heteroallelic to a genomic deletion affecting exons 2-3 of MUSK as cause of a limb-girdle CMS in two brothers of Turkish origin. Clinical symptoms included fatigable limb weakness from early childhood on. Upon diagnosis of a MUSK-related CMS at the age of 16 and 13 years, respectively, treatment with salbutamol was initiated leading to an impressive improvement of clinical symptoms, while treatment with esterase inhibitors did not show any benefit.
Our findings highlight the importance of a molecular diagnosis in CMS and demonstrate considerable similarities between patients with MUSK and DOK7-related CMS in terms of clinical phenotype and treatment options.

Combined linkage analysis and exome sequencing in a large Italian family with distal myopathy

*M. L. Mostacciuolo[1], C. Bertolin[1], F. Boaretto[1], C. Salvoro[1], W. Hairong[2], W. Bin[2], C. Angelini[3], E. Pegoraro[3], **G. Vazza**[1];*
[1]Dipartimento di Biologia, Università di Padova, Padova, Italy, [2]Dipartimento di Neuroscienze, Università di Padova, Padova, Italy, [3]BGI-Shenzhen, Shenzhen, China.

Distal myopathies (DM) belong to a larger group of rare progressive genetic disorders characterized by atrophy and weakness of the voluntary distal muscles of the upper and lower limbs. Based on clinical and molecular findings, more than 20 different genetic entities have been reported to date and for 14 of them, the causative gene has been identified. We studied a large Italian family affected by an autosomal dominant form of DM characterized by adult onset of the disease and a more prominent involvement of hand muscles. After exclusion of known DM-causing genes, we performed a genome-wide linkage analysis with high density SNP-array and identified 3 regions co-segregating with the disease in all affected subjects. Two patients were then subjected to whole exome sequencing and the obtained sequence variants were prioritized in accordance with linkage information. We identified a heterozygous mutation in the CHRNE gene (L241F) which encodes for the ε-subunit of muscle nicotinic acetylcholine receptors (AChR). This mutation has been already associated to slow-channel congenital myasthenic syndrome (SCCMS), a disease clinically characterized by the selective weakness of cervical, scapular, and finger extensor muscles. Interestingly, all patients share a second functional relevant mutation in a gene located in the same linkage region. Despite the recognized power of combining exome sequencing and linkage information for studies of mendelian disorders, we cannot rule out the possibility that the phenotype in our family may result from the contribution of multiple rare mutations.

Novel phenotypic variant of MYH7 mutation associated with dominant distal myopathy in a Roma family

K. Komlósi[1], *K. Hadzsiev[1], L. Garbes[2], L. A. Martínez Carrera[2], E. Pál[3], J. H. Sigurðsson[4], O. Magnusson[4], B. Melegh[1], B. Wirth[2];*
[1]Department of Medical Genetics and Szentagothai Research Center, University of Pécs, Hungary, Pécs, Hungary, [2]Institute of Human Genetics, Institute for Genetics, and Center for Molecular Medicine Cologne, Cologne, Germany, [3]Neurology Clinic, University of Pécs, Hungary, Pécs, Hungary, [4]deCODE genetics, Reykjavik, Iceland, Reykjavik, Iceland.

We describe a Hungarian Roma family, in which the clinical picture originally raised the possibility of a novel form of autosomal dominant atypical spinal muscular atrophy. To identify the causative genetic abnormality, whole-exome capture and next-generation sequencing was performed in two affected girls and their unaffected father. The analysis unexpectedly revealed the *MYH7* mutation c.4849_4851delAAG (p.K1617del) in both affected girls, a mutation previously reported to be causative for Laing distal myopathy. Subsequent dideoxy sequencing confirmed the same mutation in the affected mother and her third affected daughter. In contrast to reported cases of Laing distal myopathy, our patients presented a more severe phenotype, with proximal and distal muscle involvement, and loss of ambulation at the age of 27 years, in the case of the mother. Furthermore, all three daughters presented with steppage gait at the age of 3 years. Progression of symptoms is variable among the affected family members. Muscle biopsies were non-specific, showing both myogenic and neurogenic lesions. Our family further underlines the importance of whole exome sequencing - as an unbiased strategy - to uncover the causes of often phenotypically indistinguishable myogenic and neurogenic diseases.

The implementation of newly developed dose-sensitive methods of quantitative analysis results in wide interpretation of complex genomic rearrangements as a cause of hereditary diseases. Sophisticated models of multiple-step pathways for their generation were proposed but still remain controversial. We report a case of complex duplication-triplication rearrangement involving exons 45 to 60 of the DMD gene. These copy number changes were detected by conventional diagnostic methods, and lately confirmed by a custom-designed array-CGH. Successful sequencing of the breakpoint junctions disclosed that a 690-kb region comprising exons from 45 to 60 was duplicated in tandem, and another 46-kb segment containing exon 51 was inserted in between them in inverted orientation, leading to the DUP-TRP/INV-DUP structure recently identified at the PLP1 and MECP2 loci. For the first time in DMD, the elucidation at the nucleotide level of the junctions of such a complex rearrangement evidences that the inverted repeat-mediated mechanism takes place at the DMD locus as two inverted homologous LINE 1 repeated elements were found to be involved in the formation of one of the junctions. The identification of a 13-bp consensus motif CCnCCnTnnCCnC, which specifically binds to PRDM9, a well-established trans determinator of allelic meiotic recombination hotspots in the vicinity of the repeat-junction suggests that the double strand break that initiated the complex DMD recombination may be indeed catalysed by meiotic-specific proteins. While microhomology-mediated processes prevail in simple DMD deletions and duplications, we show that the formation of complex rearrangements follows a different model.

P07.12
Modelling and severity prediction in Moldavian DMD/DMB patients

V. C. Sacara[1], *E. Mocan[2], V. Scurtu[1];*
[1]the Institute of Mother and Child, Chisinau, Moldova, Republic of, [2]the State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of.

The main task of our study was to evaluate the relationship between the progress and/or severity of DMD/DMB and the four different genetic polymorphisms *MTHFR*C677T and A1298C, *MTR*A2756G, *MTRR*A66G as the main participants in the folat/homocysteine metabolism (FHMG).
Methods: A retrospective long-term follow-up study was carried out in DMD/DMB patients included in the NRHD. The genotyping of dystrophin gene were performed by the MPCR to detect the long deletion in dystrophin gene and the PCR-RFLP to identify the *MTHFR*C677T and A1298C, *MTR*A2756G, *MTRR*A66G polymorphisms using HinfI, MboII, HaeIII and NdeI enzymes respectively. Statistical analysis were included 179 corticosteroids-free DMD/DMB patients using software SPSS 20.0 for Windows 15.0.
Results: **Model A** - dependent variables was wheelchair up 9 years and factors-4 mutation of FHMG - general model fitting is not significant, but -2log-likelihood of reduced model gave the significant parameters estimates for *MTHFR*C677T (p=0.011) and two variants with heterozygous compound polymorphisms of 3 loci (*MTHFR* C677T, *MTHFR*A1298C and *MTR*A2756G (β=33.7) and (*MTHFR*C677T, *MTRR*A66G and *MTR*A2756G (β=34,7) showed as the highest category of dependent variables, respectively, have a high degree of influence on wheelchair up 9 years. **Model C** for appreciating the role of in/out of frame mutation in DMD gene and "modifier genes" and diagno-

sis (DMD/DMB) on up 9 years wheelchair is significant.
Conclusion:Prognosis frequencies that the MDD patient will be in wheelchair up to 9 years if he has out of frame deletion in DMD gene and heterozygous compound of MTR, MTRR and MTFHR1298 and homozygous MTHFRT677T is 75.4%.

The exon skipping approach is a promising therapy for Duchenne muscular dystrophy (DMD), aiming to correct the underlying genetic defect, which is currently being evaluated in phase III clinical trials. DMD is characterized by the absence of functional dystrophin, an important protein for maintaining muscle stability during contractions and protection against damage, due to frame-shifting mutations and/or premature stop codons. The exon skipping therapy aims to restore the DMD transcript's open reading frame by skipping a specific exon during pre-mRNA splicing with antisense oligonucleotides (AONs). This allows production of partly functional proteins, similar to those found in the typically milder BMD patients. To support clinical studies pre-clinical experiments on optimization of treatment regimens in dystrophin-deficient animal models, i.e. mdx mice, are highly informative. We studied the pharmacokinetic (PK) and pharmacodynamic (PD) profile of 2'-O-methyl phosphorothioate AONs in mdx mice. First, we tested the effect of different dosing regimens, i.e. the same total dosage (200 mg/kg/wk for eight weeks) divided over one, two or seven injections per week. Multiple smaller doses showed increased effects at PK, mRNA and protein level, compared to other regimens. Furthermore, we studied the effect of different maintenance regimens on the preservation of AON-effects, the time-course of the turn-over of the compound and its effect on RNA and protein level. This revealed that the AON and its induced exon skipping could still be detected at least 12 weeks after the last injections and dystrophin protein even up to 24 weeks.

P07.14

The carrier frequency in the mothers of 158 Japanese cases with Duchenne/Becker muscular dystrophy

T. Lee[1], *N. Kusunoki*[1], *M. Yagi*[1], *Y. Takeshima*[1], *M. Matsuo*[2], *K. iijima*[1];
[1]*Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan,* [2]*Department of Medical Rehabilitation, Kobegakuin University, Kobe, Japan.*

Duchenne/Becker muscular dystrophy (DMD/BMD) is an X-linked recessive muscular disease caused by mutations in the dystrophin gene. Theoretically, two-thirds of the DMD patients are inherited through carrier mothers, however the carrier frequency seems to be different with the type of mutations. The aim of this study was to clarify the carrier frequency in the mothers of DMD patients based on the type of mutation, and to compare with that of BMD. 139 DMD cases and 19 BMD cases were included. Only one patient was included within a same family. Mutations in the dystrophin gene were detected in probands in Kobe University Hospital, and carrier status was determined by molecular analysis in their mothers. 113 cases (99 DMD/14 BMD) and 13 cases (12/1) had deletions or duplications of one or more exons, respectively. Small mutations including nonsense mutation, small deletion/insertion, and splice site mutation, were identified in 32 cases (28/4). In DMD cases, the carrier frequency was 53.5% in the cases with deletion mutations, which was lower than duplication cases (66.7%) or small mutation cases (67.9%). This result suggests that the carrier frequency is different depending on the type of mutations. Deletion mutations seemed to occur more often as de novo mutation. On the other hand, the carrier frequency was 57.6% in DMD cases including all types of mutations, which was significantly lower than that in BMD cases (89.5%) ($p<0.05$). BMD cases can leave offsprings, which results in the higher carrier frequency.

Fragile X syndrome, Duchenne muscular dystrophy and X-linked ichthyosis in a single carrier. How these pathologies are transmitted to the next generation?

A. Todorova[1,2], *I. Litvinenko*[3], *T. Todorov*[2], *R. Tincheva*[3], *D. Avdjieva*[3], *S. Tincheva*[1,2], *V. Mitev*[1];
[1]*Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*University Pediatric Hospital, Medical University Sofia, Sofia, Bulgaria.*

The human X chromosome is characterized by genomic instability and rearrangements, associated with X-linked disorders. Deletions in the Xp22.31 region, involving steroid sulfatase gene (STS) cause X-linked ichthyosis. Rearrangements in the Xp21.2 region are associated with Duchenne/Becker muscular dystrophy (DMD/BMD). The Xq27.3 unstable region, containing the (CGG)n repeated expansion in the FMR1 gene is associated with fragile X syndrome. We report a family with two affected boys, the elder diagnosed as fragile X syndrome, the younger as DMD, and both suffering from severe ichthyosis. The family members were analyzed by PCR, MLPA and genotyping analysis. The mother was proved to be a nonsymptomatic carrier of all three noncontiguous mutational events, involving STS gene, DMD gene and FMR1 expansion. The boy with fragile X syndrome has inherited a recombinant maternal X chromosome, this way inheriting FMR1 expansion and ichthyosis, originating from different X chromosomes and overcoming the DMD gene deletion. The most probable explanation of this finding is DMD gene conversion between the deleted and nondeleted X chromosome and double-strand-break model for recombination with two Holliday joints formation, resulting in recombination of the flanking chromosomal regions. In our opinion, this is the first description of a nonsymptomatic carrier of three different X-linked pathologies, involving severe genetic rearrangements on both long and short arms of the X chromosomes. The transmission of these extremely defective chromosomes in the next generation involves genetic events like gene conversion and recombination, as an attempt to escape severe rearrangements and to try to restore genetic information.

Recovery of Dysferlin Function after Exon-Skipping

M. Bartoli[1], *F. Barthélémy*[1], *C. Blouin*[2], *G. Butler-Browne*[3], *C. Lamaze*[2], *N. Lévy*[1], *M. Krahn*[1];
[1]*AMU, Marseille, France,* [2]*Curie Institute, Paris, France,* [3]*Myology Institute, Paris, France.*

Dysferlinopathies are disabling muscular dystrophies including LGMD2B and Miyoshi myopathy as the main phenotypes. They are associated with molecular defects in DYSF, encoding dysferlin, a key player of sarcolemmal homeostasis. Previous investigations suggest that exon-skipping is a promising therapy for a subset of patients with dysferlinopathies. Such an approach aims to rescue almost functional proteins, when targeting modular proteins and specific tissues. This has been well documented in another myopathy, Duchenne Muscular Dystrophy, for which exon-skipping recently led to encouraging results in phase II/III clinical trials.
We intended to translate into clinics our pre-clinical proof of principle of exon-skipping feasibility for dysferlinopathies, and evaluated the dysferlin function recovery following exon 32 skipping in muscle cells obtained from patients. Exon-skipping efficacy was characterized at the protein level, and by use of new in vitro myotubes formation assays and quantitative membrane repair and recovery tests. Data obtained confirm that dysferlin function is rescued by a quasi-dysferlin expression in treated patients' cells, paving the way towards an antisense based trial in a subset of dysferlin deficient patients.

Clinical and genetic diversity of Emery-Dreifuss muscular dystrophy in Russia

T. Adyan[1], *G. Rudenskaya*[1], *E. Dadali*[1], *O. Ryzkova*[1], *O. Groznova*[2], *A. Polyakov*[1];
[1]*Research Center for Medical Genetics, Moscow, Russian Federation,* [2]*Moscow Scientific Research Institute of Pediatrics and Child Surgery, Moscow, Russian Federation.*

Emery-Dreifuss muscular dystrophy (EDMD) is a rare genetically heterogeneous muscular disease. In EDMD, 6 causative genes have been identified, including EMD, LMNA, SYNE-1, SYNE-2, FHL1, and TMEM43. Despite the identification of mutations in these genes, no genetic mutation was confirmed in >60% of patients with EDMD, indicating the existence of other causative genes.

We herein present the results of EDMD diagnosing in patients from Russia. We have confirmed the diagnosis in 30 families of the 89 examined. 13 mutations identified in EMD gene, 16 mutations in LMNA gene, and one mutation in FHL1 gene.

In probands with mutations in EMD and LMNA genes onset (1-45 years), severity, and progression of disease are highly variable. Some patients were followed at the cardiomyopathy, and contractures and /or myopathy were later, sometimes a random finding. Creatine kinase (CK) level ranged from normal to 1800 U/L. Only in two probands skeletal myopathy was very heavy, deeply debilitating. In most cases, the lead was cardiac disease. There is no clear genotype-phenotype correlation for LMNA and EMD mutations.

Mutation in FHL1 gene was identified in family with five male patients in four generations. The clinical picture in the examined 35-year-old proband included proximal myopathic syndrome, „rigidity" of the cervical spine, moderate contraction ankles, the high activity of CK (1550 U/L). Significant pathology of heart was not found.

Our observations support the hypothesis of the existence of other causative genes and emphasize the need for further search of candidate genes.

FSHD 1 and 2 testing - a clinical diagnostic service perspective

D. Smith[1], *R. Whittington*[1], *J. Corfield*[1], *S. O'Shea*[1], *E. Clements*[1], *P. Lunt*[2], *M. Williams*[1];
[1]*Bristol Genetics Laboratory, Bristol, United Kingdom,* [2]*Dept of Clinical Genetics, St Michaels Hospital, Bristol, United Kingdom.*

FSHD is the third most common muscular dystrophy, characterized by progressive wasting of upper body muscles. ~95% of cases are associated with contraction of D4Z4 tandem repeat in the subtelomere region of 4q35 (FSHD1, OMIM 158900).

Bristol Genetics Laboratory offers a UKGTN specialist diagnostic FSHD service. First level testing for FSHD1 by Southern blotting uses EcoRI/BlnI/ApoI digests and the probe p13E-11 (to determine chromosome of origin and size contraction); where appropriate the permissive haplotype is confirmed. Patients with an extended deletion of the p13-E11 region (~2%) are identified using the D4Z4 1kb probe. The remaining ~3% of patients have clinically indistinguishable FSHD2 (OMIM 158901).

A five year audit of 1190 diagnostic FSHD referrals indicated 37% showed a contraction of the D4Z4 repeat at 4q35 including 6 individuals with two pathogenic 4qA fragments, where further haplotyping was required. 87 patients were referred for extended testing and a deletion was confirmed in 4 patients. 91% of patients showed no deletion of the p13E-11 probe region; for these patients (6.6% of diagnostic referrals) a diagnosis remains on clinical grounds.

Lemmers *et al* (2012) showed 80% of patients with a negative FSHD1 result and D4Z4 hypomethylation have a mutation *SMCHD1* (18p11.23) indicating digenic mode of inheritance for FSHD2; giving a recurrence risk for FSHD2 between 25-50%.

We present a pilot study of FSHD2 testing on 20 clinically typical FSHD1 negative patients (assessed by clinical proforma), a five year audit, and interesting cases highlighting the clinical utility and complexity of FSHD genetic testing.

Genetic epidemiology of Charcot-Marie-Tooth disease in the Voronezh region of Russia

V. P. Fedotov[1], *O. A. Schagina*[2], *T. Milovidova*[2], *S. A. Kurbatov*[1], *A. V. Polyakov*[2];
[1]*Genetic counseling, Regional Clinical Hospital, Voronezh, Russian Federation,* [2]*Russian Research Center for Medical Genetics, Moscow, Russian Federation.*

Charcot-Marie-Tooth (CMT) neuropathy is one of the most common hereditary diseases of the nervous system. The thesis provides information on more than twenty years experience of clinical, electromyographic and molecular-genetic survey the disease in the Voronezh region.

We included 436 patients from 210 unrelated families with CMT to the register for the last period. Prevalence of the disease was established it amounted to 17.4 per 100 000 population. To share CMT1 and CMT2 are 73% and 27%, respectively. Diagnoses of 323 patients from 129 families were verified by molecular-genetic tests. We studied PMP22, CX32, MPZ, MFN2 and HSPB1 genes. Mutations in this genes were found in 61% of all families. The most frequent CMT1 cause in is a duplication of the PMP22 gene (71% of all cases). The frequency of Cx32, MPZ and MFN2 mutation are 13%, 7% and 3% respectively. At CMT2 families mutations were detected in MFN2 (3%) and HSPB1 (7%) genes. Frequent occurrence of the S135F mutation in HSPB1 gene is very interesting. For the first time CMT2F has been mapped by us in the Voronezh family (MIM 606595). We have proved the presence of the founder effect for this mutation in the region. Moreover we identified mutations in GDAP1 (two families) and NDRG1 (one family) in ARCMT.

Analysis of clinical, electromyographic and molecular genetic correlations in CMT-disease allows optimize molecular diagnosis of this group and increase the effectiveness of genetic counseling.

Limb Girdle Muscular Dystrophy in the Czech Republic

K. Stehlikova[1,2], *D. Paclova*[1,2], *Z. Hruba*[1], *D. Kuncova*[1], *L. Fajkusova*[1,2];
[1]*Centre of Molecular Biology and Gene Therapy, University Hospital, Brno, Czech Republic,* [2]*The Central European Institute of Technology, Masaryk University, Brno, Czech Republic.*

Limb girdle muscular dystrophy (LGMD) is a group of disorders characterised by atrophy and weakness of proximal limb girdle.We perform analysis of the most common LGMD types (LGMD2A, LGMD2D, LGMD2I and LGMD2L) in a cohort of patients with preliminary diagnoses of LGMD at both the mRNA level using reverse transcription-PCR or at the DNA level using PCR and direct sequencing.

LGMD2A is an autosomal recessive disorder caused by mutations in the *CAPN3* gene (15q15) that encodes the muscle specific protein, calpain-3 (p94). LGMD2A is the most frequent form of LGMD in many European countries.LGMD2D is caused by mutations in the α-sarcoglycan gene (*SGCA*). *SGCA* (17q21) is an integral membrane glycoprotein that forms part of the dystrophin associated glycoprotein complex.LGMD2I is caused by mutations in the *FKRP* gene (19q13.3) that encodes a protein which participates in the glycosylation of α-dystroglycan in the muscle fibre. LGMD2L is caused by mutations in the by *ANO5 gene* (11p14.3), which encodes a putative calcium-activated chloride channel possibly involved in membrane repair mechanism in muscular dystrophies.

Using this conventional molecular diagnosis based on a gene-by-gene approach the molecular causes remain unknown for approximately 65 % of patients.

At present, we are introducing next-generation sequencing to accelerate patient diagnosis. We designed capture library to target the coding and all exon-intron boundaries of genes responsible for all known types of LGMD and genes responsible for muscular dystrophy with similar phenotype to LGMD.

This work was supported by research grants CEITEC-CZ.1.05/1.1.00/02.0068, SuPReMMe - CZ.1.07/2.3.00/20.0045

Limb-girdle muscle dystrophies mutation analysis in Latvian and Lithuanian patients using Illumina's VeraCode GoldenGate Genotyping Assay

I. Inashkina[1], *J. Stavusis*[1], *I. Vasiljeva*[1], *E. Jankevics*[1], *I. Micule*[2], *B. Lace*[1];
[1]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [2]*Children's University Clinical Hospital, Riga, Latvia.*

Limb-girdle muscular dystrophies (LGMDs) is a group of muscular dystrophies characterized by a predominant involvement of the scapula, pelvic girdle and trunk muscles without affecting the facial muscles. Different autosomal recessive LGMDs (>10) have been identified as distinct entities with a similar phenotype and clear clinical overlap that makes their differential diagnosis difficult. To date, several hundreds different mutations have been

described with their biological relevance remaining unclear.
We have developed genotyping microarray of 96 mutations - insertions/deletions and SNP, within different genes related to LGMD-2 (SGCA, SGCB, SGCD, SGCG, CAPN3, DYSF), several polymorphism and gender controls using Illumina's VeraCode GoldenGate Genotyping Assay.
Here we report study analysing six patients from Latvia and 25 patients from Lithuania with clinical symptoms of LGMD, elevated creatine kinase values, EMG data of myopathy and suggestive/putative autosomal recessive inheritance. 204 healthy unrelated randomly selected individuals as control group from the Genome Database of Latvian Population were analysed. After data cleaning was completed, the data analysis revealed mutation CAPN3 550delA in homozygous position in eight cases within Lithuanian group (32%). Mutation was confirmed by direct sequencing in all cases. Controls showed no 550delA, but four other SNPs: DYSF_00178, CAPN3_00119, rs2287717 (one heterozygous allele each) and rs2306942 (four heterozygous individuals).
Our data suggest that CAPN3 550delA, previously referred as Slavic origin, is the most frequent mutation in LGMD patients of Baltic populations as well. Thus, we suggest direct sequencing of 550delA as the first step of LGDM molecular diagnostics before using other high throughput genotyping assays.

Identification and confirmation of homozygous RYR1 mutation status in Malignant hyperthermia individuals.

I. Valášková[1,2], *E. Pindurova*[1], *Z. Svestkova*[1], *R. Spesna*[1], *I. Shröderova*[3], *R. Gaillyova*[1,2];
[1]*University Hospital Brno, Medical Genetics Dpt., Brno, Czech Republic,* [2]*Masaryk University, Faculty of Medicine, Brno, Czech Republic,* [3]*St. Anne´s University Hospital, Anaesthetic/Resuscitation Clinic, Brno, Czech Republic.*

Background:
Malignant hyperthermia (MH), linked to the ryanodine receptor 1 gene (RYR1) on chromosome 19, is a potentially fatal autosomal dominant disorder which may lead to a disturbance of intracellular calcium homeostasis when susceptible individuals are exposed to volatile anesthetics.
Methods and results:
Fourteen members of the large pedigree were investigated, with a clinical examination, a caffeine halothane contracture test on the muscle biopsies, and mutational analysis on the genomic DNA isolated from family blood samples. Fifteen RYR1 amplicons covering major hotspots were screened for mutations in the RYR1 by direct sequencing. Two siblings homozygous for the missense mutation R614C were observed. There was no evidence of consanguinity parents. The presence of only mutated allele and the absence of wt allele were confirmed using melting point analysis on real-time PCR. Haplotype analysis using microsatellite markers linked to the RYR1 gene and qHRM were performed to exclude the loss of heterozygosity. The loss of a functional allele at any heterozygous locus can be due to multi locus chromosomal events like deletions and mitotic recombinations or gene conversions at a particular locus. We performed further analysis to exactly define the change in the genome of siblings homozygous for the affected RYR1 allele, e.g.MLPA and Amplicon-Based Ultra-Deep Next-Generation Sequencing.
Conclusion:
We here demonstrate methodical assays and results of confirmation the presence of two MHS RYR1 alleles in the homozygotes.
Genetic characterization was necessary because the sensitivity of muscle sample to caffeine halothane contracture test no clearly distinguished two homozygotes from other heterozygous individuals.

Clinical and genetic study of hereditary motor-sensory neuropathy patients from Republic Bashkortostan with novel mutations in MFN2 gene

E. Saifullina[1], *R. Magzhanov*[1], *I. Skachkova*[2], *I. Khidiyatova*[2], *E. Khusnutdinova*[3];
[1]*Bashkir State Medical University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [3]*2Institute of Biochemistry and Genetics, Ufa, Russian Federation.*

Hereditary motor-sensory neuropathy 2A occurs in 3 % of all HMSN cases in the Republic of Bashkortostan. We found four missense mutations in MFN2 gene, one of them was previously described: c.2113G>A (p.Val705Ile). Mutations c.775C>T(p.Arg259Cys); c.776G>A(p.Arg259His); c.2171T>C (p.Leu724Pro) were novel. These mutations were found in 8 patients from four unrelated families of different ethnic groups. The family with c.2171T>C (p.Leu724Pro) mutation in the MFN2 gene demonstrated is an autosomal-dominant pattern of inheritance. Three patients had apparently sporadic disease. In the families with novel mutations the disease began during the first or the second decade of patient's life. The initial symptoms were muscle weakness and wasting of distal extremities, gait disorder. The clinical picture was presented by progressive weakness and wasting of distal extremities, distal sensory loss, bilateral pes cavus deformity. The postural tremor in the hands was the most common additional symptom. Scoliosis and vasomotor troubles were seen in three of the patients. One female patient with (c.776G>A(p.Arg259His) mutation in the MFN2 gene had dysphagia and dysphonia. Neurophysiological data were available from three patients. All of patients had median motor nerve conduction velocities greater than 38 m/s and reduced compound motor action potential.

VRK1 mutations associated with complex motor and sensory axonal neuropathy plus microcephaly

W. Wiszniewski[1], *C. Gonzaga-Jauregui*[1], *T. Lotze*[1], *J. V. Hunter*[1], *L. Jamal*[2], *J. R. Lupski*[1], *R. Gibbs*[1];
[1]*Baylor College of Medicine, HOUSTON, TX, United States,* [2]*Kennedy Krieger Institute, Baltimore, MD, United States.*

Here we report three children from two unrelated families with a previously uncharacterized complex axonal motor and sensory neuropathy accompanied by severe non-progressive microcephaly and cerebral dysgnesis. The patients did not meet clinical criteria for any known hereditary neuro-developmental disorder, and extensive molecular investigations that included sequencing of known hereditary peripheral neuropathy genes failed to delineate the molecular cause of the disease. We performed whole-genome and targeted whole-exome sequencing in these three affected subjects. Using genome-wide sequence analysis we identified compound heterozygous mutations in two affected siblings from one family and a homozygous nonsense mutation in the vaccinia-related kinase 1 (*VRK1*) gene. *VRK1* encodes a serine/threonine kinase that is crucial for cell cycle progression and cell division and is proposed to be involved in nervous system development and maintenance.
It is an early response gene that directly phosphorylates and regulates p53 and has crucial roles throughout the cell cycle. We hypothesise that the VRK1 mutations lead to abnormal neural apoptosis and secondary brain dysgenesis and axonal neuropathy.

P07.25

In search of genetic modifiers for Emery-Dreifuss muscular dystrophies and related striated muscle laminopathies

I. P. Nelson[1], *B. Granger*[2], *R. Ben Yaou*[1], *S. Tézenas du Montcel*[2], *G. Bonne*[1];
[1]*INSERM U974-UM76, UPMC-Univ Paris 06-Institut de Myologie, Paris, France,* [2]*UPMC/Unité de Biostatistiques et Informatique Médicale-CHU Pitié-Salpêtrière, Paris, France.*

Emery-Dreifuss muscular dystrophy (EDMD) is characterised by early onset joint contractures, humero-peroneal muscle wasting/weakness then and cardiac disease within adulthood. Mutations in the *LMNA* gene, encoding nuclear envelop proteins lamins A and C, are responsible for autosomal dominant EDMD forms. Important intra-familial clinical variability in terms of age at onset, severity and progression of skeletal muscle and cardiac involvements has been reported in several EDMD families with *LMNA* mutations. Modifier genes have been suggested to explain such variability. The p.Glu6Stop *LMNA* mutation was previously identified in a large French family associated with a wide range of age at onset of myopathic symptoms (AOMS) (Becane et al. PACE, 2000). Two modifier loci that could contribute to that variability have been mapped on 2q36-q37 and 6q25-q27 (Granger et al. Hum Genetics, 2011).We have designed a sequence capture array that includes the entire genes and intergenic regions of the 28Mb covering those two loci (198 genes on chr2 and 61 genes on chr6). DNA samples from 19 members of the family carrying the *LMNA* mutation with various ages

at onset of myopathic symptoms (AOMS) have been sequenced using next generation sequencing (NGS). The mean coverage depth was 113x and only 3% regions was not covered. Three phenotypic subgroups were considered including those with AOMS before 20 years, those with AOMS after 30 years and finally those with isolated cardiac disease and without musculoskeletal symptoms. The analysis of sequenced variants will be presented.

P07.26

Progressive muscular dystrophies with life-threatening arrhythmias

O. Groznova[1], *G. Rudenskaya*[2], *T. Adyan*[2], *E. Dadali*[2], *O. Ryzkova*[2], *A. Polyakov*[2];
[1]*Moscow Scientific Research Institute of Pediatrics and Child Surgery, Moscow, Russian Federation,* [2]*Research Center for Medical Genetics, Moscow, Russian Federation.*

Cardiomyopathy (CMP) is typical for many muscular dystrophies (MD). A special place takes MD in which CMP characterized by impaired intracardiac conduction with arrhythmias, causing severe complications, including sudden death.

In our work we perfomed clinical and molecular-genetic diagnosis of X-linked Emery-Dreifuss MD (EDMD), associated with EMD gene, autosomal dominant EDMD and limb-girdle MD 1B, associated with LMNA gene, myofibrillar myopathy 1, caused by mutations in DES gene, in MD patients with arrhythmic CMP. Mutations in studied genes were found in 30 families: 13 mutations in EMD gene (13 families), 14 mutations in LMNA gene (16 families), one mutation in DES gene. It is revealed clinically interfamilial diversity and in 6 family cases intrafamilial diversity, especially in families with mutations in LMNA. There is no clear genotype-phenotype correlation for LMNA and EMD mutations. Onset (1-45 years), severity, and progression of disease highly variable. Of the total sample, only one patient with EDMD had a very severe myopathy, in other cases the state is mainly determined by the severity of the CMP. Early, including pre-clinical detection of these MD with molecular genetics verification is important not only for the prevention of new cases in families, but especially for the prevention of fatal cardiac events in patients.

Given the clinical diversity of MD with life-threatening arrhythmias, the indications for DNA-diagnosis should not limit the „classic" phenotype of some forms. On pre-laboratory stage of examination of patients with MD should make greater use of daily holter monitoring.

P07.27

Carrier frequency of the c.525delT mutation in gamma-sarcoglycan gene and estimated prevalence of Limb Girdle Muscular Dystrophy type 2C among the Moroccan population

F. El Kerch[1], *I. Ratbi*[1,2], *A. Sbiti*[1], *F. Laarabi*[1], *A. Barkat*[3], *A. Sefiani*[1,2];
[1]*Département de génétique médicale, Institut National d'Hygiène, Rabat, Morocco,* [2]*Centre de génomique humaine, Faculté de médecine et pharmacie, Université Mohammed V Souissi, Rabat, Morocco,* [3]*Centre National de Référence en Néonatologie et en Nutrition, Rabat, Morocco.*

Autosomal recessive Limb-Girdle Muscular Dystrophies (AR-LGMD) are characterized by clinical and genetic heterogeneity. LGMD type 2C or γ-sarcoglycanopathy is the most frequent in North-African populations, as a result of the founder c.525delT mutation in SGGC gene. Its epidemiology is poorly known in Morocco and its prevalence among the Moroccan population has never been evaluated.

26 patients with a LGMD2C and 45 patients with an AR-LGMD phenotype were screened for the c.525delT mutation. DNA extracted from umbilical cord blood samples of 250 newborns was tested for the same mutation. We used molecular epidemiological methods to calculate the frequency of heterozygotes for this mutation in Moroccan newborns and estimate the prevalence of LGMD2C in the Moroccan population.

The carrier frequency was estimated to be 1/250 which would imply that the prevalence of LGMD2C would be approximately 1/20 492 considering the effect of consanguinity. The homozygous c.525delT mutation was found in 65% of all AR-LGMD.

These findings suggest that AR-LGMD are prevalent in Moroccan population and LGMD2C is one of their most common forms. This might be useful for the development of diagnosis strategies in a large scale for a better management of patients with AR-LGMD and genetic counseling of families.

Limb girdle muscular dystrophies (LGMDs) are genetically heterogeneous disorders, characterized by a progressive weakness that begins from the proximal limb muscles. In addition to the genetic heterogeneity, the different forms are clinically heterogeneous, with different ages of onset and diverse distribution of the muscle damage. The primary distinction is made between the autosomal dominant (LGMD1) and the autosomal recessive forms (LGMD2). LGMD1F is very puzzling disease. It is characterized by muscle weakness affecting earlier the pelvic girdle. The critical interval was mapped to a 3.68-Mb interval on chromosome 7q32.1-7q32.2. We studied the same linked family with additional family members by exome sequencing using two different NGS platforms. We sequenced four affected individuals and identified a number of new variations: only one of which was completely new, shared by all affected subjects, and mapped to 7q32. They all shared heterozygous frame-shift variant in the Transportin 3 (TNPO3) gene, encoding a member of the importin-β super-family. In addition, we identified an isolated case of LGMD with a new missense mutation in the same gene. The TNPO3 gene encodes a 923-amino acid product that is also expressed in skeletal muscle. We localized the mutant TNPO3 around the nucleus, but not inside. Our present data indicate that TNPO3 is the gene mutated in LGMD1F. The involvement of gene related to the nuclear transport suggests a novel disease mechanism leading to muscular dystrophy.

Identified novel mutations in two families with limb girdle muscular dystrophy using whole exome sequencing

S. Abedini[1], *Z. Fattahi*[1], *K. Kahrizi*[1], *M. Akbari*[2], *H. Najmabadi*[1,3];
[1]*Genetics Research Center, University of Social Welfare & Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Women's College Research Institute, University of Toronto, Toronto, ON, Canada,* [3]*Kariminejad – Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran.*

Introduction: Neuromuscular disorders are a progressive heterogeneous group with considerable heterogeneity. The frequency of these diseases is one in 3000 to 4000 live births. The most common form of these disorders is muscular dystrophies of which Limb girdle muscular dystrophy (LGMD) has a higher prevalence.

LGMDs are generally characterized by progressive muscle weakness and wasting which are restricted to the limb musculature and caused by autosomal dominant or recessive gene mutations. There are 25 known genetic loci including 21 genes for LGMDs that makes genetic testing for this group of disorders somehow impractical using conventional Sanger sequencing method; however, the availability of next generation sequencing technology has provided an opportunity for identifying the causal mutations in these patients with screening all the known genes together using disease specific gene panel sequencing or whole exome sequencing (WES).

Materials and methods: We ascertained two families with autosomal recessive LGMD with unknown genetic mutations. To identify the causal mutations in these families, WES was performed on affected individuals using Agilent SureSelect V4 exome enrichment kit combined with Illumina Hiseq2000 sequencing.

Results: We identified two novel recessive mutations in CAPN3 gene (c.795_800delCATTGA/ p.266_267delIleAsp and c.1967G>A/p.Arg656Gln) in the germline DNA of the two tested individuals.

Discussion: By using WES for identifying mutations responsible for LGMD in these families, we can obtain better understanding of the genotype-phenotype correlation and provide more focused approach for molecular diagnosis of other families who suffered from this disease.

Myasthenia gravis (MG) is a heterogeneous autoimmune disease, but patients with early-onset MG (before age 50; EOMG) are a particularly well defined subgroup. Their MG is clearly mediated by autoantibodies against the acetylcholine receptor at the neuromuscular junction. With the goal to identify genetic loci that predispose to EOMG, a two stage genetic association study was performed on 384 SNPs in 35 candidate genes selected based on MG pathophysio-logy. Top hits were replicated in about 1200 EOMG patients and 1000 matched controls collected from nine European centres. First, significant frequency differences were found for 11 SNPs in 6 genes: HLA-DRA, tumor necrosis factor alpha (TNF-α), CD86, AKAP12, VAV1, and B-cell activating factor (BAFF). Second, haplotype analysis supported the SNP association results identifying several haplotypes with a frequency significantly different between MG patients and controls. Both HLA-DRA and TNFα have been previously associated with EOMG, but the association with VAV1 and BAFF are novel. VAV1 is a key signal transducer that is essential for the development and activation of T- and B-cells, and BAFF is a cytokine that plays important roles in the proliferation and differentiation of B-cells. TNF loci showed the largest and most consistent differences, with 20% difference in both allele and haplotype frequencies in each of 9 patient cohorts genotyped. We identified a statistically significant interaction between VAV1 and BAFF, suggesting shared functional pathways, that, if perturbed, might contribute to EOMG predisposition.

Molecular, electrophysiological and behavioural evidence of cerebellar dysfunction in a mouse model of myotonic dystrophy type I

G. Sicot[1], *C. Prigogine*[2], *D. Gall*[2], *F. Medja*[1], *C. Chhuon*[3], *C. Guerrera*[3], *F. Fernandez-Gomez*[4], *D. Furling*[5], *A. Munnich*[1], *G. Cheron*[2], *N. Sergent*[4], *L. Servais*[5], *G. Gourdon*[1], *M. Gomes-Pereira*[1];

[1]*Inserm U781, Hôpital Necker-Enfants Malades, Paris, France,* [2]*Laboratory of Neurophysiology and Movement Biomechanics, Université Libre de Bruxelles, Brussels, Belgium,* [3]*Plateau Protéomes Necker, PPN, IFR94, Paris, France,* [4]*Inserm UMR 837-1, Université Lille Nord de France, Lille, France,* [5]*Inserm UMR 787, Institut de Myologie, Paris, France.*

Myotonic dystrophy type I (DM1) is caused by a non-coding CTG trinucleotide repeat expansion in the DMPK gene. Disease pathogenesis is mainly mediated by a trans-dominant role of toxic DMPK transcripts: CUG-containing RNA accumulates in nuclear foci and perturbs important developmental splicing regulators, resulting in missplicing of downstream genes. The DMSXL transgenic mice generated in our laboratory express expanded DMPK transcripts in multiple tissues, notably in the central nervous system (CNS), recreate important aspects of the disease and provide a useful tool to study DM1 molecular pathogenesis.
Clinical, neuropsychological and imaging evidence have demonstrated the involvement of the CNS in DM1, however, the molecular pathways, neuronal circuits and brain regions preferentially affected remain largely unknown. During the behavioural phenotyping of DMSXL mice, transgenic animals showed impaired motor coordination in the elevated runway test, as well as electrophysiological abnormalities in the cerebellum, suggestive of changes in the firing rate and rhythmicity of Purkinje cells. In addition, we found signs of RNA toxicity in DMSXL cerebellum (nuclear foci, MBNL sequestration, missplicing of downstream genes). Interestingly, RNA toxicity appears to be more pronounced in glial cell subpopulations of the cerebellum, suggesting cells-specific susceptibility.
We have confirmed RNA toxicity in human DM1 cerebellum samples, which show abundant nuclear foci, missplicing events and deregulation of splicing regulators. Taken together, the mouse and human data open the possibility of cerebellar dysfunction in DM1, which may contribute to the neurological manifestations of the disease.

