases, with i(18)(p10) syndrome – in 4 cases. Small marker ring chromosomes were identified in 3 cases: one case - r(20) and two cases - r(16). Neocentromere- sSMCs were revealed in 2 cases: unbalanced inv dup(8)(p23) and balanced r(1)(p13p21). One case was mosaic marker chromosome derived from chromosome Y – i(Y)(p10). Unusual case with sSMCs mosaicism - 47,XY,+ i(18)(p10)/47,XY,+der(18)t(18;21)(q21.1;q11.2)- was identified in proband with abnormal phenotype.Thus FISH methods are highly suited to define the chromosomal origin and the composition of sSMCs.

Deletions at 18q21.1-q21.2 associated with an apparently balanced translocation t(6;18)(q13;q22.3) in a patient with developmental delay, agenesis of the corpus callosum and craniofacial dysmorphisms

A. C. S. Fonseca, *A. Bonaldi, A. M. Vianna-Morgante;*
Department of Genetics and Evolutionary Biology, University of São Paulo, São Paulo, Brazil.

We report an apparently balanced de novo translocation t(6;18)(q13;q22.3) in an 3-year-old boy with developmental delay, agenesis of the corpus callosum (ACC) and craniofacial dimorphisms. The chromosome 6 breakpoint was mapped by FISH to a 762 kb segment at 6q13 (chr6:70,302,791-71-,064,771; hg19). *LMBRD1, COL19A1, COL9A1* genes that might have been disrupted by the breakpoint were discarded as candidates for the phenotype based on their function. The chromosome 18 breakpoint was mapped to a 962 kb gene negative region at 18q22.3 (chr18:68,777,622-69,739,381). After a-CGH (180K platform; Agilent) and FISH, two deletions were detected on the der(18): a 2.7 Mb segment at 18q21.1-q21.2 (chr18:47,555,744-50-,276,170), and a 375 kb segment at 18q21.2 (chr18:50,600,596-50,976,024). The deletions encompass 12 genes (*MYO5B, CCDC11, MBD1, CXXC1, SKA1, MAPK4, MRO, ME2, ELAC1, SMAD4, MEX3C, DCC*), three of them (*ME2, DCC* and *MBD1*) with a function in the central nervous system. The *DCC* encodes a netrin-1 receptor. Netrin-DCC signaling regulates corpus callosum formation (Fothergill et al. Cereb Cortex 2013; Epub), and ACC is documented in null *DCC* or null netrin-1 mice (Fazeli et al. Nature 1997; 386:796). ACC, however, was not associated with a heterozygous *DCC* deletion in humans (Kato et al. Birth Defects Res A Clin Mol Teratol 2010; 88:132). In our patient, the deletion on chromosome 18 might have unmasked a *DCC* mutation on the normal chromosome 18. The imbalances were located more than 22 Mb from the chromosome 18 breakpoint demonstrating the importance of array analysis of apparently balanced translocations.
Financial support: FAPESP (CEPID 98/14254-2; 2011/14293-4).

New mutation in the FBN1 gene in a patient bilateral ectopia lentis

V. Procopio, *C. Liuzzo, I. Loddo, S. Briuglia, L. C. Rigoli, C. D. Salpietro;*
Genetics and Pediatric Immunology, Messina, Italy.

Background: FBN1 gene mutations increase the susceptibility of fibrillin-1 to proteolysis, resulting in fragmentation of microfibrils. The alteration of fibrillin also interferes with signaling pathways between the different cells. The penetrance is high and the phenotypic expression is variable.
The known mutations of the gene FBN1 are more than 500. In 75% of cases mutations are inherited from one parent (autosomal dominant); in 25% of cases they occur de novo.
Materials and methods: We describe the case of a 4 years-old girl affected by bilateral ectopia lentis. Analysis of the coding sequence of the FBN1 gene (MIM #126900) was performed in the proband and her parents.
Results: We found the heterozygous mutation p.Cys154Tyr, corresponding to a nucleotide substitution G>A in exon 6, only in the proband. This variant has not been previously described in literature. The analysis extended to the parents was negative for this mutation.
Conclusions: The FBN1 gene mutations are associated with different pathologies presenting ectopia lentis as major clinical sign. These include the Marfan syndrome and Weill-Marchesani syndrome. However, they may also be associated with isolated ectopia lentis.

The loss of a cysteine residue at position 154 of the protein FBN1 causes deletion of a disulfide bridge necessary for correct folding and for the definition of the tertiary structure.
The follow up of the patient will be useful to characterize the pathogenicity of this allelic form.

J20.10
9q34.4 deletion and large inversion of chromosome 9 - a new case report of Kleefstra syndrome

D. A. Ochiana[1], *V. Plaiasu*[1], *G. Motei*[1], *D. Galetzka*[2], *J. Schroder*[2], *O. Bartsch*[2];
[1]*Mother and Child Care Institute, Bucharest, Romania,* [2]*Institute of Human Genetics, Mainz, Germany.*

Kleefstra syndrome is caused by a rare constitutional microdeletion of the subtelomeric region of the long arm of chromosome 9. This disease is characterized by developmental delay, moderate to severe MR, hypotonia, congenital heart defects, seizures and facial dysmorphism. The characteristic phenotype observed for these individuals is mainly caused by the deletion or loss of function mutations of EHMT1 (euchromatic histone methyltransferase 1) gene.
Here we report the case of a 9 month old female presenting a *de novo* del(9)(q34.4) detected by aCGH and confirmed by telomeric FISH, presenting also an unusual inversion on the other chromosome 9. The deletion spans 1,513 kb and encompasses some 86 genes, including EHMT1 and CACNA1B. The phenotypic features where mildly suggestive for Kleefstra syndrome, with dysmorphic facies, congenital heart defect, axial hypotonia, growth retardation and no clinical evidence for epileptic seizures.
Submicroscopic deletion of 9q34.3 (OMIM 610253) is a relatively newly characterized genomic disorder. The phenotypic and genetic features of our patient are compared with those of patients previously reported, along with a short review of the literature.