Myotonic dystrophy type 2 - healthy range, premutation range and mutation range alleles in the general population

J. Radvanszky[1], *M. Surovy*[2], *E. Polak*[2], *L. Kadasi*[1,2];

[1]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.*

Myotonic dystrophy type 2 (DM2) is a multisystemic disorder caused by expansion of the $(CCTG)_n$ repeat tract in the *CNBP* gene (also called *ZNF9*). The CCTG tract is generally interrupted in healthy range alleles and is uninterrupted in pathologically expanded alleles. Our study reports the variability of the healthy range CCTG tracts of the *CNBP* gene in a population of Slovakia. Using repeat-primed PCR, we identified wider range and higher frequency of healthy range alleles containing uninterrupted CCTG tracts, than it was previously reported. Altogether, we identified 12 alleles with uninterrupted tracts, in a range of 12 CCTG repeats up to 70 CCTG repeats and 2 additional alleles exceeding the sizing limit of our assay (>60 CCTG repeats). As uninterrupted alleles were so far reported mainly on larger alleles, they have been considered as possible DM2 premutations. Our findings, however, suggest that uninterrupted CCTG parts are not restricted to large alleles and can be found continuously throughout the whole range of healthy range alleles. In 6 cases we were able to track the inheritance of the alleles. The rs1871922 marker was also genotyped in all of the uninterrupted alleles. Our results suggest that uninterrupted alleles with less than approximately 30 CCTG repeats are likely stable during transmission, while instability increases with increasing length of uninterrupted tracts above this approximate threshold. Unstable DM2 premutation alleles likely contain from approximately 30 to 55 CCTG repeats, as the smallest pathogenic alleles identified so far had 55 and 75 repeats.

Myotonic dystrophy type I (DM1) is an autosomal dominant multisystemic disease caused by the expansion of an unstable CTG repeat in the 3' non-coding region of the DMPK gene. DMPK transcripts carrying CUG expansions form nuclear foci and affect splicing regulation of various RNA transcripts. Furthermore, bidirectional transcription over the DMPK gene and non- conventional RNA translation of repeated transcripts have been described in DM1. It is clear now that this disease may involve multiple pathogenic pathways including changes in gene expression, RNA stability and splicing regulation, protein translation and micro-RNA metabolism. We previously generated transgenic mice with 45-kb of the DM1 locus and > 300 CTG repeats (DM300 mice). Recently, mice carrying over 1000 CTG (DMSXL) were obtained due to CTG instability over successive generations. In the present study, we described for the first time, the expression pattern

of the DMPK sense transcripts in DMSXL and human tissues. Interestingly, we also demonstrate that DMPK antisense transcripts are expressed in various DMSXL and human tissues. Molecular features of DM1-associated RNA toxicity in DMSXL mice (such as foci accumulation and mild missplicing) were associated with high mortality and growth retardation. In addition, significant changes in functional properties and morphology of the skeletal muscle were measured in these mice.
These data demonstrate that the human DM1 locus carrying very large expansions induced a variety of molecular and physiological defects in transgenic mice. As a result, DMSXL mice provide an animal tool to decipher various aspects of DM1 mechanisms and for preclinical assay.

P07.34

New methods for nemaline myopathy diagnostics - NM-CGH microarray and exome sequencing

K. Kiiski[1], *V. L. Lehtokari*[1], *L. Laari*[1], *C. Wallgren-Pettersson*[1], *K. Pelin*[2];
[1]*The Folkhälsan Institute of Genetics and the Department of Medical Genetics, University of Helsinki, Haartman Institute, Helsinki, Finland,* [2]*Department of Biosciences, Division of Genetics, University of Helsinki, Helsinki, Finland.*

Nemaline myopathy (NM) constitutes a heterogeneous group of disorders among the congenital myopathies. Mutations in the nebulin gene (*NEB)* are a main cause of recessively inherited NM. We have identified compound heterozygous *NEB* mutations in 91 families, and homozygous mutations in 14 NM families. The mutations are located all along the 183 exons of *NEB.* Novel mutation detection methods are needed as there still remain dozens of families in whom the causative mutations have not yet been identified. We have approached this issue by designing a custom NM-CGH microarray to detect copy number variations in the currently known seven NM genes. To date we have studied 160 samples from 130 families and identified four novel disease-causing aberrations in *NEB* in four different families. Two of these aberrations are the largest deletions characterized in *NEB* to date (53 and 88 kb) encompassing 24 and 68 exons, respectively. Copy number variation, both deletions and duplications, have also been identified in the triplicate region of *NEB* in 13 different families. Further study is ongoing to elucidate the potential pathogenicity of these variants. In addition to these, one potential mutation is currently being verified in another NM gene besides *NEB*.
We have recently launched an exome sequencing pilot study with the aim to sequence 50 NM samples to find the causative mutations. We believe that the combination of exome sequencing and NM-CGH microarray analysis will accelerate mutation analysis and improve the diagnostics of nemaline myopathy and related disorders.

Genetic findings and detection rate in patients tested for neurofibromatosis over a six years period.

W. Brechan[1], *E. K. Svaasand*[1], *S. Zahl-Brathaug*[1], *W. Sjursen*[1], *W. Sjursen*[2];
[1]*Department of Pathology and Medical Genetics, St.Olavs University Hospital, Trondheim, Norway,* [2]*Department of Laboratory Medicine Children's and Women's Health, Norwegian University of Science and Technology, Trondheim, Norway.*

Neurofibromatosis type 1 (NF1) is one of the most common autosomal dominant disorders, with a worldwide incidence of 1 in 3000 individuals. The diagnosis of NF1 show high variation in expressivity and is usually based on clinical findings. The diagnostic criteria are met in a patient who has two or more of the following main characteristics: six or more café au lait spots, neurofibromas, freckling, optic glioma, iris Lisch nodules, distinctive bone lesion and first-degree relative with NF1. NF1 is characterized by lack of neurofibromin, a GTPase activating protein encoded by the NF1-gene.
Department of Pathology and Medical Genetics, St. Olavs University Hospital has performed genetic testing for NF1 over a six years period. Mutation detection in the NF1 gene is complex due to size of the gene (58 exons), existence of several pseudogenes, lack of clustering of the mutations and great variety of possible changes.
We have performed mutation analysis of the entire NF1 gene in a total of 287 patients since 2006, using different techniques such as high resolution melt (HRM) analysis, multiplex ligation-dependent probe amplification (MLPA), Sanger-sequencing and RNA-analysis.
This study presents the mutation detection rate in NF1 found in our laboratory, both for individuals fulfilling the diagnostic criteria of NF1, and in those with more diffuse symptoms (uncertain NF1 clinical diagnosis). The most common mutations reported found in NF1 patients are nonsense mutations, frameshift mutations and splice mutations. We will present an overview of frequencies of different types of mutations found in our population.

Duchenne/Becker, limb-girdle and congenital muscular dystrophies represent a wide range of conditions caused by various types of mutations, including point mutations, small indels, and large deletions/duplications. During the two past decades, diagnostic laboratories have been faced with an ever-increasing range of disease genes that could be tested individually by Sanger sequencing. However, since the advent of NGS technologies, it appears to represent a limited approach for those heterogeneous genetic disorders.
The EU-funded NMD-Chip project was meant to design, develop and validate new sensitive high throughput tools to efficiently diagnose patients carrying mutations in genes already known to be involved in neuromuscular disorders (NMDs), but also to identify new disease-causing mutations using a candidate-gene approach. A specific custom in-solution sequence-capture DNA library including 820 genes was developed. Among them, 50 are known to be involved in common NMDs, the others being candidate genes selected from experimental and published data. To validate this approach, we have selected 10 patients: 5 with one known mutation either at hemizygous or heterozygous states, including point mutations and large rearrangements, and 5 with no molecular diagnosis. Sequencing of the captured sequences was performed using HiSeq2000.
Mutations in control DNAs were correctly detected, and we identified the causal mutations in *TRIM32*, *RYR1*, *GNE* and *DMD* genes in 4/5 patients without previous diagnosis. We show that this approach is technically robust and accurate, and also that NGS is likely to represent a time and cost-reducing alternative to the Sanger process, that will accelerate molecular diagnostics of NMDs.

Introduction. Pelizaeus-Merzbacher disease and its allelic disorder, spastic paraplegia type 2 are X-linked recessive dysmyelinating disorders affecting the central nervous system. Pelizaeus-Merzbacher disease is caused in most cases by either duplication or point mutations in the *PLP1* gene. Less frequently it has been reported the presence of large deletions of the gene. This disease has a wide clinical spectrum and its causing mutations act through different molecular mechanisms. Methods. Eighty-eight male patients from non-related families with leukodystrophy were studied. *PLP1* gene analysis was performed by the Multiplex Ligation-dependent Probe Amplification technique (MLPA) and DNA sequencing, and in duplicated cases of PLP1 do-

sage were completed by using a custom oligonucleotide (8x15K) array-CGH. Results. We have identified 21 patients with mutations in the *PLP1* gene, including duplications, short and large deletions and several point mutations in our cohort. To address the extension of *PLP1* duplications we used a customized array-CGH within PLP1 region at the Xq22.2 area, identifying several duplications and triplications including *PLP1* gene, with sizes ranging from 181 Kb to 5,17 Mb. Conclusions. Mutations found in the *PLP1* gene are the cause of Pelizaeus-Merzbacher disease in around 20% of the patients in this series. Interestingly, we described eight new mutations. Array-CGH results demonstrate that there is not a correlation between the extension of the duplication and the severity of the illness.

A nonsense mutation in the Acid α-Glucosidase gene causes Pompe disease in both humans and dogs

E. H. Seppälä[1,2,3], *A. J. J. Reuser*[4], *H. Lohi*[1,2,3];
[1]*Research Program for Molecular Neurology, University of Helsinki, Helsinki, Finland,* [2]*Department of Veterinary Biosciences and Department of Medical Genetics, University of Helsinki, Helsinki, Finland,* [3]*Folkhälsan Institute of Genetics, Helsinki, Finland,* [4]*Departments of Clinical Genetics and Paediatrics, Center for Lysosomal and Metabolic Diseases, Erasmus MC, Rotterdam, Netherlands.*

Pompe disease is a recessively inherited and often fatal disorder caused by the deficiency of acid α-glucosidase, an enzyme encoded by the *GAA* gene and needed to break down glycogen in lysosomes. This glycogen storage disease type II has been reported also in Swedish Lapphund dogs. Here we describe the genetic defect in canine Pompe disease and show that three related breeds from Scandinavia carry the same mutation. The affected dogs are homozygous for the *GAA* c.2237G>A mutation leading to a premature stop codon at amino acid position 746. The corresponding mutation has previously been reported in humans and causes infantile Pompe disease in combination with a second fully deleterious mutation. The affected dogs from both the Finnish as well as the Swedish breed mimic infantile-onset Pompe disease genetically, but also clinico-pathologically. Therefore this canine model provides a valuable tool for preclinical studies aimed at the development of gene therapy in Pompe disease.

Twenty years of experience in the diagnosis of Spinal Muscular Atrophy in Hungary

L. Tímár[1], *H. Pikó*[2], *Á. Herczegfalvi*[3], *K. Hajdú*[4], *V. Karcagi*[2];
[1]*National Institute of Child Health, BUDAPEST, Hungary,* [2]*National Institute of Environmental Health, BUDAPEST, Hungary,* [3]*Dept. of Pediatric Neurology, 2nd Pediatric Clinic, BUDAPEST, Hungary,* [4]*Istenhegyi Clinic, BUDAPEST, Hungary.*

Spinal Muscular Atrophy (SMA) represents the second most common autosomal recessive disorder, characterised by degeneration of spinal motoneurons.
Since 1993 blood samples have been collected from 452 Hungarian patients with all types of SMA. Clinical diagnosis of all probands were estabilished by using the inclusion and exclusion criterias. Direct mutation analyses have been performed in the SMN1 gene by using PCR-RFLP and real-time PCR techniques. Homozygous deletions of exon 7 (and 8) of the SMN1 gene were detected in 159 of SMA I patients, 82 of SMA II patients and in 105 of SMA III patients. In 106 (23,5 %) of the patients no homozygouse deletion in the SMN1 gene has been found so we defined them as uncertain cases. Out of the 106,
55 uncertain patients were analysed for the SMN1 exon 7 copy number by quantitative real-time PCR and 21 patients were detected as compound heterozygouse. The second mutation has to be established later on by direct sequencing. For carrier screening, SMN1 copies were determined in 246 related family members and 131 carriers were detected. Prenatal diagnosis for all families with confirmed genetic diagnosis were offered during these twenty years. The outcome of the prenatal testing resulted in 59 affected and 153 unaffected fetuses. Additionally, SMN2 copy number were estimated in 164 patients and good correlation was found between copy number and severity of the disease.
SMA is a common and fatal disorder, therefore carrier detection and prenatal testing is essential for prevention and proper genetic counselling.

Neurosciences, Ospedale Bambino Gesù Research Institute, Roma, Italy,* [7]*Child Neurology Unit, Department of Pediatrics, Hacettepe University, Ankara, Turkey.*

Spinal muscular atrophy (SMA) is a clinically and genetically heterogeneous disease characterized by degeneration of lower motor neurons. The most frequent form is linked to mutations of the SMN1. Childhood SMA associated with progressive myoclonic epilepsy (SMA-PME) has been reported as a rare autosomal recessive condition unlinked to SMN1 mutation. Through linkage analysis, homozygosity mapping and exome sequencing in three unrelated SMA-PME families, we identified a homozygous missense mutation (c.125C>T; p.Thr42Met) in the ASAH1 exon 2 in affected children of two families and the same mutation associated with a deletion of the whole gene in the third one. Expression studies of the c.125C>T mutant cDNA in Farber fibroblasts showed an acid ceramidase activity deficiency of 32% of that generated by normal cDNA. More recently, two additional living patients were analyzed: identical *ASAH1* mutation was found leading to reduction of acid ceramidase activity (17-20 % of the control value*)* in patient fibroblasts. Ceramide content was normal. These *in vivo* results confirmed *in vitr*o data. Morpholino knockdown of ASAH1 ortholog in zebrafish led to a marked loss of motor neuron axonal branching associated with increased apoptosis in the spinal cord. Our results reveal a wide phenotypic spectrum associated with ASAH1 mutations. An acid ceramidase activity below 10% results in Farber disease, an early onset disease starting with subcutaneous lipogranulomata, joint pains and hoarseness of the voice whereas a higher residual activity may be responsible for SMA-PME, a later onset phenotype restricted to the CNS and starting with lower motor neuron disease.

Re-interpretation of mutations in the Tudor domain of SMN1 as splicing mutations

K. Mahias[1], *P. Saugier-Veber*[1,2], *S. Drunat*[3], *T. Frébourg*[1,2], *A. Martins*[1];
[1]*Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France,* [2]*Department of Genetics, University Hospital, Rouen, France,* [3]*Department of Genetics, Robert-Debré Hospital, APHP, Paris, France.*

Spinal muscular atrophy, an autosomal recessive neuromuscular disorder, is a frequent cause of death in early childhood. In 95% of the cases, the disease is due to homozygous deletion of the survival motor neuron gene (*SMN1*). In rare cases (about 5%), patients are compound heterozygous with a *SMN1* deletion in one chromosome and a subtle *SMN1* mutation in the other. This study focused on mutations identified in the highly conserved Tudor domain of the SMN protein, a domain encoded by the exon 3 of the *SMN1* gene and where numerous *SMN1* mutations have been detected (n=17). We hypothesized that, besides altering the coding sequence of the gene, a subset of these mutations could also affect the splicing pattern of the SMN1 transcripts. To address this question, we performed *ex vivo* splicing assays using representative minigenes. Our results showed that 5 out of the 17 mutations altered the splicing pattern of exon 3: four by probably altering splicing regulatory elements and one by creating an internal splice site leading to a deletion of part of the exon. Because the effect of this latter mutation was very drastic in the minigene assay and confirmed on the RNA from a patient, we propose that it should be classified not as a missense substitution but as a deleterious splicing mutation. This study brings clues into the splicing regulation of exon 3 and contributes to a better understanding of the structure-function features of the Tudor domain of the SMN protein.

Functional prediction analysis of coding and non-coding regions of TTR gene: insights on phenotype expression of transthyretin-related amyloidosis

R. Polimanti[1], *M. Di Girolamo*[2], *D. Manfellotto*[2], *M. Fuciarelli*[1];
[1]*Department of Biology, University of Rome „Tor Vergata", Rome, Italy,* [2]*Clinical Pathophysiology Center, AFaR - "San Giovanni Calibita" Fatebenefratelli Hospital, Rome, Italy.*

Pathogenesis of transthyretin-related amyloidosis (ATTR) is focused on mutations of TTR protein. Significant heterogeneity in the genotype-phenotype correlation has been reported and other genetic and epigenetic factors may interact on phenotype and penetrance of this autosomal dominant trait. In particular, additional genetic variants in the TTR gene and its surrounding regions may influence the phenotype of the disease. In order to explore this hypothesis, we provided a functional prediction analysis of coding and non-coding variants in TTR gene.
Using databases of 1,000 Genomes project and of Mutations in Hereditary Amyloidosis, we provided a deep analysis of TTR gene. Several bioinformatic tools were used to identify the functional impact of the identified variants, analyzing their potential involvement in disease phenotypes.
Our analysis highlighted the presence of different non-coding variants potentially associated with large impact in TTR gene function. In particular, genetic variation in promoter region and in untranslated regions seems to be involved in the regulation of gene expression. Furthermore, investigation on coding variants (disease-causing mutations, and polymorphisms) suggested that amyloid aggregation variability mong coding variants is present. Finally, combining functional effect of coding and non-coding, we predicted the disease phenotypes associated with different haplotypes.
In conclusion, our data support the hypothesis that genetic variation in cis-regulatory regions affects ATTR phenotypes. Confirmation of these in silico outcomes in ATTR patients may strongly improve the disease genetic testing, enhancing our capacity to assist individuals carries of TTR mutation.

P08.01

Kohlschutter-Tonz Syndrome*:* Clinical and Genetic Insights gained from sixteen cases deriving from a close knit village in Northern Israel.

A. Mory[1], *E. Dagan*[2], *R. Gershoni-Baruch*[3,1];
[1]*The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, Israel,* [2]*Department of Nursing, Faculty of Social Welfare and Health Sciences, University of Haifa, HAIFA, Israel,* [3]*Institute of Human Genetics, Rambam Health Care Campus, Haifa, Israel.*

Kohlschutter-Tonz
syndrome (KTZS) (MIM 22675) is a rare autosomal recessive disorder, characterized by intellectual impairment, spasticity, epilepsy and amelogenesis imperfecta. Here we report on 16 cases of KTZS (8 females, 8 males), from 7 families (5 kindreds), originating from the same Druze village in Northern Israel and show that the extent of the convulsive disorder, as regards age of onset, frequency, severity and response to treatment predicts the magnitude of mental and motor deficiencies and that amelogenesis imperfecta and deficient speech occur in all cases. We have recently identified the causative gene and mutation underlying KTZS in our cohort of patients, namely, p.R157X corresponding to *ROGDI*
c.571C>T that creates a premature stop codon in ROGDI homolog (Drosophila), a gene of unknown function. A screen of the healthy Druze population inhabiting the village, revealed a carrier frequency of 1:10. The unique KTZS phenotype that compiles mental and verbal deficiency, motor deterioration, seizures and amelogenesis
imperfecta is common to all affected individuals. However, age at onset and severity of convulsions parallel the progression of mental and motor disability and invariably vary among affected sibs. By late adolescence and early twenties KTZS individuals are bedridden, fed by gastrostomy, spastic, practically with no cognitive and language perception.

P08.02

POLR3A and POLR3B mutations in 4H syndrome.

R. M. L. Vervenne - van Spaendonk*, E. A. Sistermans, T. E. M. Abbink, M. S. van der Knaap, N. I. Wolf;*
VU university medical center, Amsterdam, Netherlands.

Hypomyelinating leukoencephalopathies form a major group among inherited white matter disorders. Additional clinical findings sometimes allow making a definitive diagnosis. The 4H syndrome has as characteristic features, in addition to Hypomyelination, Hypodontia and Hypogonadotropic Hypogonadism (4H), but dental and hormonal anomalies are not obligatory. Cerebral MRI shows hypomyelination, additionally cerebellar atrophy and relative T2-hypointensity of the lateral thalami, allowing a tentative diagnosis of this disease also in the absence of all clinical features. Recessive mutations in two genes coding for subunits of the RNA polymerase III, POLR3A and POLR3B, were shown to cause this disease.
We sequenced the entire coding region and splice junctions of POLR3A and POLR3B in 28 patients (age 2 - 40 years) with hypomyelination and clinical and/or MRI features suggesting 4H syndrome. All patients were found to carry mutations in POLR3A (7 patients) or POLR3B (21 patients). Eleven new mutations were identified in POLR3A: 10 missense and 1 nonsense mutation. In POLR3B, 17 new mutations were identified: 5 splice site, 3 frameshift, 2 nonsense and 7 missense mutations. Nineteen of the 21 patients with POLR3B mutations shared the common exon 15 mutation (p.Val523Glu), but none was homozygous for this mutation. These results further support POLR3A and POLR3B mutations as the major cause of 4H syndrome and stress that if patients fulfill clinical and/or MRI criteria, the chance of confirming mutations in either of the 2 genes is high. It also makes 4H syndrome the second most common entity after Pelizaeus-Merzbacher disease among hypomyelinating white matter disorders.

Analysis of candidate genes with non-coding hexanucleotide GGGGCC-repeats in French patients with Amyotrophic lateral sclerosis

P. Vourc'h[1,2,3], *F. Wurmser*[3], *S. Kassem*[2], *I. Daoudi*[2], *T. Le Berre*[2], *A. Dangoumau*[1], *C. Veyrat-Durebex*[1,2], *H. Blasco*[1], *P. Corcia*[1,4,5], *C. R. Andres*[1,2];
[1]*INSERM U930, Université François-Rabelais, Tours, France,* [2]*Laboratoire de Biochimie et Biologie moléculaire, Hôpital Bretonneau, CHU de Tours, CHU de Tours, Tours, France,* [3]*Département de Génomique, PPF ASB, Université François-Rabelais, Tours, France,* [4]*Service de Neurologie, Hôpital Bretonneau, CHU de Tours, Tours, France,* [5]*For the French Amyotrophic Lateral Sclerosis (ALS) Study Group, Tours, France.*

Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by the loss of motor neurons in brain and spinal cord. Large expansions of the non-coding hexanucleotide GGGGCC-repeat in the first intron of the *C9ORF72* gene have been demonstrated to be a major genetic cause of ALS. Interestingly this GGGGCC-repeat could form RNA G-quadruplexes affecting transcription and splicing by sequestration of various proteins, and/or could produce a pathogenic poly-(Gly-Ala) dipeptide-repeat protein. We hypothesized that other genes expressed in brain and spinal cord, and carrying GGGGCC-repeats may be involved in ALS.
Using *in silico* analysis we identified 65 genes in the Human genome (genome browser UCSC) carrying 3 or more GGGGCC-repeats. The repeats were located in the first intron for 28 of them. Some of these genes were expressed in brain and spinal cord (bioGPS.org) and participate in cellular or physiological pathways implicated in neurodegenerative diseases. For example, *NUB1* gene encodes an ubiquitin-related protein which accumulates in neuronal and glial inclusions in various neurodegenerative diseases. Another example is *MARCKSL1*, a gene highly expressed in spinal cord and encoding the myristoylated alanine-rich C kinase substrate implicated in cytoskeletal plasticity during nerve degeneration.
We next developed repeat-primed PCR and Genescan analyses to study the hexanucleotide repeats in these genes in French patients with ALS. Our results on *C9ORF72* show a frequency of pathogenic repeats (>30) in 33% of familial ALS and 3% of sporadic ALS. Preliminary results indicated that no amplification of the repeat was present in *NUB1* and *MARCKSL1* genes in ALS patients.

P08.04

Mutational analysis of the major Amyotrophic lateral sclerosis genes in French ALS patients

A. Dangoumau[1], *C. Veyrat-Durebex*[1,2], *E. Hammouche*[2], *H. Blasco*[1,2], *J. Pouget*[3], *A. Verschueren*[3], *J. Praline*[1,4], *P. Corcia*[1,4,5], *C. Andres*[1,2], *P. Vourc'h*[1,2];
[1]*UMR INSERM U930, Université François Rabelais, Tours, France,* [2]*CHU de Tours, Laboratoire de Biochimie et Biologie moléculaire, Tours, France,* [3]*Centre de référence des maladies neuro musculaires et de la SLA CHU La TIMONE, Marseille, France,* [4]*CHU de Tours, Service de Neurologie, Tours, France,* [5]*for the French Amyotrophic Lateral*

Sclerosis (ALS) Study Group, Tours, France.

Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by the selective death of motor neurons in the brain and spinal cord. The aim of our study was to quantify the overall contribution of mutations in the major ALS genes in a cohort of French ALS patients and to perform functional analysis on novel mutations.

We screened the *C9ORF72* hexanucleotide expansion, and *SOD1*, *TARDBP*, *FUS* genes in 118 familial ALS cases (FALS) and 602 sporadic ALS cases (SALS). The frequency of mutations in FALS patients was 33% (17/52) for *C9ORF72*, 11.9% (14/118) for *SOD1*, and 10.5% (2/19) for *TARBP*. In the SALS group, the frequency of mutations was 3% (4/115) for *C9ORF72*, 3.3% (20/602) for *SOD1*, 1.5% (3/195) for *TARBP*, and 0.9% (1/109) for *FUS*. We identified five novel mutations in the *SOD1* gene, three heterozygous nonsens mutations and two heterozygous missense mutations, $SOD1^{V31A}$ and SOD^{E121G}. Motor neurons-like cells NSC-34 over-expressing $SOD1^{31A}$ showed cytoplasmic aggregates and decreased cell viability in presence of oxidative stress (H_2O_2 1mM for 3h).

These results confirmed the major roles of the *C9ORF72* hexanucleotide expansion and *SOD1* gene mutation in the etiology of FALS, and consequently have relevant implications in clinical practice. We described novel mutations in *SOD1* and performed functional analysis to support their implication in the disease. We are currently analyzing whether or not the groups of patients with mutation have differences with regard to age and site of onset, clinical phenotypes, and survival.

Amyotrophic lateral sclerosis (*ALS*) is a late-onset neurodegenerative disease affecting upper and lower motor-neurons. Different genes and cellular events, including glutamate-mediated excitotoxicity, are though to contribute to *ALS*. Mutations in the superoxide dismutase-1 (*SOD1*) accounts for 20% of familial *ALS*. Our recent studies with mice expressing human *SOD1* carrying the G93A mutation (*SOD1^{G93A}*) indicate that glutamate release is abnormally increased in the spinal cord neurons by mechanisms involving presynaptic metabotropic glutamate type 1 (mGlu1R) and type 5 (mGlu5R) autoreceptors activation and mGlu5R overexpression.

mGlu1R and mGlu5R are the only members of group I mGlu receptors, G protein-coupled receptors implicated in synaptic plasticity, feed-back control of glutamate release and excitotoxicity mechanisms of neurodegeneration.

We thought to explore whether the excessive mGlu1R activity plays a role in the pathogenesis of *ALS*. To this end, we generated mice carrying half dosage of mGlu1R in the *SOD1^{G93A}* background by crossing the *SOD1^{G93A}* mouse with the *Grm1^{crv4}* mouse, which lacks mGlu1R because of a spontaneous recessive mutation, thus providing a genetic tool to evaluate the mGlu1R role in *ALS*. *SOD1^{G93A}Grm1$^{crv4/+}$* mice showed prolonged survival and amelioration in motor skills. Histological studies revealed as mGlu1R half dosage in the *SOD1^{G93A}* background protects motor neurons from degeneration, preserves integrity of mitochondria and reverts astroglia activation. Over-expression of mGlu5 receptors and abnormal glutamate release were also normalized.

These results demonstrate that mGlu1R deletion has a significant impact in *ALS* mice, thus providing the rationale for pharmacological approaches to *ALS* by blocking Group I metabotropic receptors.

Association of ApoE polymorphisms in Bulgarian patients with Alzheimer disease and Frontotemporal dementia.

K. Mihova[1], *S. Mehrabian*[2], *E. Boiadjieva*[1], *O. Beltcheva*[1], *R. Pavlova*[2], *Y. Zhelev*[2], *R. Kaneva*[1], *A. Jordanova*[1,3], *V. Mitev*[1], *L. Traykov*[2];
[1]*Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Medical University, Sofia, Bulgaria,* [2]*Clinic of Neurology, University Hospital „Alexandrovska", Department of Neurology, Medical University, Sofia, Bulgaria,* [3]*VIB Department of Molecular Genetics, University of Antwerp, Antwerp, Belgium.*

Background: Alzheimer disease (AD) is characterized by cognitive impairment and is the most common form of dementia caused by degeneration of the brain neurons resulting in memory and personality disorders. Apolipoprotein E plays important role in cholesterol metabolism, immune regulation, synaptic function, intracellular signaling and Aβ-trafficking. ApoE4 is known risk factor for AD and other diseases.

Materials and methods: In this study 197 patients with AD, 32 patients with Frontotemporal dementia (FTD) and 84 healthy control individuals (HC) were included. ApoE alleles (E2, E3, and E4) and genotypes were determined using restriction fragment length polymorphisms (RFLP) after simultaneous digestion of an amplified segment by AflIII and HaeII. Statistical analysis was done using chi square test.

Results and discussion: The ApoE4 allele frequency showed significant difference between the AD group (22%) and HC group (12%). It was associated with increased risk of AD (P=0.0047, OR=2.11), compared to E2 and E3 alleles. ApoE2 allele was found in 4% of AD and in 9% of HC group and was associated with decreased risk of AD (P=0.012, OR=0.38). ApoE4 allele in FTD (16%) compared to HC group (12%) shows difference as well as ApoE2 allele in FTD (3%) compared to HC group (9%) but did not reach significance due to the small sample size.

Conclusions: Our findings confirm the role of ApoE4 allele as risk factor for AD in Bulgarian patients. The study adds to the understanding of the molecular basis of neurodegenerative diseases and may have implications for diagnostic testing and genetic counseling.

Genome-wide association study of CSF biomarkers for identifying quantitative trait loci influencing the progression from MCI to AD

Y. Sun, *M. Nilsson, A. Bresell, H. Salter;*
AstraZeneca, Stockholm, Sweden.

Background: CSF biomarkers of t-tau and p-tau_{181p} are predictive of future conversion from mild cognitive impairment (MCI) to Alzheimer disease (AD). Other common genetic risk factors associated with CSF biomarkers that influence progression are still unknown. **Method**: Quality controlled data from 51,4932 SNPs and 177 Caucasian subjects from the ADNI cohort was included in the analysis. The main effect of SNP and SNP/progression interaction was assessed on the CSF biomarkers of t-tau, p-tau181, and two ratios t-tau/Aβ1-42 and p-tau181 /Aβ1-42, respectively. General linear regression models were performed with adjustment for age, sex and APOε4 status.

Results: The two genetic marker rs1445093 and rs12327358 in high linkage disequilibrium (LD) (r^2 =0.9) reached genome-wide significance for association with both endophenotypes t-tau and t-tau/Aβ1-42. These two SNPs are located in the upstream of the gene Netrin receptor DCC for which amyloid precursor protein (APP) functionally acts as a co-receptor to mediate axon guidance [1]. Further investigation is needed to see if these SNPs belong to the promoter or regulatory elements of DCC. We also discovered that SNP rs1983298, in the gene encoding the receptor-type tyrosine-protein phosphatase-like N (PTPRN), differentially affected the CSF ptau levels (p= 6.73E-07) in the MCI to AD converter group and MCI stable group. In situ *hybridization* (*ISH*) showed that PTPRN was specifically expressed in the neurons but that severely degenerated neurons with aggregated ptau are associated with low or no mRNA expression of PTPRN. These genetic markers might be potential prognostic biomarkers and biomarkers for patient segmentation.

Expression Profiling of Medial Temporal Gyrus in Alzheimer's Disease Patients Reveals an Enrichment in Neurotransmission Signaling Pathways

J. Krate[1], *I. S. Piras*[2], *E. R. Delvaux*[3], *J. D. Nolz*[3], *T. G. Beach*[4], *P. D. Coleman*[3], *A. M. Persico*[2], *M. J. Huentelman*[1];

[1]Neurogenomics Division, Translational Genomics Research Institute (TGen), Phoenix, AZ, United States, [2]Laboratory of Molecular Psychiatry and Neurogenetics, University Campus Bio-Medico, Rome, Italy, [3]L.J. Roberts Center for Alzheimer's Research Banner Sun Health Research Institute, Sun City, AZ, United States, [4]Civin Laboratory of Neuropathology at Banner Sun Health Research Institute, Sun City, AZ, United States.

We performed whole genome differential expression analysis on medial temporal gyrus (MTG) tissue from clinically characterized and neuropathologically verified Alzheimer's disease (AD) cases and controls (ND, n=100 in each group). Quantile normalization followed by moderated t-statistic for differential analysis on data from Illumina HumanHT-12 BeadChip was performed. After P-value (FDR<0.05) and Fold Change (>|0.8|) filtering, we identified 143 DEGs in the AD/ND comparison. The DEGs were enriched for two groups of genes (both underexpressed in AD) belonging to pathways labeled "Synaptic Vesicle Trafficking" (SVT) and "Muscarinic Acetylcholine Receptor Signaling" (MARS, Table 1). The AD/ND comparison when analyzed by gender showed 45 and 328 DEGs for males and females, respectively. SVT was significantly enriched in both gender groups while MARS was only significant in the female group suggesting a potential gender difference in the pathways affected by AD. The major finding in the AD/ND group comparison was the decreased expression of several SNARE complex components involved in synaptic vesicle docking at the presynaptic membrane.
Our data replicates prior findings in AD that include a decreased expression of SVT genes in frontal cortex and a demonstrable SNARE complex protein expression loss in the hippocampus and entorhinal cortex. In conclusion, in the MTG of AD patients we demonstrate a decreased expression of SNARE complex members and highlight that MARS gene expression changes are only found in females.

P08.09

Comparison of amplicon sequencing on Ion Torrent PGM with Sanger- and whole exome-sequencing

H. Thonberg[1], *L. Lilius*[2], *C. Forsell*[2], *C. Graff*[1,2];

[1]Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institute-ADRC, Stockholm, Sweden.

Background: At the Department of Geriatric Medicine, patients with family-history of dementia that indicates autosomal dominant inheritance are referred to mutation screening to identify causative mutations. Generally, Alzheimer patients are screened by Sanger-sequencing for variations in APP, PSEN1 and PSEN2, and patients with frontotemporal dementia are screened for variations in MAPT, GRN, and C9orf72. A less discriminative and a more time-efficient strategy of mutational screening, is to employ massive parallel-sequencing on all possible dementia causing genes in a single analysis.
Aim: To compare the detection of genetic variations between different method/platforms of sequencing and to validate the usefulness of custom AmpliSeq panel for screening of dementia causing genes.
Material: DNA was collected from 10 patients at the Memory Clinic, Karolinska University Hospital, Stockholm Sweden, with an informed consent.
Method: Sanger sequencing was performed on ABI 3100-instrument and massive-parallel sequencing was done on an Ion Torrent PGM with a custom made AmpliSeq panel amplifying 196 different targets in 17 known dementia genes.
Results and Discussion: Sanger-sequencing of the patient DNA identified 134 genetic variations in subsets of the genes. Sequencing on PGM detected 775 variants in all of the genes. Further analysis will compare the correlation between Sanger- and PGM-sequencing to validate the use of massive-parallel sequencing in a clinical setting. The analysis will also compare variants detected by whole-exome sequencing and PGM. Data from the comparison will be presented and compared at the ESHG, 2013 conference.

P08.10

Positive association of C677T MTHFR polymorphism in Alzheimer Disease

F. Paula[1], *D. Camporez*[1], *L. Belcavello*[1], *R. L. Morelato*[2], *I. D. Louro*[1], *M. C. P. Batittuci*[1];

[1]Federal University of Espírito Santo, Vitória, Brazil, [2]Santa Casa de Misericórdia Hospital, Vitória, Brazil.

Alzheimer's disease (AD) is a progressive neurological disorder characterized by loss of memory and cognition. In the last years, many genes were identified as a risk factor for AD through Genome-Wide Association Studies. However, only few of them showed association in case controls studies. Although a meta analysis for C677T *MTHFR* polymorphism to suggest risk for AD, case control studies show discordants results in different populations. The confirmation of positive association of specific polymorphisms in different population can help us to identify the contribution of the particular genes in the etiology of the AD according to the ethnic background. The objective of this work was to analyze through case control study the contribution of C677T polymorphism as a risk factor for AD in population from Vitória (Southeast of Brazil). Eighty-two patients, selected by NINCDS-ADRDA clinical parameters and 182 controls matched by gender, age and ethnicity were genotyped through PCR-RFLP. Positive association was found in CT genotype (OR=1.852; 95% IC.: 1,084- 3,162; p=0.0243), but not in other genotypes or alleles. The very small number of T allele observed in studied population can explain the absence of positive results for TT genotype. This research suggests that carries of C677T *MTHFR* polymorphism has 1,8 more chance to develop AD than other in studied population. This work may improve our knowledge about alleles of risk in AD and could help in future providing a profile of genetic susceptibility for AD in specific populations. Supported by FAPES, FACITEC, and MCTI/CNPQ/MEC/Capes.

P08.11

UBQLN-2 and *PFN1* mutation screening in French FTLD and FTLD-ALS patients

S. Lattante[1], *I. Le Ber*[1,2], *A. Camuzat*[1], *J. Pariente*[3], *T. French research network on FTD and FTD-ALS*[1], *A. Brice*[1,4], *E. Kabashi*[1];

[1]Centre de Recherche de l'Institut du Cerveau et de la Moelle Epinière, Paris, France, [2]Hôpital Pitié-Salpêtrière, Centre de référence Démences Rares, Paris, France, [3]Service de Neurologie; Pôle Neurosciences; CHU Purpan, Toulouse, France, [4]Hôpital Pitié-Salpêtrière, Département de Génétique et Cytogénétique, Paris, France.

Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal Lobar Degeneration (FTLD) are two adult onset neurological disorders with overlapping symptoms and clinical characteristics. It is well established that they share a common pathological and genetic background. The most common mutated gene in both conditions is *C9ORF72* but there are a number of other genes responsible in different percentages of a limited number of sporadic and familial cases. Ubiquilin-2 (*UBQLN*-2) is at the moment the only ALS-related gene mapping on the X-chromosome, with mutations in the PXX domain first described in ALS patients with a mutational frequency of 2.6% in familial ALS cases with no evidence of male-to-male transmission. Recently, mutations in profilin 1 gene (*PFN1*) have been identified in patients with familial ALS, suggesting a role for this gene in the pathogenesis of the disease. To determine the genetic contribution of *UBQLN-2* and *PFN1* in FTLD and FTLD-ALS, we screened a cohort of 136 French patients. We did not find any variant in *PFN1* gene, while we identified a novel missense variant (c.1006A>G, p.T336A) in *UBQLN-2* gene in one FTLD patient (0.7%). The variant is not present in dbSNP137, 1000 Genomes database and Exome Variant Server. Its pathogenicity is suggested by the high conservation of Thr336 residue through the evolution but its role is still unclear. We conclude that *UBQLN-2* and *PFN1* mutations are extremely rare in a French cohort of FTLD and FTLD-ALS patients and should not be analyzed systematically.

P08.12

Mutations in the 3′ Untranslated Region of *FUS* causing FUS overexpression in primary fibroblast coltures are associated with Amyotrophic Lateral Sclerosis.

M. Sabatelli, *A. Moncada, A. Conte, S. Lattante, G. Marangi, M. Lucchini, M. Luigetti, M. Mrabella, M. Zollino;*
Catholic University of Rome, Rome, Italy.