Functional analysis of Midnolin and Taube Nuss genes: Potential approach for identification of cardiac specific physiological processes

B. Ozsait-Selcuk[1,2], *B. Yuzbasiogullari*[1], *N. Erginel-Unaltuna*[1];
[1]*Department of Genetics, Institute for Experimental Research, Istanbul University, Istanbul, Turkey,* [2]*Assisted Reproductive Techniques Laboratory, Department of Obstetrics and Gynecology, Istanbul University Medical Faculty, Istanbul, Turkey.*

Differential gene expression has importance in the regulation of tissue specific physiological processes. In our previous studies,
heart specific subtractive hybridization cDNA library was constructed in order to identify heart specific novel genes and related biological processes. In this study, we first performed bioinformatics analyses regarding the genes that have increased expression levels in the cardiac tissue and we then concentrated on two genes, Midnolin (Midn) and Taube Nuss (Tbn). Midn is a novel gene with unknown function other than having an ubiquitin-like domain. Human homolog of Tbn gene is Taf8 which encodes a subunit of TFIID. Briefly, Midn gene was silenced by siRNA transfection in the BALB/c neonatal primer cardiomyoblast cells whereas Tbn gene was silenced in rat cardiyomyoblast cell line (H9C2). RNA isolation was performed at the 24th and 48th hours of transfection. Target genes were selected after bioinformatics analysis and gene expressions were analyzed by qRT-PCR. Gapdh, Actb and MAPK were the control genes used in experiments. When compared to the untreated controls, the expression of the Midnolin target genes Bat3, Nedd8 and Ubc were 3.7, 2 and 2.4 fold increased espectively. These genes involve in the regulation of stability and degradation processes of the proteins. Additionally, the expression of the Tbn target gene PAPR-gamma was 3.75 fold increased whereas expression of MYOCD was significantly decreased (-0.04-fold). Both Midn and Tbn genes express in early stages of embryogenesis and might have important roles in the regulation of proper cardiac development and function.

Cytogenetic findings in patients with myelodysplastic syndromes in the Presov region (Slovakia)

I. Boronova, *J. Bernasovska, I. Bernasovsky;*
University of Presov, Presov, Slovakia.

Myelodysplastic syndromes (MDS) are a heterogenous group of clonal disorders of haematopoetic stem cells characterized by dysplasia and ineffective haematopoiesis in one or more myeloid cell lines and peripheral cytopenias with high risk of progression to acute myeloid leukemia. MDS is characterized by non-random chromosomal abnormalities. The aim of the study was to analyze the results of cytogenetic examinations of 180 patients with MDS in the Prešov region (1995-2012). Chromosome analyses were performed from unstimulated bone marrow cell cultures, karyotypes were analysed by G-banding techniques. The median onset age in analyzed survey of patients was 69.7 years. Chromosomal analyses declosed structural and numerical chromosomal abnormalities in 28.9% of examined samples. Among 52 chromosomally abnormal patients, 13 patients (25%) showed numerical aberration, 26 patients (50%) showed structural aberration, and the other 13 patients (25%) showed both numerical and structural aberration. In 61.5% of cases only one chromosomal anomaly, in 15.4% two chromosomal anomalies and in 23.1% a complex karyotype was identified. The atypical chromosomal findings, that have not been described in literature yet, were detected also. Chromosomal analysis provides important diagnostic and prognostic informations which are helpful in determination of survival and risk of leukemic transformation. The risk of leukemic transformation is evaluated using the International Prognostic Scoring System for MDS, which is the sum of the scores of bone marrow blasts, peripheral cytopenias and cytogenetic characteristics. The results of cytogenetic methods are complemented by molecular genetics, the combination of these methods could improve the sensitivity of chromosome aberrations detection.

CYP2C9 gene and the metabolism of diclofenac

M. Martin de Saro[1], *L. M. Gonzalez-Huerta*[2], *H. Urueta-Cuellar*[2], *O. Amancio Chasin*[1], *S. Cuevas-Covarrubias*[1];
[1]*Hospital General de Mexico, PAPIIT IN21612-2, Universidad Nacional Autonoma de Mexico, Mexico, D.F., Mexico,* [2]*Hospital General de Mexico, Mexico, D.F., Mexico.*

INTRODUCTION: Several studies have analyzed the relationship between the CYP2C9 genotype and its influence in the metabolism of diclofenac. CYP2C9 catalyzes the 4´-hydroxylation of diclofenac. The presence between several polymorphisms and pharmacokinetics parameters is controversial. OBJECTIVE: The aim of the present study is to analyze the wild type CYP2C9 gene and its effect in the metabolism of diclofenac in a sample of healthy Mexican subjects. METHODS: We conducted a genotyping study in 25 female healthy volunteers which previously had been submitted to a pharmacological study with one-single 50mg dose of diclofenac using High Performance Liquid Chromatography and measuring AUC (0-t), AUC (0-∞), C(max), T(max) and T1/2. Genotyping of the CYP2C9 gene was performed through DNA automatic sequencing. RESULTS: Mean (SD) AUC (0-t) was 3214.062 (1009.1 ng*h/ml) and AUC (0-∞) 3334.559 (998.895 ng*h/ml), with minima and maxima values of 1399.983-6329.641 ng*h/ml and 1995.008-6390.294 ng*h/ml, respectively. CONCLUSION: These results show that bioavailability of diclofenac does not only depend on the function of CYP2C9. It is important to consider the effect of other CYPs in the metabolism of diclofenac.

Chromosomal microarray analysis(CMA) in a boy with ring chromosome 22.

T. Zvi[1], *A. Orr-Urtreger*[1,2], *Y. Yaron*[1,2], *A. Bar-Shira*[1], *M. Goldstein*[1], *A. Reches*[1], *S. Ben-shachar*[1];
[1]*Genetic Institute, Tel-Aviv Sourasky Medical Center, Tel Aviv, Israel,* [2]*Sackler Faculty of Medicine, Tel-Aviv, Israel.*

Introduction: Ring 22 chromosome is a rare chromosomal aberration with only ~60 cases reported. The clinical phenotype is variable and includes: severe developmental delay, speech disturbance, hypotonia and microcephaly. No clear correlation between deletion size and phenotype has been reported.
Case presentation: We present a 2.5 year-old boy with global developmental delay, hypotonia, and dysmorphic features including coarse facies, broad nasal bridge, long eyelashes, large hands and feet, small umbilical hernia,

bilateral inguinal hernia scars. Brain MRI showed a thickened corpus callosum and mild changes in the white matter that may represent periventricular leukomalacia. Chromosomal analysis from blood leukocytes revealed an abnormal karyotype: 46,XY,r(22)(pq).
Chromosomal microarray analysis (CMA) was performed by Affymetrix CytoScan HD Array that contain ~ 2.7 millions genetic markers revealed copy number loss of about 4.8Mb, arr22q13.31(46,386,970-51,197,724)x1 including more than 60 genes. Both parents had a normal karyotype.
Discussion: The deleted region in 22q13.31 found by CMA includes many genes, some of them found to be responsible for clinical significant disorders include *ARSA* (metachromatic leukodystrophy), *TYMP* (mitochondrial nero-gastrointestinal encephalomyopathy), *MLC1* (megalencephalic leukoencephalopathy with subcortical cysts), *ALG12* (congenital disorders of glycosylation) and *SHANK3* which is known to be associated with autistic spectrum disorders.
Up to date, very few CMAs were performed in case of ring chromosome 22. Our report emphasizes the potential contribution of CMA in order to better understand the spectrum of abnormalities in each case, and assess genotype-phenotype correlation.

Molecular cytogenetic analysis in patients with Turner syndrome

D. Miclea[1,2], *M. Devernay*[2], *L. Kerdjana*[3], *A. Aboura*[3], *B. Gerard*[3], *A. C. Tabet*[3], *B. Benzacken*[3], *I. V. Pop*[1], *J. C. Carel*[2];
[1]*"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj, Romania,* [2]*Université Paris Diderot, Assistance Publique-Hôpitaux de Paris Hôpital Robert Debré, Institut National de la Santé et de la Recherche Médicale Unité CICEC5, Paris, France,* [3]*Assistance Publique-Hôpitaux de Paris, Hôpital Robert Debré, Paris, France.*

Context. It has been suggested that most of the cases with Turner syndrome are mosaics that conventional cytogenetic techniques cannot diagnose and homogeneous monosomy would be incompatible with life, knowing that 99% of the 45,X conceptuses abort spontaneously. FISH techniques show a higher frequency of the mosaics, because it allows the analysis of much more cells. The aim was to determine sex chromosomes mosaicism using FISH in patients diagnosed with homogeneous X monosomy by conventional cytogenetic analysis. **Material and method.** We studied patients with Turner syndrome who were selected from the database records for monitoring patients treated with GH in France. The karyotype made at diagnosis was established by the analysis of 4 to 100 metaphases. The mosaics were investigated applying FISH technique on lymphocytes of peripheral blood. **Results.** Using standard cytogenetics we observed that 738(51%) patients presented homogeneous X monosomy, the others cases being represented by karyotypes in mosaic(45,X/46,XX, 45,X/47,XXX, 45,X/46,XX/47,XXX) in 203(14%) patients or by others structural abnormalities of sex chromosomes, homogeneous or in mosaic, in 496(35%) patients. FISH techniques used in patients with homogeneous X monosomy show the results summarized in the next table.

Karyotype	Patients n,(%)	Level of mosaicism
45,X	178(93%)	0%
45,X/46,XX	9(5%)	2-32%
45,X/47,XXX	1(0,5%)	19%
45,X/46,XX/47,XXX	3(1,5%)	7-16%
Y chromosome	0(0%)	-

Conclusions. FISH technique is useful to better characterize the karyotype but the results obtained on this large study group does not support the hypothesis that in order to be viable a 45,X conceptus should possess another cell line.

De novo duplication of chromosome(5)(p13p15)

D. Gun, *N. Kocak, T. Cora, H. Acar;*
Department of Medical Genetics Faculty of Medicine, Selcuk University, Konya, Turkey.

Duplication of the short arm of chromosome 5 can be seen in the literature, which is a rare abnormality. We report a two months girl who was born from unrelated parents. The mother was diabetic, father was healthy. Physical examination of the patient showed a facial dysmorphism which were brachycephaly, frontal bossing, bitemporal narrowing, short palpebral fissures, low-set ears, micrognathia, microphthalmia, bulbous nasal tip, sparse brows and eyelashes. These findings are specific for 5p duplication syndrome. The cytogenetic and FISH studies showed 46,XX(5)(p13p15) karyotype and the telomeres belong to 5p and 5q. Both parents have normal karyotypes. Theuse of conventional and molecular cytogenetics in this case confirms diagnosis and phenotype/genotype correlation.