Amyotrophic Lateral Sclerosis (ALS) is a severe neurodegenerative disorder involving upper and lower motor neurons. Mutations in the genes encoding FUS have been identified in a subset of sporadic and familial ALS patients.
We studied whether mutations in the 3' Untranslated region (3'UTR) of *FUS* are associated with ALS. Sequencing the whole 3' UTR region of *FUS* in 555 ALS patients revealed 4 variants (c.*48 G>A, c.*59 G>A, c.*108 C>T and c.*110 G>T) in 4 sporadic ALS patients. Identified mutations were not detected in 400 ethnically matched controls. Primary fibroblast coltures were studied in patients harbouring the c.*59 G>A, c.*108 C>T and c.*110 G>T variants, and results were compared with those of four controls, of one patient with the *FUS* R521C variant , and of two sporadic ALS patients without mutations in ALS genes. By immunostaining, patients with mutation in 3'UTR of *FUS* showed huge FUS deposits in the cytoplasm. The patient with the R521C mutation showed a slight increase of cytoplasmic FUS associated with a loss of detection in nuclei. Compartmental fractionation of fibroblasts and immunoblotting of these fractions disclosed a large amount of FUS in the cytosol of cells from patients with mutated 3'UTR and, in a lesser extent, from the R521C patient.
Our findings indicate that mutations in 3'UTR of *FUS* lead to translation deregulation and suggest that FUS deposits in the wild type configuration is the underlying cause of the disease in these cases.

Amyotrophic lateral sclerosis (ALS) is a devastating neurological disease characterized by motor neuron degeneration of motor cortex, brainstem and spinal cord. The majority of ALS cases are sporadic (sALS) and only 5-10% have a family history (fALS). Whereas 60-80% of fALS cases are explained by germinal mutations, the genetic etiology of sALS remains unclear. Nonetheless, it's important to keep in mind that current genetic evidences for sALS come from genetic examinations mainly made using blood DNA. Here, we hypothesize that somatic mutations appear early during the development of embryonic spinal cord and could later trigger the development of sALS. Given ALS is a motor neuron disease affecting the corticospinal tract, we are in the process of preparing 1000 sections using flash frozen spinal cords obtained from sALS patients. These sections will be individually screened for the presence of mutations in the most commonly observed ALS genes. At first, we will look for repeat expansion in C9ORF72 by repeat-primed pcr (RP-PCR), since repeat mutations have been shown to be unstable during replication and DNA repair. Following this, we will look for point mutations in SOD1, TARDBP and FUS using a targeted deep sequencing method specifically designed to identify rare somatic events. To date, we have examined 251 spinal cord sections derived from 10 sALS patients for the presence of expanded C9ORF72 alleles, but none was thus far detected. This nonetheless enabled us to establish RP-PCR conditions that are sensitive enough to detect expansions at a low level of mosaicism (20%).

Autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) is the second most frequent form of spastic ataxia and is caused by mutations in the SACS gene encoding sacsin. Previous subcellular localization study demonstrated that 30% of sacsin is localized to the mitochondria but its specific function is still unknown.
We have searched for mutations by direct sequencing and customized CGH array in SACS in a series of 310 patients affected by progressive spastic ataxia with age at onset < 45 years. We identified 21 mutations (5 missenses and 16 truncating) that correspond to 6% of mutated patients definitely diagnosed with ARSACS. A search for phenotype-genotype correlations is in progress.
We obtained primary cultures of patients' fibroblasts in order to perform functional analyses of sacsin. One patient carries two heterozygous nonsense mutations (p.L1180LfsX8 and p.K3747X) and the other is homozygous for a missense mutation (p.R272H). The mitochondrial network appeared quantitatively altered (with a decrease of 50% of the global mitochondrial mass) and we observed an abnormal mitochondrial shape with the presence of bubbles in both patients. We also began to study potential interactions of sacsin with partners, particularly with proteins involved in the control of mitochondrial dynamics such as DRP1 and MFN1/2.

De novo TITF1 gene mutation causing Benign Hereditary Chorea with Hypothyroidism and Pituitary Mass

L. Veneziano[1], *M. Frontali*[1], *E. Mantuano*[1], *M. Parkinson*[2], *K. P. Bhatia*[2], *P. Giunti*[2];
[1]*Institute of Translational Pharmacology. National Research Council of Italy, Rome, Italy,* [2]*Institute of Neurology. National hospital for Neurology and Neurosurgery. UCL, London, United Kingdom.*

Benign hereditary chorea (BHC) is an autosomal dominant disorder of early onset characterised by non progressive choreic movements with normal cognitive function occasionally associated with hypothyroidism and respiratory problems. This condition is caused by mutations in TITF-1 gene (also known as NKX2.1), encoding the Thyroid Transcription Factor-1
The proband of the described family, affected with BHC, presented in infancy with delayed walking and ataxic features, then chorea and developed hypothyroidism at the age of 33. She never experienced any respiratory symptoms, and on imaging she was found to have a large cystic pituitary mass.
Genetic testing showed that the proband carries a novel TITF-1 nonsense mutation. This mutation was transmitted to her affected child, which presented in infancy with delayed walking and mild non-progressive chorea.
The genetic analysis of the whole family confirmed that the mutation arose de-novo in the proband.
We discuss the effect of this new mutation and the phenotype heterogeneity of the disease

Association of leukocyte telomere length and MRI correlates of brain aging: Results of the Austrian Stroke Prevention Study

A. Sen[1], *P. Freudenberger*[1], *M. Schallert*[2], *C. Nagl*[1], *S. Seiler*[2], *K. Petrovic*[2], *R. Schmidt*[2], *H. Schmidt*[1,2];
[1]*Research Unit for Genetic Epidemiology,Institute of Molecular Biology and Biochemistry, Medical University Graz, Graz, Austria,* [2]*Department of Neurology, Medical University Graz, Graz, Austria.*

Background: Telomeres shortening is a consequence of cell division and is biological factor related to cellular aging. Shorter leukocyte telomere length (LTL) is linked to age-related diseases. The objective of the present study was to explore the relation between LTL and magnetic resonance imaging

(MRI) detected structural and morphological changes in the normal elderly individuals.
Hypothesis: We hypothesize that shorter LTL is related to loss of MRI detected total brain volume and increase in white matter lesions (WML).
Methods: Relative LTL was measured by quantitative RT PCR in 909 participants (mean age=66years, 57%female) of the Austrian Stroke Prevention Study, a community-based cohort study. All subjects underwent brain MRI with automated assessment of brain parenchymal fraction (BPF,%) by use of SIENAX and semi-automated measurement of WML volume (cm^3). The effect of LTL on MRI correlates was tested using multiple linear regressions by adjusting for age and sex (Model1) and by additionally adjusting for vascular risk factors such as hypertension, diabetes, cardiovascular disease, smoking, apoϵ4 carrier status, BMI (Model2).
Results: We observed significant association between LTL and BPF (Model1:β=0.01,*p*<.001) when adjusted for age and sex. The association remained significant when additionally adjusted for vascular risk factors (Model2:β=0.01,*p*<.001). A trend for association was observed between LTL and WML (Model1:β=0.11,*p*=0.10;Model2:β=.14,*p*=0.05).
Conclusion: Our results suggest that LTL attrition independently of vascular risk factors may be involved in the development of brain atrophy or risk of dementia. Further longitudinal studies are needed to investigate if LTL may represent a biomarker for brain aging.

Pediatric intracranial calcification may be caused by inherited or acquired factors. An autosomal recessive form also referred to as pseudo-TORCH syndrome is characterized by calcium accumulation in the brain, congenital microcephaly and severe developmental impairment. Mutations in the gene encoding the tight junction protein occludin (OCLN) at exon 3 or at the 5-6 intron splice site result in brain calcification and polymicrogyria with no evidence of extra-cranial phenotypes. We ascertained a consanguineous family with two cases of brain calcification coupled with significant renal dysfunction, and identified a previously unknown rearrangement of the OCLN gene. A combination of molecular techniques was used to characterize the underlying genetic cause for the disease. SNP genotyping defined a genomic region shared between affected individuals, while whole exome data revealed a deletion at exon 9 of the OCLN gene. MLPA, PCR and Sanger sequencing confirmed this deletion and further identified a rearrangement of the genetic region. Detection of the rearrangement was complicated by the presence of a replication within the genome of a section that extends from exon 5 to beyond the OCLN gene. Of the seven OCLN splice variants described by UniprotKB, all make use of exon 9 while the OCLN variants that use exons 3, 5, and 6 are tissue specific. The mutation in exon 9, as was observed in our patients, would lead to the loss of OCLN in all tissues and likely explains the observed phenotypes in our cohort that extends beyond the brain.

P08.18
Neuroimaging algorithm of Neurodegeneration with Brain Iron Accumulation (NBIA) directs molecular genetic analyses and prompts gene identification

N. Boddaert[1,2], *I. Desguerre*[1,3], *A. Rotig*[1,4], *M. Rio*[1,4], *F. Brunelle*[1,2], *A. Munnich*[1,4];
[1]*Hopital Necker, paris, France,* [2]*Department of Peadiatric Radiology, Hôpital Necker-Enfants Malades and University Paris Descartes, Sorbonne Paris Cité, Imagine Institute, Paris, France,* [3]*Department of Peadiatric Neurology, Hôpital Necker-Enfants Malades and University Paris Descartes, Sorbonne Paris Cité, Paris, France,* [4]*Department of Genetics, Hôpital Necker-Enfants Malades and University Paris Descartes, Sorbonne Paris Cité, Imagine Institute, Paris, France.*

Neurodegeneration with Brain Iron Accumulation (NBIA) is an emerging class of hereditary neurodegenerative diseases resulting in extrapyramidal movement disorders, intellectual deterioration and characteristic deposition of iron in the basal ganglia. The best MRI sequence to visualize iron accumulation is T2*.
While a number of NBIA causes have recently been reported, we propose a diagnostic-algorithm based on neuroimaging features to direct molecular genetic analyses. This algorithm relies on 5 very simple MRI criteria namely:
1/"Eye of the tiger" in the globi pallidi on T2
2/ Hypointensity of globi pallidi, either isolated or associated with caudate/putamen hypointensity onT2
3/ Hyperintensity of substantia nigra on T1
4/ White matter anomalies on T2
5/ Cerebellar and/or brainstem atrophy
Combining these 5 criteria in a paediatric series of 23 NBIA cases referred to our paediatric-genetic department, led to molecular diagnosis in 16/23 patients. The diagnoses comprised: Pantothenate kinase (PKAN) deficiency: 3 cases); Mitochondrial membrane protein (MPAN) deficiency: 1 case; Neuroaxonal Dystrophy (NAD): 9 cases; Fatty-Acid-Hydroxylase-associated Neurodegeneration (FAHN): 2 cases; Beta-propeller-protein associated-neurodegeneration (BPAN): 1 case.
The remaining 7 cases are still undiagnosed. Among them, 4/7 fulfilled clinical and brain MRI criteria of slowly progressive NAD. We have launched a systematic trio-exome screening of undiagnosed cases and eventually identified a novel disease gene delineating a novel physiopathological mechanism of NBIA.
In conclusion, we suggest giving consideration to brain MRI to direct molecular genetic testing in NBIA. This approach is a prerequisite for future studies aimed at identifying novel diseases genes in this increasingly recognized group of disorders.

P08.19
MiRNA expression profiling in cortical neurons under conditions of transient focal ischemia

V. A. Gusar[1], *A. V. Timofeeva*[1], *I. S. Zhanin*[1], *A. Y. Asanov*[2], *S. I. Shram*[3], *N. Myasoedov*[3], ***V. G. Pinelis***[1];
[1]*Scientific center for children's health, RAMS, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State medical University, Moscow, Russian Federation,* [3]*Institute of molecular genetics, RAS, Moscow, Russian Federation.*

Background. One of the important problems of modern medicine is to protect neurons against ischemia, traumatic brain injury and some neurodegenerative diseases. To understand the nature of these pathological processes at the molecular level it is reasonable to analyze the expression of genes and their post-transcriptional regulators, microRNAs (miRs), involved in the pathogenesis of these diseases.
Materials & Methods. Unilateral focal ischemia was performed by photochemically induced thrombosis in adult male rats. Total RNA and miRs were extracted from ischemic penumbra of rat cortex sensorimotor area and from control ipsilateral cortical region after 24 hours reperfusion by miRNeasy Miro Kit and RNeasy MinElute Cleanup Kit (Qiagen), respectively.
MiRs expression profiling of ischemic and control samples were carried out by quantitative real time RT-PCR using Custom miScript Primer Assay and miScript SYBR Green PCR Kit (Qiagen).
Results. Selection of 45 specific miRs was carried out following two criteria: cortical-specific miRs expression and target-specific regulation of genes potentially involved in ischemia using database miRanda, PicTar, TargetScan and Pubmed. Ischemic and control samples from the same rat were analyzed simultaneously on the same Custom plate. Of these 45 miRs, 3 miRs (rno-miR-30a-5p, -30a-3p, -21-5p) were upregulated and 8 miRs (rno-miR- 186-5p, -29a-3p, -223-3p, -23a-3p, -29a-5p, -497-5p, -551b-3p and rno-let-
7f-5p) were down regulated significantly.
Conclusions. We have obtained preliminary data on miRNAs expression profiling during transient focal ischemia. Further studies are needed to evaluate the possible use of miRNAs as biomarkers in stroke and related pathologies.

Candidate Cacna1a modifier genes in a C. elegans large scale functional RNAi screen

M. C. Pereira[1,2], *S. Morais*[1,2], *J. Sequeiros*[1,2,3], *I. Alonso*[1,2,3];
[1]*IBMC, Porto, Portugal,* [2]*ICBAS, Porto, Portugal,* [3]*CGPP, Porto, Portugal.*

Mutations in the *CACNA1A* gene that encodes the pore-forming α_1-subunit of human voltage-gated $Ca_v2.1$ (P/Q-type) Ca^{2+} channels cause several autosomal-dominant neurologic disorders, including familial hemiplegic migraine type 1 (FHM1), episodic ataxia type 2 (EA2), and spinocerebellar ataxia type 6 (SCA6).
In order to identify modifiers of uncoordination in movement disorders, we performed a large scale functional RNAi screen using the *C. elegans* strain CB55, which carries a truncating mutation in the *unc-2* gene, the worm ortholog for the human *CACNA1A*.
The screen was carried out by the feeding method in 96-well liquid culture format using the ORFeome v1.1 feeding library as previously described. We used time-lapse imaging of worms in liquid culture to assess changes in thrashing behaviour. Raw imaging data was analysed with open source Image J, and the thrashing analysis results were loaded on CellHTS2 for further exploration.
We looked for genes that when silenced either ameliorated the slow and uncoordinated phenotype of unc-2 or interacted to produce a more severe phenotype. Raw data was collected for the full library and 95% of the primary screen has been analysed by CellHTS2. During the primary screen we found 142 candidate genes improving CB55 motor function, and 148 candidate genes increasing *unc-2* impairment, through interaction with *Cacna1a*. Gene ontology revealed an overrepresentation of genes involved in development, growth, locomotion, signal transduction and vesicle mediated transport.
We are now following with more detail the genes that already scored in the first screen by expanding the panel of behavioural and neurodegeneration assays.

NOTCH3 unclassified variants leading to CADASIL. Importance of skin biopsy to establish causality and CADASIL diagnosis.

C. Debout[1], *M. Amador*[2], ***C. Prieto Morin***[2], *M. Mine*[2], *M. Coquemont*[3], *F. Chapon*[4], *E. Tournier-Lasserve*[2];
[1]*Université de Caen Basse-Normandie, Laboratoire d'Histologie, Caen, 14032, France, CAEN, France,* [2]*AP-HP, Service de Génétique Neurovasculaire, Hôpital Lariboisière, PARIS, France,* [3]*Université de Caen Basse-Normandie, Laboratoire d'Histologie, CAEN, France,* [4]*Université de Caen Basse-Normandie, Laboratoire d'Histologie- INSERM, U 1075 COMETE, CAEN, France.*

CADASIL (Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy), the most common familial vascular dementia, is characterized by stereotyped *NOTCH3* mutations leading to an odd number of cysteine residues in the EGF like motifs of this receptor and the presence of typical GOM (Granular Osmiophilic Material) in the basal membrane of vascular smooth muscle cells as shown by electronic microscopy (EM) study of skin biopsy.
Some patients referred for molecular diagnostic of CADASIL harbor missense variants which do not affect the number of cysteine residues and are absent from databases, raising the question of their causality. Our current hypothesis is that some of these "missense" variants might behave as splice variants leading to an odd of number of cysteine residues and therefore be true CADASIL mutations.
18 Patients showing NOTCH3 missense variants absent from EVS, 1000genomes and dbSNP137 were included. All 23 exons known to be mutated in CADASIL were sequenced and EM analysis of skin biopsy was performed in all patients.
Only one patient (P18) showed typical GOM. This patient has a G73R mutation (c. 295G>C, exon 3). cDNA analysis is on going to analyze the putative splicing effect of this mutated allele, using mRNA extracted from skin biopsy and cultured fibroblasts.
In summary, some patients with missense variants which do not affect the number of cysteine residues are true CADASIL patients showing typical GOM on EM skin biopsy. This study emphasizes the need to conduct a skin biopsy for *NOTCH3* unclassified variants.

P08.23

West syndrome, general psychomotor retardation and dysmorphic features in a female patient due to a 2.92 Mb microdeletion leading to a haploinsufficiency of the CDKL5 gene and several additional flanking genes.

P. M. Kroisel[1], *U. Pichler*[2], *D. Kuchernig*[2], *M. Mach*[1], *C. Pischler*[1], *T. Schwarzbraun*[1], *K. B. Wagner*[1], *M. R. Speicher*[1];
[1]*Institute of Human Genetics, Medical University of Graz, Graz, Austria,* [2]*Department of Pediatrics and Adolescent Medicine, General Hospital of Klagenfurt, Klagenfurt, Austria.*

By array CGH-analysis we identified a X-chromosomal microdeletion that occurred de novo in a now 14.5 month old girl, the second child of a Austrian couple, according our result: arr Xp22.2p22.13(15,767,378-18,684,139) x1. This microdeletion causing the loss of less than 20 genes was confirmed by Q-PCR. The first born child of this couple, a boy, is healthy. The female patient was able to sit with 8 month however still cannot walk or speak. With 7 month she showed first myoclonic seizures. Up to that age her general development was within the normal range. Since seizures became more frequent and severe, with12 month antiepileptic drugs like Keppra were applied. Several female and at least one male patient with similar but apparently not identical chromosomal breakpoints were thus far reported or communicated in databases like DECIPHER or ISCA. The apparent lack of obvious recurrent chromosomal breakpoints could suggest that for these microdeletions no common molecular mechanism might be involved. But there is a considerable overlap of the described microdeletions and because loss of the CDKL5 gene is causing a severe form of a variant of Rett syndrome, this disorder is certainly a main clinical feature of a potential contiguous gene syndrome from that genomic region. Since differences in X-inactivation may modify onset and severity of this and linked disorders, like PDHC, as reported recently, it is clearly important to determine precisely the deletion size with number of affected genes and X-inactivation (79% in our patient) to allow a better comparison and prognostic considerations.

Genome-wide analysis of genotype-dependent CTCF DNA binding

W. M. C. van Roon-Mom, *B. A. Pepers, A. Mastrokolias, J. T. den Dunnen, P. A. C. ,t Hoen; LUMC, Leiden, Netherlands.*

The aim of the current study was to assess the effect of genetic variation in the DNA binding protein recognition sequence of CCCTC-binding factor (CTCF) and its potential involvement in Huntington's disease. CTCF is an ubiquitously expressed, highly conserved protein containing an 11 zinc finger DNA binding domain. It is essential for viability and considered to play an important role in local and long-range inter- and intra-chromosomal interactions and transcriptional regulation. CTCF is also known to act as insulator (as chromatin barrier or enhancer blocker), regulate nuclear localization, or participate in imprinting control. The DNA binding site of CTCF has a well-characterized and highly conserved binding motif. 95% of the CTCF binding sites identified by ChIPseq experiments contain the consensus motif. Single nucleotide variants within DNA binding sites are known to have a major impact on protein binding and consequently its function. Genome wide statistical analysis was performed in ChIPseq data from two fibroblast cell lines from control subjects and two from subjects with Huntington's disease. We detected 21 sites that differed significantly in CTCF binding. Twelve of these sites contained a single nucleotide polymorphism (SNP) in the binding site thereby explaining differential CTCF binding. We confirmed this SNP specific binding with an Electro Mobility Shift Assay. Examination of the SNPs in 14 more brain samples (7 for each group) showed no segregation with the neurological condition.

Genetic testing in hereditary neuropathies: our 10 years experience

A. Gal[1], *B. Bereznai*[1], *E. T. Varga*[1], *P. Balicza*[1], *G. M. Milley*[1], *Z. Aranyi*[2], *J. Boczan*[3], *P. Dioszeghy*[4], *L. Kalaydiyeva*[5], *M. J. Molnar*[1];
[1]*Semmelweis University, Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary,* [2]*Semmelweis University, Department of Neurology, Budapest, Hungary,* [3]*Department of Neurology, Medical and Health Science Center of the University of Debrecen, Debrecen, Hungary,* [4]*Department of Neurology, Andras Josa Hospital, Nyiregyhaza, Hungary,* [5]*Centre for Human Genetics, Edith Cowan University, Perth, Australia.*

Objectives: Charcot-Marie-Tooth neuropathies (CMT) are a clinically and ge-

netically heterogeneous group of rare inherited neuropathies. Their prevalence is 1:2,500. Until now more than 50 CMT genes have been identified.
Aims: In this study we analysed the mutation frequencies of the most common genes (PMP22 duplication, deletion, MPZ, MFN2, Connexin 32 and EGR2 mutations) in an electrophysiologically well-characterized group of patients. In patients with gypsy origin two founder mutations (NDRG1-R148X; CCFDN-IVS6+389C>T) were also tested.
Patients and methods:
450 Caucasian (256 male and 194 female) and 15 Roma (4 male and 11 female) clinically and electrophysiologically characterized patients with neuropathy have been investigated (196 were familial cases from 85 families). The mutation analysis was performed by MLPA, real-time PCR, PCR-RFLP and bidirectional sequencing.
Results: The quantitative analysis of the PMP22 gene found 84 duplications and 65 deletions. Pathogenic mutations in the MPZ gene were detected in 11, in the EGR2 gene in 2, in the MFN2 gene in 5 and in the Connexin32 gene in 17 cases. In the Roma patients LOM type of neuropathy was present in 8, CCFDN mutation in 4 cases. In 1 family the PMP22 deletion and a pathogenic EGR2 mutation coexisted.
Conclusion: Pathogenic mutation has been identified in 41,5% of the investigated patients. In our presentation we would like to emphasize that mutation analysis of clinically and electrophysiologically well-characterized neuropathic patients reveals the genetic etiology in a relatively large percent of cases.

Second case of COFS Syndrome type 2 confirmed by compound heterozygous mutations in ERCC2

S. Krüger[1], *A. Bier*[1], *J. Plaschke*[1], *S. Reif*[1], *M. Jatzwauk*[1], *F. R. Kreuz*[1], *A. Storcks*[2], *S. Spranger*[3];
[1]*Gemeinschaftspraxis für Humangenetik, Dresden, Germany,* [2]*St. Marien-Hospital, Klinik für Kinder-und Jugendmedizin, Vechta, Germany,* [3]*Praxis für Humangenetik, Bremen, Germany.*

Cerebrooculofacioskeletal syndrome (COFS, Peña-Shokeir syndrome type II) is a very rare progressive neurodegenerative disorder characterised by microcephaly, severe intellectual disability, congenital cataracts, facial dysmorphism, and arthrogryposis. By far, the most common subtype is COFS type 1 (COFS1), which is caused by biallelic mutations in *ERCC6*, the major gene underlying Cockayne syndrome (CSB). Most COFS1 patients originate from the Manitoba aboriginal population, in which the condition was originally described. Furthermore, a founder mutation has been identified to cause COFS1 in six individuals from a large consanguineous pedigree from northern Finland.
In contrast, until now only one patient has been described with COFS type 2 (COFS2), which is caused by biallelic mutations in *ERCC2*, the gene underlying Xeroderma pigmentosum, group D (XPD), and trichothiodystrophy (TTD). This patient was the child of nonconsanguineous Ashkenazi Jewish parents. He showed typical COFS symptoms and died at the age of 3.5 years.
Here we report on the second COFS2 case carrying compound heterozygous mutations in *ERCC2*. This 6 month old male infant was born to nonconsanguineous Kosovo Albanian parents who previously had two healthy children and one induced abortion due to prenatal diagnosed arthrogryposis. The patient presented with intrauterine growth retardation, microcephaly, developmental delay, congenital cataracts, facial dysmorphism, and congenital arthrogryposis. While complete analysis of *ERCC6* did not reveal any mutation, two heterozygous mutations in *ERCC2* could be identified: c.1703_1704delTT, p.Phe568Tyrfs*2 in exon 18 and c.1843G>A, p.Gly615Arg in exon 20. Analysis of parents indicated the compound heterozygous state of the patient.

Presymptomatic testing in hereditary Creutzfeldt-Jakob disease

E. Schaerer[1], *M. Babonneau*[1,2], *A. Herson*[1], *C. Boucher*[1], *J. Laplanche*[3], *J. Brandel*[2], *J. Feingold*[1], *M. Gargiulo*[1,4], *A. Durr*[1,5,6];
[1]*APHP, Département de Génétique et Cytogénétique, Groupe Hospitalier Pitié-Salpêtrière, Paris, France,* [2]*APHP, Cellule Nationale de référence des maladies de Creutzfeldt-Jakob, Groupe Hospitalier Pitié-Salpêtrière, Paris, France,* [3]*APHP, UF de Génétique Moléculaire Biochimie-Hémostase, Laboratoire associé au CNR ATNC, Pôle B2P, GH Saint-Louis-Lariboisière-Fernand-Widal, Paris, France,* [4]*Laboratoire de Psychologie Clinique et Psychopathologie (EA 4056), Université Paris Descartes, Sorbonne Paris cité, Institut de Psychologie, Paris, France,* [5]*INSERM, UMR_S975 - Institut du cerveau et la moelle épinière, Paris, France,* [6]*UPMC University Paris 06, UMR_S975, Paris, France.*

This study aims to describe motivations and attitudes of persons at risk for hereditary Creutzfeldt-Jakob Disease (CJD) and to compare with those at risk for Huntington's Disease (HD). Two features distinguished being at risk for CJD from HD: incomplete penetrance and the reduced time to risk discovery. In most instances, it was during the illness/death of the index case that descendants discover there at risk status whereas in HD, risk awareness might be years. Since 1992, there were 1930 requests for presymptomatic testing for late-onset neurological diseases. Most were at risk for HD (HTT, n= 1624; 85%), and CJD (PRNP, n= 20; 1%). There were 15 women and 5 men, mean age at request was 40.2 ± 9.5 years (versus 35.1 ±12.1 in HD n=1612, p=.054). The reasons to take the test was to inform descendants of their risk (n=8), " to know" (n=8) and parental choice (n=3). Only 6/20 did choose not to take the test (comparable to 33% in HD p=.78) and 13 obtained a test result (6 carriers). Parents at risk for CJD reported difficulties to inform their descendants after an unfavourable result and, as in HD, it was difficult to distinguish between being a carrier and being affected after an unfavourable test result. In conclusion, despite incomplete penetrance and the reduced time to risk discovery in CJD the outcome of presymptomatic testing for CJD is similar to HD.

Investigation of SORL1 variants in a Turkish cohort of dementia patients

G. Guven[1], *R. Guerreiro*[2,3], *E. Lohmann*[4], *J. Brás*[2], *J. R. Gibbs*[2,3], *A. Singleton*[3], *M. Emre*[4], *H. Hanagasi*[4], *H. Gurvit*[4], *B. Bilgic*[4], *J. Hardy*[2], *N. Erginel-Unaltuna*[1];
[1]*Istanbul University Institute of Experimental Medicine, Istanbul, Turkey,* [2]*Department of Molecular Neuroscience, Institute of Neurology, UCL, Queen Square, London, United Kingdom,* [3]*Laboratory of Neurogenetics, National Institute on Aging, National Institutes of Health, Bethesda, MD, United States,* [4]*Department of Neurology, Istanbul University, Istanbul Medical Faculty, Istanbul, Turkey.*

Background: SORL1 (Sortilin related receptor 1) is involved in intracellular trafficking and localization of Amyloid precursor protein (APP). It binds APP and regulates its sorting into endocytic or recycling pathways. Several studies showed that genetic variations in this gene increased the risk of Alzheimer's disease (AD) and down regulation of SORL1 was associated with increased amyloid beta production in cells.
Materials and Methods: We used allelic discrimination to investigate the association of rs2282649 C/T polymorphism in 116 LOAD patients and 120 controls. We also performed exome and Sanger sequencing to analyze SORL1 rare genetic variants in a cohort of 62 Alzheimer disease, 13 dementia and 16 FTD cases.
Results: Exome sequencing identified 7 non-synonymous variants in 10 patients. Five of these variants are known (N371T, R330W, E270K, A172V, T1788I) and other two are new variants. No significant differences in the genotypic distribution for SORL1 rs2282649 polymorphism in case-control, female-male, APOEe4 carrier-non carrier groups were found. As expected, the frequency of APOEe4 allele was significantly higher in the patients group (patients %39.8, controls % 19.2 p: 0.001).
Conclusions: Our results suggest that rare variants in SORL1 may be associated with Alzheimer disease while the common intronic rs2282649 C/T polymorphism is not associated with the risk of developing Alzheimer's disease in our study group. However, this study was performed in a small cohort and replication in a larger number of samples is needed.

Myoclonus-dystonia (DYT11) - first experience in genetic testing in Serbia

M. Z. Jankovic[1,2], *V. S. Dobricic*[2], *G. Vlahovic*[3], *V. Ralic*[1], *N. Kresojevic*[2], *A. Tomic*[2], *M. Svetel*[1,2], *I. Novakovic*[1,2], *V. Kostic*[1,2];
[1]*Faculty of medicine, University of Belgrade, Belgrade, Serbia,* [2]*Neurology Clinic, Clinical center of Serbia, Belgrade, Serbia,* [3]*Mother and Child Health Care Institute, Belgrade, Serbia.*

Myoclonus-dystonia (DYT11) is an autosomal dominant disorder charac-

terized by dystonia and myoclonic jerks; the onset is most commonly during childhood and adolescence. DYT11 is caused by mutations in the gene coding for epsilon sarcoglycan (SGCE). More than 80 distinct mutations of SGCE have been described to date; most of them are localized in exons 3 to7, and in exon 9. Mutations detected in patients include nonsense, missense, splice site, insertions, partial and complete exon deletions. We have established molecular genetic testing of all coding exons, promoter and 3'UTR region of SGCE gene. The analysis comprised DNA samples of 45 Serbian patients with clinical diagnosis of myoclonus-dystonia. Detection of substitutions and small in/del mutations was performed by direct sequencing, on ABI 310 Genetic Analyzer. Also, large duplication/deletion analysis was performed using MLPA method. Three different mutations were detected in total number of 4 samples (4/45, 8.9 %). One patient harbored (nonsense) mutation in exon 6 (c.709C>; p.Arg237Ter). Small deletion in exon 7 (c.966delT; p.Val323Cysfs*11) was found in one patient. In two patients another small deletion was detected (c.835_839delACAAA; p.Thr279Alafs*16) in exon 7. The latter two patients are non consanguineous, but originate from the same geographical region. No large duplications/deletions were detected using MLPA method. These results indicate that introduction of mutation detection in SGCE gene should be considered as routine diagnostic tool in clinical practice.

SLC2A1 gene mutation in Serbian exercise-induced paroxysmal dyskinesia (DYT18) patient: Nonsense-mediated decay as possible pathogenesis mechanism

V. S. Dobricic[1], *M. Z. Jankovic*[2], *N. Kresojevic*[1], *M. Zarkovic*[2], *A. Tomic*[1], *M. Svetel*[1,2], *I. V. Novakovic*[1,2], *V. S. Kostic*[2,1];
[1]*Neurology Clinic, Belgrade, Serbia,* [2]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia.*

Exercise induced paroxysmal dyskinesia (DYT18) is an autosomal dominant disorder caused by mutations in the *SLC2A1* gene coding for a glucose transporter type 1 (GLUT1), the main glucose transporter across the blood-brain barrier. DYT18 is just a part of phenotypic spectrum associated with GLUT1 deficiency. This condition is characterized by sudden attacks of movement disorders of various types triggered by prolonged exercise. More than 150 distinct mutations in *SLC2A1* have been described so far. In this study, we performed genomic sequencing of the entire *SLC2A1* coding region in 10 patients with clinical signs of DYT18. Novel mutation (c.516delG) was revealed in one proband. Detected mutation occured *de novo* and disrupts consensus sequence of intron 4 donor splice site. Using the splice sites analysis tool it was predicted that alternative donor splice site exists at position c.389_390 in exon 4; this splice site would create mRNA encoding truncated protein 192ak long. The cDNA sequencing of region encompassing exon 3-5 in proband showed a strong wild-type signal and a much weaker signal that corresponds to truncated allele. Real time PCR quantification by SYBR Green chemistry (ΔΔCT method) revealed that proband has 60% SLC2A1 mRNA expression compared with his unaffected father. The result indicates that described mutation exerts a major effect at the mRNA level, most likely via nonsense-mediated mRNA decay. According to our knowledge, this is the first time that nonsense mediated decay is described as pathogenesis mechanism in exercise induced paroxysmal dyskinesia.

Juvenile myoclonic epilepsy (JME) comprises 5-10% of all epilepsies. To date, several genes have been associated with JME and other idiopathic generalized epilepsies (IGEs), although only a few presented mutations segregating with affected members in family studies. The most relevant genes are *EFHC1* and the GABA receptor α1-subunit gene (*GABRA1*). The aim of this study was to search for mutations in both genes in patients with JME and other IGEs. We performed mutation screening in 102 patients with JME and 33 with other IGEs. Missense mutations were investigated in 100 control individuals. Eight algorithms were used to estimate the impact of mutations. We identified three novel missense mutations in *EFHC1* (c.896A>G, c.887G>A, c.1766G>A) and seven previously described (c.475C> T, c.475C>G, c.545G> A, 685T> C, c.1343T> C, c.1821A> G and c.1855A> C). Only one patient with alterations did not have JME. Deleterious prediction was controversial, with most substitutions considered pathological by at least two algorithms. However, only four mutations, corresponding to the second DM10 domain and the EF-Hand motif, were not identified in control individuals. In *GABRA1*, three silent SNPs were identified. In conclusion, the absence of consensus in the algorithm predictions for *EFHC1* mutations highlights the genetic complexity of JME. In addition, most mutations were also identified in controls, suggesting that *EFHC1* is not acting as a single major gene causing JME, although it could be a predisposition factor of known significance. Therefore, our results suggest that genetic testing for *EFHC1* and *GABRA1* does not seem to be clinically relevant.

Mutation analysis of SLC2A1 gene in Bulgarian patients with IGE featured with absence seizures

N. I. Ivanova[1], *D. Kancheva*[1], *D. Todorova*[2], *G. Sarailieva*[2], *I. Alexandrova*[2], *G. Maximov*[2], *P. Dimova*[2], *V. Tomov*[2], *D. Hristova*[3], *V. Bozhinova*[2], *V. Mitev*[1,4], *R. Kaneva*[1,4], *A. Jordanova*[1,5,6];
[1]*Molecular Medicine Center, Sofia Medical University, Sofia, Bulgaria,* [2]*Clinic of Child Neurology, St. Naum University Hospital of Neurology and Psychiatry, Sofia, Bulgaria,* [3]*Children Neurology Unit, Pediatrics Clinic, Tokuda Hospital-Sofia, Sofia, Bulgaria,* [4]*Department of Medical Chemistry and Biochemistry, Sofia Medical University, Sofia, Bulgaria,* [5]*Neurogenetics Group, VIB Department of Molecular Genetics, University of Antwerp, Antwerpen, Belgium,* [6]*Laboratory of Neurogenetics, Institute Born-Bunge, University of Antwerp, Antwerpen, Bulgaria.*

Mutations in the *SLC2A1* gene are the major cause for idiopathic generalized epilepsy (IGE) featured with absence seizures and an age at onset being dated from the early childhood to the early adult life. To define the mutation spectrum and related clinical characteristics in Bulgarian patients, we performed a mutation screening of the *SLC2A1* gene in 29 patients from 3 different ethnic groups (25 Bulgarians, 2 Roma gypsies and 2 Turks). All of them were displaying IGE featured by absence seizures.Sequencing data analysis of the *SLC2A1* gene revealed 3 different sequence variations - 2 of them located in the coding region (c.1078C>T, p. 360 Q>X and c.480C>A, p.160H>Q) and 1 sequence variation affecting the consensus splice-site (c.1075-14G>A).
Segregation analysis revealed that in one family the disease-causing mutation arises *de novo* and in the other two families the molecular defects came from a parent who had reported a single febrile seizure during the first year of life and latter in life.
In all three cases, the clinical picture was present with diverse forms of absence epilepsy - MAE with developmental problems, EOAE and CAE. In one family, the epileptic syndrome had begun with
febrile seizures and after that the absence and GTCS had been added to the clinical picture. This patient had been sent initially for *SCN1A* analysis.
In summary,our results broaden the mutation spectrum of the *SLC2A1* gene and enrich the clinical data of IGE with absence seizures.

Search of the genetic bases of a dog epilepsy: a model for the human epilepsies

P. Quignon[1,2], *A. Grall*[1,2], *A. Vaysse*[1,2], *C. Escriou*[3], *P. Margaritte-Jeannin*[4,5], *C. Hitte*[1,2], *C. André*[1,2];

The dog, by its numerous distinct breeds considered as genetic isolates, represents a powerful model to identify genes and alleles implicated in genetic diseases. In addition, dog diseases are spontaneous, breed specific and homologous to human diseases. In dogs, epilepsy is the most widespread neurological disorder, with 5% of affected dogs, spread over 100 breeds.

The high prevalence in some breeds (>20%) supposes a genetic origin. Each affected breed is affected by a specific form of epilepsy and genetic studies in these breeds are expected to identify the responsible genes, thus constituting good candidate genes for human epilepsies. About 10% of Greater Swiss Mountain dogs are affected by a generalized epilepsy with tonic-clonic seizures, and we hypothesize that it is an autosomal recessive disease. A linkage study on a 95 dogs pedigree performed by the genotyping of 340 microsatellite markers evenly spaced on the whole dog genome, allowed the identification of a 20 Mb locus on the dog chromosome 16. The orthologous human region of this locus correspond in part to a locus previously implicated in human GEFS+ epilepsies but the genes have not been identified to date. In order to reduce this locus in dogs, we genotyped 101 dogs on the canine HD array (170 000 SNPs, Illumina). Both genetic association and genetic linkage studies are ongoing. The identification of the genetic bases of epilepsies in dog can bring novel candidate genes for human epilepsies and will allow the development of new therapies for human and dog patients.

Genome-wide Copy number variations in Rolandic Epilepsy

A. Labalme[1], *G. Lesca*[1], *N. Bruneau*[2], *S. Dimassi*[1], *A. de Saint Martin*[3], *C. Boulay*[3], *M. Valenti*[3], *J. de Bellescize*[1], *J. Motte*[4], *N. Boutry-Kryza*[1], *A. Arzimanoglou*[1], *E. Hirsch*[3], *G. Rudolf*[3], *P. Szepetowski*[2], *D. Sanlaville*[1];

[1]Lyon University Hospital, Lyon, France, [2]INMED, Marseille, France, [3]Strasbourg University Hospital, Strasbourg, France, [4]American Memorial Hospital, Reims, France.

Benign Rolandic epilepsy (RE), or benign childhood epilepsy with centro-temporal spikes (BECTS), the most common type of epilepsy in children, is a neurodevelopmental disorder with common neurocognitive impairment in speech, language, attention and executive skills. It is considered the benign end of a spectrum, including the most severe continuous spike and waves during slow-wave sleep syndrome (CSWSS) and the Landau-Kleffner (LKS) syndrome that are rare epileptic encephalopathies. An impairment of brain development with complex interplay between genetic and non-genetic factors has been suspected for RE but its pathophysiology is still elusive. We have recently reported genomic variations in patients with LKS and CSWSS, suggesting potential candidate genes.
In the present study, the involvement of rare CNVs was questioned in 50 patients with RE using aCGH (4x180K, Agilent microarrays).
We found 19 CNVs in 50 patients. Sixteen are potentially pathogenic (not reported in the database of genomic variant) and are still under investigations. Whereas highly heterogeneous CNV were found in the RE cohort, the same 16p11.2 microduplication was found in two patients. This microduplication has been associated with different neurocognitive disorders and included the PRRT2 gene, recently reported in infantile seizures. We also detected a deletion disrupting a potential major gene responsible for LKS/CSWSS, hence providing a possible biological basis for this clinical continuum. Of note, the frequent involvement of various cell adhesion molecules as detected previously in LKS/CSWSS, was not found here, suggesting that the two ends of this spectrum may be, at least partially, influenced by different genetic factors.