[1]*National Research Center, Cairo, Egypt,* [2]*Faculty of Science, Banha, Egypt,* [3]*Faculty of medicine, Cairo, Egypt.*

Background Fanconi anemia is an inherited bone marrow failure syndrome associated with congenital abnormalities. The high frequency of chromosomal breaks in Fanconi anemia (FA) lymphocytes has been related to the increased oxidative damage. Reactive oxygen species (ROS) are derived from the metabolism of molecular oxygen. Antioxidants have the ability to transform ROS into stable and harmless compounds. Astaxanthin is a natural and safe source of antioxidant; its effect might protect cells from oxidative damage.
Aim of work This study was designed to compare between the antioxidant effect of both astaxanthin and vit E as measured by their ability to reduce the frequency of chromosomal breakage.
Subjects and methods The study included 15 Fanconi anemia (FA) patients 9 females and 6 males, their age ranged from 4 to 21 years. The diagnosis of FA was confirmed by DEB. Astaxanthin and vit E were added at the start of the peripheral blood lymphocyte cultures then caffeine was added at last 6 hrs of culture to induce chromosomal breakage.
Results and conclusion The level of breakage was markedly reduced by using astaxanthin and vitamin E however, there was no significant difference between the effect of both substances. Astaxanthin was found in wide diversity of natural sources also it is 10 times potent than vitamin A and much safer than vitamin E. Our study is the first to investigate the effect of astaxanthin on chromosomal breakage in-vitro. We conclude that admistration could be beneficial for patients with FA to improve their hematopoietic state.

Arginine vasopressin receptor genes (AVPR1A, AVPR1B) and their involvement in personality traits variation

Y. Y. Kutlumbetova[1], *A. Kazantseva*[2], *S. Malykh*[3], *E. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation,* [3]*Psychological Institute of Russian Academy of Education, Moscow, Russian Federation.*

Arginine vasopressin and its receptors affect many social and behavioral traits in sexually-specific manner. We aimed to assess the main, haplotypic and GxG effect of AVPR1A (rs11174811, microsatellite RS1) and AVPR1B gene (rs28632197, rs33911258) on personality traits variation.
We recruited 1018 healthy individuals (68% women) of Caucasian origin (Russians-357, Tatars-549, Udmurts-112) from Russia (mean age: 19.53±2.24 years) without any history of psychopathologies subjected to personality assessment (EPI, TCI-125). Genotyping of SNPs was performed using PCR, PCR-RFLP. AVPR1A RS1 alleles were designated as S-allele (≤10 repeats) and L-allele (>11 repeats). Statistical analysis was conducted with PLINK v.1.07, Haploview 4.1.
The main effect of AVPR1B rs28632197 and rs33911258 on Self-transcendence (ST) was observed in total group (P=0,013 and P=0,003 for rs28632197 and rs33911258, respectively) and in females (P=0,024 and P=0,028). Haplotype analysis revealed an association of AVPR1A C*S-haplotype (rs11174811, RS1, respectively, D'=0,546) and increased Extraversion (P=0,015) and A*S-haplotype and decreased Reward Dependence in total group (P=0,024). AVPR1B A*G- and G*A-haplotypes (rs28632197, rs33911258, D'=0.87) were associated with higher (P=0,012) and lower

ST (P=0,002), respectively, in total group and in females. Epistatic effect of rs33911258 and RS1 on Neuroticism (P=0,045 in total group and P=0,019 in females) and on ST (P=0,018 and P=0,019 for total group and females, respectively) was demonstrated.
Our findings indicate gender-mediated main, haplotypic (AVPR1B) and epistatic effect of studied genes on Self-transcendence - trait reflecting spirituality, self-awareness, creativity; while AVPR1A haplotypic effect on sociability-related traits (Extraversion, Reward Dependence) was observed.
Study was supported by Russian Foundation for Basic Research (№11-04-97032-r_povolzhye_a).

Conventional Cytogenetic assays and the recent CBMN Cyt assay: could they be used as biomarkers to predict the genetic instability in the high risk groups?

R. Saraswathy;
VIT University, Vellore, India.

The genetic instability in the diseased individuals was estimated by the application of conventional cytogenetic techniques such as chromosomal aberration (CAs) and the frequency of micronuclei (MN) analysis in peripheral blood lymphocytes (PBLs). However, the recent CBMN Cyt assay endpoints provide valuable information about the gene expression, measure of the chromosomal damage events and individual susceptibility. For this study, PBLs of healthy individuals (n=50) and the patients with Dilated Cardiomyopathy (n=50), Diabetes and complications (n=50), Head and Neck Cancers (n=25), Aplastic Anemia (n=10), Down syndrome (n=25) were subjected to the conventional cytogenetic assays and CBMN Cyt assay. Their demographic characteristics were also analyzed. It was observed that there was a significantly increased frequency of CAs and MN in the patients and the use of CBMN Cyt assay could give information about the chromosome damage events such as nuclear buds (NBUDs) and nucleoplasmic bridges (NPBs) which were significantly higher in the patient group in comparison to the control group (p<0.001). Thus these findings provide preliminary evidence that CBMN Cyt assay could measure the genetic damage events in the etiology of the diseases and used as biomarker. The identification of individual susceptibility and high risk groups by CBMN Cyt assay could serve as a potential tool for public health screening.

In silico personal omics profiling on the basis of whole genome array CGH analysis uncovers disease pathways

S. G. Vorsanova[1,2,3], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[2,1];
[1]*Institute of Paediatrics and Children Surgery, Ministry of Health, Moscow, Russian Federation,* [2]*Mental Health Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [3]*Moscow State University of Psychology and Education, Moscow, Russian Federation.*

Regardless of significant efforts made towards definition of personified disease pathways in clinical populations using whole genome array CGH analysis, there is still a need for developing new tools to process whole genome scan data for definition of causative genome variations. To succeed, we have proposed an original bioinformatic strategy of CNV/gene prioritization by rating data acquired from clinical, cytogenetic and genomic variation databases and by means of bioinformatic tools for genome, epigenome and pathway analysis. To test the strategy, we have evaluated the Russian cohort of children with intellectual disability, autism, epilepsy and congenital anomalies (116 individuals; partially described in Iourov I.Y. et al. Mol. Cytogenet. 2012; 5:46.). Causative CNVs were deletions of 1q42.13, 2q31.1, 2q35, 2q37.3, 3p22.1, 3p11.1, 7q31.1, 9q34.3, 10q21.3, 13q32.2, 17q25.3, 19p12, 20p12.2, Xq12 and duplications of 2q24.1, 7p14.3, 10p13, 12p13.31, 16p13.3, 19p13.3, 19q13.2, Xp22.12. Accordingly, alterations to such pathways as apoptosis, axon guidance, brain (fetal) development, transcriptional regulation, cell-cycle regulation, Fanconi anemia, histone acetylation, mitotic checkpoint, o-glycan biosynthesis, p53-pathway, V(D)J recombination as well as calcium, carbohydrates and zinc metabolism or transport were found to be associated with phenotypic outcome. Moreover, we have determined a Y chromosome locus associated with autism and intellectual disability. Our results demonstrate that a bioinformatic strategy encompassing all the “omics” approaches, which are performed in silico on the basis of data obtained by whole genome array CGH analysis, is a valuable tool for uncovering disease pathways in personalized genomic medicine.Supported by the President of the Russian Federation Grant MD-4401.2013.7

Paternal Uniparental Isodisomy 11p mosaicism in a patient with Beckwith Wiedemann

M. Garcia-Hoyos[1], *M. Molero*[1], *L. Rausell*[1], *M. Lazaro*[1], *M. Bermejo*[1], *C. Ruiz-Lafora*[1], *M. Perez-Alonso*[1], *A. Lopez-Arizteguí*[2], *J. Garcia-Planells*[1];
[1]*Instituto de Medicina Genomica (IMEGEN), Paterna, Spain,* [2]*Genetica. Hospital U Cruces, Bilbao, Spain.*

We present the genetic molecular characterization of a male with clinically diagnosis of Beckwith-Wiedemann syndrome (BWS, MIM#130650) seeking reproductive genetic counselling.
BWS is the most common genetic overgrowth disorder, characterized by somatic overgrowth, macroglosia and abdominal wall defects. BWS is a multigenetic disorder associated, up to 90% of patients, with dysregulation of the expression or function of one or more gene encompassing the imprinted 11p15 chromosomal region. This region is organized into two imprinting centers or domains, telomeric (IC1) and proximal or centromeric (IC2). The phenotypic and genotypic heterogeneity makes reproductive genetic counseling a challenging situation in many cases. The main genetic causes of BWS are: a) loss of methylation at the IC2 (40-50% of cases), b) paternal UDP of 11p15 (10-20%), c) gain of methylation at the IC1 (10%) and d) mutations in the maternal CDKN1C allele. Chromosomal rearrangements are relative rare (2-3% of cases).
We have analyzed the methylation pattern of the IC1 and IC2 imprinting centers by methylation-specific restriction enzyme digestion and STRs segregation of a panel of 6 six microsatellites mapping to short arm of chromosome 11 has been performed in patient and their parents.
Methylation analyses are compatible with IC1 hipermethylation and IC2 hipomethylation patterns. STR analyses show a dosage increase of microsatellites encompassing the 11p15 region. Both results suggest the presence of a paternal uniparental isodisomy 11p mosaicism in the patient. The identification of the genetic cause of the disease makes easier a subsequent reproductive genetic counseling.

Evaluation of stem cell markers expression in breast cancer cells in relation to other disease prognostic factors.

D. Karandrea[1], ***E. Boutou***[2], *M. Fragou*[1], *N. Goutas*[1], *D. Vlachodimitropoulos*[1];
[1]*Athens University, Athens, Greece,* [2]*Laiko Hospital, Athens, Greece.*

Cancer stem cells are considered to be responsible for tumor formation. CD44, CD24 and CD133 antigens have been reported as markers of cancer stem-like cells in breast cancer. The aim was to investigate any correlation between expression of these antigens and the accompanying clinicopathological features. For this purpose 39 paraffin embedded breast cancer samples were analysed by IHC. In all cases grading, hormonal receptor status, c-erbB-2 expression, Ki-67 index and p53 gene expression were also analyzed. Lymph node status was known only for a subset of the studied samples.
No significant relation was found between expression of these markers and the differentiation of the tumor, lymph node status and p53 expression. Nevertheless, studying the estrogen receptor status, CD24 expression was detected in the 80% of the negative cases vs 25% of the positive cases (p=0,02), while CD44 and CD133 had no expression differences. Moreover, CD44 was expressed in the 39,2% of cerbB-2 negative cases vs 72,7% positive cases(p=0,060). The Ki-67 index showed statistically significant correlation with CD24 expression (68,1% for >15% and 35,2%<15%).According to these results, tumors with high CD24 expressing breast cancer cell populations tend to have poorer prognosis as they are related to negative ER status and high Ki-67 index. CD44 expression is found to be more common in cerbB-2 positive cases, possibly rendering these cancer cells more tumorigenic. Such information may prove supporting towards planning more effective treatments, as a small fraction of cells can determine the overall

course of the disease.