Clinical application of high resolution array Comparative Genomic Hybridization (array-CGH) in epileptic disorders

K. Giannikou[1,2], *M. Tzetis*[1], *H. Fryssira*[1], *K. Kosma*[1], *V. Oikonomakis*[1,3], *A. Syrmou*[1], *A. Xaidara*[1], *S. Kitsiou-Tzeli*[1], *E. Kanavakis*[1,3];

[1]Department of Medical Genetics, Medical School, University of Athens, Athens, Greece, [2]Alexander S. Onassis Public Benefit Foundation, Athens, Greece, [3]Research Institute for the Study of Genetic and Malignant Disorders in Childhood, "Aghia Sophia, Children's Hospital, Athens, Greece.

Epileptic disorders, often co-existing with other neuropathological manifestations and/or multiple congenital anomalies/peculiar facies, compose a clinically and genetically heterogeneous entity, with a variety of unspecific and diffuse phenotypes, thus raising difficulties on genetic evaluation and diagnosis. The array Comparative Genomic Hybridization (array-CGH) technique has proved reliable and valid, allowing the detection of submicroscopic imbalances (CNVs) in the diagnostic settting. From a total of 436 unrelated patients investigated in our department, 82 presented epileptic disorders of unknown etiology accompanied by at least one additional manifestation of pathological phenotype, but with normal previous conventional karyotype and negative genetic tests (FRAX, RETT, FISH tests or metabolic screens). High resolution 4x180K and 1x244K Agilent arrays (>170.000 and >236.000 probes respectively, average resolution 8.9Kb) were used in this study. Submicroscopic genomic imbalances were detected in 55/82 patients featuring epilepsy among other phenotypic anomalies, ranging in size from 0.037 to 17Mb and involving well-known and new susceptibility chromosomal loci as; 1q44, 2q24.2-q31.1, 3p25.3, 4q34.1-q35.2, 6q21-q22.1, 7p23.2, 7q11.23, 8q24.3, 10q26.3, 12p13.31, 22q11.21, Xp22.31. Genes, implicated in syndromes which are associated with epilepsy, were identified in 36/55 cases (65.4%) as; APOD, OCLN, GABA, FLNA, LIMK1, STX1A, GTF2I, FAM36A, MBD5, C1orf199, HNRNPU, KIF26B, OGG1, IRAK2, SLC6A11, ATG7, CDKL5, NIPA1/NIPA2, IGH, CHRM5, GABRB3, SCN1A/SCN2A/SCN3A/SCN7A/SCN9A, SST, MBD5, GLRA3, RALBP1, JRK, BNIP3, KNDC1, COMT, RTN4R, GHRL, RAC1, ACTB, TUBA8, LGI3, LBX1, CLCN2, TPPP, MARCKS, HDAC2. Array-CGH offers a high yield for the identification of so far undefined or underdiagnosed epilepsy cases, elucidating plausible novel syndromes and enabling improved delineation of genotype-phenotype correlations.

Novel mutations in FA2H in three Arab families with a clinical spectrum of neurodegeneration and complex features of hereditary spastic paraplegia

M. S. Zaki[1], *L. A. Selim*[2], *L. Mansour*[2], *A. Fenstermaker*[3], *J. L. Silhavy*[3], *S. Gabriel*[4], *J. G. Gleeson*[3];

[1]Clinical Genetics Department, National Research Centre, Dokki,, Egypt, [2]Pediatric Neurology Department, Cairo University, Cairo, Egypt, [3]Neurogenetics Laboratory, Department of Neurosciences, Howard Hughes Medical Institute, University of California, San Diego, CA, United States, [4]Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, MA, United States.

Fatty acid 2-hydroxylase gene (*FA2H*) is involved in the alpha-hydroxylation of the N-acyl ceramide moiety of sphingolipids fatty acids, essential components of myelin (15337768). Mutations in the *FA2H* were first identified in nine patients with recessive childhood onset spasticity, dystonia, cognitive dysfunction, and periventricular white matter disease (19068277). Mutations were also identified in a novel form of neurodegeneration with brain iron accumulation (NBIA) (20853438) as well as in a recessive complicated form of hereditary spastic paraplegia (SPG35, MIM#612319) (20104589). Together these genotype-phenotype correlations have defined a condition known as the fatty acid hydroxylase-associated neurodegeneration (FAHN). To date, few individuals with mutations in the FA2H gene have been described. Herein we report seven patients from three unrelated consanguineous Arab families with novel homozygous *FA2H* gene mutations. They were presented with progressive spastic paraparesis beginning after the age of 4 years associated with mild intellectual disabilities. Cerebellar manifestations predominated in all families including ataxia, nystagmus, intention tremors and dysarthia while infrequent limb dystonic movements were obvious with disease progression. Spastic quadriparesis and bulbar manifestations were highly evident in the oldest affecteds. Magnetic resonance imaging revealed cerebellar atrophy, high signal of white matter especially around occipital horn and low signal of basal ganglia that was also more pronounced with progression of the disease. Interestingly, nerve conduction velocity revealed sensory neuropathy of axonal nature in all affecteds; a finding recently assigned with FAHN. We suggest that FAH2 mutations result in clinical spectrum of a combined presentation of the above mentioned three disorders.

Phosphatidylserine increases IKBKAP levels in a humanized knock-in IKBKAP mouse model

R. Bochner;

Department of Human Molecular Genetics and Biochemistry, Sackler Faculty of Medicine, Tel-Aviv University, Ramat Aviv, Israel.

Familial dysautonomia (FD) is a severe neurodegenerative genetic disorder restricted to the Ashkenazi Jewish population. The most common mutation in FD patients is a T-to-C transition at position 6 of intron 20 of the *IKBKAP* gene. This mutation causes aberrant skipping of exon 20 in a tissue-specific manner, leading to reduction of the IKAP protein in the nervous system. We established a homozygous humanized mouse strain carrying human exon

20 and its two flanking introns; the 3' intron has the transition observed in the *IKBKAP* gene of FD patients. Although our FD humanized mouse does not display FD symptoms, the unique, tissue-specific splicing pattern of the *IKBKAP* in these mice allowed us to evaluate the effect of therapies on gene expression and exon 20 splicing. The FD mice were supplemented with phosphatidylserine (PS), an FDA-approved food supplement that slows cognitive degeneration in human and that increases mRNA and protein levels of *IKBKAP* in cell lines generated from FD patients. Here we demonstrated that PS treatment increases *IKBAKP* mRNA and IKAP protein levels in various tissues of FD mice without affecting exon 20 inclusion levels. We also observed that genes associated with transcription regulation and developmental processes were up-regulated in the cerebrum of PS-treated mice. Thus, PS holds promise for treatment of FD.

R. Bochner: None.

Mutations in PRRT2 result in familial infantile convulsions with marked variability in clinical expression and SUDEP

P. Tarantino[1], *G. Palamara*[1], *A. Labate*[2,3], *M. Gagliardi*[1,4], *L. Mumoli*[2], *E. Ferlazzo*[2], *G. Iannello*[1], *U. Aguglia*[2], *G. Incorpora*[5], *A. Gambardella*[1,2], *G. Annesi*[1];
[1]*Institute of Neurological Sciences - National Research Council, Cosenza, Italy,* [2]*Institute of Neurology University Magna Graecia, Catanzaro, Italy, Catanzaro, Italy,* [3]*Neuroimaging Research Unit, National Research Council, Germaneto, Catanzaro, Italy, Catanzaro, Italy,* [4]*University of Magna Graecia, Catanzaro, Italy, Catanzaro, Italy,* [5]*Unit of Paediatrics, University Hospital "Arezzo-Trifiletti", Ragusa, Italy, Ragusa, Italy.*

Benign familial infantile seizures (BFIS) is an autosomal dominant disorder characterized by afebrile seizures that begin at age 3-12 months with a favorable outcome. A recent discovery has identified heterozygous mutations in PRRT2, which encodes proline-rich transmembrane protein 2, in most families affected by BFIS. PRRT2 is also the major causative gene for familial paroxysmal kinesigenic dystonia (PKD), a rare disorder characterized by episodic attacks of choreoathetosis or dystonia. These results have corroborated the existence of familial infantile convulsions with paroxysmal choreoathetosis that shares overlapping clinical features with BFIS and PKD. In this study, we performed mutation screening of PRRT2 in our families with BFIS, ICCA or PKD phenotypes. The whole genomic region of PRRT2 was sequenced in seven Italian families, of which six with BFIS or ICCA phenotype, and one family with PKD phenotype. The previously reported mutation, p.R217Pfs*7, was found in two families with BFIS phenotype, and in one family with ICCA. In an additional BFIS family, a missense mutation, R240X, was identified. All these mutations co-segregated with the disease in these families and were not observed in 300 control subjects. In the ICCA family, two affected members displayed a more complex phenotype with episodic ataxia, mental retardation and migraine attacks. In one family that also carried the c.649dupC mutation, one affected member died at age of 13 years of SUDEP. This study confirms the major role of PPRT2 mutations in families with BFIS phenotypes and underscore the complexity of the phenotypic consequences of mutations in this gene.

Application of Artificial Neural Networks to link one-carbon metabolism to Alzheimer's disease risk

L. Migliore[1], *E. Grossi*[2], *M. Buscema*[3], *F. Coppedè*[1];
[1]*Department of Translational Research and New Technologies in Medicine and Surgery, Medical Genetics Unit, University of Pisa, Pisa, Italy,* [2]*Bracco Medical Department, San Donato Milanese, Italy,* [3]*Semeion Research Centre, Rome, Italy.*

Folate metabolism, also known as one-carbon metabolism, plays a fundamental role in DNA synthesis and integrity, in chromosome stability, in antioxidant defence mechanisms, as well as in epigenetic processes, and impairments of this pathway have been often linked to Alzheimer's disease (AD) risk. In addition, increasing evidence from large scale case-control studies, genome-wide association studies, and meta-analyses of the literature suggest that polymorphisms of genes involved in one-carbon metabolism influence the levels of folate, homocysteine and vitamin B12, and might be among AD risk factors.
We aimed to analyze a dataset of genetic and biochemical data (folate, homocysteine, vitamin B12, and the genotypes generated by 9 common biallelic polymorphisms of genes involved in folate metabolism) obtained from 40 AD patients and 40 matched controls to assess the predictive capacity of artificial neural networks assembled in TWIST system in distinguish consistently these two different conditions and to identify the variables expressing the maximal amount of relevant information to the condition of being affected by dementia of Alzheimer's type. Moreover, we constructed a semantic connectivity map to offer some insight regarding the complex biological connections among the studied variables and the two conditions (being AD or control).
TWIST system selected 16 variables that allowed to discriminate between AD and control subjects with over 90% accuracy. The semantic connectivity map provided important information on the complex biological connections between the studied variables highlighting the importance of folate metabolism in AD pathogenesis.

Family history has been reported in up to 50% of patients with frontotemporal lobar degeneration (FTLD), a major neurodegenerative disease of the brain. In most families the pattern of inheritance is consistent with a Mendelian segregation of a dominant mutation. Mutations in seven known genes explain the disease in approximately 40% of FTLD families. We use whole genome sequencing (WGS) to identify rare, highly penetrant genes in genetically unexplained FTLD families. The genome sequences of three affected sib pairs were obtained with an average coverage of 81-fold capturing both alleles of 96.5% of the genome, and revealing about four million variations per genome. Annotation and analysis of the genome sequences was performed using GenomeComb. Variations were filtered and prioritized using multiple strategies based on genetic and functional criteria. About 380 selected missense or splice site variations were further prioritized using mutation prediction programs, resulting in about 80 predicted harmful mutations per sib pair. The frequency of the variations was determined in neurologically healthy control individuals. About 25 variations were absent or present in less than 1% of control individuals. We tested the frequency of these rare variations in a series of 370 unrelated FTLD patients and identified around 12 variations that were present in additional patients. The genes harboring these variations are being sequenced in patients and control individuals to define their mutation profile. The identification of novel FLTD genes will provide valuable insights into the pathogenesis of FTLD and might provide insight in potential novel therapeutic targets.

The Fronto-Temporal Lobar Degeneration (FTLD) is a genetically and pathologically heterogeneous degenerative disorder characterized by progressive decline in behavior or language associated with frontal and temporal lobe degeneration. The phenotypic heterogeneity consistently revealed the presence of at least two clinical manifestations such as behavioral variant FTLD (bvFTLD) and Primary Progressive Aphasia (PPA).
Several mutations either in the same gene or in different genes show a great degree of heterogeneity associated with FTLD, up to 40% of familiar cases have been described as carrying mutation/s in GRN and/or MAPT genes.

Here we describe a four-generation Southern Italian family segregating FTLD. The family consists of five siblings, three of which affected by FTLD. The three phenotypes are clinically heterogeneous with behavioral variant (bvFTLD) apathetic or disinhibited behavioral syndrome in the males and Primary Progressive Aphasia (PPA) in the female. We collected 2 of the affected individuals (one of the male and the female), and one of the non affected sibs and analyzed these for GRN and MAPT gene in search for a mutation. Specifically, we analyzed the sequence of all exons, exon-intron boundaries and 5' and 3' regulatory regions. We found g.101349_101355delCTGCTGT mutation on exon 6 of GRN, only in the affected siblings. This deletion we know causing a premature stop codon with frameshift induction and mRNA non-sense mediated decay involving GRN protein haploinsufficiency. Up to now only two sporadic cases have been described carrying these deletion, further investigation are in progress to better describe the molecular defect causing this FTLD.

P08.42

Comparative RNA-Seq profiling from FUS mutations found in amyotrophic lateral sclerosis and essential tremor cases.

M. Therrien[1], *J. Parker*[1,2], *G. A. Rouleau*[3], *P. A. Dion*[1,2];
[1]*The Centre of Excellence in Neurosciences, CHUM Research Center, Montréal, QC, Canada,* [2]*Pathology and cell biology department, Université de Montréal, Montréal, QC, Canada,* [3]*Montreal Neurological Institute and Hospital, Montréal, QC, Canada.*

Fused in sarcoma (FUS) is a protein involved in DNA and RNA processing and tumorigenesis. The presence of nonsense mutations affecting FUS has been observed in Amyotrophic Lateral Sclerosis (ALS) (p.Q519X) and Essential Tremor (ET) (p.Q290X) patients. While the two mutant proteins are sequestered to the cytoplasm, only the FUS(p.Q519X) still contains its RNA binding domain which could lead the FUS aggregates to act as cytoplasmic RNA trap that would prevent the normal re-entry into the nucleus of some of the RNA. Massively parallel RNA sequencing (RNA-Seq) experiments are now easily feasible and we propose to delineate the transcriptome of N2a cells expressing either FUS(WT), FUS(p.Q519X) or FUS(p.Q290X). For each of these, we would make a total, nuclear and cytoplasmic RNA preparation, converted these to cDNA and assemble them into a library compatible with a Illumina MiSeq apparatus. Cufflink will be used to align sequencing reads and evaluate the abundance of each transcript. Relative expression changes between FUS(WT), FUS(p.Q519X) and FUS(p.Q290X) will be evaluated on a transcriptome wide basis. In addition, the datasets will also be assessed for splicing defect between FUS(WT) and the two mutated FUS. Interesting variations will be confirmed by quantitative PCR and Taqman probes in the readily available ALS and ET patient's lymphoblastoid cell lines. With the implication of TDP-43, FUS, and C9ORF72 in ALS, the clues point towards disrupted RNA metabolism as a pathogenic mechanism for the disease. Thus our findings may be applicable to ALS in general and other neurological disorders associated with FUS.

P08.43

Genomics of FXTAS (Fragile X associated Tremor Ataxia) mouse brains reveals hallmarks of altered neurodevelopmement and neurodegeneration.

S. Zongaro[1], *R. Hukema*[2], *R. Willemsen*[2], *B. Mari*[3], *B. Bardoni*[1];
[1]*Institut de Pharmacologie Moléculaire et Cellulaire, Valbonne, France,* [2]*Erasmus University, Rotterdam, Netherlands,* [3]*Instutut de Pharmacologie Moléculaire et Cellulaire, Valbonne, France.*

While FMR1 is silenced in Fragile X syndrome (FXS) patients carrying the full mutation, its expression is elevated (2-8 fold) in premutated individuals. These subjects may develop the Fragile X-associated Tremor/Ataxia syndrome (FXTAS), a late onset neurodegenerative disorder characterized by ataxia and parkinsonism. In addition, people carrying the premutation can be affected by a set of neurological and behavioural disorders during young age. Memory problems have been detected in these patients as well as in the mouse model for FXTAS. In those animals, by transcriptome analysis we have shown a profound deregulation of the expression levels of genes involved in learning, memory and autistic behavior, Parkinson disease and neurodegeneration. These findings suggest the presence of a synapthopathy (Zongaro et al., HMG, 2013). Furthermore, we studied gene expression profiles of whole brain obtained from both young and old FXTAS mice. We observed that in this context different neurodegenerative pathways are involved at different ages. In FXTAS mice, we also studied the expression level of several microRNAs that target FMR1 mRNA and we observed that one them, miR-221, is down-regulated at the synapse of young FXTAS mice and in the full brain of the older ones. Interestingly, many of those deregulated mRNAs at the synapse, as well as in whole brain, are target of miR-221. These findings suggest a network regulation - including miRNAs and mRNAs- for FMR1 mRNA.

Evaluation of NTF4 gene mutations in Brazilian patients with primary open angle glaucoma (POAG) in a case-control study

H. F. Nunes[1], *V. P. Costa*[1], *N. I. T. Zanchin*[2], *J. P. C. de Vasconcellos*[1], *M. B. de Melo*[1];
[1]*UNICAMP, Campinas, Brazil,* [2]*FIOCRUZ, Curitiba, Brazil.*

Primary open-angle glaucoma (POAG) is a chronic neurodegenerative disease that leads to progressive damage to retinal ganglion cells (RGC) resulting in visual field loss. Although the pathophysiology of glaucoma is not well understood, members of the neurotrophin family are known to support the survival of neuronal populations, including RGCs. The goal of this study was to investigate the contribution of Neurotrophin-4 (NTF4) gene mutations in the etiology of glaucoma in a sample of Brazilian POAG patients. A case-control study involving 130 POAG patients and 90 control subjects was performed through direct sequencing of the coding region of the NTF4. Here, we report four different heterozygous mutations in the NTF4 gene, accounting for about 3% of POAG patients; no mutations were observed in the control group.
Two of the mutations were in the 3' untranslated region and the other two led to amino acid changes in the protein. The mutations D196Y and R164M imply in changes of an Aspartic acid for a Tyrosine and an Arginine for a Methionine, respectively. Both changes correspond to amino acids with different side chain polarity and charge that may affect NTF4 either the monomer or dimer structure. To confirm this hypothesis investigation about the functional consequences and phenotypic implications must be performed.
NTF4 is functionally related to POAG but the mutation frequency in Brazilian POAG patients is low, although higher than in Caucasians and Asians POAG cases. Therefore, NTF4 does not have a major contribution in the genetics of POAG in the Brazilian population.

Founder SPG7 mutation causing hereditary spastic paraplegia in Gypsies - clinical and genetic considerations

D. Kancheva[1,2], *A. Andreeva*[3], *T. Chamova*[3], *B. Morar*[4], *N. Ivanova*[1], *D. Azmanov*[4], *V. Mitev*[1], *L. Kalaydjieva*[4], *I. Tournev*[3], *A. Jordanova*[2];

Hereditary spastic paraplegias (HSP) are a group of clinically and genetically heterogeneous neurodegenerative disorders characterized by progressive spasticity and weakness of lower limbs, due to retrograde degeneration of corticospinal axons. Mutations in the SPG7 gene cause autosomal recessive HSP, characterized by both pure and complicated forms of spastic paraplegia. Recently, several heterozygous SPG7 mutations were reported in affected individuals, although the evidences for their dominant disease-causing effect are vague and contradictory. Here, we describe 6 Gypsy HSP pedigrees from Bulgaria harboring the p.L78X mutation in the SPG7 gene. The same mutation was reported in Gypsy patients with spastic paraplegia from Spain and in 2 Italian HSP pedigrees. We identified a common haplotype shared between all families, suggesting a founder effect. Importantly, the p.L78X mutation caused the HSP phenotype in both homo- and heterozygous state. Sanger sequencing excluded SPG7 compound heterozygosity in the symptomatic carriers. Genotype-phenotype correlation study of over 20 homozygous and 45 heterozygous Gypsy individuals with a homogeneous genetic background allowed characterizing the p.L78X penetrance and phenotype expressivity. Our findings broaden the clinical spectrum of SPG7 mutations, provide strong evidences favoring the dual nature of molecular defects in this gene, and allow establishing diagnostic and counseling guidelines for HSP patients from Gypsy origin.

Hereditary spastic paraplegia (HSP) is considered one of the most heterogeneous group of neurological disorders, both clinically and genetically. It comprises pure and complex forms that clinically include slowly progressive lower-limb spasticity resulting from degeneration of the corticospinal tract. At least 50 loci accounting for these diseases have been mapped to date, and mutations have been identified in 29 genes, most of which playing a role in intracellular trafficking. Here, we identified mutations in two functionally related genes (DDHD1 and CYP2U1) in individuals with autosomal recessive forms of HSP by using either the classical positional cloning or a combination of whole-genome linkage mapping and next-generation sequencing. Interestingly, three subjects with CYP2U1 mutations presented with a thin corpus callosum, white-matter abnormalities, and/or calcification of the basal ganglia. Furthermore, we recently identified a new mutation of *CYP2U1* in a Switzerland family: c.1A>C/ p.M1L. This mutation is also present in an asymptomatic sister aged of 50 years; suggesting an incomplete penetrance or a metabolic compensation in this individual. These genes code for two enzymes involved in fatty-acid metabolism, and we have demonstrated in human cells that the HSP pathophysiology includes alteration of mitochondrial architecture and bioenergetics with increased oxidative stress. Our combined results focus attention on lipid metabolism as a critical HSP pathway with a deleterious impact on mitochondrial bioenergetic function.

P08.47

Functional study of swiss cheese, ortholog of the Hereditary Spastic Paraplegia gene

G. Kislik, *S. Sarantseva, N. Tkachenko;*
National Research Centre, Gatchina, Russian Federation.

Hereditary spastic paraplegias (HSP) are a clinically and genetically heterogeneous group of neurodegenerative diseases characterized by degeneration of corticospinal tract axons and progressive lower-limb spastic paralysis. Neuropathy target esterase (NTE) is one of the HSP genes and responsible for the development of the early-onset
autosomal-recessive HSP form. NTE is also involved in the pathogenesis of organophosphorous compound-induced delayed neuropathy (OPIDN). Both HSP and OPIDN are characterized by the distal axonopathy. The molecular mechanisms underlying the axonopathy involved in HSP and OPIDN as well as in many other neurodegenerative human disorders are poorly understood. NTE is a highly conservative gene with orthologs in many species. Mutation of NTE's Drosophila ortholog swiss cheese (sws) leads to neurodegeneration, motor impairment, and reduced life span in the insect. An understanding of sws role in axon formation, growth and deneration will help to gain insight into NTE's role in similar processes in the human nervous system. To study sws functions we use the system of the 3rd instar larval neuromuscular junctions (NMJ) of Drosophila melanogaster. In this study we show that mutations in sws (sws1, sws4, sws7615, swsolfE) alter NMJ morphology, cause abnormal distribution of synaptic proteins, disruption of axonal transport and tubulin network in NMJ of Dr. melanogaster. We propose that sws plays an important role in synaptogenesis processes as well as axon formation and functioning in Drosophila melanogaster.

Huntington Disease: two case reports of pregnancies continued after a positive prenatal diagnosis

S. Creighton[1], *S. Kieffer*[1], *P. Goldberg*[1], *M. Hayden*[2];
[1]*Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada,* [2]*Centre for Molecular Medicine and Therapeutics, University of British Columbia, Vancouver, BC, Canada.*

Prenatal diagnosis for Huntington Disease (HD) is uncommon. Rarer still is deciding to continue a pregnancy when the fetus has a CAG expansion in the HD range. We report two cases of continued pregnancies following a positive prenatal test. In both cases the mothers were known carriers of a CAG expansion following HD predictive testing.
Case 1: The patient was referred at 6 weeks' gestation for predictive testing Following a positive predictive test, she had amniocentesis, with the intent of ending the pregnancy if the test were positive. Testing was performed which revealed that the fetus also carried a CAG expansion. She altered her original plans, electing to continue the pregnancy. She subsequently underwent preimplanation genetic diagnosis (PGD) for her second child.
Case 2: The patient had a normal prenatal diagnosis in her first pregnancy. Subsequently, following unsuccessful PGD attempts, she had four natural conceptions which were all found to have a CAG expansion and were discontinued. When the fetus again was affected in the next pregnancy, the couple elected to continue the pregnancy.
We are not aware of any reports in the literature regarding the long term outcome for families when the presence of a gene mutation for HD is known before the birth of their child. We will discuss the follow up and general wellbeing of the current case families, including ethical and psychosocial issues raised by the circumstances. We anticipate they will help inform our practice regarding prenatal diagnosis for HD and other adult onset disorders.

Modulation of age at onset in Tunisian Huntington disease patients: Implication of 5 new modifier genes: DRPLA, ATXN1, TBP, DMPK and JPH3

M. Chourabi[1], *D. H'mida-Ben Brahim*[1], *S. Ben Amor*[2], *I. Harrabi*[3], *S. Trabelsi*[1], *M. Mastouri Haddaji*[1], *S. Sassi*[1], *M. Gribaa*[1], *S. Ben Ammou*[2], *A. Saad*[1];
[1]*Laboratory of cytogenetics, molecular genetics and reproductive biology, Farhat HACHED Hospital, Sousse, Tunisia,* [2]*Department of neurology, Sahloul Hospital, Sousse, Tunisia,* [3]*Department of epidemiology and medical statistics, Farhat HACHED Hospital, Sousse, Tunisia.*

Our study aims to investigate the implication of CAG repeat expansion and 9 modifiers genes in age at onset (AO) of 10 Huntington's disease (HD) Tunisian patients.
The diagnosis of HD is already confirmed in our laboratory in 10 patients. Disease onset was noticed between 24 and 72 years. The number of CAG repeat varied between 40 and 49 CAG. Our patients were screened for 9 modifiers genes: JPH3, DRPLA, ATXN1, GRIN2A, GRIN2B, IT15, TCERG1, DMPK and TBP. For this we used triplet primed PCR and direct sequencing.
CAG repeat expansion varies between 40 and 49 repeats. Using SPSS 17.0 we established an inverse correlation between CAG repeat and the AO (R = -0.809, p=0.005). This CAG expansion was found to be implicated in 65.5% of the AO variance. We also established the implication of DRPLA CAG repeat at 66.3% (R square= 0.884; p=0.003) and the implication of DMPK CTG repeat at 22.02% (R square= 0.731; p=0.004) of the unexplained variance. DRPLA CAG repeat and DMPK CTG repeat were inversely correlated to the AO at respectively (R=-0.823, p=0.003) and (R=-0.641; p=0.046).
TBP, ATXN1, JPH3, GRIN2B (rs 890) and TCERG1 genes were also implicated in the AO unexplained variance at respectively 1.44%, 4.34%, 8.69%, 13.04% and 25.5%, whereas GRIN2A (rs1969060) did not show any impli-

cation in our population.
We report here the first North African study on HD. We investigated 5 new polymorphisms located at DRPLA, TBP, ATXN1, DMPK and JPH3 genes.

Dog as an animal model for idiopathic epilepsy: the Schipperke breed as an example

L. L. E. Koskinen[1,2,3], *E. H. Seppälä*[1,2,3], *M. Virta*[1,2,3], *P. Pilve*[1,2,3], *T. Jokinen*[4], *P. Jokinen*[1,2,3], *R. Viitmaa*[4], *H. Lohi*[1];
[1]*Research Programs Unit, Molecular Neurology, University of Helsinki, Helsinki, Finland,* [2]*Department of Veterinary Biosciences and Department of Medical Genetics, University of Helsinki, Helsinki, Finland,* [3]*Folkhälsan Institute of Genetics, Helsinki, Finland,* [4]*Department of Clinical Veterinary Sciences, University of Helsinki, Helsinki, Finland.*

Idiopathic epilepsy (IE) is a common neurological disease in human and dog. Relatively few risk genes have been identified for common IE to date. We have used the Schipperke dog breed as an animal model for human IE to identify disease risk genes. The seizure characteristics are similar between the two species and reduced genetic heterogeneity of purebred dogs is advantageous for genetic studies.
62 epilepsy patients were analysed through detailed owner-filled epilepsy questionnaires. 12 cases and 8 controls were clinically studied. 56 cases and 66 healthy controls were genotyped for genome-wide association (GWAS) with Illumina 170K SNP arrays. The data was analysed with the GenABEL Grammas test.
The age of onset varied between 6 months and 5.5years (mean 3years). The median seizure frequency was 5/year and the typical seizure duration was 7min (range 0.5min-30min). One-third of the owners were able to identify phenomenology preceding convulsions as a sign of focal seizure activity. The clinical examinations confirmed IE in the studied cases. In the GWAS, two loci showed tentative association on CFAs 10 (p(raw)=1.76e-05, p(gwas)=0.30) and 37 (p(raw)=5.97e-06, p(gwas)=0.12).
Based on the epilepsy questionnaires and clinical examinations, we described focal and generalised IE with variable expression in Schipperkes. The associated locus on CFA37 is also a risk locus for IE in Belgian Shepherds. This indicates that these two breeds related with each other also share common risk factors for epilepsy. We currently aim to replicate our findings in larger materials and investigate the associated loci in more detail.

No evidence for a role of Cystatin ß dodecamer repeat expansion in Juvenile Myoclonic Epilepsy

M. GAGLIARDI[1,2], *P. Tarantino*[1], *G. Annesi*[1], *G. Iannello*[1], *R. Michelucci*[3], *A. Bianchi*[4], *A. Gambardella*[1,5], *O. n behalf of Italian League against Epilepsy*[6];
[1]*Institute of Neurological Sciences,National Research Council, MANGONE (CS), Italy,* [2]*University of Magna Graecia, Catanzaro, Italy, Catanzaro, Italy,* [3]*Division of Neurology, "Bellaria" Hospital, Bologna, Bologna, Italy,* [4]*Division of Neurology, Ospedale "S. Donato" Arezzo, Arezzo, Arezzo, Italy,* [5]*Institute of Neurology, University of Magna Graecia, Catanzaro, Italy, Catanzaro, Italy,* [6]*c/o PTS Congressi srl - Roma, Roma, Italy.*

Juvenile myoclonic epilepsy (JME) is a common form of idiopathic generalized epilepsy (IGE) that has a relevant genetic contribution, but so far genes related to JME families remain largely unknown. JME shares electro-features with Unverricht-Lundborg disease (EPM1) that is a form of the progressive myoclonic epilepsy characterized by myoclonus, epilepsy and progressive neurologic deterioration. EPM1 is caused by mutations in the gene that codes for cystatin ß, an inhibitor of cysteine protease. The most common mutation in EPM1 is an expansion of a dodecamer repeat located in a non coding region upstream of the transcription start site of the cystatin ß gene. Since JME and EPM1 are both myoclonic epilepsies, we investigated the role of dodecamer repeat expansion in patients with JME. Thirty-five patients (26 women; mean age: 22.4, + 6,3; mean age at onset: 15,7 + 3,5) with JME were enrolled. Twenty-four had a positive family for JME or IGE. DNA was extracted by standard methods. Dodecamer repeat expansion was amplified by expand long template PCR system and detected by electrophoresis analysis. All subjects provided written informed consent, as required by ethics committees in each epilepsy centre of all the participating investigator. The analysis of the dodecamer repeat expansion did not evidence any expanded alleles in all 35 patients with JME. Our study did not support a role for cystatin ß dodecamer repeat expansion in JME. It remains to be clarified if the so-called minor EPM1 mutations might account for a proportion of the genetic susceptibility to JME.

Leukodystrophies are a group of orphan genetic diseases that affect the white matter (WM) and its main component, the myelin. Diversity of the genes involved in the development and homeostasis of the WM explains the large heterogeneity of this group of disorders. During this last decade, we collected through the LeukoFrance netwok a total of 1182 leukodystrophic families. Despite advances made in gene identification of UL, 68% of our families remain without genetic marker. We selected for whole exome sequencing a cohort of 70 families with reliable clinical and neuroradiological data. We used homozygosity as an effective filter in consanguineous families (27 families). The preliminary Exome results of 11 families revealed (i) one patient mutated for a gene already involved in a leukodystrophy (POLR3) with isolated ataxia. This patient born of consanguineous union was found to be compound heterozygous, therefore genetic diagnosis have been missed by homozygosity mapping only.; (ii) for two patients mutations were found in genes known to cause other type of neurodegenerative diseases with therapeutic approaches (BOLA3 and FOLR1). The two reported patients exhibited unusual phenotypes; (iii) in 5 patients, variants have been found as possible causative mutations in 5 genes not previously reported in neurodegenerative disorders. However, the biological role of these genes and the type of mutations found highly suggested their deleterious effects. This study underlines the particular interested of Exome sequencing in leukodystrophies, in which the molecular strategy for diagnosis is up to now based on WM "MRI recognition pattern".

P08.53
A severe form of Pelizaeus-Merzbacher disease caused by *PLP1* triplication.

M. Hully[1], *J. Masliah-Planchon*[2], *C. Grisel*[1], *C. Vignal*[2], *N. Boddaert*[3], *M. Eisermann*[4], *H. Cavé*[2], *S. Drunat*[2], *I. Desguerre*[1];
[1]*Neuropédiatrie_Hôpital Necker, Paris, France,* [2]*Genetic department_Robert-Debré hospital, Paris, France,* [3]*Radiologie pédiatrique_Hôpital Necker, Paris, France,* [4]*Explorations fonctionnelles neurologiques_Hôpital Necker, Paris, France.*

INTRODUCTION: Pelizaeus-Merzbacher disease (PMD) is a rare X-linked myelination disorder caused by genomic alterations of the *PLP1* gene. Typical forms of PMD are characterized by early nystagmus and hypotonia that later evolves into spastic tetraparesis, dystonia, and ataxia. *PLP1* gene duplications are responsible for 60% of the cases. In addition to duplication, other rearrangements, including deletions, translocations, and triplications, have been described underlying a complex genomic architecture.
CLINICAL REPORT: We report the case of a 5-month-old boy, second child of unrelated parents. Pregnancy was uneventful but nystagmus was noticed at birth and subsequent psychomotor development was severely delayed. At the age of 2 months the patient exhibited opisthotonic postures. On examination at 5 months of age, we report absent visual fixation, nystagmus, constant choreoathetoid movements, and severe hypotonia. The brainstem auditory evoked potentials (BAEP) results were seriously altered showing only wave I. His brain magnetic resonance imaging (MRI) displays a typical profound diffuse hypomyelination.
MOLECULAR ANALYSIS: *PLP1* gene dosage analysis using multiplex ligation-

dependent probe amplification (MLPA) and custom CGH array (Agilent) revealed a triplication of a 110 Kb genomic segment containing the *PLP1* gene embedded in a larger duplicated segment of 510 Kb.
CONCLUSION: To our knowledge, only 7 PMD patients with more than 2 copies of the *PLP1* gene were reported in the literature so far. Our case brings additional evidence that patients with *PLP1* triplications exhibit a more severe phenotype than patients with duplications.

Molecular characterization of *PLP1* duplication in a large cohort of Pelizaeus-Merzbacher disease patients

J. Masliah-Planchon[1,2], *I. Dorboz*[2], *E. Eymard-Pierre*[3], *C. Vignal*[1], *C. Chambion*[1], *F. Renaldo*[4,5,2], *D. Tonduti*[4,2], *H. Cavé*[1], *M. Elmaleh*[6], *S. Drunat*[1], *O. Boespflug-Tanguy*[4,2];
[1]*Genetic department_Robert-Debré hospital, Paris, France,* [2]*INSERM U676, Paris, France,* [3]*Cytogénétique médicale_CHU Clermont Ferrand, Clermont Ferrand, France,* [4]*Neurologie et maladie métabolique_Hopital Robert-Debré, Paris, France,* [5]*Neurologie pédiatrique_Hopital Armand Trousseau, Paris, France,* [6]*Imagerie pédiatrique_Robert-Debré hospital, Paris, France.*

INTRODUCTION: Pelizaeus-Merzbacher disease (PMD) is an X-linked dysmyelinating disorder characterized by nystagmus, hypotonia, spasticity, ataxia and psychomotor developmental delay. The most frequent molecular aberration responsible for about 60% of cases is a duplication of a genomic segment of variable length containing the entire *PLP1* gene. *PLP1* encodes a major protein component of central nervous system myelin and *PLP1* duplication-subsequent overexpression in oligodendrocytes results in cellular toxicity and subsequent hypomyelination. **MATERIALS AND METHODS:** This study has been performed in a large cohort of 48 duplicated patients with reliable and long term clinical data (leukofrance database). We analyzed *PLP1* gene dosage and size of the duplicated segments with high-resolution custom array-based CGH including 30,032 probes spanning a 20Mb region surrounding the *PLP1* gene. Precise breakpoint mapping has subsequently been performed using breakpoint junctions sequencing and genome walking strategy. **RESULTS:** This custom *PLP1* array-based CGH analysis in a large cohort of patient confirmed a great diversity of duplication size and breakpoints. Sequencing of the successfully amplified duplication breakpoint junction reports complex rearrangement mechanisms involving the *PLP1* gene. **CONCLUSION:** The complex local genomic architecture of the *PLP1* locus likely drives the DNA susceptibility to complex rearrangements. More investigation is required to fully understand the mechanisms involved in those genomic rearrangements and their correlation with the variability observed in the disease severity.

Array CGH and undetermined leukodystrophy

M. Gay-bellile[1,2], *E. Eymard-Pierre*[1,2], *C. Pebrel-Richard*[1,2], *P. Combes*[1,2], *S. Kemeny*[1,2], *L. Gouas*[1,2], *C. Goumy*[1,2], *C. Sarret*[3], *O. Boespflug-Tanguy*[4,5], ***P. Vago***[1,2];
[1]*Cytogénétique Médicale - CHU Estaing, Clermont-Ferrand, France,* [2]*ERTICa, Univ Clermont 1, UFR Médecine, Clermont-Ferrand, France,* [3]*Pédiatrie - CHU Estaing, Clermont-Ferrand, France,* [4]*Neurologie Pédiatrique et Maladies Métaboliques - Hôpital Robert Debré AP-HP, Paris, France,* [5]*INSERM UMR 676, Univ Paris Diderot, Sorbonne, Paris, France.*

Objective: Research of small-size chromosomal rearrangements in patients with undetermined leukodystrophy.
Methods: Thirty patients with undetermined hypo or demyelinating leukodystrophy were analysed by array CGH (Agilent 4x180K). Rearrangements not found in databases as polymorphism variants were confirmed by Quantitative Multiplex Fluorescent PCR (QMF-PCR). To determine their inherited or de novo status we realised familial cytogenetic investigations by QMF-PCR. Finally, in order to evaluate the deleterious status and clinical implication, expression study and X-inactivation analysis were performed to argument in favour of pathogenic or polymorphic rearrangements.
Results: Thirteen among the 30 explored patients present 1 or 2 rearrangements not described as polymorphism variants. Array CGH allowed us to identify 2 pathogenic deletions already described in leukodystrophies and taking out known causative genes: *MCT8* (Xq13.2 – 31kb) and *MBP* (18q22.3q23 – 7,88Mb). Two possible pathogenic rearrangements were identified, one deletion taking out part of *CNTNAP2* gene (Xq22.2 – 26kb) and one duplication upstream *PLP1* gene involved in Pelizaeus-Merzbacher Disease. Finally, for 4 patients, we concluded on VOUS (Variation Of Unknown Signification).
Discussion: Because of their clinical and genetic heterogeneity, array CGH, high resolutive and pangenomic technique, has its entire place in the etiologic diagnostic strategy of undetermined leukodystrophy. Indeed, this study shows that array CGH allows both to highlight rearrangements implicating genes already involved in these pathologies and to identify new candidate genes. However, because of the difficulty to conclude in some cases about the pathogenic or polymorphism status, additional analyses are still in progress (expression study, mutations screening…).

Protective effects of epigallocatechin-3-gallate against hydrogen peroxide-induced apoptosis in transformed lymphoblastoid cells from patients with Machado-Joseph disease

H. TSAI[1], *J. Huang*[1], *T. Chen*[2];
[1]*CHUNG SHAN MEDICAL UNIVERSITY, Taichung, Taiwan,* [2]*Graduate School of Computer Science and Information Technology,, Taichung, Taiwan.*

Machado-Joseph disease (MJD) or spinocerebellar ataxia type 3 (SCA3), the autosomal dominant neurodegenerative disorder, is caused by an increased number of CAG trinuclear expansion repeats in coding regain of *SCA3/MJD1* and resulted in a disease protein with a higher polyQ domain. The study of rare, inherited mutations underlying familial forms of MJD's disease has provided insight into the molecular mechanisms of disease pathogenesis. Neurodegenerative disorders are a class of disease in which elevated levels of reactive oxygen species (ROS) and apoptosis lead to tissue damage. Epigallocatechin-3-gallate (EGCG) is a major component of green tea polyphenols which displays potential properties of neuroprotection. We investigated the protective effects of EGCG extract against hydrogen peroxide (H_2O_2), a toxin created by oxidative stress and implicated in neurodegenerative disease, in mutant ataxin-3 cells. Our results demonstrated that EGCG against H_2O_2-induced cytotoxicity in a dose-dependent manner ($p<0.05$). We examined the effect EGCG against H_2O_2-induced apoptosis through reciprocal regulating pro-apoptotic protein Bax and anti-apoptotic protein Bcl-2. Interestingly, EGCG against H_2O_2-induced apoptosis in mutant ataxin-3 cells was accompanied by the up-regulation of heat shock protein (Hsp) 70 expression. These results show that EGCG may be a potential therapeutic candidate for neurodegenerative diseases involving glutamate excitotoxicity such as MJD.

Autosomal Dominant Microcephaly: Identification of a Novel Locus

R. Kadir[1], *T. Harel*[1], *S. Shalev*[2], *J. Zlotogora*[3], *O. S. Birk*[1];
[1]*Human Genetics and the Genetics Institute, Soroka Medical Center, Ben-Gurion University, Beer Sheva, Israel,* [2]*Haemek Genetic Institute, Haemek Medical Center, Haemek, Israel,* [3]*The hebrew university of Jerusalem, Jerusalem, Israel.*

Autosomal dominant microcephaly with mild to moderate mental retardation with no dysmorphism or other anomalies was diagnosed in eleven individuals of an Arab Israeli family. Craniosynostosis and environmental factors were ruled out per history as possible contributors to the disease, thus verifying the diagnosis of primary microcephaly. Brain CT scan of affected individuals showed no architectural anomalies. Nine living affected individuals were available for clinical and genetic evaluation. Association with all known microcephaly-associated loci was ruled out using polymorphic markers and genome wide linkage analysis data. Genome-wide linkage analysis revealed association of the disease to a region on chromosome 4 which was fine mapped with polymorphic markers to an area of approximately 20Mbp between markers D4S1558 and D4S2460, with a maximal LOD score of Z = 3.44, at marker D4S1534 ($\theta=0$). Whole exome sequencing has yielded several SNP mutations which are being explored in the affected family.

Six Novel mutations in MLC1 from 15 Iranian patients with Megalencephalic Leukoencephalopathy with Subcortical Cysts.

*A. Rajaee[1], A. Kariminejad[1], B. Bozorgmehr[1], M. Afshari[2], S. H. Tonekaboni[3], M. Mirzazadeh[1], H. Alizadeh[2], G. A. B. Shooshtari[4], **M. H. Kariminejad**[1], T. Abbink[5], M. Van Der Knaap[5];*

[1]Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran, [2]Markaz Tebi Hospital, TUMS, Tehran, Islamic Republic of Iran, [3]Pediatric Neurology Research Center, SBMU, Tehran, Islamic Republic of Iran, [4]Ahwaz Behzisti Genetic Counseling Center, Ahwaz, Islamic Republic of Iran, [5]Department of Pediatrics,Child Neurology, Amsterdam, Netherlands.

Megalencephalic leukoencephalopathy with subcortical cysts (MLC) (MIM #604004) is a rare autosomal recessive neurological disorder characterized by macrocephaly, motor and cognitive decline, ataxia, spasticity and occasional seizures. Magnetic resonance imaging (MRI) shows diffusely abnormal and swollen white matter of the cerebral hemispheres, presence of subcortical cysts in the anterior temporal and frontoparietal region. Mutations in MLC1(22q13.33) and GLIALCAM have been identified in patients with MLC. Mutations in MLC1 account for 75% of mutations.

MLC was suspected in fifteen Iranian patients from thirteen families based on positive clinical findings including macrocephaly beginning in the first year, neurocognitive deterioration, seizure or loss of consciousness after minor head trauma. All except one were born to consanguineous parents. Brain MRI images were compatible with MLC and confirmed the diagnosis. Sequencing of entire coding region of MLC1 was performed for 12 patients and six novel mutations and six previously reported mutations were identified. This report shows that MLC is relatively common in Iranian population, as expected for rare diseases with high inbreeding, with surprisingly high frequency of novel mutations.

Cell model for Sanfilippo C syndrome using iPS cells

I. Canals[1,2,3], *Y. Richaud[3,4], S. Jiménez[3,4], R. Torrent[3,4], L. Vilageliu[1,2], Á. Raya[3,4,5], D. Grinberg[1,2];*

[1]Universitat de Barcelona, IBUB, Barcelona, Spain, [2]Center for Networked Biomedical Research on Rare Diseases (CIBERER), Barcelona, Spain, [3]Control of Stem Cell Potency Group, Institute of Bioengineering of Catalonia (IBEC), Barcelona, Spain, [4]Center for Networked Biomedical Research on Bioengineering, Biomaterials and Nanomedicine (CIBER-BBN), Barcelona, Spain, [5]InstitucióCatalana de RecercaiEstudisAvançats (ICREA), Barcelona, Spain.

Mucopolysaccharidosis III (MPS III), or Sanfilippo syndrome, includes four autosomal recessive diseases characterized by deficient heparan sulfate degradation. Clinical symptoms similar for all the types, include progressive and severe deterioration of the central nervous system during childhood. HGSNAT, the gene responsible for MPS IIIC, encodes the acetyl CoA:α-glucosaminide N-acetyltransferase, a lysosomal membrane protein. No therapies are available for Sanfilippo syndrome.

Human induced pluripotent stem cells (iPSc) offer a unique opportunity to model human neurodegenerative diseases. Several models have been obtained using that technology.

We developed a neuronal cell model for Sanfilippo C syndrome from patients' fibroblasts. Patient 1 was heterozygous for a missense (p.L445P) and a splicing (c.633+1G>A) mutation, while patient 2 was homozygous for a splicing mutation (c.372-2A>G) prevalent in Spanish patients.

Retroviral vectors encoding KLF4, OCT4, and SOX2, were used to obtain different clones of iPSc from each patient and a control healthy individual. One clone of each line was validated. Cells were positive for alkaline phosphatase, showed normal karyotypes, expressed markers of pluripotency (SSEA3, SSEA4, NANOG and TRA-1-81) and the genes encoding for the different factors were integrated in their genome. Quantitative PCR to establish the efficient repression of the exogenously introduced genes was carried out, and the ability of the cells to differentiate to the 3 germ layers was assayed in vitro and in vivo. OCT-4 and NANOG promoters were demethylated. After the validation, the cells were differentiated to neurons and astrocytes in order to study the molecular basis of the disease into these cellular types.

A *CIITA* gene polymorphism (rs4774*C) in conjunction with the *HLA-DRB1*15:01* allele increases susceptibility to multiple sclerosis in Brazilian females.

*E. R. Paradela[1], A. L. S. Figueiredo[1], F. R. Malfetano[2], I. Meira[2], V. C. S. R. Pereira[2], L. Fêzer[3], L. A. Agostinho[1], C. F. Rocha[1], **C. L. A. Paiva**[1], S. V. Alves-Leon[1];*

[1]Universidade Federal do Estado do Rio de Janeiro (UNIRIO), Rio de Janeiro, Brazil, [2]Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil, [3]Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil.

We investigated the association of 83 alleles of polymorphic HLA-Class II genes with multiple sclerosis (MS) susceptibility, as well as the association of two CIITA alleles. Blood samples were taken from 52 patients (35 female) and from 126 healthy control subjects matched for ancestry, sex and age. Patients were classified according to the criteria laid out by McDonalds et al. (2001). After DNA extraction, the alleles of HLA-DRB1, DQB1 and DQA1 were identified by PCR-SSP. Sequencing of single nucleotide polymorphisms +1614G/C (rs4774*C; G500A) and -168A/G (rs3087456) on CIITA was performed by PCR, followed by capillary electrophoresis in the platform ABI PRISM® 3500 Genetic Analyzer. All data were subjected to Bonferroni´s correction. The RR for MS associated with the HLA-DRB1*15:01 allele was 2.79 (OR=3.52; p value=0.001) and the RR associated with the DQB1*06:02 allele was 2.42 (OR=2.72, p value=0.020). Mantel Haenszel-corrected p values were 0.001 and 0.020 for the OR and RR, respectively. After Bonferroni's correction, only DRB1*15:01 data within our set of polymorphic alleles were statistically significant. In addition, MS association with DRB1*15:01 seemed to be conspicuous only in female patients: 31.43% of female patients (RR=4.78; OR=3.59; p value=0.001) and 23.53% of male patients (RR=2.05; OR=1.80; p value=0.159) had the allele. The CIITA polymorphism rs4774 (+1614G/C) together with HLA-DRB1*15:01 increased the RR to 3.63 (OR = 2.65, p value = 0.005) and this finding was especially female-related (RR = 4.05; OR= 4.55; p= 0.016).These results reinforced the multifactorial and polygenic trait of the disease.

P08.61

Exome sequencing in multiplex families reveals novel genetic variants related to multiple sclerosis

A. Maver, *B. Peterlin;*

Clinical institute of Medical Genetics, Ljubljana, Slovenia.

Multiple sclerosis (MS) is a chronic inflammatory neurological disorder belonging to a group of genetically complex disorders. It is known that MS accumulates in the families and it has been proposed that burden of genetic variants contributing to disease development might be particularly high in such families. Deep sequencing in subjects from families with a large number of affected individuals may thus present a promising opportunity for delineation of key genes conferring susceptibility to MS.

With this aim, we performed whole exome re-sequencing in 12 individuals originating from distinct multiplex families and 10 control subjects from the same background population. In familial MS patients, we observed an excess of rare and damaging mutations in immunoregulatory genes associated with MS in a recent large-scale GWAS by the WTCCC2 consortium (p=0.015). In 10 of 12 patients investigated, at least one predicted pathogenic rare variant in MS-associated genes was detected. We have also detected a novel pathogenic mutation in the TYK2 gene, which was previously reported to contain mutations segregating with familial MS. Literature-based relatedness analyses revealed that genes carrying detected mutations in familial disease were 10.7 times more directly or indirectly related to MS in comparison to those found in background control population.

In the present study, we demonstrate how exome sequencing in families with MS may assist in pinpointing specific genetic variants potentially contributing to disease susceptibility and thus provide novel insight into genetic architecture and pathogenesis of MS.

Background: Multiple sclerosis (MS) is a complex inflammatory disease of the central nervous system. Both environmental and genetic factors contribute to the development of the disease. We used an integratomic approach for discovery of putative regions and genes related to MS, using a comprehensive and unique set of data sources (GWAS, linkage studies, expression studies and proteomic studies). Among 381 genomic regions and 409 genes we selected STAT3 and STAT5A for association and expression studies.
Objectives: The aim of study was to investigate the association and expression of STAT3 and STAT5A genes in patients with MS from the Central South East Europe.
Methods: A total of 1045 Caucasian patients and 986 healthy unrelated ethnically matched controls without family history of MS, were included in the study. For gene expression in blood we analyzed 50 patients and 40 controls. Diagnosis of MS was established according to McDonald's criteria. Altogether, 5 SNP were included in our study, 3 in STAT3 gene: rs7211777, rs963987 and rs1053005; and 2 in STAT5A gene: rs6503695 and rs12601982.
Results: We found a statistically significant difference in the allelic distribution of STAT5A gene (rs6503696 with P value $7{,}5 \cdot 10^{-4}$), which was supported by haplotype distributions (haplotype CA $P=3 \cdot 10^{-5}$). We haven't found any diffrences in gene expression in blood in STAT5A.
Conclusion: We provide evidence for association between genetic variation in STAT5A gene and multiple sclerosis. Further studies are required to substantiate the significance of these genetic variations.

P08.63
High resolution genotyping analysis of Multiple sclerosis in Saudi patients.

Y. Alhaidan*, I. Alabdulkareem, M. Albalwi, M. Aljumah;*
King Abdullah internationla medical Research Center; NGHA, Riayddh, Saudi Arabia.

Multiple sclerosis (MS) has been clearly associated with human leukocyte antigen (HLA) complex that reported in several studies; nevertheless; this association is poorly examined in Saudi MS patients. This disease is spreading widely through Saudi population; apart from parental consanguinity; no clear understanding of environmental and/or genetics factors responsible. However; recent population studies reflect that the consanguinity marriages presented in 37.6% of the familial MS (FMS); 16% were first degree relatives.
This project is focus on the investigation of HLA-A, HLA-B, DRB1, and DQB1 alleles in 150 FMS and non FMS affected, 100 healthy controls were recruited. The high-resolution genotype sequencing using Roche 454 FLX+ Titanium chemistry was carried out.
MHC class I (A, B) and class II (DQ) were indicated with an odds ratio (OR) = 2.96 (95% confidence interval Cl 1.46-6.02 p=0.004) for HLA-A*01:01, and for HLA-B*41:01 the OR 3.77 (95% Cl 1.64-8.63, p=0.0025), while for DQB1*03:02 the OR 2.20 (95% Cl 1.29-3.75, p=0.0051). No differences between FMS and non FMS were observed. These findings representing the Saudi MS population and HLA complex association that may be unique when compare with other populations.
A further investigation should be carried out to confirm the above finding and attempting to understand more on the involvement of environmental/genetics of MS in Saudi and Gulf region.

C19ORF12 Mutations in Neurodegeneration with Brain Iron Accumulation (NBIA)

G. Annesi[1], *P. Tarantino*[1], *G. Lesca*[2,3], *E. Broussolle*[4,5], *M. Gagliardi*[1,6], *G. Iannello*[1], *A. Gambardella*[1], *A. Quattrone*[7];
[1]*Institute Of Neurological Science, National Research Council, Mangone, Cosenza, Italy,* [2]*Department of Medical Genetics, Hospice Civiles de Lyon and ClaudeBernard Lyon, University Lyon France, Lyon, France,* [3]*CRNL, CNRS UMR 5292, INSERM U1028, Lyon, France, Lyon, France,* [4]*Université Lyon I; Centre de Neurosciences Cognitives, CNRS UMR5229, Lyon, France,* [5]*Service de Neurologie C, Hôpital Neurologique Pierre Wertheimer, Lyon, France, Lyon, France,* [6]*University of Magna Graecia, Catanzaro, Italy, Catanzaro, Italy,* [7]*Neuroimaging Research Unit, National Research Council, Catanzaro, Italy, Catanzaro, Italy.*

Neurodegeneration with Brain Iron Accumulation (NBIA) comprise heterogeneous group of progressive neurodegenerative disorders that present with a progressive extrapyramidal syndrome and excessive iron deposition in the brain, particularly affecting the basal ganglia, mainly the globus pallidus. Genetic defects in PANK2 gene are the most common cause of NBIA, followed by mutations in PLA2G6, few reported NBIA families are known to carry mutations in FA2H, a gene previously associated with familial leukodystrophy and spastic paraparesis. Mutations within C19orf12 have recently been identified in patients with NBIA.This gene C19orf12, codes for a mitochondrial membrane protein and the acronym MPAN (mitochondrial membrane protein-associated neurodegeneration). In this study we report the clinical description of five patients from five families with NBIA and the subsequent molecular genetic investigation. Sequencing of PANK2, PLA2G6 and FA2H was normal; whereas the molecular analysis of C19orf12 gene revealed a novel homozygous and heterozygous C19orf12 mutations in our patients with NBIA.
Further studies are needed to explore the function of C19orf12 in NBIA, and extended genetic analysis of larger patients cohorts will provide more information about the frequency of this disease.

P08.65
Neurodegeneration with brain iron accumulation, type 4 (NBIA4) in Russian families

E. Y. Zakharova*, G. E. Rudenskaya;*
Medical Genetics Research Centre, Moscow, Russian Federation.

NBIA4 is autosomal recessive disease produced by *C19orf12* mutations [Hartig et al, 2011]. NBIA group also includes most common NBIA1/Hallervorden-Spatz disease (*PANK2* gene), NBIA2A/2B (*PLA2G6*), NBIA3 (*FTL1*) and adjoining SPG35 (*FA2H*), Parkinson disease 9 (*ATP13A2*), aceruloplasminemia (*aCP*). Common features are neurological signs, mainly dystonia and spasticity, and MRI picture of iron accumulation in globus pallidum. Though recently recognized, NBIA4 was found in several populations and seems not very rare. Its clinical distinctions from NBIA1 are later onset, slower course, less pronounced dementia and subtle MRI differences. We diagnosed NBIA4 in two Russian and one mixed Ukrainian/German (Patient 3) non-consanguineous families. Patient 1, 19-year-old female, had slowly progressing leg spasticity since 12 yrs, moderate dystonia in neck, hands and feet since 17-18 yrs, optic atrophy detected in 18 yrs and borderline intelligence. Her MRI was normal in 14 yrs, but in 17 yrs showed NBIA signs. Patient 2, 16-year-old male, had slowly progressing spasticity, dystonia, ataxia and mild dementia since 11-12 yrs; MRI was normal up to 16 yrs when NBIA signs appeared; optic atrophy was seen at the same age. In both patients other NBIA were excluded and homozygosity for *C19orf12* mutation c.204_214del11 was detected. Patient 3, 36-year-old female of whom we have no clinical information, was found heterozygous for c.204_214del11 (allelic mutation is in search). The mutation was most common in the first NBIA4 cohort of 20 Polish families with founder effect [Hartig et al, 2011]. Our preliminary results point to c.204_214del11 spread in other Slavic populations.

P08.66
Altered brain development and neurodegeneration in Clp1 knockout zebrafish

V. R. C. Eggens*, J. L. Cazemier, P. R. Kasher, M. A. J. Weterman, F. Baas;*
Genome Analysis, Academic Medical Centre Amsterdam, Amsterdam, Netherlands.

Cleavage and polyadenylation factor I subunit (*Clp1*) is an important kinase in RNA metabolism. It is involved in processes as tRNA maturation and

mRNA 3'processing. We have created an ENU induced zebrafish mutant, harbouring a p.R44X nonsense mutation in the *Clp1* gene. *Clp1* knockout fish do not survive beyond 4 days post fertilisation (dpf), have a reduced head size and show an S-curved body. At 2dpf, *Clp1* knockout fish show reduced expression of midbrain marker otx2, and increased cell death in the brain.
We show that *Clp1* is an essential gene in brain development. In humans, various RNA processing genes have been associated with neurological diseases, such as the TSEN complex - which associates with *CLP1* - in pontocerebellar hypoplasia and the *SMN1* gene in spinal muscular atrophy. Our data supports the hypothesis that RNA processing plays a crucial role in neuronal development. The exact mechanism how disturbed RNA metabolism leads to neurological diseases is still unknown.

P08.67

A novel FTL mutation responsible for neuroferritinopathy with asymmetry of clinical features and brain anomalies

S. Moutton[1], *N. Houcinat*[1], *V. Planté-Bordeneuve*[2], *J. Trocello*[3], *V. Larue*[1], *D. Lacombe*[1,4], *B. Arveiler*[1,4], *C. Goizet*[1,4], *P. Fergelot*[1,4];
[1]*Service de génétique médicale - CHU de Bordeaux, Bordeaux, France,* [2]*Service de Neurologie, APHP, Hôpital Henri Mondor, Créteil, France,* [3]*Centre National de Référence de la Maladie de Wilson, service de Neurologie, APHP, hôpital Lariboisière, Paris, France,* [4]*Laboratoire „Maladies Rares: Génétique et Métabolisme", Université Bordeaux Segalen, Bordeaux, France.*

Neuroferritinopathy is a rare autosomal dominant neurodegenerative disease caused by mutations in *FTL* gene and which belongs to the group of Neurodegeneration with Brain Iron Accumulation (NBIA). Progressive iron and ferritin deposition in basal ganglia, substantia nigra, red nuclei and dentate nuclei is responsible for abnormal movements including chorea, dystonia and parkinsonism which represent the most common features of this disorder. To date, 7 mutations in *FTL* gene have been reported, 6 *frameshifts* in exon 4 and a missense in exon 3. Here we report a patient carrying a novel *FTL* mutation with original clinical and imaging features.
First manifestations occurred by 29 years by focal dystonia limited to right foot for 10 years. At 40, dystonia extended to left upper limb, neck and was associated with dysarthria. Ferritinemia was below the normal range (49 µg/L, norm within 80-250). Brain MRI revealed hypointensities on T2* weighted images, asymmetric in basal ganglia with left predominance and symmetric in motor rolandic cortex, substantia nigra, red and dentate nuclei. The previously unknown c.468dup mutation (p.Gly157TrpfsX24) was identified and appeared to be *de novo*. The mutation leads to C-terminus modification of the protein similar to recurrent c.460dup mutation, and alters E-helix structure affecting ferritin folding, assembly and stability.
Our report confirms involvement of *frameshift* mutations located in 3' coding region of *FTL* in pathophysiology of neuroferritinopathy. This observation highlights that this disorder can manifest with asymmetric clinical features and brain anomalies. Neuroimaging and especially T2* sequences is the most sensitive investigation for NBIA diagnosis.

Peripheral Neuropathy and Lymphedema Associated with Mental Deficiency - Homozygosity Mapping and Gene Indentification

A. Kurolap[1], *E. Dagan*[2], *R. Gershoni-Baruch*[3,1];
[1]*The Bruce and Ruth Rappaport School of Medicine, Technion, Haifa, Israel,* [2]*Dept of Nursing, Faculty of Welfare and Health Sciences, University of Haifa, Haifa, Israel,* [3]*Institute of Human Genetics, Rambam Health Care Campus, Haifa, Israel.*

Background: We present an extended consanguineous Muslim Israeli-Arab family, comprising of individuals exhibiting peripheral neuropathy, peripheral lymphedema or both. The neuropathic phenotype varies between family members in age of onset, spasticity and the existence of mental retardation. Both peripheral lymphedema and peripheral neuropathy segregate independently in affected family members as autosomal recessive traits. This study aimed to investigate the molecular basis for both disorders.
Methods: Homozygosity mapping using Illumina CytoSNP6000 and CytoSNP300K arrays was employed, followed by whole-exome sequencing in one patient.
Results: A 6K SNP array linkage analysis and whole-exome sequencing of a sibling affected with both disorders lead to the discovery of a missense mutation in the FLT4 gene (known to highly associate with lymphatic disruption). The mutation segregates as a homozygous trait within the family in line with the lymphedema phenotype, unrelated to the neuropathy phenotype. The whole-exome analysis revealed a missense mutation in the SPG7 gene (causing autosomal recessive spastic paraplegia) in the tested individual, but it did not segregate well within the family. A 300K SNP array narrowed the candidate areas to ten essentials. Areas with highest LOD scores or containing candidate genes were excluded using microsatellite markers. We are currently evaluating additional mutations identified via exome sequencing, in parallel to the linkage analysis described above.
Conclusion: While peripheral lymphedema in affected individuals was caused by a mutation in FLT4 gene, the gene causing peripheral neuropathy remains to be pinned down. Our findings reinforce the separation between both disorders within the extended family.

Niemann-Pick type C disease: Characterization of NPC1 mutations on mRNA and protein level

L. Dvorakova, *F. Majer, H. Vlaskova, G. Storkanova, L. Stolnaya, A. Louzecka, D. Musalkova, H. Jahnova, K. Peskova, M. Elleder, M. Hrebicek;*
Instit. of Inherited Metabolic Disorders, General University Hospital in Prague and First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.

Niemann-Pick type C disease (NPC, OMIM #257220, #607625) is a severe autosomal recessive neuro-visceral disorder characterized by progressive neurological deterioration and hepatosplenomegaly. It is associated with complex lysosomal storage of lipids, mainly of free cholesterol and glycolipids, and with mutations in one of two genes (NPC1, NPC2). We have found disease causing mutations in 38 NPC1 families and characterized molecular consequences of a subset of NPC1 mutations on mRNA and protein levels. Six genotypes (p.R1186H/S954L; p.R1186H/P1007A; p.R1186H/Y276H; p.P1007A/V950G; p. S954L/L176R; p.V664M/Arg404Glyfs*45) identified in 10 patients were inspected. We used PCR/RFLP followed by fragmentation analysis to determine the allelic expression ratio of the mutated alleles in cultured skin fibroblasts. NPC1 protein levels were assessed semi-quantitatively by Western blotting. Interestingly, the amount of immunoreactive NPC1 in p.V664M/Arg404Glyfs*45 cell line was comparable to the controls and RNA allelic transcript ratio was 50/50. In other samples RNA transcript ratios ranged from 22/78 to 30/70 and the amount of immunoreactive NPC1 protein was diminished but detectable. We have also analyzed NPC1 promoter region (up to 2 kb upstream from the start codon). We have found six common polymorphisms forming four probable haplotypes. We did not identify any rare variants, which could potentially affect regulation of NPC1 transcription.
In summary, the results show that the analyzed missense mutations allow residual protein synthesis and that the fibroblast cultures may be useful for testing of compounds stabilizing mutant NPC1 protein.

Recessive truncating NOTCH3 mutation in a case of severe, early-onset, progressive vascular leukoencephalopathy

T. Pippucci[1], *A. Maresca*[2], *G. Cenacchi*[2], *C. Tonon*[2], *V. Donadio*[2], *P. Magini*[1], *F. Palombo*[1], *V. Papa*[2], *R. Lodi*[2], *A. Parmeggiani*[2], *V. Carelli*[2], *M. Seri*[1];
[1]*U.O. Genetica Medica, Policlinico Sant'Orsola-Malpighi, Università di Bologna, Bologna, Italy,* [2]*Dipartimento di Scienze Biomediche e Neuromotorie, Università di Bologna, Bologna, Italy.*

We report on a 24 years-old male patient, born to consanguineous parents, presenting with infantile-onset, progressive neurodegeneration, small vessel disease and leukoencephalopathy. Brain MRI showed marked hyperintensity on T2-sequences of cerebral white matter (WM) with enlarged ventricles and diffuse cavitations, subcortical lacunar infarcts and disseminated microbleeds. Focal hyperintensities on T2-sequences were present in the asymptomatic parents, especially in the father.
Whole Exome Sequencing (WES) identified a homozygous c.C2742A NOTCH3 mutation, inherited from heterozygous parents. No other obvious mutation emerged from WES/mtDNA sequencing. The c.C2742A mutation introduced a p.C914X stop-codon leading to a prematurely truncated protein. Testing cDNA from muscle biopsies, we observed drastically reduced NOTCH3 expression in the proband and parents vs.controls ($p<.001$), and in the proband vs.parents ($p<.05$). Alterations of smooth muscle cells (SMC)

surrounding small arteries were visible in skin biopsies of the proband and parents, showing a multilayered basal lamina. An abnormal pattern of collagen staining, characterised by unpacked collagen wall, was evident in skin vessels of proband and parents, although it was less pronounced in the mother.
Heterozygous missense NOTCH3 mutations are known to underlie CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy), the most common heritable cause of cerebral arteriopathy. Notably, no granular osmiophilic material (GOM) deposition (a hallmark of CADASIL arterioles) was detected. Molecular mechanisms by which NOTCH3 mutations predispose to ischemic stroke are poorly understood. Here, we described a novel recessive NOTCH3-related leukoencephalopathy, linking reduced NOTCH3 expression and signaling to arterial SMC degeneration and ultimately to small vessel leukoencephalopathy.

Identification of a novel splice site mutation of STXBP1 in Ohtahara syndrome

L. Ortega-Moreno[1], *R. Guerrero-López*[1], *A. Verdú*[2], *G. Sánchez-Martín*[1], *O. García-Campos*[2], *B. G. Giráldez*[1], *J. M. Serratosa*[1];
[1]*Neurology Laboratory-Epilepsy Unit, Neurology Department, IIS- Fundación Jiménez Díaz and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain,* [2]*Neuropediatric Unit, Hospital Virgen de la Salud, Toledo, Spain.*

Ohtahara syndrome (OS, OMIM#308350, ORPHA1934) is early infantile epileptic encephalopathy characterized by tonic spasms and a continuos burst-suppression pattern resulting in intractable seizures and severe mental retardation. Brain malformations or metabolic disorders are often associated with this syndrome but some cases remain etiologically unexplained. Mutations in *ARX*, *CDKL5*, *SLC25A22* and *STXBP1* have been identified.
We report the case of a 19-months old infant which presented with tonic, focal clonic and oculogyric seizures in the first 15 days of life. An EEG performed at the age of 45 days showed a burst-suppression pattern suggestive of Otahara syndrome. Physical examination did not reveal any specific dysmorphic features. Neuroimaging and extensive screening for inborn metabolic errors and congenital infections were uninformative. At 5 months spasms appeared. Treatment with vigabatrin and corticosteroids was effective but refractory complex partial seizures appeared. The infant has a severe psychomotor delay.
We found a novel inherited heterozygous mutation (c.1249+2T>C, G417AfsX7) in *STXBP1*, a gene that codes for syntaxin binding protein 1 involved in synaptic vesicle exocytosis. This mutation is localized in a donor splice site and eliminates exon 14 producing a truncated protein.
Loss of domain III-b and part of domain II due to this mutation could affect Rab binding and consenquently exocytosis process.

Evaluation of variants in Parkin, PINK1, DJ1 and SCNA genes in early-onset Parkinson's disease patients of Turkish population

U. Egeli[1], *S. Ozbek*[2], *G. Tezcan*[1], *G. Cecener*[1], *B. Tunca*[1], *E. Demirdogen*[1], *S. Ak*[1];
[1]*Department of Medical Biology, Medical Faculty, Uludag University, Bursa, Turkey,* [2]*Department of Neurology, Medical Faculty, Uludag University, Bursa, Turkey, Bursa, Turkey.*

Parkinson's disease (PD) causes by the interaction of genetic and environmental factors. Recent reports showed that, variations in PARK loci genes (*Parkin, PINK1, DJ-1* and *SNCA*) cause inherited forms of typical PD in different populations. However, the knowledge about the frequency of these alterations in Turkish population is very limited. In current study, we aimed to evaluate the phenotype and frequencies of variations in these genes in Turkish early-onset PD patients.
All coding regions and exon-intron boundaries of the *Parkin, PINK1, DJ-1* and *SNCA* genes were screened by Heteroduplex analysis (HDA) followed by direct sequencing of detected variants in 27 early-onset PD patients.
Alterations were determined in 12 (44,4%) patients; 1 patient had 2 different alteration. Alterations were found in *Parkin* (n=6; IVS-35G>A and n=1; V379L) for 7 patients, in *PINK1*(IVS1-7A>G) for 5 patients and in *DJ1*(n=1; IVS3+40T>G and n=1; R98E) for 2 patients. According to Ensemble Genome Browser, IVS-35G>A in *Parkin,* IVS1-7A>G in *PINK1* and IVS3+40T>G in *DJ1* were novel alterations. There was no significant correlation between having PARK loci gene alterations and family story (P = 0,452).
Despite current data is preliminary findings, we identified three novel alterations in *Parkin, PINK1* and *DJ1*genes in PD patients of our population. Although, increasing the number of cases is required to clarify clinical significancy, we suggest that these informations may be helpful in predicting the prognosis of Turkish PD patients.

Analysis of *SNCA* (alpha-synuclein) mutations in Slovak Parkinson disease patients

C. Bognar[1], *M. Baldovic*[1], *A. Zatkova*[2], *L. Kadasi*[1,2];
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [2]*Institute of Molecular Physiology and Genetics,Slovak Academy of Sciences, Bratislava, Slovakia.*

Parkinson disease (PD) is a chronic neurodegenerative movement disorder characterized by selective loss of nigrostriatal dopaminergic neurons and formation of Lewy bodies. Clinical manifestations include motor impairments involving tremor, bradykinesia, postural instability and rigidity. PD is generally considered to be the result of the interaction between genetic and environmental factors. Mutations responsible for the recessive early-onset PD (EOPD) were identified in *parkin* (*PARK2*), *DJ-1* (*PARK7*) and *PTEN-induced kinase 1* (*PINK1*), while mutations within *Leucine-rich repeat kinase 2* (*LRRK2*) and *α-synuclein* (*SNCA*) are associated with autosomal dominant, late onset form of PD. To detect the most common mutations (A30P, E46K, A53T) in exons 2, 3 of the *SNCA* gene, we sequenced in both direction 160 unrelated Slovakian patients with familial or sporadic PD, including early and late onset patients. However, none of these mutations was identified in our cohort. We have found three novel exonic polymorphisms (SNCA-23T>C; c.467T>C, p.V15V; c.518C>A, p.K32K), one intronic polymorphism (c.121+11C>T, IVS3+11C>T, rs35135226) in exon 2 of *SNCA* gene. But in the exon 3 we did not observe any variation after sequencing.
However, we could not completely exclude the possibility that the patients carry other mutations or rearrangements within SNCA gene. In the follow up of this study also a gene dosage studies, especially of *SNCA* and *PARK2* genes have to be considered, in order to uncover possible larger genomic deletions/duplications.
This study was supported by GUK/494/2013.

A rapid and simple PCR-RFLP test for the diagnosis of PARK8 form of Parkinson disease in the Algerian population

T. Hamadouche[1], *S. Belarbi*[2], *N. Hecham*[2], *S. Lesage*[3], *A. Brice*[3], *M. Tazir*[2], *T. Benhassine*[4];
[1]*Molecular Biology Laboratory, Faculty of Sciences, UMBB, Boumerdes, Algeria,* [2]*Department of Neurology, CHU Mustapha Bacha, Algiers, Algeria,* [3]*INSERM UMR_S975, CRICM, Hôpital Pitié-Salpêtrière, Paris, France,* [4]*Cellular and Molecular Biology Laboratory, Faculty of Biological Sciences, USTHB, Algiers, Algeria.*

PARK8 form of Parkinson's disease is a common disorder in Algeria (40% of familial or sporadic cases) because of the high prevalence of the c.6055G>A (p.Gly2019Ser) mutation in the LRRK2 gene. The aim of our work was to highlight the occurrence of this alteration by a simple, fast and accurate test, thus signing a diagnosis of PARK8 Parkinson's disease. Our screening strategy consisted of a targeted amplification of exon 41 of LRRK2 by a PCR-RSI approach, followed by an enzymatic digestion using restriction endonuclease AluI, with the goal of individualizing precisely and unambiguously all possible genotypic statuses: healthy homozygous and affected heterozygous/homozygous. The choice of primers allowing amplification and introducing a mismatch site downstream of the coding nucleotide c.6055 was conducted by bioinformatic analysis. Optimization of PCR conditions helped ensure the success of the amplification and the subsequent AluI digestion. Genotypes of individual controls (healthy c.6055G/G, affected c.6055G/A and affected c.6055A/A) were clearly individualized on the basis of restriction profiles obtained. The availability of this test, also avoiding the use of sequencing, provides a powerful approach for the diagnosis of the common form of Parkinson's disease PARK8, allowing to recognize the status of individuals and offering the opportunity to make a differential diagnosis among the great genetic heterogeneity that characterizes this disease. The power of our diagnostic test of PARK8 allows us to screen at first instance this form of the disease and suggests that it may be used for routine screening of the disease in the Algerian population.

Analysis of Parkinson's disease brain DNA reveals the novel H50Q alpha-synuclein (*SNCA*) mutation which affects copper co-ordination

C. Proukakis[1], *C. Dudzik*[2], *C. Pegasiou*[1], *M. Katsianou*[1], *M. Shoaee*[1], *T. Brier*[1], *A. Hummel*[1], *G. Millhauser*[2], *J. M. Cooper*[1], *H. Houlden*[1], *A. H. V. Schapira*[1];
[1]*UCL Institute of Neurology, London, United Kingdom,* [2]*University of California Santa Cruz, Santa Cruz, CA, United States.*

Misfolding and aggregation of alpha-synuclein (SNCA) is crucial to the pathogenesis of Parkinson's disease (PD), yet mutations in the gene are very rare, with only three missense mutations and occasional copy number variants described. The possibility of sporadic cases being due to somatic mutations leading to mosaicism, which might be undetectable in peripheral lymphocyte DNA which is usually analysed, has not been formally investigated.
We screened *SNCA* coding exons in DNA from at least one brain region from 457 cases. Sanger sequencing in five samples revealed a novel change (c.150T>G, p.H50Q) in the cerebellum and substantia nigra of one apparently sporadic, late onset, typical PD case. As no relatives or other DNA sources were available, indirect evidence of mosaicism by analysis of phase in relation to a nearby polymorphism was sought, but none was found. Subcloning of PCR products revealed 14/30 colonies with the mutation. Further samples were analysed using High Resolution Melting (HRM) analysis, which has higher sensitivity than sequencing for low level mosaicism.
Serial dilution confirmed HRM could detect 1-5% level of H50Q/ A53T. No evidence of somatic mutations was seen, although rare synonymous SNPs were detected. The conservation of H50, the absence of the mutation in controls, and bioinformatic predictions, suggested pathogenicity. As H50 participates in SNCA binding of Cu(II), recombinant wild-type and H50Q proteins were compared using electron paramagnetic resonance, and altered copper co-ordination was observed. Stably transfected neuroblastoma cell lines were established for further studies. H50Q appears to be a likely pathogenic rare germline variant.

Analysis of *SNCA* mRNA splicing variants in human post-mortem tissue through Real Time PCR

L. F. Cardo*, L. d. Mena, E. Coto, M. Díaz, V. Álvarez;*
Hospital Universitario Central de Asturias, Oviedo, Spain.

Parkinson's disease (PD) is the second most common neurodegenerative disorder affecting 1-2% of people over 60 years-old. Abnormal expression and post-translational modification of *SNCA* gene have been associated with both familial and sporadic PD. The *SNCA* gene has four mRNA transcripts: SNCA-140 (full-length isoform), SNCA-126 (lacking exon 3), SNCA-112 (lakking exon 5) and SNCA-98 (lacking exons 3 and 5). Recently, it has been proposed that a *SNCA* polymorphism in the 3'UTR (rs356165) could play a role in the risk of PD through its association with differential mRNA expression.
Our aim was to determine the level of the four α-syn isoforms through Real time PCR in human post-mortem brains from 9 PD patients and 6 controls. We obtained tissue samples from affected and non-affected brain areas, and compared the α-syn levels between rs356165 genotypes (5AA, 7AG, 3GG).
We analyzed a total of 43 samples from *sustantia nigra* (SN), cerebellum (CB) and occipital cortex (OC). We did not find significant differences in the levels of *SNCA* transcripts; patients vs. controls in the three regions. The minor transcripts (SNCA-112 and 98) were increased in the SN in PD-affected brains, without difference between the rs356165 genotypes. The level of the SNCA-140 transcript was increased in OC.
In conclusion, we found different expression levels of the *SNCA* transcripts in different brain regions, but without difference between patients and controls. However with our sample we could not support the influence of rs356165 in *SNCA* mRNA levels.

The study of a role of monoamine metabolizing enzyme genes in Parkinson's disease development and neuropsychological abnormalities in Parkinson's disease patients

G. Akhmadeeva[1], *I. Khidiyatova*[2], *I. Gilyzova*[3], *A. Baytimerov*[1], *R. Magzhanov*[1], *E. Khusnutdinova*[3];
[1]*Bashkir State Medical University, Ufa, Russian Federation,* [2]*1Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [3]*Institute of Biochemistry and Genetics, Ufa, Russian Federation.*

The purpose of this investigation was to search for genetic factors in the development of Parkinson's disease (PD) as a whole and neuropsychological impairment in Parkinson's disease patients. The analysis of association of PD with polymorphic variants of monoamine metabolism genes - TH, DAT1, COMT, MAO-B, TPH1,DRD1, DRD2, DRD3, DRD4 , 5-HTT, HTR2A, - was performed using DNA collection of PD patients (560) and controls (670). DNA samples included three ethnic groups living in Bashkortostan Republic (BR) - Russians, Tatars and Bashkirs. In all three ethnic groups PD was associated with the polymorphic variants of the DRD4 gene: allele * 7 of the polymorphic variant 48 bp in VNTR-locus (in exon 3) was revealed to be the risk marker for PD development (p = 0,02; OR = 2,0). In Tatars the genotype *H/*H (p = 0,0006; OR = 2,3) and allele *H of polymorphic locus Val108Met of the COMT gene, genotype * C/* C (p = 0,002; OR = 1,7) and allele *C (p = 0,02; OR = 1,34) of rs1800532 of the TPH1gene and allele *12 of the polymorphic locus STin2 (p = 0,04; OR = 1,3) of the gene 5-HTT were markers of the increased risk for PD development. In Bashkirs allele *C of rs6280 of DRD3 gene (p = 0,02; OR = 1,85) was the risk marker for PD. Study of neuropsychological impairments found influence of polymorphic locus Val108Met of the COMT gene on the development of dementia in PD patients.