Constitutive heterochromatin regions of chromosome from human chorionic villi with properties euchromatin regions

I. Trofimova[1,2], *E. Zolnerovich*[1], *K. Solovyov*[3], *E. Fedorova*[3], *V. Vasilyev*[3], *T. Kuznetzova*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*D.O. Ott Institute of Obstetrics & Gynecology RAMS, Saint-Petersburg, Russian Federation,* [3]*Institute of Experimental Medicine of the North-West Branch of the Russian Academy of Medical Sciences, Saint-Petersburg, Russian Federation.*

Higher eukaryote genomes contain satellite DNAs, often concentrated in transcriptionally inactive constitutive heterochromatin regions (**CHRs**).) CHRs of the autosomes 1, 9, 16 from chorion villi are characterized by decondensation, early replication, hypomethylation and DNAse 1 hypersensitivity.

We studied peculiarities of CHRs in direct and semi-direct slides from chorionic villi dyed by Acridine orange (**AO**). AO is nucleic acid selective metachromatic stain that discriminates single-stranded from double stranded nuclei acids as orange-red and yellow-green fluorescence respectively. After standard AO staining of untreated direct chromosomal preparations CHRs manifests unusually bright red fluorescence in 1qh, 9qh, 16qh. The nature of this fluorescence was studied on direct chromosomal preparations pretreated with different enzymes (RNase A, RNase H, DNase I, DNA ligase T4) followed by AO staining. Results of these work show that ssRNA and DNA*RNA hybrids are present in CHR of chromosome 1 (1q12) on fixed chromosomes.

It is known that CHRs are associated with nuclear periphery and form chromocenter. Our 3D-FISH results showed a significant repositioning of 1q12 towards the centre of the nucleus and near of chromocenter in chorionic villi sample from early pregnancy (4-5 week). We found no change in the position of 1q12 in chorionic villi from 5-6 week to 36 week pregnancy. Almost all of FISH-signals were closer to the nuclear periphery and in chromocenter.

Our results confirm for unusual properties of CHRs which could be attributed to the feasible transcriptional activity of pericentromeric satellite DNA in chorionic cells during embryogenesis.

A novel 1p32.1p31.1 deletion: evidences for a 1p32p31 deletion syndrome subtype

I. A. Demidova[1,2,3], *S. G. Vorsanova*[1,2,3], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[1,2];
[1]*Institute of Paediatrics and Children Surgery, Ministry of Health, Moscow, Russian Federation,* [2]*Mental Health Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [3]*Moscow State University of Psychology and Education, Moscow, Russian Federation.*

Interstitial deletions of 1p32p31 are rare. Currently, no fewer than 8 cases (including a case of prenatal diagnosis) of deletions involving this chromosomal region have been reported. Here, we describe a boy showing severe intellectual disability, hypoplasia of the corpus callosum, vantriculomegaly, dismorphic features, hypospadias, congenital heart defect, dolichocephaly, polydactyly. Cytogenetic analysis lead to a suggestion that a deletion within the short arm of chromosome 1 is present, i.e. 46,XY,?del(1)(pter->p32.3::p32.1->qter). Array CGH using a set of platforms (resolution from 1 Mb to 1 kb) has demonstrated the presence of a deletion (size: 12 Mb) that lead to a loss of 39 OMIM genes. Among the latter, there was NFIA, suggested to be the main contributor to the phenotype outcome of 1p32p31 microdeletion syndrome. Despite of reproducibility of phenotypic findings in the index case, we have suggested that congenital heart defects, polydactyly and hypospadias are likely to be produced by losses of genes, which are more proximal, in contrast to those typically deleted in the microdeletion syndrome [OMIM: 613735]. Furthermore, one can propose that a deletion affecting genomic loci within the interval between 59 and 72 Mb on chromosome 1 is more likely to lead to a condition, arbitrarily designed as a 1p32p31 deletion syndrome subtype. In addition to typical phenotypic findings, this subtype is also featured by congenital heart defects, hypospadias and polydactyly, which are atypical for the microdeletion syndrome with a critical region 1p32.1-p31.3.

Molecular variability of delF508 mutations in CFTR gene

A. B. Maslennikov[1,2], ***Y. A. Nasykhova***[3], *L. F. Mitrohina*[1], *A. R. Shorina*[1], *E. V. Maslova*[1];
[1]*State Novosibirsk Regional Clinical Diagnostic Center, Novosibirsk, Russian Federation,* [2]*Scientific research institute of molecular biology and biophysics of the Siberian branch of the Russian Academy of Medical Science, Novosibirsk, Russian Federation,* [3]*Ott's Institute of Obstetrics & Gynecology, St-Petersburg, Russian Federation.*

Cystic fibrosis (CF MIM 219700) is the most common genetic disease among Caucasians. The frequencies of CF are 1:4000 - 1:7000 newborns in Western-Siberian and North Western regions respectively. Molecular-genetic analysis DNA of CF patients from Novosibirsk and St. Petersburg has shown that frequencies of delF508 among all mutations of CFTR gene are 0,425 and 0,520 respectively. The main element of molecular diagnosis for cystic fibrosis is based on the direct identification of this mutation in the CFTR gene.