PEHO syndrome (Progressive encephalopathy with Edema, Hypsarrhythmia and Optic atrophy; MIM 260565) is an autosomal recessive inherited progressive infantile encephalopathy. The main features include hypotonia, infantile spasms and/or hypsarrhythmia, psychomotor retardation, absence or early loss of visual fixation, edema of the face and limbs, and typical dysmorphic features. Brain atrophy is progressive and most prominent in the cerebellum. Imaging findings suggest the presence of two subtypes of the PEHO syndrome, cortical atrophy and loss of myelin being more pronounced in type 2. In a heterogenous group of PEHO-like patients some but not all of PEHO features exist. Our aim is to characterize the molecular basis of PEHO.
Using SNP genotyping and homozygosity mapping we identified in Finnish patients with PEHO type 1 a missense mutation in a gene not previously associated with human disease. The encoded protein is strongly expressed in neural progenitor and migrating premature granular cells and its tissue expression pattern is compatible with the neuropathological findings in PEHO type 1 patients. The detected mutation affects stability and coregulatory abilities of "PEHO1". Moreover, knocking down "PEHO1" expression by RNAi in ex vivo cerebellar cultures resulted in disturbed granule cell migration consistent with previous observations of ectopic granule neurons in PEHO patient cerebellum. To identify the gene underlying PEHO type 2 we are currently analyzing exome data on two siblings and two clinically similar unrelated Finnish patients.

Pontocerebellar hypoplasia (PCH) associated with spinal cord anterior horn cell loss has been named PCH type 1 by Barth in 1993. PCH1 is an autosomal recessive disease characterized by an early- often antenatal -onset, with arthrogryposis and limited survival. Recently mutations of the EXOSC3 gene were reported in classical as well as in mildly affected PCH1 patients.
We report 4 patients affected with cerebellar and anterior horn cell degeneration and EXOSC3 mutations. Two sibs were affected from birth and presented with hypotonia, proximal muscular deficiency, respiratory and swallowing difficulties. Electromyogram showed neurogenic changes. PCH was evident on the MRI performed at 4 months in the older child but no change was noted at day 4 in the younger. Death occurred at, respectively, 11 months and 15 days. Neuropathology showed a severe atrophy of the pons, cerebellum and anterior horn.
Patient 3 presented with a progressive disease which began at 3 months. He had severe progressive hypotonia, proximal limb weakness and amyotrophy, nystagmus, spasticity, and increased tendon reflexes. He developed respiratory failure and died at 3 years.
Patient 4 had a non progressive psychomotor retardation with PCH on MRI and he was able to sit in the first years of life. At age 10, he started to decline and presented with spastic paraplegia and proximal weakness, nystagmus and respiratory and swallowing difficulties.
The gene EXOSC3 is a major PCH1 gene but is responsible for others, milder, phenotypes of cerebellar and anterior horn cell degeneration with cerebellar atrophy without brainstem involvement.

Background: Spinocerebellar ataxia type 5 is a very rare form of autosomal dominant cerebellar ataxia that is caused by mutations in SPTBN2. Mutations in SPTBN2 affect the stability of EAAT4, a glutamate transporter specifically expressed in Purkinje cells, which also negatively regulates the inhibition of GABA release. We investigated the functional consequences of SPTBN2 mutations on glutamate and GABA metabolism in 3 SCA5 patients. Methods: The levels of glutamate, glutamine and free versus total GABA were measured in patients' CSF by LC-MS/MS. In vivo 1H-NMR spectroscopy (MRS) was performed at 3T using a dedicated sequence to obtain GABA-edited spectra. The regional concentrations of N-acetyl-aspartate (NAA), GABA and glutamate-glutamine (Glx) were determined in the primary sensory-motor cortex, the striatum and the cerebellum of SCA5 patients. We also assess peripheral glutamate metabolism by measuring glutamate uptake in patients' fibroblasts. Results: The CSF levels of glutamate, glutamine and GABA in SCA5 patients were comparable to diseased controls. MRS showed normal metabolic profile in the basal ganglia and motor cortex of SCA5 patients. In the cerebellum, the levels of GABA and Glx were markedly reduced compared to controls, even when correcting for neuronal loss using NAA. The ratio of GABA/Glx was also decreased in patients' cerebellum, indicating altered GABA release. Glutamate uptake in patients' fibroblasts was normal emphasizing that glutamate metabolism is only impaired in the brain. Conclusion: We have identified a selective alteration of glutamate and GABA homeostasis in the cerebellum of SCA5 patients.

Spinal muscular atrophy with progressive myoclonic epilepsy (SMAPME, OMIM#159950) is a rare childhood syndrome characterized by progressive myoclonic epilepsy and proximal weakness. A homozygous mutation (c.125C>T, T42M) in *ASAH-1*, a gene encoding acid ceramidase, has been recently indentified in three families with SMAPME and a homogeneous clinical picture. However, previous reports depicted a heterogeneous syndrome with respect to age at onset, associated neurological symptoms and prognosis.
Here we describe a new case of SMAPME harboring the homozygous c.125C>T mutation and compare it with those previously reported.
The patient is a 12-years-old girl born to unrelated healthy Spanish parents. Despite her early developmental milestones she walked with an unsteady gait. Progressive, predominantly proximal, muscle weakness was evident from the age of 5 years. Muscle biopsy and EMG showed evidence of a chronic denervation process. At age 7 years she began presenting frequent absences and myoclonic jerks of the upper limbs. An EEG showed frequent 3-4 Hz generalized discharges of polyspikes-slow waves. Mild cognitive decline, and distal tremor appeared later. Other diagnostic procedures ruled out common lysosomal storage disorders and mitochondrial disease. Sequencing of *ASAH-1* revealed a homozygous mutation (c.125C>T, T42M) due to paternal uniparental disomy.
Our patient shows a clinical picture that is almost identical to that described in other patients harboring this mutation. Thus SMAPME associated to the homozygous c.125C>T mutation represents an apparently clinically homogenous disorder.
Further cases are needed to confirm this clear apparently straight phenotype-genotype correlation.

Paradoxical somatic genetics of neurodegeneration: spotlight on post-zygotic chromosome instability in the ataxia telangiectasia brain and implications for neurodegenerative diseases

Y. B. Yurov[1,2,3], *S. G. Vorsanova*[1,2,3], *A. D. Kolotii*[1,2], *I. A. Demidova*[1,2,3], *T. Liehr*[4], *I. Y. Iourov*[1,2];
[1]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [2]*Institute of Paediatrics and Children Surgery, Ministry of Health, Moscow, Russian Federation,* [3]*Moscow State University of Psychology and Education, Moscow, Russian Federation,* [4]*Institute of Human Genetics, Jena, Germany.*

Ataxia-telangiectasia (AT) is a chromosome instability (CIN) disease caused by ATM mutations. Probably, the most striking AT feature is a progressive neurodegeneration limited to the cerebellum. To explain this, we hypothesized that progressive neuronal death is driven by post-zygotic chromosomal (genomic) instability in the AT cerebellum. Experimental testing of this hypothesis using brain autopsy specimens showed dramatically increased level of CIN in the cerebellum. However, molecular cytogenetic analysis revealed a paradoxical feature of neurodegeneration in AT. Firstly, global aneuploidization affecting 20-50% of brain cells (20% - neurons; 80% - non-neuronal cells) in the brain unaffects basic cognitive and mental functions. Secondly, the role of CIN affecting chromosomes 7 and 14 in the degenerating cerebellum is unclear. Thirdly, pathological CIN rates have not accelerated neurodegeneration, but have been associated with increased lifespan. To explain the paradox, we hypothesized that neurodegeneration in the cerebellum can be associated with (i) activation of adult neurogenesis, (ii) migration of undifferentiated blood stem cells into the affected brain areas, and (iii) activation and proliferation of microglia (phagocyte system of the brain). Thus, the increase of numbers of glial and neuronal cells with CIN in the AT cerebellum is, probably, a result of endogenous neuroprotective processes. Finally and paradoxicaly, propagation of CIN in the brain is a sign of natural neuroprotection applicable to neurodegenerative diseases, as a whole. Supported by in part by BMBF/DLR (RUS09/006), the Grant of the President of the Russian Federation MD-4401.2013.7 and RFBR 12-04-00215-a.

Spastic paraplegia 11 (SPG11), the most frequent (21%) clinico-genetic entity of autosomal recessive spastic paraplegia, is essentially characterized by the degeneration of the pyramidal tract, thinning of the corpus callosum (TCC) and white matter abnormalities (WMA) at brain MRI, leading to spasticity in lower limbs, mental impairment and peripheral neuropathy in patients. The disease is predominantly associated with loss of function mutations in the *SPG11* gene, coding for Spatacsin. We report the first neuropathological analysis of a 27 years-old woman presenting with a severe progressive disability and mental deterioration, TCC, periventricular WMA, marked frontal and parietal cortical, cerebellar and medullar atrophy. Mutational analysis revealed two heterozygous stop mutations in SPG11 gene. The mutations in the Spatacsin gene cause a wide spectrum of clinical and pathological features. We show that the neuropathological profile overlaps with amyotrophic lateral sclerosis (ALS).

Adaptor protein complex-4 (AP4) is a component of intracellular transportation of proteins, which is thought to have a unique role in neurons. Recently, mutations affecting all four subunits of AP4 (*AP4M1*, *AP4E1*, *AP4S1*, and *AP4B1*) have been found to cause similar autosomal recessive phenotype consisting of tetraplegic cerebral palsy and mental retardation, which was named as AP4 deficiency syndrome. Using homozygosity mapping followed by whole-exome sequencing, we identified two novel homozygous mutations in *AP4M1* and a homozygous deletion in *AP4B1* in three pairs of siblings from Turkey. Spastic quadriplegia, microcephaly, severe mental retardation, limited or absent speech, and stereotypic laughter were common findings in our patients. All patients also had similar facial features consisting of bitemporal narrowing, bulbous nose with broad nasal ridge, short philtrum, and hypotonic face which were not described in patients with *AP4M1* and *AP4B1* mutations previously. The patients presented here and previously with *AP4M1*, *AP4B1*, and *AP4E1* mutations shared brain abnormalities including asymmetrical ventriculomegaly, thin splenium of the corpus callosum, and reduced white matter volume. The patients presented here also had hippocampal globoid formation and thin hippocampus. In conclusion, disorders due to mutations in AP4 complex have similar neurological, facial, and cranial imaging findings. There is no genotype-phenotype correlation. Thus, these four genes encoding AP4 subunits should be screened in patients with autosomal recessive spastic quadriplegic cerebral palsy, severe mental retardation, and stereotypic laughter, especially with the described facial and cranial MRI features.

Introduction

Spastic paraplegia 7 (SPG7) is an autosomal recessive form of Hereditary Spastic Paraplegia (HSP) caused by mutations in the SPG7 gene, which encodes paraplegin, a member of the AAA family of ATPases, located at the inner mitochondrial membrane. Paraplegin is involved in the processing of mitochondrial proteins. Respiratory chain dysfunction has been reported in muscle in SPG7 patients, but its molecular aetiology and pathogenic role remains unknown. We report a novel SPG7 mutation in two Norwegian families presenting with a phenotype consistent with mitochondrial disease, and study the disorder`s molecular pathogenesis.

Material and methods

Four patients from two Norwegian families with a phenotype of progressive external ophthalmoplegia (PEO) and spastic paraplegia were examined clinically. Muscle histology and molecular mitochondrial DNA studies were performed in one of the index patients, an additional SPG7 patient from an unrelated family and ten controls.

Results

We found a novel SPG7 missense mutation, c.2102A>C, p.H701P, which was homozygous in the first family and compound heterozygous in trans with the known pathogenic mutation c.1454_1462del in the second family. Molecular studies showed multiple mitochondrial DNA (mtDNA) deletions and deficiency of respiratory complexes I, III and IV in skeletal muscle.

Discussion

We report a novel SPG7 mutation causing a complex HSP phenotype with PEO, a common mitochondrial disease phenotype. Moreover, our findings reveal novel aspects of the molecular pathogenesis of SPG7. We show that SPG7 mutations lead to respiratory dysfunction by causing secondary mtDNA damage and therefore link paraplegin to the homeostasis of the mitochondrial genome.

Microrearrangements in recessive type of hereditary spastic paraplegia - SPG 11 in a group of Polish patients. Molecular findings and clinical presentation.

W. Krysa[1], *M. Rajkiewicz*[1], *E. Elert-Dobkowska*[1], *I. Stepniak*[1], *W. Lojkowska*[2], *M. Rakowicz*[3], *J. Antczak*[3], *J. Zaremba*[1], *M. Schinwelski*[4], *A. Sulek*[1];

[1]*Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland,* [2]*Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland,* [3]*Department of Neurophysiology, Institute of Psychiatry and Neurology, Warsaw, Poland,* [4]*Department of Neurology, St Adalbert Hospital, Gdansk, Poland.*

There are about 27 types of autosomal recessive spastic paraplegias (AR-HSP), with the SPG11 appearing the most frequent in the European population. It is caused by mutations in the SPG11 gene, coding the spatacsin. Clinically SPG11 is characterized by early age at onset and manifests mainly as complicated HSP with mental retardation including also neuroradiological hallmark - thin corpus callosum.

The group of 116 patients, 39 familial cases with excluded autosomal dominant inheritance pattern and 77 isolated cases, were screened for SPG11 mutations by MLPA analysis.

The results of MLPA screening revealed 6 different microrearrangements in 5 families, two of them have unequivocal molecular verification of SPG11 so far. In the first family homozygotic deletion ranging from 31 to 34 exon was identified, and in the second one heterozygous variant of 31 to 34 and single 37 exon deletion were detected. Furthermore in three probands intragenic deletions in only one allele of SPG11 gene were found: ranging from 9 to 11 and single exon deletions involving exon 2 and 29. To provide molecular verification of spastic paraplegia type 11 in above mentioned three cases, direct sequencing is planned.

The phenotype of affected subjects from studied families corresponds to the complicated form of spastic paraplegia with thin corpus callosum, white matter abnormalities and polyneuropahy as well as mild to moderate cognitive impairment.

Although MLPA technique is reliable screening tool for recessive SPG11 the future analysis of SPG11 point mutations will permit more efficiently determine molecular status in our group of patients.

P08.87

Molecular mechanism of microrearrangements in the most prevalent hereditary spastic paraplegia (HSP) - SPG4.

E. Elert-Dobkowska[1], C. Beetz[2], W. Krysa[1], M. Rajkiewicz[1], I. Stepniak[1], W. Lojkowska[3], M. Rakowicz[4], J. Zaremba[1], A. Sulek[1];
[1]Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland, [2]Department of Clinical Chemistry and Laboratory Medicine, Jena University Hospital, Jena, Germany, [3]Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland, [4]Department of Neurophysiology, Institute of Psychiatry and Neurology, Warsaw, Poland.

Spastic paraplegia type 4 (SPG4) is the most frequent HSP genetic type and accounts for up to 40% of families with pure or complicated hereditary spastic paraplegia. Mutations in the SPG4 corresponding gene SPAST are scattered along its coding region and include all types of DNA modifications: missense, nonsense, splice site as well as microrearrangements - deletions or duplications.
To detect the deletion/duplication in the SPAST gene, the autosomal dominant spastic paraplegia MLPA (Kit P-165-B1) containing probes for all SPAST gene exons was performed for 196 patients. MLPA data were analyzed using the GeneMarker Software v.1.90 (SoftGenetics) after electrophoresis of the PCR products on ABI 3130 Genetic Analyzer with ROX500 internal size standard.
To define the breakpoints and the range of identified in MLPA analysis microrearrangements (7 deletions and 1 duplication) long-range PCR was performed. The used sets of primers were specific to the breakpoints regions of deletions and duplication. Selected LR-PCR products were directly sequenced with BigDye Terminator v.3.1.
Among 8 studied SPG4 families, 6 fusion sequences in breakpoints regions for deletions of exons: 1-9, 4-7, 5-7, 8, and 10-12 and exons 14-15 duplication were detected. Sequencing analysis revealed the microhomologic sequences flanking the microrearrangements. The presence of various, directly orientated short consensus regions, identified in 6 studied families affected with SPG4, may suggest the possible mechanism of the mutation occurrence known as non allelic homologous recombination-NAHR.
The SPAST gene architecture including distribution and frequency of repetitive elements may facilitate genomic rearrangements as a causative molecular defects of SPG4.

SCA36 molecular analysis in patients with spinocerebellar ataxia

***D. Di Bella**, E. Sarto, C. Mariotti, L. Nanetti, C. Gellera, S. Magri, F. Taroni;*
Unit of Genetics of Neurodegenerative and Metabolic Diseases, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy.

Autosomal dominant spinocerebellar ataxias (SCA) are a heterogeneous group of neurological disorders characterized by cerebellar dysfunction mostly due to Purkinje cell degeneration. Recently, a novel form of spinocerebellar ataxia (SCA36) with motor neuron involvement was described in Japanese and Galician patients. It is caused by a GGCCTG repeat expansion in intron 1 of NOP56 gene. This gene encodes a component of the ribonucleoprotein complex and plays a role in transcription and splicing. We screened a large cohort of Italian unrelated patients with familiar (n=142) or sporadic/unknown (n=254) spinocerebellar ataxia for GGCCTG repeat expansion in NOP56 intron 1. All patients were negative for the common SCA1 and SCA2 mutations. The NOP56 repeat was analysed by fluorescent triplet repeat-primed PCR analysis. NOP56 expansion was detected in 5 probands from 4 different unrelated Italian families with dominant ataxia and also in one sporadic patient and, subsequently, in his affected brother. Interestingly, all probands originated from a relatively small area in central Italy, suggesting a common ancestor and a founder effect for this mutation. In conclusion, SCA36 accounts for approximately 3% of Italian autosomal dominant SCA families negative for the common SCA mutations. Clinically, mutated patients presented with slow progressive gait ataxia with late onset (40-60 yrs) with pyramidal signs, eye movement abnormalities and, in some cases, motor neuron involvement (tongue atrophy). Neuroimaging revealed prominent cerebellar atrophy affecting the vermis, with minor involvement of cerebellar hemispheres and brainstem in later stages [Supported in part by Telethon-Italia grant GGP09301].

P08.89

Multiple genetic testing of 10 types of autosomal dominant spinocerebellar ataxias by multiplex PCR and repeat-primed PCR

***S. Sawai**[1,2], T. Ishige[1,2], S. Itoga[1,2], K. Sato[1,2], E. Utsuno[2], M. Beppu[1,2], M. Nishimura[1,2], K. Matsushita[1,2], S. Kuwabara[3], F. Nomura[1,2];*
[1]Department of Molecular Diagnosis, Graduate School of Medicine, Chiba University, Chiba, Japan, [2]Division of Laboratory Medicine and Clinical Genetics, Chiba University Hospital, Chiba, Japan, [3]Department of Neurology, Graduate School of Medicine, Chiba University, Chiba, Japan.

The autosomal dominant spinocerebellar ataxias (ADCAs) are clinically and genetically heterogeneous, and over 30 types of causative mutations have been reported. Although some clinical and radiological features may help in their differential diagnosis, genetic testing is required for a definitive diagnosis and adequate genetic counseling. Since genetic testing of ADCAs is widely conducted in medical genetic laboratories around the world, simple procedures are warranted. Also, the different types of ADCAs have a considerable ethnic variation in prevalence. In this study, we established simple and multiple genetic testing for the causative mutations in 10 types of ADCAs whose prevalences are higher than the other types in Japan; they include SCA1-3, SCA6-8, SCA12, SCA17, SCA31 and DRPLA. To evaluate the mutations in a concurrent manner, we designed and optimized the procedures by using multiplex PCR, repeat-primed PCR methods and DNA fragment analysis. The amplifications of 10 loci were performed with the same thermal cycle protocol. The sizes of the nucleotide repeats were determined by DNA fragment analyses, the results of which were confirmed by DNA direct sequencing. A total of 168 DNA samples obtained from patients with clinically suspected ADCAs were analyzed. Written informed consent with appropriate genetic counseling was obtained from each patient. Genetic tests were positive in 84 cases (50%). SCA3 was most common (29% of the positive cases), followed by SCA6 (26%), SCA31 (19%) and DRPLA (12%). This multiple genetic testing of ADCAs may be valuable as a routine method in medical genetic laboratories.

SCA28 is an autosomal dominant ataxia associated with AFG3L2 gene mutations. We performed a whole genome expression profiling using lymphoblastoid cell lines (LCLs) from four SCA28 patients, and six unrelated healthy controls matched for sex and age. We found 66 genes whose expression was statistically different, 35 of which were up-regulated (Fold Change - FC = 2.5-10) and 31 down-regulated (FC = 0.1-0.3). The differentially expressed genes were clustered in five functional categories: (1) regulation of cell proliferation; (2) regulation of programmed cell death; (3) response to oxidative stress; (4) cell adhesion, and (5) chemical homeostasis. To validate these data, we performed functional experiments that proved an impaired SCA28 LCLs growth compared to controls ($p < 0.005$), an increased number of cells in the G0/G1 phase ($p < 0.001$), and an increased mortality of patients cells due to apoptosis ($p < 0.05$). We also showed that respiratory chain activity and reactive oxygen species levels were not altered, although lipid peroxidation in SCA28 LCLs was increased in basal conditions ($p < 0.05$). We did not detect mitochondrial DNA large deletions. An increase of TFAM, a crucial protein for mtDNA maintenance, and a decrease of DRP1, a key regulator of mitochondrial fission, suggested an alteration of the mitochondrial network remodeling system.
In conclusion, whole genome expression profiling in SCA28 LCLs allowed

the identification of several altered pathways that may be related to the disease.

Background: Spinocerebellar ataxias (SCAs) belong to the group of polyglutamine repeat disorders and lead primarily to neurodegeneration in the cerebellum and the pons. We recently demonstrated that even the most sensitive clinical scores would require large number of patients to assess any therapeutic benefit. Therefore, the identification of robust biomarkers is critical to assess disease progression for therapeutic development. Methods: 1H-NMR spectroscopy was performed at 3T to determine the neurochemical profile of 24 metabolite concentrations in the vermis and pons of a unique cohort of SCA1 (N=8), SCA2 (N=11), SCA3 (N=17) and SCA7 (N=10), as well as in healthy controls with similar median age (N=24). Results/Interpretation: Compared to controls, SCAs patients displayed a significant decrease of neuronal metabolites, N-acetylaspartate and glutamate, but increased glia-related metabolites, glutamine and myoinositol. The neuronal loss in both affected regions was associated with a significant increase in creatine and phosphocreatine suggesting compensatory energetic mechanisms. Of note, there was a strong negative correlation between the ataxia rating scores (SARA) and N-acetylaspartate levels in the pons of SCA2-3-7 patients. In the vermis, myoinositol and creatine levels were also significantly correlated with the SARA scores of SCA2 and SCA3 patients. Principal component analyses showed that the metabolic profile of SCA1-2-3 tend to differ from SCA7, which is consistent with previous observation of slower disease progression in SCA7. The correlation matrix also confirmed that the most robust biomarkers of SCAs are N-acetylaspartate, glutamate, myoinositol and total creatine, which supports preliminary data from a pilot study conducted in SCA1.

To date, 37 different dominantly inherited spinocerebellar ataxia types are known. Currently, genetic testing of the most frequent mutations via routine DNA diagnostic screening leaves 30% of the cases genetically undiagnosed. Here, we used a combination of shared haplotype analysis with exome sequencing to identify the disease-causing variants in 10 small Dutch families with hereditary cerebellar ataxia. We set out to pinpoint regions that have the highest probability to contain disease-causing variants by searching for shared haplotypes following genotyping affected family members on Illumina 320k cytoSNP-12-arrays. In parallel, exome sequencing was performed in 2 most distantly related affected individuals of each family. Next, we used Ingenuity software for the data-analysis and filtered subsequently for: 1. variants shared by both affected individuals, 2. novel variants, i.e. absent in dbSNP, the Exome Variant Database and GoNL, a Dutch control database containing 500 exomes, 3. variants present in genes that are located in shared haplotype regions of at least 10 Mb, 4. variants in genes that are part of an in silico generated ataxia gene-network (based on co-expression-data of known ataxia genes; unpublished data) Finally, all selected variants were validated by Sanger sequencing and cosegregation analysis.
This strategic analysis leads to relatively short lists of unique variants per family. Although the validation process is not completely finished for all families, our preliminary data strongly suggest we indeed identified novel candidate ataxia genes and that the majority of these are involved in modulating synaptic transmission.

Autosomal recessive spinocerebellar ataxia 7 (SCAR7) is caused by variants in *TPP1*, the gene involved in classic late-infantile neuronal ceroid lipofuscinosis 2 disease (CLN2 disease)

Y. Sun[1], *R. Almomani*[1], *G. Breedveld*[2], *G. Santen*[1], *E. Aten*[1], *D. Lafeber*[3], *J. Hoff*[4], *E. Brusse*[5], *F. Verheijen*[2], *R. Verdijk*[6], *M. Kriek*[1], *B. Oostra*[2], *M. Breuning*[1], *M. Losekoot*[1], *J. den Dunnen*[1], *B. van de Warrenburg*[7], ***A. Maat-Kievit***[2];

Spinocerebellar ataxias are phenotypically, neuropathologically and genetically heterogeneous. We reported a unique family with a childhood onset, slowly progressive autosomal recessive spinocerebellar ataxia, referred to as SCAR7. A genome-wide linkage study mapped the causative gene on a 5.9 cM region on chromosome band 11p15. No obvious candidate gene could be assigned. Here we report the results of exome sequencing, revealing disease-causing variants in the *TPP1* gene, encoding the lysosomal enzyme tripeptidyl peptidase 1. A missense and a splice site variant in *TPP1*, cosegregating with the disease, were found in the SCAR7 family and also in another patient with a SCAR7 phenotype.
TPP1, is the causative gene for late infantile neuronal ceroid lipofuscinosis disease 2 (CLN2 disease). CLN2 disease is characterized by epilepsy, loss of vision, ataxia and a rapidly progressive course, leading to early death. SCAR7 patients showed ataxia and low activity of tripeptidyl peptidase 1, but no ophthalmologic abnormalities or epilepsy. Also, the slowly progressive evolution of the disease until old age and absence of ultra structural curvilinear profiles is different from the known CLN2 phenotypes.
Our findings expand the phenotypes related to *TPP1*-variants to SCAR7. In spite of the limited sample size and measurements a putative genotype-phenotype correlation may be drawn: loss of function variants abolishing TPP1 enzyme activity lead to CLN2 disease, while variants that diminish TPP1 enzyme activity lead to SCAR7. This finding illustrates the sometimes unexpected clinical spectrum of variants in known genes. We will encounter this phenomenon with increasing frequency using new techniques.

Autosomal dominant (AD) cerebellar ataxias (CA) are severe neurodegenerative disorders, characterized by movement incoordination, variably associated with other neurological signs. As of today, 35 loci and 20 genes have been described in ADCA, but the causative gene is still unknown in half of the patients. We report a large French family with adult-onset rapidly progressive ataxia, associated with pyramidal signs, spasticity, decreased pallaesthesia and ophthalmoplegia. After exclusion of polyglutamine expansions or mutations in the commonest causative genes, susceptibility loci including

about 450 genes were identified through linkage analysis. Analysis of variants obtained from exome sequencing in two patients, filtered with data from 2 healthy controls and 6 patients with other neurodegenerative disorders, and cosegregation verification, lead to the identification of a missense mutation in the *GSN* (gelsolin) gene that was shown to appear *de novo* in the affected grandfather. The variant was not found in 380 healthy controls or in online databases. A point mutation in *GSN* is already responsible for Finnish amyloidosis. However, the mutation described here differs, and the phenotype was excluded in our family through immunohistochemistry of patient skin sample. Mutation screening in 39 patients with AD spastic ataxia revealed two new potential variants. Further screening is ongoing for another 95 patients, with a broader clinical picture. Functional studies aiming at the cytoskeleton function of fibroblasts, including immunofluorescent staining and migration tests are ongoing to validate and understand the causative nature of the mutations.

Dizygotic twins with ataxia telangiectasia

M. Podralska[1], *A. Jakiel*[2], *B. Basiewicz-Worsztynowicz*[3], *A. Lewandowicz-Uszyńska*[3], *M. Sąsiadek*[2], *R. Słomski*[1], *A. Stembalska*[2];
[1]*Institute of Human Genetic, Poznań, Poland,* [2]*Department of Genetics, Wroclaw Medical University, Wroclaw, Poland,* [3]*Department of Pediatric Immunology and Rheumatology, Wroclaw Medical University, Wroclaw, Poland.*

We present the case of dizygotic twins (girl and boy) with ataxia telangiectasia. They both were diagnosed with strabismus, dysarthria, an ataxic gait. The girl presented dysmorphic features and muscular hypotonia, while only in the boy choreoathetotic movements and positive Romberg test was observed. The girl's electroencephalogram presented paroxysmal changes in median, central and parietal region (however, without seizures), while electromyogram showed no changes. The girl also was diagnosed with autoimmunohaemolytic anaemia, leucopenia with lymphopenia and suffered from recurrent infections. In both cases elevated level of serum AFP was observed. The concentrations of IgA and IgG were low in a girl as well as a boy. The percentage of T-cells positive with CD4 and CD19 were reduced but percentages of CD3 and NK-cell were at the normal levels in girl. The boy presented reduced percentages of T-cells positive with CD3 and CD4. However, the levels of CD8, NK-cells, B-cells, CEA, IgM, IgE (global), CRP, CPK were within the normal limits. Cytogenetic studies confirmed increased frequency of spontaneous chromosomal aberrations in both children. Additional analysis performed using PowerPlex®16 led to the observation of loss of maternal allele at locus 8q24.13. Molecular studies revealed two mutations in *ATM* gene. First mutation involves a G>A substitution of the last nucleotide of exon 43 (c.6095G>A), and it results in the deletion of exon 43. Second mutation detected in twins was deletion at position c.6754_6754delA, p.T2252PfsX5. Supported by grant NN401098240 from the Ministry of Science and Higher Education in Poland

P08.96

Analysis of the role of GAA repeat expansion instability in Friedreich ataxia pathology in a humanised mouse model

J. Sarsero[1,2];
[1]*Murdoch Childrens Research Institute, Parkville, Victoria, Australia,* [2]*The University of Melbourne, Parkville, Victoria, Australia.*

There is evidence that age-dependent and tissue-specific somatic instability of the GAA repeat expansion may be a determinant of the progressive pathology of Friedreich ataxia (FRDA), and is evident in FRDA patients and a YAC-based GAA repeat expansion mouse model. Interruptions in GAA repeat sequences can alleviate transcription inhibition and reduce genetic instabilities. We explored the role of instability of the GAA repeat expansion on FRDA pathology using a humanised mouse model containing an interrupted GAA repeat expansion.

An interrupted GAA repeat expansion was introduced into the first intron of the human FXN gene present on a BAC clone by recombineering. The genomic insert was used to generate humanised transgenic/KO mice.

The presence of the introduced interrupted GAA repeat expansion resulted in markedly decreased levels of human FXN transcript and frataxin protein in humanised mouse tissues. The region immediately upstream of the interrupted GAA repeat expansion region was found to be almost completely methylated. The assessment of phenotypic symptoms of FRDA by a series of behavioural, neurological, biochemical and histological tests did not reveal any significant phenotypic differences between humanised and wild type mice. Somatic instability of the interrupted GAA repeat expansion was not detected using the small pool PCR technique.

The interruption of the GAA sequence contributes to the somatic stability of the repetitive element, which in turn results in the mice lacking an obvious phenotype despite the low levels of FXN mRNA and frataxin protein and repressive epigenetic changes.

Uncommon phenotypes associated with mutations in the *WFS1* gene

M. Plutino[1], *A. Chaussenot*[1], *S. Saadi*[1,2], *C. Rouzier*[1], *S. Bannwarth*[1,2], *M. Barth*[3], *H. Dollfus*[4], *P. Charles*[5], *B. Vialettes*[6], *V. Paquis-Flucklinger*[1,2];
[1]*Department of Medical Genetics, Archet 2 Hospital, Nice, France,* [2]*IRCAN, UMR 7284 / INSERM U1081 / UNS, Nice, France,* [3]*Department of Biochemistry and Genetics, Angers University Hospital, Angers, France,* [4]*Department of medical genetics, EA Inserm 3949, Strasbourg, France,* [5]*Department of Genetics, Pitié-Salpêtrière hospital, Pierre and Marie Curie University, Paris, France,* [6]*Nutrition, Metabolic Diseases and Endocrinology Department, Timone Hospital, Marseille, France.*

Background.*WFS1* gene mutations were mainly described in Wolfram syndrome (WS). The minimal diagnostic criteria for the autosomal recessive WS are juvenile-onset diabetes mellitus (DM) and optic atrophy (OA), frequently associated with diabetes insipidus, deafness, renal tract abnormalities and neuropsychiatric disorders. *WFS1* has also been involved in two autosomal dominant syndromes: Low Frequency Sensorineural Hearing Loss (LFSNHL) and OA associated with Sensorineural Hearing Loss (SNHL).

Patients and methods.We analysed the *WFS1* gene in a cohort of 13 families including patients presenting LFSNHL or a clinical phenotype different from typical WS with at least two symptoms including diabetes mellitus, OA, SNHL or neurological disorders. *WFS1* was sequenced in the Department of Medical Genetics, CHU of Nice (France).

Results.In this cohort, we identified *WFS1* mutations in one LFSNHL family, 3 families with autosomal dominant OA and SNHL, 5 families with late-onset WS (DM and OA occurring after 15 years of age), 1 family with recessive OA and neurological disorders and 3 sporadic cases with only one mutation in *WFS1* associated with an atypical phenotype (including isolated deafness, late-onset diabetes associated with hearing impairment, and infancy-onset DM and deafness).

Conclusion.Our data show that the *WFS1* gene is involved in a clinical spectrum wider than the commonly described WS. *WFS1* should be also tested in LFSNHL, late-onset WS and phenotypes, transmitted either in dominant or recessive fashion, presenting at least OA or SNHL associated with additional features including DM or neurological signs.

The mutation p.G1341D in Wilson's disease patients: how to explain clinical polymorphism?

N. Mocanu[1], *S. Groppa*[1], *T. Todorov*[2], *A. Zibert*[2], *V. Sacara*[1], *H. Schmidt*[2];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*Klinik fürTransplantationsmedizin, Universitätsklinikum, Münster, Germany.*

Background: Wilson's disease (WD) is a progressive and genetically determined disease with deterioration of copper metabolism and it's accumulation in different organs and tissues due to their functional and structural changes. The aim of the study was to evaluate the clinical forms of WD in correlation with type of ATP7B gene mutations. Material and methods: The diagnosis was based on clinical survey, biochemical and genetic tests (Germany).

Results: The missence mutation p.G1341D was the second prevalent mutation and has been revealed in 10 of 37 patients (27 %), from who 8 was heterozygous (21,6 %) and 2 homozygous (5, 4 %). The most common cha-

racteristics of this mutation was the early age of onset, mixed clinical manifestations with severe hepatic deterioration and neurological changes what lead to disability with difficulty in treatment. In a family with 2 homozygous (p.G1341D) siblings the girl had severe neurological damage and cirrhosis. In contrast, the boy didn't have neurological changes, and the liver damage was less aggressive. In the other family also with 2 heterozygous (p.G1341D) siblings the younger boy had severe clinical manifestations but his older sister had no clinical manifestations. Analysis of heterozygous and homozygous patients revealed discrepancy in neurological signs progression and efficiency of treatment being more severe in heterozygous ones. Conclusion: Discordance in clinical manifestation and age at onset in patients with similar mutations may indicate that not only genetic factors play a role in the development of the disease but also genetic or environmental modifiers.

P08.99

Serious neurologic entity in two unrelated patients with Xq13.1 duplication

K. Kosma[1], *M. Tzetis*[1], *K. Giannikou*[1,2], *V. Oikonomakis*[1], *A. Xaidara*[3], *A. Dinopoulos*[4], *S. Youroukos*[5], *A. Syrmou*[1], *S. Ktsiou-Tzeli*[1], *E. Kanavakis*[1];
[1]*Department of Medical Genetics, Medical School, University of Athens, Athens, Greece,* [2]*Alexander S. Onassis Public Benefit Foundation, Athens, Greece,* [3]*1st Department of Pediatrics, Medical School, University of Athens, Athens, Greece,* [4]*3rd Department of Pediatrics, Medical School, University of Athens, Athens, Greece,* [5]*1 st Department of Pediatrics, Medical School, University of Athens, Athens, Greece.*

The use of array-CGH substantially improves the diagnosis of chromosomal abnormalities that are not evident by conventional karyotype. Recently in an extended family with global developmental delay and autistic features, a novel Xq12-q13.3 duplication was identified which contained amongst others *TAF1, GJB1* genes.(Kaya et al.2012).The *GJB1* gene is associated with morphology of myelin sheath and peripheral neuropathy, while *TAF1* has been linked with torsion dystonia -3.
We present the clinical and molecular findings in two unrelated patients with Xq13.1 duplication. The first one is a 5 year old boy with truncal hypotonia, low deep tendon reflexes and proximal weakness. The other patient is a 16 year old boy with progressive difficulties in walking, tremor and learning disorder, while his mother has an identical positive family history in three deceased males. High resolution 4X180K Agilent arrays used in the study (> 236.000 probes, average resolution of 8.9 Kb) revealed a duplication on Xq13.1 (0.423 Mb) containing the *TAF1* and *GJB1* genes in both patients, while the second patient had an additional deletion on 17q21.31 (0.63 Mb) containing *KANSL1* gene. To our knowledge this is the second report of the Xq13.1 duplication extending the previously described phenotypic spectrum in that a more serious neurologic entity could be attributed to the *TAF1* and *GJB1* genes.

Three HLA-B*5801 positive allopurinol-induced severe cutaneous hypersensitivity reaction cases

E. Kim*;*
Inje University Busanpaik Hospital, Busan, Korea, Republic of.

Allopurinol-induced severe cutaneous hypersensitivity reaction such as Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) has been reported on the genetic association with HLA-B*5801. Clinicians occasionally request HLA genotyping for evaluating the causality of drug hypersensitivity based on the evidence between HLA genotype and drug hypersensitivity. Three patients with serious cutaneous hypersensitivity reaction after allopurinol administration were tested for HLA-B genotyping. One (72-yr old woman) showed drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome and the others (63-yr old and 22-yr old men) turned out to be SJS. All patients were treated with allopurinol due to gout. The onset of the symptoms was 2-4 weeks after the drug exposure. HLA-B genotyping was performed using PCR-SBT (sequence-based typing) method. All patients have one HLA-B*5801 allele. While a patient with DRESS syndrome has HLA-B*4801/*5801, two SJS patients showed HLA-B*1302/*5801 and HLA-B*4403/*5801 genotypes, respectively. The results implied that patients with HLA-B*5801 may suffer from severe cutaneous hypersensitivity reaction with allopurinol administration. Thus PCR-SBT HLA-B genotyping could be helpful for preventing the serious problem due to allopurinol treatment although the PCR-SBT HLA-B genotyping takes long time. Therefore a simple diagnostic genotyping technology needs to be developed for using in practice.

P09.02

A 1p36 polymorphism in the cannabinoid receptor 2 gene region is associated with CNR2 gene expression, atopic childhood asthma onset, severity, and treatment outcome with inhaled corticosteroids

C. E. P. Kozmus[1,2], *V. Berce*[3], *U. Potocnik*[4,5];
[1]*Center for Human Molecular Genetics and Pharmacogenomics, University of Maribor, Maribor, Slovenia,* [2]*Institute for Molecular and Cell Biology, University of Porto, Porto, Portugal,* [3]*Department of Pediatrics, University Medical Centre Maribor, Maribor, Slovenia,* [4]*Center for Human Molecular Genetics and Pharmacogenomics, Maribor, Slovenia,* [5]*4Laboratory for Biochemistry Molecular Biology and Genomics, Faculty for Chemistry and Chemical Engineering, University of Maribor, Maribor, Slovenia.*

Asthma pathogenesis is currently understood through the interaction of several genes and environmental influences. It is believed that endocannabinoids act as native modulators of immune system, probably through cannabinoid receptors activation. Recent expression quantitative trait loci studies linked single nucleotide polymorphisms (SNPs) on chromosome 1p36 with cannabinoid receptor 2 (CNR2) gene expression. We analyzed rs4237 association with childhood asthma, and the effect of rs4237 on the response to inhaled corticosteroids (ICS) treatment and CNR2 gene expression. We studied a case-control cohort of 229 children with newly detected mild/moderate persistent asthma (150 atopic, 79 non-atopic, 13 undetermined atopy), and 271 controls. Blood samples were collected before treatment and 72 matching samples 4-6 weeks after treatment with ICS. According to recessive model of genetic association the frequency of CC genotype in atopic asthmatics was lower (13.2%) than in controls (21.0%, p=0.0284). Forced expiratory volume in 1 second (FEV1) was higher in atopic asthmatics with CC genotype (98%±11%) compared to those with CT or TT (90%±15%, p=0.0155). Median relative expression of CNR2 in asthmatics with TT genotype was higher (0.79±0.81) compared to those with CT or CC (0.28±0.81, p=0.0041). FEV1 increased significantly by 10.6%±11.6% of predicted value after ICS treatment in atopic asthmatics with TT genotype, compared to 6.4%±10.5% in those with CT or CC homozygotes (p=0.034). Our results suggest rs4237 is associated with asthma onset, with asthma severity, CNR2 gene expression and with inhaled corticosteroids treatment response in children with atopic asthma, and suggest the involvement of the endocannabinoid system in asthma.

Genetic basis of primary immunodeficiencies in Croatian patients

A. Merkler*, D. Richter, J. Kelecic, H. Ljubic, D. Caban, J. Sertic;*
University Hospital Centre Zagreb, Zagreb, Croatia.

Introduction: Primary immunodeficiency diseases (PID) are a heterogenic group of rare inherited conditions that occur in individuals born with malfunctioned immune system.
Objective: The objective was to confirm clinical diagnosis at molecular genetic level in patients with PID and to define carrier status by analyzing DNA samples of individuals with PID in family history.
Methods: We analyzed 24 samples of genomic DNA: 11 samples of patients with suspicion on one of the PID and 13 samples of their family members. For identification of mutations in the coding region of analyzed genes, we used the sequencing method on Applied Biosystems 3130xl Genetic analyzer and BigDye® Terminator v3.1 Cycle Sequencing Kit.
Results: In 2 patients with X-linked agammaglobulinemia, mutations in the BTK gene were found. In the first patient, mutation occurred de novo in mother's egg cells and, in the other, mutation was inherited from the mother. 3 patients with XLA suspicion didn't have mutation in the BTK gene. In 4 patients with cyclic and severe congenital neutropenia, 4 mutations occurred de novo in mother's egg cells were found. In 2 patients with suspicion on Shwachmann-Diamond syndrome mutation in SBDS gene inherited from the parents were found.
Conclusions: Understanding the genetic basis of PID is the final step in confirmation of the PID diagnosis as it provides comprehension of disease mechanisms at the molecular level and correlation between genotype and phenotype of PID.

EQTLs and allele specific expression of HLA haplotypes and amino acids associated to autoimmune diseases.

A. Zhernakova[1], *M. R. vd Sijde*[1], *J. Gutierrez-Achury*[1], *P. J. McLaren*[2], *D. V. Zhernakova*[1], *P. I. W. de Bakker*[3,4], *H. Westra*[1], *L. Franke*[1], *C. Wijmenga*[1], *J. Fu*[1];
[1]*University medical centre Groningen, Groningen, Netherlands,* [2]*School of Life Sciences, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland,* [3]*University medical centre Utrecht, Utrecht, Netherlands,* [4]*Division of Genetics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States.*

HLA is the strongest associated locus in autoimmune diseases. Recent studies in celiac disease (CelD) and rheumatoid arthritis (RA) indicated the major role of DR3-DQ2 and DR4-DQ8 in both diseases, and identified additional independently associated variants both in the DR-DQ locus and in the extended HLA locus.
We hypothesized that the mechanism of downstream effect of associated variants and haplotypes is due to an impact on the expression level of HLA genes We investigated this hypothesis in a dataset of 60 unrelated CEU individuals, for whom RNAseq data, dense HLA genotyping and imputation of HLA alleles was available. We selected CelD and RA associated amino acids, HLA-haplotypes and SNPs, and assessed allele specific expression and eQTLs in the HLA locus. eQTL analysis allowed us to assess the dosage effect of HLA variants on gene expression, whereas the allele-specific analysis, performed in heterozygous individuals for each variant, indicated if one or another allele of a SNP or amino acid was preferentially expressed.
In both analyses we observed that an amino acid at position 52 of the DQB1 gene (DQB1_AA52) was significantly associated with expression of DQB1 gene both in eQTL and in allele-specific analysis. DQB1_AA52 is associated to CelD independently from the most associated DQB1 variant (AA55). We therefore confirmed that imbalanced allelic expression is the downstream effect of some HLA variants associated with autoimmune diseases. The analysis in extended number of individuals is currently in progress.

P09.05

The IL-10 promoter genotype AA at -592 is correlated with increased susceptibility to hepatitis B but not HIV infection in Caucasian intravenous drug users.

E. Kallas[1], *K. Huik*[1], *R. Avi*[1], *M. Pauskar*[1], *E. Jõgeda*[1], *T. Karki*[1], *K. Marsh*[2], *D. Des Jarlais*[3], *A. Uusküla*[2], *I. Lutsar*[1];
[1]*Tartu University Institute of Microbiology, Tartu, Estonia,* [2]*Tartu University Institute of Public Health, Tartu, Estonia,* [3]*Beth Israel Medical Center, New York, NY, United States.*

BACKGROUND: Interleukin (IL)-10 -592A has been associated with rapid HIV disease progression. Whether and how the IL-10 polymorphisms at the positions -592 and -1082 are associated with susceptibility to HIV and its co-infections in IDUs population is largely unknown.
METHODS: A total of 345 IDUs were recruited and of them 50% were HIV-. A control group was formed by HIV-, HCV-, HBV- 496 healthy volunteer blood donors. The IL-10 C-592A and A-1082G were determined using TaqMan allelic discrimination assay. The statistical analysis was performed using Fisher's exact test.
RESULTS: Of IDUs 88.7% were HCV+, 67.2% HBV+ and 40.6% with triple infection. IL-10 -592C allele (allelic frequencies 0.78 in IDU and 0.79 in donors) and -1082 A allele (allelic frequencies 0.57 in IDUs and 0.55 in donors) were the most common in all groups. Both polymorphisms were under Hardy-Weinberg equilibrium and the allelic frequencies did not differ between the three groups. The -592 CC/-1082 AG was the most common haplotype (29.3% in IDUs and 30.4% in donor group). No associations were found in distribution of IL-10 -592 and -1082 genotypes and HIV or HCV infections. However, persons possessing IL-10 AA had increased odds for acquiring HBV infection (OR=4.37; 95% CI = 1.01-39.63; p=0.042). After adjustment for HIV, HCV and duration of intravenous drug use, the association was not significant
CONCLUSIONS: IL-10 genotypes are not associated with HIV acquisition in Caucasian IDUs. However, IL10 -592AA genotype predisposes of being HBV positive and therefore might play an important role in HBV susceptibility.

Homozygous deletion of *IL-17RA* and *ADA2* in siblings with severe recurrent infections

M. Belfiore[1], *F. Fellmann*[1], *J. Wassenberg*[2], *M. Perreau*[3], *S. Christen-Zaech*[4], *P. Bochud*[5], *M. Beck Popovic*[6], *P. Bart*[3], *J. Beckmann*[1], *M. Hofer*[2], *D. Martinet*[1];
[1]*Service of Medical Genetics, University Hospital, Lausanne, Switzerland,* [2]*Immunoallergology and Rheumatology Unit, Department of Pediatrics, University Hospital, Lausanne, Switzerland,* [3]*Divisions of Immunology and Allergy, University Hospital, Lausanne, Switzerland,* [4]*Pediatric Dermatology Unit, Department of Pediatrics and division of Dermatology, University Hospital, Lausanne, Switzerland,* [5]*Service of Infectious Diseases, Department of Medicine, University Hospital, Lausanne, Switzerland,* [6]*Hematology Oncology Unit, Department of Pediatrics, University Hospital, Lausanne, Switzerland.*

Chronic systemic and mucocutaneous infections can be associated with human inborn errors of immunity but the genetic background remains poorly understood. Here we report two siblings suffering since childhood from chronic severe infections mediated by *Candida albicans* and *Staphylococcus aureus,* refractory to classical treatments. DNA analysis by Array-based Comparative Genomic Hybridization (array-CGH) shows that both sibs are homozygous carriers of a 22q11.1 deletion of about 770 Kb encompassing the *IL-17RA* and *ADA2* genes. IL-17RA is one receptor for the pro-inflammatory IL-17 cytokines involved in protection against extra cellular pathogens. A homozygous nonsense mutation in *IL-17RA* has been recently reported in a patient suffering from isolated chronic mucocutaneous candidiasis. ADA2, adenosine deaminase 2, is secreted by monocytes undergoing differentiation into macrophages or dendritic cells and by dendritic cells themselves, and might be involved in immune responses. By genetic and functional analyses, we confirmed the relationship between chronic mucocutaneous infections by *C. albicans* and *Staphylococcus* species and the lack of expression of IL-17RA. Severity of the symptoms might be further exacerbated by the absence of ADA2.
This study underscores the usefulness of whole genetic analyses, allowing for precise diagnosis and genetic counselling, thereby improving the management of chronic infectious diseases.

Identification of molecular markers playing role in predicting anti-HCV treatment outcome would facilitate therapy optimizing. IL28B rs12979860 polymorphism has been identified as strong predictor of Sustained Virological Response (SVR) in chronic hepatitis C (CHC) patients. The aim of this study was to examine association between IL28B rs12979860 polymorphism and VR in 35 CHC patients treated with pegIFN+RBV. Serum HCV-RNA was measured on first day and then at 4 and 12 week of treatment by quantitative RT-PCR. DNA, isolated from PBL, was used for IL28B rs12979860 genotyping by High Resolution Melting method.13 patients (37.1%) became HCV RNA negative at week 4 (RVR-Rapid Virological Response) and 10 (28.6%) at week 12 (cEVR-complete Early Virological Response). 12 patients (34.3%) did not achieve virological response until 12 weeks (PNR-Primary Non-Response). The mean baseline viral load was comparable - 6.69x10000 IU/ml vs 7.32x10000 IU/ml vs 3.51x10000 IU/ml in RVR, cEVR and PNR group, respectively. The rs12979860 CC, CT and TT genotypes found in 8 (22.9%), 23 (65.7%), 4 (11.4%) patients, respectively. Among patients with CC genotype, 75% achieved RVR and 25% achieved cEVR. Among CT genotype RVR, cEVR and PNR were observed in 30.5%, 30.5% and 39% of patients, respectively. 25% of patients with genotype TT achieved cEVR and 75% achieved PNR. The initial results confirm that IL28B rs12979860 C/T polymorphism may identify those CHC patients, who achieve RVR during early phase of treatment and thereby who are more likely to achieve SVR.

Effects of aging and sex difference on immune-related phenotypes.

*G. Sole[1], V. Orrù[1], E. Fiorillo[1], **M. Steri**[1], M. Dei[1], S. Lai[1], F. Virdis[1], D. Schlessinger[2], F. Cucca[1], S. Sanna[1];*
[1]Istituto di ricerca genetica e biomedica - CNR, Monserrato - Cagliari, Italy, [2]Laboratory of Genetics, NIA, Baltimore, MD, United States.

The complexity of the healthy human immune system and the immunological changes that occur during life have been only partially described. Furthermore several autoimmune diseases have been associated with phenotypic changes that can be interpreted as accelerated immune aging, and others show different incidence or severity in males and females. To investigate the impact of age and sex in specific immune cell types, we measured 266 immune-related traits, representing the majority of leukocyte cell populations (monocytes, T and B cells, Natural Killer cells, regulatory T cells, dendritic cells, and their subsets) as well as T cell maturation, in 1921 volunteers (aged 14-99 years) of the SardiNIA project by polychromatic flow cytometry. We then evaluated the impact of age and sex using linear regression models. We observed statistically significant ($p<0.0005$) differences for 17 traits between younger and older subjects (<= or >60 years), including the already described decrease of naïve CD8+ T cells in elderly. We also confirmed previous observations reporting stable granulocytes and monocytes, but a light increase of NK cell counts, with aging. Differences between males and females were not significant, but moderate changes were observed for dendritic cells and subtypes, as well as B cells ($p<0.005$). While this study sample already represents the largest and deepest characterized set ever described, we are currently performing immune-phenotyping in additional 2000 volunteers, including 200 healthy centenarians (aged >90 years). Our results will improve our knowledge on the immune system in health, diseases, and aging.

Methylation status of immune response genes promoters in cell-free DNA differ in hemodialyzed patients treated with low and high doses of erythropoietin therapy

***M. Korabecna**[1], E. Pazourkova[1], A. Horinek[1], M. Mokrejsova[2], V. Tesar[1];*
[1]1st Faculty of Medicine of Charles University in Prague, Prague, Czech Republic, [2]3rd Faculty of Medicine of Charles University in Prague, Prague, Czech Republic.

Anemia is a major complication of end-stage renal disease, occurring as a result of reduced erythropoietin production from the peritubular cells of kidney. Recombinat human erythropoietin therapy is successfully applied to correct the anemia but significant number of dialysis patients remain hyporesponsive to this therapy. As specific interleukins are generated during hemodialysis and monocytes are activated, the process of hemodialysis may be regarded as a stimulus activating mechanisms of inflammation. It is known that pro-inflammatory cytokines are able to suppress erythropoiesis. Therefore we decided to study the changes in methylation status of promoters of immune response genes in the cell-free DNA which is thought to fulfill regulation function in intercellular communication. We focused on hemodialyzed subjects affected with diabetic nephropathy (n=18). In our pilot study the patients were divided according to the recombinant erythropoietin therapy into two groups - with low (n=8) and with higher doses (n=18).

Cell free DNA from plasma of all patients was isolated before and after the hemodialysis procedure. The extent of promoter methylation of 24 genes involved in immune response was examined using the EpiTect Methyl qPCR Array Inflammatory Response and Autoimmunity and cluster analysis (SA-Biosciences, Qiagen). Using cluster analysis we demonstrate the complex changes in the methylation profiles of selected immune response genes and the significant differences between the profiles of patients with low and higher doses of recombinant erythropoietin.

Five new cases of Nijmegen breakage syndrome in Chile

***M. I. Aracena**[1], C. Cares[2], S. Arredondo[3], J. Pincheira[4], K. Marcelain[4], P. González-Hormazábal[4];*
[1]Hospital Dr. Luis Calvo Mackenna and División de Pediatría Pontificia Universidad Católica de Chile, Santiago, Chile, [2]Hospital Dr. Luis Calvo Mackenna, Santiago, Chile, [3]Hospital Regional de Talca, Talca, Chile, [4]Programa de Genética Humana, ICBM Facultad de Medicina Universidad de Chile, Santiago, Chile.

Introduction: Nijmegen Breakage Syndrome (NBS) is a rare autosomal recessive disease. It is characterized by congenital microcephaly, intrauterine growth retardation and short stature, immunodeficiency, chromosome instability and cancer proneness. The disease seems to occur worldwide, but has a much higher prevalence among Central and Eastern European Slavic populations. Over 90% of identified patients bear a common deletion. We report five new patients from Chile, South America.
Patients: Since June 2000, five patients were referred to our genetic clinic, because of Microcephaly. Their diagnosis workup established NBS.
Results: Three probands are female, referred from 10mo to 14y. Strikingly they came from one region of Chile; four had no history of consanguinity. Only one patient was referred with diagnosis of NBS. Two patients have already developed non-Hodgkin lymphoma, one dead. DNA analysis was carried out in four patients; tested individuals were homozygous for the common Slavic mutation 657del5 in the *NBS1* gene.
Discussion: NBS can be suspected in clinical grounds, although there is considerably clinical overlap with other inherited conditions. Its confirmation is useful for an appropriate surveillance and for genetic counseling. The fact that all our patients came from the same region let us to propose a founder effect. Although historical records tell us that the Chilean population was founded by the admixture of local Amerindian populations and colonizing Spaniards, it is probable that the genomic make up of current Chileans is much more complex, with multiple ethnic groups contributing at different times since the initial contact between Americans and Europeans.

P09.12

Identification of the gene responsible for an autosomal dominant form of Common Variable Immunodeficiency

*V. Di Pierro[1], P. Lyons[2], R. Zuntini[1], A. Schaffer[3], I. Quinti[4], **S. Ferrari**[1];*
[1]S.Orsola-Malpighi University Hospital, Bologna, Italy, [2]Cambridge Institute for Medical Research, Cambridge, United Kingdom, [3]NCBI, Bethesda, MD, United States, [4]Dept. of Immunology, University of Roma „La Sapienza", Roma, Italy.

CVID is the most common symptomatic antibody deficiency in adults, including a heterogeneous group of disorders characterized by markedly reduced immunoglobulin serum levels, poor response to vaccines and increased susceptibility to bacterial infections. The majority of CVID cases are sporadic. Approximately 20% are familial: rare autosomal recessive mutations in ICOS, BAFF-R, CD19, CD20, CD81 and CD21 coding genes have been recently reported and mutations in the TACI gene have been found in about 15% of cases.
We report a large family with autosomal dominant inheritance of CVID, diagnosed according to the ESID/PAGID criteria for CVID based on at least 2 SD below the mean for age in serum IgG and IgA, onset age >2 years, poor response to vaccines.
In this five-generation family, nine affected and eight unaffected individuals were available for the study. Based on the genomewide linkage scan, the CVID locus has been mapped to the long arm of chromosome 3 on band q27.2-q29. The CVID locus is localized in a region of 9.2 Mb spanning from marker D3S3570 to marker D3S1265, with a maximum LOD score of 3.90 at $\theta=0.00$ for marker D3S2747.
In collaboration with the Wellcome Trust Sanger Institute, we performed exome sequencing in four affected and four unaffected individuals, in order to identify shared rare variants within the linkage region. After the filtering procedure to extract heterozygous variants with a low frequency (<0.01) in the general population, we found a candidate disease-causing allele shared among the four affected subjects analyzed.

P09.13

NLRP1 mutation in a novel autosomal recessive autoinflammatory disease with dyskeratosis and arthritis

*E. Sanchez[1,2], S. Grandemange[2,3], D. Bessis[4], C. Coubes[1], P. Plence[2], E. Jeziorski[5], A. Carbasse[5], M. Rodière[5], C. Jorgensen[2], I. Touitou[2,3], **D. Geneviève**[1,2];*
[1]Département de Génétique Médicale, Montpellier, France, [2]Unité, INSERM U844, Institut des Neuroscience Montpellier, Montpellier, France, [3]Unité médicale des maladies Auto-inflammatoires, Hôpital Arnaud de Villeneuve, Montpellier, France, [4]Service de dermatologie, Hôpital Saint Eloi, CHRU Montpellier, Montpellier, France, [5]Pédiatrie, Hôpital Arnaud de Villeneuve, CHRU Montpellier, Montpellier, France.

The inflammasomes correspond to multiprotein complexes that sense pathogens and trigger biological mechanisms in an attempt to control infection. The NLRP family (Nucleotide-binding domain leucine-rich repeat containing a PYRIN domain) plays a key role in this innate immune system by regulating inflammation via caspase recruitment. Sequence variants in genes encoding NLRPs, have been associated with autoinflammatory and autoimmune diseases. Indeed, mutations in *NLRP3* are linked to hereditary cryopyrinopathies, whereas polymorphisms in *NLRP1* are associated to autoimmune disorders such as vitiligo and rheumatoid arthritis. Recently, a non-synonymous *NLRP1* mutation in the pyrin domain (M77T) was observed in an autosomal dominant hereditary benign intraepithelial dyskeratosis.
Using an exome sequencing strategy, we have identified a non-synonymous homozygote mutation in the *NLRP1* gene in two cousins born from consanguineous parents originating from Algeria. The patients present with diffuse skin dyskeratosis (2/2), biological inflammation (2/2) and arthritis (1/2). The mutation (c.2733C>T; p.R726W) is localised near the leucine-rich repeat and is neither observed in 192 chromosomes from healthy Algerian volunteers nor web databases.
An immune phenotype in 1/2 patient revealed high numbers of granulocytes, CD64^{+} neutrophils, NK cells and immature blood B cells (CD20^{+}CD27^{-}CD38^{high}CD24^{high}).We demonstrate for the first time that *NLRP1* is involved in an autosomal recessive autoinflammatory disorder. These data, combined to the literature, highlights the pleiomorphic roles of *NLRP1* in inflammation and immunity.

Multiple sclerosis is (MS) a complex inflammatory disease that is characterized by lesions in the central nervous system. Several studies have highlighted the association of the 12q13.3-12q14.1 region with MS, coeliac disease, type 1 diabetes, rheumatoid arthritis and; however, the causal variants underlying diseases are still unclear.
To identify the polymorphism determining the association with MS we performed a fine mapping of the associated region encoding 15 genes by a Tag-SNP approach (2876 MS patients and 2910 healthy Caucasian controls) and functional studies to determine the involvement of the associated MS risk variants in gene expression.
rs6581155, which tagged 18 variants within a region where 9 genes map, was sufficient to model the association. This SNP was in total linkage disequilibrium with other polymorphisms that associate with expression quantitative trait loci (eQTLs) for FAM119B, AVIL, TSFM, TSPAN31 and CYP27B1 genes . Functional annotations from ENCODE project showed that six out of these rs6581155-tagged-SNPs were located in regions with regulatory potential and only one of them, rs10877013, exhibited allele-dependent (ratio A/G=9.5-fold) and orientation-dependent (forward/reverse=2.7-fold) enhancer activity as determined by luciferase reporter assays. This enhancer is located in a region where a long-range chromatin interaction among the promoters and promoter-enhancer of several genes has been described, possibly affecting their expression simultaneously.
This study determines a functional variant which alters the enhancer activity of a regulatory element in the locus affecting the expression of several genes and explains the association of the 12q13.3-12q14.1 region with MS.

P09.15

Expression of Mx1, OAS1, PKR (EIF2AK2) and TP53 genes during treatment of chronic HCV patients.

*B. Swiatek[1], D. Januszkiewicz-Lewandowska[1,2,3], I. Bereszynska[2], J. Rembowska[1], I. Mozer-Lisewska[2], A. Kowala-Piaskowska[2], J. Wysocki[2], **J. Nowak**[1];*
[1]Institute of Human Genetics Polish Academy of Sciences, Poznan, Poland, [2]University of Medical Sciences, Poznan, Poland, [3]Department of Medical Diagnostics, Poznan, Poland.

Interferon stimulated genes (ISGs) play key role in antiviral responses against HCV. Aim of this prospective study was to examine association between *Mx1, OAS1, PKR* and *TP53* expression and response to pegIFN+RBV in 35 chronic hepatitis C (CHC) patients. Rapid Virological Response (RVR) and complete Early Virological Response (cEVR) was achieved by 13 (37.1%) and 10 (28.6%) patients, respectively. 12 (34.3%) did not response to therapy during 12 weeks (Primary Non-Response, PNR; less than 2 log^{10} decrease in viral titer after 12 weeks). Mean baseline viral load was comparable in RVR, cEVR and PNR group (6.7, 7.3 and 3.5x10^{4} IU/ml, respectively). Expression of *Mx1, OAS1, PKR*, but not *TP53* was low in RVR and higher in cEVR and PNR patients before therapy, but increased noticeable in cEVR and PNR and poorly in RVR patients at week 4. Between weeks 4 and 12 of therapy, expression of ISGs was stable or poorly decreased in RVR, was stable or poorly increased in cEVR and noticeable decreased in PNR group. These results indicate that exogenous IFN can stimulate transcription of *Mx1, OAS1, PKR* but not *TP53* in PBL in CHC patients. Pre-activation of endogenous interferon system (higher ISGs expression) is associated with RVR and thereby with high likelihood of achieving SVR. Treatment failure may be related to decrease in ISGs expression between week 4 and 12 of anti-HCV therapy. So, we concluded that expression of ISGs may predict the outcome of CHC.
This research was supported by National Science Centre grant no 2011/01/B/N26/04258.

P09.16

Association of Perforin codon His222 missense mutations with non-immune hydrops fetalis in familial hemophagocytic lymphohistiocytosis

***G. Balta**[1], S. Topcuoglu[2], T. Gursoy[2], A. Gurgey[1], F. Ovali[2];*
[1]Hacettepe University, Faculty of Medicine, Department of Pediatrics, Section of Hematology, Ankara, Turkey, [2]Zeynep Kamil Maternity and Children's Education and Training Hospital, Neonatology Intensive Care Unit, Istanbul, Turkey.

Familial hemophagocytic lymphohistiocytosis (FHL) is a rare, if untreated, fatal autosomal recessive immune dysregulation disorder of early childhood. FHL may scarcely display presenting symptoms in the intrauterine life. The etiology of non-immune hydrops fetalis (NIHF), on the other hand, remains unknown in most cases and their association is of great importance to the scientists in the related fields. This is the first study demonstrating that NIHF in identical twin neonates is associated with biallelic gene defect in one of the genes causing FHL. Preterm male twins (31 wk), products of a

consanguineous family, with NIHF and hepatosplenomegaly gradually developed pancytopenia, hyperferritinemia, hyponatremia, hypoalbuminemia, and elevated ALT, AST, bilirubin, LDH levels but fever and hypertriglyceridemia of hemophagocytic lymphohistiocytosis diagnostic criteria were absent. Suspected sepsis led to antibiotic therapy. Upon detection of hemophagocytosis in bone marrow, multiorgan failure and pulmonary bleeding led to death on 15th and 18th days of life. Mutation analysis in Perforin, UNC13D, Syntaxin 11 and STXBP2 genes causing FHL revealed homozygous c665A>G substitution leading to His222Arg missense mutation in Perforin. Parents were heterozygous for this known disease causing mutation. Same mutation in heterozygous state was reported in a case with fetal acides and homozygous another missense mutation in the same codon (His222Gln) was described in a stillborn case with NIHF in the literature previously. Therefore, it is plausible to suggest that biallelic missense mutations of Perforin codon His222 may be associated with intrauterine presentation of FHL, hence with hydrops fetalis. This study was supported by TUBITAK (Grant Number:105S386-SBAG-3193).

Primary immunodeficiencies (PIDDs) constitute a heterogenous group of genetic diseases affecting the immune system. Dependent on the genetic aetiology, symptoms range from mild to severe and life-threatening. Knowledge of the molecular genetic cause and disease mechanism is important and can direct targeted and curative therapy. However, categorization of the subtypes is difficult as patients with different immunodeficiencies may have overlapping immunological and clinical phenotypes. In addition, more than 200 causal genes have been reported, and few are offered for genetic testing.

We examined the utility of exome sequencing in the diagnostic workup and research of PIDDs. As of February 2013, totally 110 patients with extensive immunological and genetic testing from 87 families have been recruited from Texas Children Hospital (Houston, USA) and from Oslo University Hospital in Norway. Based on the clinical and immunophenotypical data, family history and knowledge from similar PIDD cases, the strategies for variant evaluation have involved both candidate gene testing with known PIDD genes, trio testing, or focused on potential novel genes in regions where LOH/deletions had been identified.

Preliminary analysis has proven exome sequencing as an efficient method to detect disease-causing variants in a large set of candidate genes. Combining data from exome sequencing and array CGH with exon coverage of all known PIDD genes has proven useful, exemplified by a patient with a heterozygous deletion and frameshift mutation in the same exon of *IL7R*. Additional benefits are expected from an in-house developed high-resolution array, in average tiling all exons by 5 probes.

P09.18

Polymorphisms and expression of PTPN22, CTLA4 and TNF-alpha genes are associated with clinical data and disease susceptibility in Rheumatoid arthritis

L. Zemljic[1], *B. Kolarič*[2], *U. Potočnik*[1,3];

[1]*Center for Human Molecular Genetics and Pharmacogenomics, Faculty of Medicine, University of Maribor, Maribor, Slovenia,* [2]*University Clinical Center Maribor, Department of Pharmacy, Maribor, Slovenia,* [3]*Faculty of Chemistry, Laboratory for Biochemistry, Molecular Biology and Genomics, University of Maribor, Maribor, Slovenia.*

Rheumatoid arthritis (RA) is a chronic, autoimmune disorder affecting about 1% of the population. Genetic factors account for 50-60% of disease susceptibility. We designed a study to test whether SNPs from selected loci and gene expression of two candidate genes are associated with the development of the disease and with clinical parameters obtained from RA patients. 4 single nucleotide polymorphisms (SNPs) and 32 bp deletion were genotyped. Expression levels of 2 candidate genes were determined. Clinical data was tested for association with genotype and gene expression.

RA patients had lower frequency of GG genotype ($p<0.0001$, OR=4.877) in rs1800896 (IL10), higher frequency of A allele and AA genotype ($p=0.008$, OR=0.529; $p=0.033$, OR=0.130, respectively) in rs2476601 (PTPN22) and higher frequency of A allele and AA genotype ($p=0.019$, OR=0.711; $p<0.0001$, OR=0.397, respectively) in rs3087243 (CTLA4).

CTLA4 gene expression was reduced in RA patients ($p<0.0001$), patients with negative family history ($p=0.027$), patients positive for rheumatoid factor (RF) ($p=0.022$) and patients with biological treatment ($p<0.0001$). CTLA4 gene expression was significantly associated with rs3087243 genotype ($p<0.0001$).

TNF gene expression was reduced in RA patients ($p<0.0001$), male patients ($p=0.049$), patients positive for RF ($p=0.011$) and patients with biological treatment ($p<0.0001$).

Our results show that genotypes in rs1800896 (IL10), rs2476601 (PTPN22) and rs3087243 (CTLA4) are associated with development of RA and that rs3087243 (CTLA4) is a cis-eQTL, regulating CTLA4 gene expression. Results also show, that TNF and CTLA4 gene expressions are affected by gender, RF presence, prescribed biological therapy and family history.

Identification of the Cia27 quantitative trait gene

L. Mellado Ranea[1], *A. de Castro Marques*[1], *X. Yu*[2], *S. Moeller*[1], *S. M. Ibrahim*[1];

[1]*Dep. of Dermatology, University of Luebeck, Luebeck, Germany,* [2]*Priority Area Asthma & Allergy, Research Center Borstel, Borstel, Germany.*

Rheumatoid arthritis (RA) is a systemic chronic autoimmune inflammatory disease that primarily impairs joints. RA affects between 0.5-1% of the adult population in developed countries and the genetic contribution to disease is estimated to be 60%. The knowledge of the genetic factors controlling complex disorders as RA is of great importance to understand pathogenic mechanism and to improve diagnosis and therapy. Human genome heterogeneity and gene-environment interactions are great challenges for the identification of RA susceptibility genes in human studies. In contrast, mouse models allow to work in homogeneous genetic background and under controlled environment. Our group has used the collagen-induced arthritis (CIA) mouse model to identify a new potential genetic factor involved in arthritis. In this study, we fine mapped the *Cia27* QTL, which is associated with antibody production in a F2 cross between the arthritis-susceptible DBA/1J strain and the arthritis-resistant FVB/N. By haplotype block analysis, 6 candidate genes were pointed out. Next, based on exon sequencing and differential gene expression analysis, *Thrap2* was pinpointed as the main candidate. This gene was confirmed to be involved in CIA by using a congenic strain approach. Knockdown assays in mouse primary B cells culture resulted in decrease of specific cell death, suggesting a role of this gene in B cell survival.

In summary, we have identified a putative gene involved in disease development, presumably by acting on B cells, in a murine arthritis model. Furthermore, we have generated a tissue-specific knock-out mouse.

Phenotypic analysis of Peptidylarginine deiminase type 4 knock-out mice

A. Suzuki[1], Y. Kochi[1], H. Shoda[2], K. Fujio[2], E. Kanno[1], R. Yamada[3,1], K. Yamamoto[2,1];
[1]RIKEN, Yokohama, Japan, [2]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3]Center for Genomic Medicine, Kyoto University, Kyoto, Japan.

Rheumatoid arthritis (RA) is well-known as an autoimmune disease and is a chronic inflammatory disorder characterized by the destruction of multiple joints. Many genome wide association studies were performed and multiple RA-susceptibility loci and autoimmune-susceptibility loci have been identified. These studies suggested that multiple genes and its functions were related with disease causing and development.
Previouly, peptidylariginine deiminase type 4 **(**PADI4) was identified as a susceptibility gene for RA in a Japanese population by case-control association study (Ref 1). PADI4 is a member of the PADI gene family and converts arginine residue (peptidylarginine) to citrulline residue (peptidylcitrulline). PADI4 is highly expressed in bone marrow, macrophages, neutrophils and monocyte. Peptidylcitrulline is an interesting molecule in RA, because it is an antigen of ACPA and only PADs (translated protein from PADI genes) can provide peptidylcitrullines, via modification of protein substrates. To evaluate the importance of PADI4 gene in the progression of RA, we generated Padi4 -/- DBA1J mice by speed congenic method. We used Padi4-/- mice to show that PAD4 is affected to development and progression of collagen induced arthritis (CIA), well known as an RA model animal. Padi4-/- DBA1-Jand WT mice were immunized with bovine type II collagen (CII) for CIA. Clinical disease score was significantly reduced. In Padi4-/- mice sera, the concentrations of serum anti-CII IgM, IgG, and TNF-a also decreased significantly rather than in WT mice. Resulting from these studies, we suggested that Padi4 enhanced collagen-initiated inflammatory responses.

P09.21

Is a functional variant of ANXA11 R230C associated with impaired apoptosis?

***R. Fillerova[1]**, M. Ordeltova[1], F. Mrazek[1], M. Zurkova[2], V. Kolek[2], E. Kriegova[1];*
[1]Department of Immunology, Faculty of Medicine, Palacky University, Olomouc, Czech Republic, [2]Department of Respiratory medicine, Faculty of Medicine, Palacky University, Olomouc, Czech Republic.

Sarcoidosis is a granulomatous disorder of an unknown aetiology, where the granuloma formation has been associated with impaired apoptosis of activated inflammatory cells. There is no information concerning the influence of *ANXA11* R230C, a functional annexin A11 variant associated with protection/disease modification of sarcoidosis, on the sensitivity of peripheral blood mononuclear cells (PBMC) to apoptosis yet.
We therefore compared the sensitivity to apoptosis of PBMC obtained from 92 sarcoid patients and 14 healthy controls. Tributyltin was used as apoptosis stimulus; annexin V positive cells were detected by flow cytometry. Additionally, sarcoid patients were subgrouped according to ANXA11 R230C (rs1049550) genotype (TT, n=13; CC, n=45) and clinical phenotype (CXR-stages, organ involvement).
When compared to healthy controls, lower number of annexin V positive cells was detected in stimulated PBMC from sarcoid patients (mean 82.0%; range 43.9–97.4%) than in cells from controls (88.9%; 71.3–96.5%; p=0.01). After subdivision according to genotypes, the number of annexin V positive cells differ between patients carrying TT genotype (71.0%; 43.9–94.2%) and those with CC genotype (82.6%; 53.4–97.4%; p=0.01). There was no difference in apoptosis between patients with particular CXR-stages or organ involvement, respectively.
In conclusion, PBMC obtained from sarcoidosis patients showed more apoptosis resistant phenotype than cells from control subjects. PBMC obtained from sarcoidosis patients with TT *ANXA11* genotype showed more apoptosis resistant phenotype than cells from CT and CC patients. Further studies in a larger patient cohort are under progress.

MTNR1B polymorphism rs10830962 in healthy women and patients with Systemic lupus erythematosus

*R. Robeva[1], **S. Andonova**[2], D. Tanev[3], V. Decheva[2], A. Savov[2], P. Kumanov[1], R. Rashkov[3], Z. Kolarov[3];*
[1]Clinical Center of Endocrinology and Gerontology, Medical University, Sofia, Bulgaria, [2]National Genetic Laboratory, Medical University, Sofia, Bulgaria, [3]Clinic of Rheumatology, Medical University, Sofia, Bulgaria.

Background: The pineal hormone melatonin is an important modulator of the immune system in animals and humans. However, the role of the melatonin receptors for the development of autoimmune diseases in humans remains obscure. The present study aimed to investigate whether the MTNR1B rs10830962 gene polymorphism could influence on the clinical characteristics of systemic lupus erythematosus (SLE) in women.
Methods: The MTNR1B rs10830962C/G gene polymorphism was determined by RFLP analysis in 95 healthy women and 101 patients with SLE. The differences between genotype distribution in patients and controls and the interrelations between the C/G alleles and clinical features (ACR criteria) of the disease were studied.
Results: No differences in the allele distribution between patients with SLE and healthy controls were found (p=0.295). CC-homozygous patients had significantly more lupus ACR criteria in comparison to heterozygous GC and GG-homozygous patients (5.79±1.47 vs. 5.07±1.09, p=0.017) and a tendency for development of the disease at younger age (31.53±12.63 vs. 35.91±11.93, p=0.090). 76.5% of CC-patients had hematological disturbances in comparison to 58.2% of patients with other genotypes (p=0.082), probably because of the increased prevalence of leucopenia (38.2% vs. 17.9%, p=0.031). No significant interrelations between CC genotype and other ACR criteria were found.
Conclusions: Our preliminary results in SLE patients showed that MTNR1B rs10830962C/G polymorphism is not crucial for the development of SLE but it could modulate some clinical characteristics of lupus patients and especially the development of some haematological disturbances.
The study was financially supported by research grants 26/2010 and 59/2011, MU - Sofia, Bulgaria

Genome-wide association study in a French familial T1D cohort using the Illumina Immunochip beadarray

*W. Luscap[1,2], N. Bendelac[3], E. Pecorella[1], W. Carpentier[4], A. Boland[5], M. Nicolino[3], C. Julier[1,2], **C. Vandiedonck**[1,2];*
[1]Inserm UMRS-958, Paris, France, [2]Univ Paris Diderot, Sorbonne Paris Cité, Paris, France, [3]Division of Pediatric Endocrinology and Metabolism, Hôpital Femme-Mère-Enfant, Lyon, France, [4]P3S Platform, Hôpital Pitié-Salpêtrière, Paris, France, [5]Centre National de Génotypage, Institut de Génomique, Commissariat à l'Energie Atomique, Evry, France.

Our objective was to characterize susceptibility alleles in a French cohort of T1D families, using a recently developed genotyping microarray, the „immunochip". Resulting from a collaborative effort, this array includes ~200,000 SNPs including some 200 loci of interest to immune phenotypes. We performed a family-based association study in 236 trios. We replicated the well-known association of HLA class II alleles DR3 and DR4 ($p < 5x10^{-8}$). The most associated SNP in this region, rs9273363 ($p = 2.21x10^{-18}$, OR = 9.36), is in linkage disequilibrium with both DR3 and DR4. Outside the MHC, we replicated the association in the *BACH2* gene, with two new SNPs showing stronger effects than previously described ($p = 7.5x10^{-6}$, OR = 3.42). Suggestive evidence of association ($P<10^{-4}$) was found in four new regions (1p21, 3q25, 6q21 and 21q22). In contrast, other previously reported loci, notably including *INS*, *PTPN22*, and *IL2RA*, did not reach this threshold. We are currently validating these findings in 796 additional trios. Altogether, this work constitutes the first whole genome association study of a French T1D cohort.