Two alternative methods were used to identify mutation delF508 in patients with CF: allele-specific Real-Time PCR and classical PCR of exon 10 CFTR gene with electrophoresis of the PCR-product in PAAG. One sample which appeared to be disputable was sequenced. The mutation c.1522_1524delTTT(delF508) have been found in this sample by direct sequencing of exon 10 CFTR gene, instead of c.1521_1523delCTT(delF508) mutation described in literature. We have developed ACRS RFLP methodology, allowing to identify and distinguish these delF508 mutations. The molecular testing of DNA samples (62 patients, 94 alleles with delF508) from St. Petersburg and (32 patients, 29 alleles with delF508) from Novosibirsk have found c.1522_1524delTTT mutation in two and one samples respectively.

Our data have shown the molecular variability of delF508 and high frequency of c.1522_1524delTTT mutation among patients of CF in the Russian population.

Cytogenetic analysis of Human dermal fibroblasts (HDF) cells using karyotyping test

M. Hashemzadeh Chaleshtori, *M. Allahbakhshian Farsani, N. Abdian, P. Ghasemi Dehkordi, S. Khosravi Farsani, M. Sadeghiani;*
Cellular and Molecular Research Center, Shahrekord University of Medical Sciences, Shahrekord, Iran, Shahrekord, Islamic Republic of Iran.

Human dermal fibroblasts (HDFs) are a common source of somatic cells for generation of induced pluripotent stem cells (iPSCs). The confirmation of HDFs cytogenetic stability is an essential step for generation of a suitable and functional iPS line. In this study, HDF cells were isolated from foreskin samples and then were cultured for 10-15 passages. The HDF's cytogenetic stability was evaluated during their first 10 to 15 passages using karyotype test. Our results showed that HDF cells have normal karyotype during their first 10-15 passages and they maintain satisfactory proliferation rate up to 10 passages. Our findings reinforce the interest to generate iPS cells from HDFs because in addition to their availability and convenient isolation, they showed good proliferation kinetic and kept cytogenetic stability for 10 to 15 passages as essential prerequisite factors before iPS generation.

J20.27

Emanuel Syndrome: breakpoints determination by NGS.

A. Gencik, *A. Lott, Z. Gencik-Guillier;*
diagenos, Osnabrück, Germany.

The recurrent constitutional translocation between chromosomes 11 and 22 is the most common non- Robertsonian translocation in humans. Clustered breakpoints involving chromosome regions 11q23 and 22q11 have been reported in unrelated families. Balanced translocation carriers are clinically normal. Their offspring have a risk to herit a supernumerary der(22) t(11;22) chromosome, which results in a rather constant phenotype. This very rare genomic syndrome was named Emanuel syndrome.
The diagnostic of our patient with Emanuel syndrome was done by aCGH. By NGS we determined that the breakpoints lie within palindromic AT-rich repeats (PATRRs) on both chromosomes 11 and 22. We used primers in reference to Kurahashi et al. 2000, who were the first to describe the exact breakpoints of this recurrent constitutional translocation.
The breakpoints 11q23 and 22q11 lie in the similar region with AT repeats and differ in size only tens to hundreds bp variable from patient to patient. The properties of this palindromic region are the explanation for recurrent translocations,
Patients with Emanuel syndrome have a reliable correlation between genotype and phenotye. This predictible phenotype is determined by a very constant size and region of the duplication of chromosomes 11 and 22. Both breakpoints of the constitutional translocation t(11;22) vary only few between the studied patients. The breakpoints on 11q23 and 22q11 are both situated in a palindromic AT-rich repeats (PATRRs) region predicted to induce genomic instability, which mediates the translocation. This confirms the the hypothesis that numerous constitutional translocationst (11;22) arise by the same mechnism.

Evaluation of genotoxic damage in patients undergoing hemodialysis, before and after vitamin supplementation

T. L. M. Batista[1], C. C. Cruz[2], ***M. P. Batitucci[1];***
[1]Universidade Federal Espírito Santo, Vitória, Brazil, [2]Instituto de Doenças Renais/ Vitória Apart Hospital, Serra, Brazil.

Haemodialysis is a most common treatment for chronic kidney disease (CKD), however it increases oxidative stress and the risk to cancer. It is supposed that the use of vitamins could decrease this risk. In this study, genotoxic effects in patients with CKD undergoing regular haemodialysis have been investigated by the cytokinesis-blocked micronucleus assay and buccal mucosa cells assay, with and without supplementation by folic acid and vitamins C, E and B_{12}. Sixteen volunteer patients provided the necessary samples for each test, before supplementation and after one or two months of vitamins therapy. Micronucleus test was effective for evaluation of genotoxic effects, showing a significant reduction of nuclear and cell damages after vitamins supplementation. It was observed a significant reduction in the cytotoxicity in lymphocytes, more evident in women. Also, there was a gradual decrease in the frequency of micronuclei in lymphocytes during the months of supplementation. The frequency of micronuclei in exfoliated cells from the oral cavity in patients undergoing haemodialysis with supplementation was inferior to that of patients undergoing haemodialysis without the use of vitamins, in both sexes, with a higher damage reduction in the first month of supplementation. The frequency of binucleated cells and apoptosis was significantly reduced after the first month of supplementation, remained decreased until the end of treatment. Additionally, different response to the vitamins therapy was observed among the genders of patients. These results may contribute to improve health of patients and prevention of possible diseases that affect individuals with CKD undergoing haemodialysis.

Genotoxicity associated with the hydroxyurea use in sickle cell anemia

W. M. Barberino[1]*, R. G. Oliveira[1], V. U. Teixeira[1], J. V. Okumura[1], L. S. Torres[1], D. G. H. Silva[1], E. Belini-Junior[1], A. M. M. Queiroz[2], C. L. C. Lobo[2], C. R. Bonini-Domingos[1];*
[1]São Paulo State University - UNESP, São José do Rio Preto, SP, Brazil, [2]Institute of Haematology - HEMORIO, Rio de Janeiro, RJ, Brazil.

Sickle cell anemia (SCA) provides to the carrier diversified and complexes manifestations. Hemoglobin S polymerization results in generation of oxygen reactive species that promotes lipids, proteins and also DNA oxidation. This event modifies cells mechanisms and provokes intensive cells and tissues damages. In the top of the mains therapies used in SCA there is the hydroxyurea (HU) administration. In short periods of administration, hydroxyurea doesn't present significant toxicity, but it is controversial considering long periods of treatment. The present study aimed evaluate the genotoxicity and citotoxicity markers using the comet assay and Howell-Jolly bodies (micronucleus) count. The data was associated with the use of HU. Were evaluated 84 individuals with SCA, 39 with HU (SCA + HU), taking for ± 930 days; 45 without HU use (SCA - HU) and 53 individuals without hemoglobinopathies (control group). Comet assay analysis demonstrated increase of DNA lesion in the both test group (SCA + HU) and (SCA - HU), in comparison with the control group ($p < 0.001$). The comparison between the two test groups doesn't showed significant difference. Micronucleus analysis demonstrated increase in DNA lesion rate in the SCA + HU group, when compared to the other two groups ($p < 0.001$). These results suggests a possible genotoxic and mutagenic effect associated to hydroxyurea use in SCA.

Comparison of genotoxic effect of dioxidine and methyl methanesulfonate measured by comet-assay and cytogenetic method

E. S. Voronina*, A. I. Chausheva, L. D. Katosova, V. I. Platonova;*
Federal State Budgetary Institution «Research Centre for Medical Genetics» of RAMS, Moscow, Russian Federation.

The aim of this study was to assess the effect of mutagens with different mechanisms on DNA and chromosome levels and compare Comet assay and chromosome aberration assay.
The levels of spontaneous and *in vitro* induced DNA damage and chromosome aberrations in peripheral blood lymphocytes of 14 healthy donors were analyzed. Whole blood samples were cultivated during 54 hours using the standard procedure. One of two mutagens: prooxidant dioxidine (0.01 and 0.1 mg/ml) and alkylating agent methyl methanesulfonate (MMS) (0.0025 and 0.01 mg/ml) was added to culture in 24 hours of cultivation.
Spontaneous level of chromosome aberrations was 2.25±0.17% in the experiment with dioxidine and 2.58±0.28% in the experiment with MMS (with the same donors). Dioxidine at concentration 0.01 mg/ml increased the level of aberrant cells to 7.63±0.36% and at concentration 0.1 mg/ml - to 15.38±0.63%. The %DNA in tail was 5.59±1.1% without dioxidine and 9.64±0.84% and 14.95±2.02% with low and high doses of dioxidine respectively. MMS at low dose (0.0025 mg/ml) increased the level of aberrant cells to 5.14±0.37% and at high dose (0.01 mg/ml) - to 6.78±0.43%. Before adding of MMS the %DNA in tail was 4.81±0.54%. MMS increased this parameter to 9.6±1.42% and to 22.7±1.33% at low and high concentration respectively. In conclusion, both mutagens significantly and dose-dependently increased level of DNA damage as well as chromosome aberrations. We revealed the correlation between these two parameters. These results may be applied in research of mechanisms of realization of primary DNA damage to chromosome aberrations.

J20.31

A rare case of Prader Willi and Jacobs syndrome

N. Andreescu[1]*, A. Chirita-Emandi[1], S. Dumitriu[1], C. Popa[1], A. Dobrescu[1], N. Cucu[2], M. Puiu[1];*
[1]University of Medicine &Pharmacy Victor Babes, Timisoara, Romania, [2]University of Bucharest, Bucuresti, Romania.

Background and aims: The association of two or more chromosomal defects is rarely reported. New molecular techniques made possible the identification of the many genetic conditions that were undiagnosed untill now. In this paper we report a case of a child diagnosed with Prader Willi syndrome and a 47,XYY karyotype.
Method: We will present the child's evolution from birth until age 14.
Results: The child exhibits rapid weight accumulation between 1 and 6 years, hyperphagia, narrow bifrontal diameter, almond shaped eyes, down slanting palpebral fissure of the eyes, thin upper lip, down turned corners of the mouth, hipogonadism, short hands, mild mental retardation, behavioural disturbances. Based on the clinical manifestations the diagnosis of Prader Willi syndrome was suspected. The cytogenetic analysis revealed a 47,XYY karyotype in all the 30 metaphase evaluated. FISH analysis showed

no deletion of the 15q11-q13 region. The DNA methylation analysis of the Prader Willi locus on the chromosome 15q11-q13 confirmed the disomy. To the best of our knowledge, the co-existence of Prader Willi syndrome and 47,XYY karyotyope has been previously reported in two cases. From these cases, only one presented disomy in a newborn. Child development till the puberty age presented several differences as compared with the Prader Willi patients or those with Jacobs syndrome.
Conclusion: We consider important to report this case as it presents the evolution of the patient having a rare association of two chromosomal aberrations and because it shows how those anomalies can modulate the phenotypic effect of each other.