Defective autophagy in TNFR associated periodic synfrom (TRAPS) accounts for mutant TNFR1 accumulation and enhanced inflammation

T. Bachetti[1], *S. Chiesa*[1], *P. Castagnola*[2], *D. Bani*[3], *E. Di Zanni*[1], *A. Omenetti*[1], *A. D 'Osualdo*[4], *A. Fraldi*[5], *A. Ballabio*[5,6,7], *R. Ravazzolo*[1,8], *A. Martini*[1,8], *M. Gattorno*[1], *I. Ceccherini*[1];
[1]*Giannina Gaslini Institute, Genoa, Italy,* [2]*IRCCS Azienda Ospedaliera Universitaria San Martino, Genoa, Italy,* [3]*University of Florence, Florence, Italy,* [4]*Sanford-Burnham Medical Research Institute, La Jolla, CA, United States,* [5]*Telethon Institute of Genetics and Medicine (TIGEM), Naples, Italy,* [6]*Baylor College of Medicine, Huston, TX, United States,* [7]*Texas Children Hospital, Huston, TX, United States,* [8]*University of Genoa, Genoa, Italy.*

Down-regulation of autophagy has been observed to enhance the inflammatory response, thus representing a possibly common pathogenic event underlying a number of autoinflammatory syndromes. So far, Tumor necrosis factor receptor associated syndrome (TRAPS) associated *TNFRSF1A* mutations have been reported to induce cytoplasmic retention of the receptor, defective TNFalpha-induced apoptosis and production of reactive oxygen species.
To search a link between *TNFRSF1A* mutations and inflammation in TRAPS, by means of both in vitro and ex vivo systems, represented by HEK293T cells transfected with expression constructs for WT and mutant TNFR proteins and by monocytes, derived by TRAPS patients, respectively, we have investigated the cellular response to mutant TNFR1 proteins.
We have found that autophagy is the main mechanism involved in mutant TNFR1 elimination and that it is impaired in the presence of TNFR1 misfolded proteins, thus likely accounting for their accumulation, for associated induction of NF-kappaB activity and excessive IL-1beta secretion.
We also show that autophagy inhibition due to TNFR1 mutant proteins can be reverted by geldanamycin, found to rescue membrane localization of mutant TNFR proteins, to reduce their accumulation, and to counteract the enhanced inflammation by decreasing IL-1beta secretion.
Overall, these observations provide a rationale to the apparent paradox that so far the most effective therapy in TRAPS is represented by inhibition of the cascade signaling induced by IL-1beta rather than by the use of drugs counteracting the TNFR-mediated pathway; as a consequence, we propose autophagy as a novel therapeutic target for TRAPS and other inflammatory diseases.

SNPs at the 3q21 -region are associated with type 1 diabetes and the appearance of beta-cell autoimmunity in Finland

A. P. Laine[1], *J. Lempainen*[1,2], *R. Veijola*[3], *O. Simell*[2], *M. Knip*[4,5,6], *J. Ilonen*[1,7], *F. D. R. The Finnish Pediatric Diabetes Register*[8];
[1]*Immunogenetics Laboratory, University of Turku, Turku, Finland,* [2]*Department of Pediatrics, University of Turku, Turku, Finland,* [3]*Department of Pediatrics, University of Oulu, Oulu, Finland,* [4]*Children's Hospital, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland,* [5]*Folkhälsan Research Center, Helsinki, Finland,* [6]*Department of Pediatrics, Tampere University Hospital, Tampere, Finland,* [7]*Department of Clinical Microbiology, University of Eastern Finland, Kuopio, Finland,* [8]*The Finnish Pediatric Diabetes Register, Finland, Finland.*

IDDM9-region on chromosome 3q21 has previously shown evidence for linkage to (LOD=3.4) and association with (TDT p=0.0002) type 1 diabetes (T1D) in Finnish families. As an extension to previous findings, we are analyzing genes at 3q21 region for association with T1D using tag-SNPs in an independent set of Finnish trio families. Currently two genes have been analyzed. Furthermore, two markers were examined by survival analysis for genotypic association with the appearance of beta-cell autoantibodies (AABs) and T1D and also for progression from autoimmunity appearance to clinical disease in a follow-up cohort of children at increased HLA associated risk for T1D.
Datasets included 977 Finnish T1D trio families and a follow-up cohort of 520 children with AABs (with or without T1D) and 992 AAB negative children. PLINK v1.07 and UNPHASED v3.0.13 were applied for TDT and haplotype-TDT and SPSS 19.0 for AAB appearance and progression analyses (Cox-regression).
Markers rs12485336 and rs777236 were significantly associated with T1D (p=0.034, p=0.009) and appearance of beta-cell autoimmunity (p=0.015, p=0.001) but not with progression to clinical disease from AAB positivity. In TDT, only haplotype analysis revealed significant association with T1D (rs9860012-rs777216, p=0.0014 and rs6796916-rs1345187, p=0.0022). Haplotypes showed independent association with T1D (rs6796916-rs1345187 conditioned by rs9860012-rs777216, p=0.018). Both AAB-associated markers were also associated with T1D in families due to LD with T1D-associated haplotypes.
Evidence from four independent data sets strongly suggests that 3q21-region is harboring T1D locus/loci. More comprehensive association studies are required to identify the functional polymorphisms affecting beta-cell autoimmunity and T1D susceptibility at this region.

P10.01

Asian-specific mitochondrial genom polymorphism (9 bp deletion) in the Hungarian population

K. Pentelenyi[1], *V. Reményi*[1], *G. Tömöry*[2], *B. Csányi*[2], *A. Gal*[1], *I. Rasko*[2], *M. Molnar*[1];
[1]*Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary,* [2]*Institute of Genetics, Biological Research Centre, Hungarian Academy of Sciences, Szeged, Hungary.*

Objectives: Several polymorphisms in the mitochondrial genome have population-genetically and anthropologically interest. The 9 bp deletion is anthropological marker for people of East-Asian origin.
Methods: The mitochondrial A8344G mutation was investigated by PCR-RFLP, performed on DNA samples isolated from blood and postmitotic muscle biopsy specimens. The mitochondrial COII/$tRNS^{Lys}$ and hypervariable regions were sequenced bidirectionally.
Results: From 890 patients we found 13 cases with 9 bp deletion (CCCCCTCTA) in the mitochondrial hipervariable non-coding region. Among them in 11 cases the 9 bp deletion was present with homoplasmic C8270T substitution. Their coexistence determines the M haplogroup. In one family (3 patients) beside these alterations we found a new heteroplasmic A8332G mutation in the $tRNA^{Lys}$ gene, wich was absent in 150 normal controls.
Conclusion: M haplogroup is in European populations very rare. It is mainly present in Asia, America and Australia, because of the human migration directions, these populations migrated eastwards. The frequency of 9 bp deletion in the Hungarian population is 1,5%. This polymorphism can be explained by the Westward migration of Hungarians from Siberia (in the matriarchal lineage). The deletion induce instability of this mitochondrial DNA-region like enough, and provoke the conformation other pathogen mutations.

P10.02

ABCC5 as a candidate gene for Type 2 diabetes

K. Direk[1], *W. Lau*[2], *C. Araiz*[2], *K. Small*[1], *L. Foukas*[2], *N. Maniatis*[2], ***T. Andrew***[3];
[1]*Kings' College London, London, United Kingdom,* [2]*University College London, London, United Kingdom,* [3]*Imperial College, London, United Kingdom.*

Type 2 diabetes (T2D) is a common, multi-factorial disorder caused by environmental and genetic risk factors. We have conducted a candidate gene study of a linkage disequilibria (LD) genomic region including *PARL* and *ABCC5* for European and African American samples, in relation to the phenotypes of healthy fasting plasma insulin and glucose levels, visceral fat accumulation and T2D disease. Previous functional studies and animal models of T2D have implicated *PARL*, but human association studies have yielded contradictory results.
We found no evidence of phenotypic association with *PARL* using commercial and fine map genomic and expression data. By contrast, we observed strong evidence of phenotypic association with *ABCC5* for European and African American samples. The genomic location estimate for the *ABCC5* functional variant associated with T2D (p=1E-06) and expression data (p=1E-11) was identical for all samples (185,136Kb), suggesting the identified genomic variant is an eQTL for *ABCC5*. We will also present preliminary hepatocyte cell culture results testing if *ABCC5* influences glucose uptake.
Previous observations of human genomic association with *PARL* may be due to LD confounding with *ABCC5*. The *ABCC5* variant is associated with expression, fasting insulin and glucose levels and T2D, while *ABCC5* expression is itself an intermediate phenotype for T2D. Given the *ABCC5* risk variant is cosmopolitan, common and observed in populations of disparate ancestry, this suggests the polymorphism is likely to be old and that the transporter gene plays an aetiological role in the onset of T2D.

P10.03

Severe Form of Niemann-pick Type B Disease in The Iranian Population

F. Hadipour[1], *Y. Shafeghati*[1], *Z. Hadipour*[1], *M. Banikazemi*[2];
[1]*Sarem Cell Research Center & Hospital, Tehran, Islamic Republic of Iran,* [2]*Westchester Medical Center, New York, NY, United States.*

The non-neuronopatic type of acid sphingomyelinase (ASM) deficiency also designated as Niemann-Pick disease type B [NPD-B] is regarded as mild, late-onset and non-neurological form of acid sphingomyelinase (ASM) deficiency that presents with visceromegaly, and interstitial lung disease.
Here we report data on ten Iranian patients (5males, 5 females, under 18 years of age) with confirmed diagnosis of NPD-B. Longitudinal data were available for all patients in this study.
Most patients presented with thrombocytopenia, while anemia and leucopenia were less common. HDL cholesterol was reduced in most patients. Viseromegaly and Pulmonary disease were extremely severe in 50% of the cases.
A unique feature of this population was the observance of facial coarseness and severe growth retardation, which were present in more than 50% of cases. There was no evidence of skeletal abnormalities. In these cases motor development was also significantly delayed, perhaps secondary to cachexia and severe organomegaly. However in all cases, mental developments assessed by language and communication skills were progressive. Consanguinity of parents were documented in all the cases and various homozygot missense mutation in exon 6 of SMPD1 gene showed a high prevalence.
This is the first report of severe form of NPD-B with high morbidity and mortality seen among the Iranian population. In these cases pulmonary disease and viseromegaly are the most debilitating features. As enzyme replacement therapy (ERT) with recombinant sphingomyelinase is being developed special attention on this group of patients is warranted.

F. Hadipour: None. **Y. Shafeghati:** None. **Z. Hadipour:** None. **M. Banikazemi:** None.

P10.04

A *de novo* novel *POLG* mutation associated with Alpers syndrome

A. Löfgren[1,2,3], *T. Van Laer*[1,2,3], *K. Jansen*[4], *G. Buyse*[4], *L. Lagae*[4], *P. De Jonghe*[2,3,5], *C. Van Broeckhoven*[1,2,3], *G. Van Goethem*[2,3,5];
[1]*Diagnostic Service Facility, Dept of Molecular Genetics, VIB, Antwerpen, Belgium,* [2]*Dept of Molecular Genetics, VIB, Antwerpen, Belgium,* [3]*Laboratory of Neurogenetics, Institute Born-Bunge, University of Antwerp, Antwerpen, Belgium,* [4]*Pediatric Neurology, Dept of Pediatrics, University Hospitals Leuven Gasthuisberg and University of Leuven, Leuven, Belgium,* [5]*Neuromuscular Reference Center, Dept of Neurology, Antwerp University Hospital, Edegem, Belgium.*

A 16-month old boy was admitted to pediatric neurology with a status epilepticus and subsequent epilepsia partialis continua, elevated liver enzymes and increased blood and CSF lactate. EEG showed epileptic discharges on both occipital regions, brain MRI showed edema of the right hippocampus and muscle biopsy revealed decreased enzyme activities of respiratory chain complexes II+III and IV. The symptoms correspond with Alpers syndrome, a recessive disease in children characterized by progressive degeneration of the central nervous system due to mutations in the gene *POLG* coding for the mitochondrial DNA polymerase gamma. We sequenced DNA of the proband for mutations in *POLG* and identified 2 heterozygous mutations: a single base mutation in exon 7 leading to the known recessive mutation p.Ala467Thr and a frameshift insertion of 1-bp in exon 17 p.Ala880Glyfs*11, leading to protein truncation deleting the polymerase domain and activity. Analysis of the parents' DNA indicated that the mother carried p.Ala467Thr while the father did not carry any mutation in *POLG*. Non-paternity could be excluded by genetic fingerprinting. Both father and son carried the common 4-bp insertion polymorphism in intron 17 which was absent in the mother. Therefore, we predicted that p.Ala880Glyfs*11 might have arisen *de novo* on the father's allele. We were able to proof the *de novo* appearance by using a primer with its 3' end matching the insertion sequence and amplifying only the mutant allele. In conclusion, the patient is a compound heterozygote carrier of 2 *POLG* loss-of-function mutations, p.Ala467Thr and p.Ala880Glyfs*11, leading to recessive Alpers syndrome.

A. Löfgren: None. **T. Van Laer:** None. **K. Jansen:** None. **G. Buyse:** None. **L. Lagae:** None. **P. De Jonghe:** None. **C. Van Broeckhoven:** None. **G. Van Goethem:** None.

P10.05

POLG-related Alpers-Huttenlocher syndrome in four Polish children.

D. Piekutowska-Abramczuk[1], *J. Trubicka*[1], *M. Tesarova*[2], *K. Strawa*[3], *M. Kaliszewska*[4], *J. Sykut-Cegielska*[5], *I. Jankowska*[6], *K. Kotulska*[7], *M. Pronicki*[8], *D. Jurkiewicz*[1], *E. Ciara*[1], *R. Płoski*[3], *J. Zeman*[2], *M. Krajewska-Walasek*[1];
[1]*Department of Medical Genetics, Children's Memorial Health Institute, Warsaw, Poland,* [2]*Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [3]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland,* [4]*Institute of Genetics and Biotechnology, Faculty of Biology, University of Warsaw, Warsaw, Poland,* [5]*Department of Metabolic Diseases, Children's Memorial Health Institute, Warsaw, Poland,* [6]*Department of Liver Diseases and Transplantation, Children's Memorial Health Institute, Warsaw, Poland,* [7]*Department of Neurology and Epileptology, Children's Memorial Health Institute, Warsaw, Poland,* [8]*Department of Pathology, Children's Memorial Health Institute, Warsaw, Poland.*

A wide spectrum of POLG-related diseases, including the most severe Alpers-Huttenlocher syndrome (AHS) is caused by dysfunction of the polymerase γ, the only mammalian enzyme able to replicate and repair mtDNA. Mutations in *POLG* account for ~25% of all mitochondrial defects. The diagnostic triad of AHS includes: drug-resistant epilepsy, hepatic impairment triggered by sodium valproate and mitochondrial DNA depletion. Here we describe four Polish children born in a good condition,

with infantile development delay due to muscle hypotonia, who died with severe liver failure at the age of 10-34 months. Intractable seizures followed by hemiplegia, and failure to thrive dominated at disease onset in all cases. Hepatic injury features were associated with valproic acid administration. Abnormalities characteristic for liver damage (hypertransaminasemia, coagulopathy, significant INR increase, decrease in fibrinogen concentration, hyperbilirubinemia, hipoalbuminemia, hipocholesterolemia), lactic acidemia, and OXPHOS dysfunction were found in most of the patients.

Severe mtDNA depletion confirmed in authopsied liver specimens ranged from <1% to 18% of control values in all cases.

Molecular analysis showed the presence of c.2243G>C(p.W748S) *POLG* mutation associated with c.3428A>G(p.E1143G) variant in all children. One homozygote and three compound heterozygotes with c.2419C>T(p.R807C), c.3630C>G(p.Y1210X), and c.2605C>T(p.R869X) were identified. This study shows similarity of genotypes identified in Polish and Nordic patients, with dominant p.W748S mutation. *POLG* mutation searching and mtDNA depletion assessment should be included in differential diagnosis of intractable epilepsy associated with hepatopathy. The study was supported by NCN grants: 2857/B/P01/2010/39, 01627/B/NZ2/2012/05, VENTURES 2011-8/3 FPS, MSHE0751/B/P01/2009/37, CMHI S126/12.

Mutations in mitochondrial aminoacyl tRNA synthetases identified by exome-sequencing

D. Diodato[1], *L. Melchionda*[1], *T. B. Haack*[2], *E. Baruffini*[3], *C. DallaBona*[3], *C. Lamperti*[1], *H. Prokisch*[2], *I. Ferrero*[3], *M. Zeviani*[4], ***D. Ghezzi***[1];
[1]*The Foundation "Carlo Besta" Institute of Neurology, Milan, Italy,* [2]*Institute of Human Genetics, Helmholtz Zentrum, Munich, Germany,* [3]*University of Parma, Parma, Italy,* [4]*MRC Mitochondrial Biology Unit, Cambridge, United Kingdom.*

Mitochondrial disorders include a group of heterogeneous clinical syndromes, frequently presenting as encephalo- and/or cardiomyopathy, with a broad range of associated causative genes. In the last years, several mutations in genes associated with defects of mitochondrial protein synthesis, affecting either the mitochondrial DNA (mtDNA) or nuclear genes, have been reported: an increasing group consists of mutations in mitochondrial aminoacyl tRNA synthetases (aARSs) genes, that are associated with diverse clinical presentations, usually with an early-onset and transmitted as autosomal recessive traits. A strict genotype-phenotype correlation has been reported for most of these genes, albeit it is not clear the reason for specific and different cellular or tissue damages, being all aARS2 ubiquitous enzymes working in the same pathway.
Whole-exome analysis in patients with clinical presentations suggestive of mitochondrial disorder, and OXPHOS deficiency, allowed the identification of mutations in: 1) *VARS2,* in one subject with microcephalia and epilepsy; ii) *AARS2,* in one subject presenting cerebellar atrophy; iii) *TARS2,* in two siblings presenting with axial hypotonia and severe psicomotor delay. All

identified variants are not present in SNPs databases, are predicted to be deleterious by bioinformatic analysis, and segregate within the families; moreover the pathogenic role of *VARS2* and *AARS2* variants was proven using yeast models.
This study reports two new mitochondrial aminoacyl-tRNA synthetase (VARS2 and TARS2) as cause of mitochondrial diseases, and presents a new phenotype associated with *AARS2* mutations; moreover, we confirm the value of exome sequencing for the identification of disease genes in mitochondrial disorders.

Autosomal dominant vitamin B12 deficiency: a new form of hereditary juvenile megaloblastic anemia

B. Isidor[1], *S. Küry*[1], *A. Kuster*[1], *M. Couec*[1], *E. Blouin*[2], *S. Bezieau*[1];
[1]*CHU Nantes, Nantes, France,* [2]*Laboratoire LABCATAL, Paris, France.*

Familial selective vitamin B12 (cobalamin, Cbl) malabsorption (Imerslund-Gra¨sbeck syndrome, IGS, OMIM 261100) is a group of autosomal recessive disorders characterized by selective malabsorption of Cbl from the terminal ileum in the presence of normal histology. Mutations in the amnionless (*AMN*), cubilin (*CUBN*) and Gastric Intrinsic Factor (*GIF)* genes are known to be causes of IGS.
Here we report, a family affected by vitamin B12 malabsorption for whom molecular analysis failed to identify any mutation for *AMN, CUBN* and *GIF.* Clinically, these patients resembled those with typical IGS; cobalamin absorption tests had been inconclusive regarding
the nature of the defect. The transmission of the disease from the mother to her children supports an autosomal mode of inheritance.
Therefore, we propose that this family shows a new form of hereditary juvenile megaloblastic anemia due to vitamin B12 (cobalamin) deficiency.

Biotin-responsive basal ganglia disease revisited: Clinical, radiologic, and genetic findings

A. m. alhashem*, S. Al Shahwan, B. Tabarki;*
Prince sultan military and medical city, Riyadh, Saudi Arabia.

Background Biotin responsive basal ganglia disease (BBGD) also called Thiamine transporter-2 deficiency, is a treatable autosomal recessive neurometabolic condition resulting from mutations in the SLC19A3 gene**.**
Objective To investigate the clinical, genetic, and neuroradiologic data of BBGD and clarify the disease spectrum.
Methods We investigated all Patients with a genetically proven diagnosis of BBGD between 2009 and 2012. All patients underwent a detailed medical history and clinical examination, extensive laboratory investigations including genetic tests, and brain MRI. Finally, we conducted a systematic review of the literature.
Rresults We enrolled 15 with BBGD, and analyzed the data on 14 patients from 4 previous reports. The BBGD occurred predominantly in preschool/school-aged patients in the Saudi population, but it was also observed in other countries. The typical clinical picture consisted of recurrent subacute encephalopathy leading to coma, seizures, and extrapyramidal manifestations. The brain MRI typically showed symmetric and bilateral lesions in the caudate nucleus and putamen, infra- and supratentorial brain cortex, and in the brainstem. Early treatment with a combination of biotin and thiamine resulted in clinical and neuroradiologic improvement. Death and neurologic sequelae were observed in those who were not treated or were treated late.
Conclusions BBGD is an underdiagnosed pan-ethnic treatable condition. Clinicians caring for patients with unexplained encephalopathy and neuroimaging showing vasogenic edema in the bilateral putamen and caudate nuclei, and brainstem should consider this disorder early because a therapeutic trial with biotin and thiamine can be lifesaving. Our study also showed that thiamine is main treatment of this disease.

P10.09
P30L and V281L mutations distribution in Macedonian and Serbian patients with nonclassic 21-hydroxylase deficiency

V. Anastasovska[1], *T. Milenkovic*[2], *M. Kocova*[1];
[1]*Genetic Laboratory, Department of Endocrinology and Genetics, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Institute for Mother and Child Health, Belgrade, Serbia.*

Background: The mild nonclassic form of steroid 21-hydroxylase deficiency is one of the most common autosomal recessive disorders, occurring in almost 1% of Caucasians and 3% of Ashkenazi Jews. Although rarely recognized in infants, it may cause premature adrenarche and pubarche, virilization in young women and variable symptoms in young men. The missense P30L and V281L mutations in CYP21A2 gene for 21-hydroxylase are commonly associated with nonclassical congenital adrenal hyperplasia (NCAH) that produce enzymes retaining 20-60% of normal activity.
Method: We have performed direct molecular P30L and V281L detection in 20 Macedonian and 13 Serbian NCAH patients diagnosed according to standard clinical criteria at the Department of Endocrinology and Genetics, University Children's Clinic, Skopje, Republic of Macedonia and Institute for Mother and Child Health, Belgrade, Serbia, using PCR/ACRS method.
Results: The P30L mutation was detected in 40% (8/20) Macedonian NCAH patients on the 27.5% (11/40) alleles and 46.2% (6/13) Serbian patients on the 34.6% (9/26) alleles. Three homozygotes for P30L in each population and 5 heterozygotes in Macedonian and 3 heterozygotes in the Serbian patients were detected. The V281L mutation was observed only in 3/20 (15%) Macedonian NCAH patients on 3/40 (7.5%) of the alleles.
Conclusion: The P30L distribution in Macedonian and Serbian NCAH patients was higher compared with other European populations. On the other hand, lower V281L distribution in Macedonian patients than other European populations was observed while it was undetected in the Serbian NCAH patients.
Key words: Nonclassical congenital adrenal hyperplasia (NCAH), CYP21A2 gene, P30L mutation, V281L mutation.

P10.10
Structural Elucidation of the Calcium-Sensing Receptor Extracellular Domain: 3D mapping of mutations observed in hyper- and hypocalcemic patients

F. Di Meo[1], *P. Trouillas*[1], *C. Magdelaine*[2], *A. Nizou*[3], *B. Funalot*[3,2], *F. Sturtz*[3,2], *A. Lienhardt-Roussie*[4], ***A. Lia-Baldini***[3];
[1]*LCSN-EA 1069, Faculté de Pharmacie, Limoges, France,* [2]*Service de Biochimie et de Génétique Moléculaire, CHU de Limoges, Limoges, France,* [3]*EA6309: Neuropathies périphériques et Maintenance Myélinique, Université de Limoges, Limoges, France,* [4]*Service de Pédiatrie, CHU de Limoges, Limoges, France.*

The Calcium-Sensing-Receptor (CASR) is a model for G-Coupled-Protein-Receptors (GPCR) more generally. The dimeric CASR protein plays a central role in regulating extracellular Ca2+ concentrations. Gain-of-function mutations of the CASR gene have been identified in patients with sporadic or familial-autosomal-dominant-hypocalcemia (ADH). Inactivating mutations of the CASR gene cause familial-hypocalciuric-hypercalcemia (FHH). More than 63% of these CASR mutations are located in the extracellular-domain (ECD). Despite more than a decade of effort, crystals of neither whole CASR nor CASR-ECD have been obtained. We developed by homology modeling and molecular dynamic (MD) simulations a complete 3D model of CASR-ECD, based on the rat mGluR1 structure. This new model allowed five regions in CASR-ECD to be precisely defined: the Membrane-Anchor-Domain (MAD), the Internal-Domain (ID), the Crown-Domain (CD), the Extended-Dimerization-Domain (EDD) and Calcium-Binding-Sites (CBS). The known amino acid substitutions associated with FHH and ADH were mapped onto this 3D model. The CD was the only domain in which all known mutations were activating. We further studied this region by functional and structural analyses of a new mutation. We showed that this mutation is an activating mutation and that it results in the loss of a disulphide bond, such that there is no covalent bonding in the CD. This new model thus provided evidence of the importance of the CD in CASR regulation activity. More generally, it will help to clarify the role of each region of this protein by allowing the effects of known and new mutations to be correlated to their 3D location.

P10.11

Nitrosylation regulates Carnosinase activity substrate-specific

B. Lanthaler[1], *A. Amberger*[1], *J. Zschocke*[1], *C. P. Schmitt*[1], *V. Peters*[2];
[1]*Divison of Human Genetics, Innsbruck, Austria,* [2]*Division of Metabolic Diseases, Centre for Pediatric and Adolescent Medicine, Heidelberg, Germany.*

Objectives: Diabetic nephropathy (DN) is the final stage in 40% of long term diabetic patients. A common variant in carnosinase (CNDP1, "Mannheim-Allele") is associated with lower activity and a reduced probability of developing a DN. Carnosinase catalyzes the degradation of histidine-containing dipeptides such as carnosine and anserine, compounds with cytoprotective functions. Several factors were identified regulating carnosinase activity. Since nitric oxide concentrations are altered under diabetic conditions, we investigated the role of both cysteine residues in the carnosinase as possible targets for nitrosylation and its effect on carnosinase activity.
Methods: We cloned three different CNDP1 variants: The wild type enzyme as well as two variants where each cysteine (Mut 1^{C102S} and Mut 2^{C229S}) residue has been substituted by a serine, respectively. Recombinant FLAG-tagged proteins were purified from CHO supernatant. The high-purified proteins have been studied for altered enzyme activity after nitrosylation with a NO donor (e.g. 3-Morpholinosydnonimine).
Results: Carnosine degradation was about 20-fold higher for the wildtype compared to anserine degradation. Enzyme activity was completely diminished for Mut 1 (Mut 1^{C102S}), whereas Mut 2 (Mut 2^{C229S}) showed activities in the same range as measured for the wildtype. Nitrosylation reduced enzyme activity of wild-type and Mut 2 carnosinase in a concentration-dependent manner. Contrary to these findings, nitrosylation had no effect on anserine degradation.
Conclusion: Nitrosylation regulates carnosinase activity in a substrate-specific manner. These findings suggest an important role of NO in the regulation of carnosinase activity. Therefore, modulation of NO-production can be of important therapeutic value.

Cerebellar ataxia and atrophy due to mutations in CABC1/ADCK3, a diverse clinical presentation in two sisters and potentially treatable.

D. Lev[1,2], *L. Blumkin*[1], *K. Yosovich*[1], *A. Zerem*[1], *C. Vinkler*[1], *M. Michelson*[1], *T. Lerman-Sagie*[1,3], *E. Leshinsky-Silver*[1,4];
[1]*Wolfson Medical Center, Holon, Israel,* [2]*Sackler School of Medicine, Tel-Aviv University, Tel- Aviv, Israel,* [3]*Tel Aviv University, Tel Aviv, Israel,* [4]*Tel Aviv University, Tel- Aviv, Austria.*

Abstract
We describe two sisters with cerebellar ataxia and atrophy. The younger sister demonstrates early onset rapidly progressive cerebellar ataxia accompanied by motor and non-motor cerebellar features, as well as cognitive decline and psychiatric problems. Mitochondrial respiratory chain enzyme analysis in muscle showed a decrease in complex I+III. Progressive cerebellar atrophy was demonstrated on serial brain MRI imagings. CoQ supplementation was started at the age of 5 years with significant improvement in motor and cognitive abilitiesand partial lessening of the cerebellar signs. Discontinuation of the treatment with CoQ resulted in worsening of the ataxia, cognitive decline and severe depression associated with significant progression in the cerebellar atrophy. The older sister, who is 32 years old, has non progressive dysarthria and clumsiness from the age of 10 years and cerebellar atrophy shown on MRI. Both were found to be compound heterozygote for 2 mutations in the CABC1/ADCK3 gene, one of the mutations was not previously described.
Patients with primary CoQ deficiency due to *CABC1/ADCK3* mutations show wide spectrum of clinical presentations even in the same family.
The remarkable clinical response of some of these patients to CoQ supplementation highlights the importance of treatment trials with CoQ10 in patients with cerebellar ataxia and atrophy even before analyzing the *CABC1/ADCK3* gene. Hence it might improve the outcome for these patients

The association of common SNPs with HDL cholesterol levels in Latvian population

I. Radovica, *D. Fridmanis, I. Vaivade, L. Nikitina-Zake, J. Klovins;*
Latvian Biomedical Research and Study Centre, Riga, Latvia.

Low level of high-density lipoprotein cholesterol (HDL-C) is one of the main risk factors for cardiovascular disease (CAD) and the heritability of HDL-C level is estimated at approximately 50%. Earlier association studies of HDL-C have found numerous genes and their respective proteins influencing lipid phenotype. The precise genetic profile determining heritability of HDL-C however are far from complete and there is substantial room for further characterization of genetic profiles influencing blood lipid levels.
Here we report an association study of 139 SNPs from more than 30 loci with HDL-C level. We genotyped 1273 individuals selected from Genome Database of Latvian Population.
58 SNPs from 13 loci were nominally associated ($p<0.05$) with HDL-C levels. 10 SNPs from CETP gene and two from MLXIPL retained significant association with low HDL-C levels (rs1800775, rs3764261, rs173539, rs9939224, rs711752, rs708272, rs7203984, rs7205804, rs11076175, rs9929488, rs17145738 and rs2286276) after Bonferoni correction. We have also prepared case-control haplotype association analysis of extreme ends of HDL-C level distribution and identified haplotypes from CETP with distinct effects on determination of HDL-C levels. Moreover we performed case-control allele dosage test of extreme tails of DHL-C level for 20 nominally associated SNPs and found that more than 25 risk alleles significantly decreases HDL-C level.
Our conclusion: CETP gene is the strongest genetic factor influencing HDL-C levels in the Latvian population.

Functional studies of novel mutations in the CYP21A2 gene of Norwegian patients with 21-hydroxylase deficiency

I. Brønstad[1], *P. Methlie*[1], *A. S. B. Wolff*[3], *E. Bratland*[1], *I. Nermoen*[2], *K. Løvås*[1], *E. S. Husebye*[1];
[1]*University of Bergen, Bergen, Norway,* [2]*University of Oslo, Oslo, Norway.*

Background: Congenital adrenal hyperplasia (CAH) with 21- hydroxylase deficiency is caused by mutations in *CYP21A2*. Recently we reported 4 novel mutations in the Norwegian population of patients with CAH.

Objective: To characterise the novel *CYP21A2* mutations by *in silico* analyses, develop an *in vitro* assay for determination of the enzyme activity of each mutations, and compare the results with the patient phenotypes.

Methods: In silico analysis was performed by Clustal Omega multiple sequence alignment tool, Polyphen, and Pymol. The QuickChange II Site Directed Mutagenesis Kit (Stratagene) was used to generate point mutations. TNT® Quick Coupled Transcription/Translation system (Promega) was used for protein expression. 21-hydroxylase activity was assayed by LCMS-MS (conversion of 17-hydroxyprogesterone to 11-deoxycortisol).

Results: The mutation p.L388R revealed no activity, while the p.E140K showed an activity of less than 10% compared to the wild type, which were in accordance with the *in silico* analysis. The mutation p.P45L gave slightly impaired activity by the *in vitro* assay, but was expected to interfere with the protein activity by Polphen. The mutation p.V211M showed an activity of 30-60% compared to the wild type, but were predicated as benign by Polyphen.

Conclusion: The results from the *in vitro* study of the novel mutations were in accordance with the severity of the phenotype of the patients, but only partly in agreement with the *in silico* results.

I. Brønstad: None. **P. Methlie:** None. **A.S.B. Wolff:** None. **E. Bratland:** None. **I. Nermoen:** None. **K. Løvås:** None. **E.S. Husebye:** None.

P10.15

Single heterozygous mutations in ABCC8 are a common cause of diazoxide-unresponsive diffuse form of congenital hyperinisulinism

C. Saint-Martin[1], Q. Zhou[2], C. Vaury[1], J. Arnoux[3], P. De Lonlay[3], S. Shyng[2], C. Bellanné-Chantelot[1];
[1]AP-HP Groupe Hospitalier Pitié Salpêtrière, Paris, France, [2]Department of Biochemistry and Molecular Biology, Oregon Health & Science University, Portland, OR, United States, [3]Reference Center for Inherited Metabolic Diseases, AP-HP Hôpital Necker-Enfants Malades, Université Paris Descartes, Paris, France.

Background *ABCC8* encodes the SUR1 subunit of the β-cell ATP-sensitive potassium channel whose loss of function is responsible for congenital hyperinsulinism (CHI). Diffuse forms of diazoxide-unresponsive CHI are classically associated with the presence of two mutations with a recessive inheritance. However several dominant missense mutations were recently reported.
Methods Clinical and molecular characterization of 27 probands with a diagnosis of diazoxide-unresponsive diffuse CHI and carrying a unique *ABCC8* mutation were performed. - Nine missense *ABCC8* mutations were subjected to in vitro studies testing 1) processing efficiency of mutant channels by Western blots and surface immunofluorescence staining and 2) channel function using inside-out patch-clamp recording.
Results Twenty-three distinct *ABCC8* heterozygous mutations were identified in these 27 patients: 15 missense mutations (62%), 4 truncating mutations (17%), 3 splice mutations (13%) and 1 in frame indel mutation. None of the missense mutations altered the processing of the SUR1 protein. All mutants but two had dramatically reduced response to MgADP or to diazoxide (<10% of WT current).
Conclusion This analysis confirms that mutated channels with preserved trafficking to the membrane are associated with a dominant inheritance. It also raises the question of the truncating mutations identified as sole event and generally associated with defective trafficking. Consequently, diffuse forms of CHI may be associated with either recessive or dominant inheritance. These findings are of major importance in terms of differential diagnosis with focal forms associated with a paternally-inherited mutation and in terms of genetic counselling.

Connexin50 mutation L7Q attenuates hypertension in spontaneously hypertensive rat SHR/OLAIPCV

M. Krupkova[1], *F. Liška[1], M. Pravenec[1,2], V. Zídek[2], Z. Vernerova[3], D. Krenova[1], V. Kren[1,2], O. Šeda[1];*
[1]First Faculty of Medicine, Institute of Biology and Medical Genetics, Charles University, Prague, Czech Republic, [2]Institute of Physiology, Academy of Sciences of The Czech Republic, Prague, Czech Republic, [3]Third Faculty of Medicine, Institute of Pathology, Charles University, Prague, Czech Republic.

The aim of this study was to determine the metabolic, hemodynamic and transcriptomic outcomes of recently identified connexin50 gene (Gja8) mutation L7Q that arose spontaneously in the spontaneously hypertensive inbred rat strain SHR/OlaIpcv, creating thus a coisogenic rat strain SHR-Dca.
Adult, standard chow-fed male rats of SHR/OlaIpcv and SHR-Dca strains were used (n = 8/strain/procedure). We assessed metabolic and morphometric profiles of the two strains, measured arterial blood pressures continuously by radiotelemetry (36 days). We used Affymetrix GeneChip® Rat Exon 1.0ST Array to assess the heart and renal transcriptome. Immunohistochemistry was performed using polyclonal rabbit anti-Connexin50 (H-65) antibody .
The distribution of triglycerides and cholesterol across major lipoprotein fractions was similar in both strains except for significantly lower high-density lipoprotein cholesterol concentrations in SHR-Dca. There were no differences in morphometry, glucose tolerance, adiponectin and leptin levels. We found significant 10-15mmHg decrease of both systolic and diastolic blood pressures in SHR-Dca compared to SHR (repeated measures ANOVA $p<0.01$ and $p<0.05$, respectively). By immunohistochemistry we localized Cx50 in heart, kidney, aorta, liver and lungs, mostly in endothelium. There were 15 transcripts common to the heart and kidney sets including S100A9, Bcl6 and Clec4d downregulated and Cyr61, Frs2 and Dusp1 upregulated in both heart and kidney of SHR-Dca compared to SHR.
We show that Cx50 mutation L7Q attenuates hypertension in SHR-Dca strain and significantly changes the renal and cardiac expression of sets of genes involved in blood pressure regulation and related pathways.
Suported by: GACR grant P301/12/0777.

COQ6 mutations in patients with nephrotic syndrom, sensorineural deafness and optical atrophy

C. Rousset-Rouvière[1,2], *M. Caillez[1,2], F. Garaix[1,2], A. Cano[1,2], O. Gribouval[3], O. Boyer[4,3,5], C. Antignac[6,3,5], M. Tsimaratos[1,2];*
[1]Néphrologie pédiatrique - Hôpital La Timone, Marseille, France, [2]CHU de Marseille, Marseille, France, [3]Inserm U983 - Institut Imagine, Paris, France, [4]Néphrologie pédiatrique et MARHEA - Hôpital Necker - Enfants malades, Paris, France, [5]Université Paris Descartes - Sorbonne Paris Cité, Paris, France, [6]Génétique médicale - Hôpital Necker - Enfants malades, Paris, France.

Primary Q10 coenzyme (COQ10) deficiency is a rare autosomal recessive mitochondrial disease accessible to a substitutive treatment. Clinical presentation is heterogeneous depending upon the gene involved. Mutations in COQ2, COQ6 and PDSS2 genes are responsible for steroid-resistant nephrotic syndrome associated to various extra-renal features. COQ6 gene mutations have been reported in 13 individuals belonging to 5 unrelated families who presented steroid-resistant nephrotic syndrome and sensorineural deafness.
We report on two brothers of Turkish decent with COQ10 deficiency with renal involvement, sensorineural deafness and optical atrophy. Patient 1 (the older brother) was diagnosed at the age of 5 years with end-stage kidney disease and bilateral sensorineural deafness. He received a kidney transplant at the age of 6. Patient 2 (the younger brother) developed nephrotic range proteinuria and bilateral sensorineural deafness at the age of 5 years. Kidney histology revealed focal segmental glomerulosclerosis not otherwise specified. ACE inhibitors and diuretics led to a sustained remission. At the age of 17 years, Patient 1 presented sudden and severe bilateral blindness with flat electroretinogram secondary to optical atrophy that did not improve with methylprednisolone pulses. Direct Sanger sequencing of the COQ6 gene revealed a previously published homozygous missense mutation (pA353D) in the two brothers. Subsequently, both patients were treated with oral COQ10 (Idebenone) which allowed a progressive improvement in visual acuity in Patient 1.
We report herein the first patient with COQ6 mutations and ocular involvement in association with renal and auditive defects. COQ10 substitution might significantly improve the disease course in the patients.

Genomic anatomy of chronic progressive external ophthalmoplegia patient (CPEO) related multiple deletions on mitochondrial genome

K. Takahashi[1], *Y. Ohnuki[1], T. Shiina[1], S. Suzuki[1], Y. Ozaki[1], Y. Goto[1], E. Iijima[1], W. Takahashi[1], A. kondo[1,2], S. Izumi[1], T. Takizawa[1], H. Inoko[1];*
[1]Tokai Univercity School of Medicine, Isehara,Kanagawa, Japan, [2]Kagawa National children's Hospital, Zentuuji,Kagawa, Japan.

Mitochondrial genome (mtgen) deletion syndromes comprise three major phenotypes, progressive external ophthalmoplegia (PEO), Kearns-Sayre syndrome (KSS), and Pearson syndrome. PEO is conventionally defined as progressive limitation of eye movements with normal pupils and ptosis of the eyelids. 1.1 kb to 10 kb of multiple deletions were previously reported from the mtgen analyses of skeletal muscle, however systematic consideration and molecular mechanism of the multiple deletions are unknown.
Here we report detail mitochondrial genome analysis using a patient (31 y/o male) who suffering from PEO, muscle weakness, hearing loss, leukoencephalopathy and hypogonadism. After receiving his agreement through a genetic counselling, we performed extraction of the genomic DNA from muscle tissue, peripheral blood cells and oral mucosa, long range PCR covering the whole mtgen region, sub-cloning of the PCR products, nucleotide sequencing of the sub-clones, and identification of the deletion points by comparing with normal mtgen sequences structures.
At least four kinds of deletions, ranging from 7627 bp to 8976 bp, were detected in the muscule tissue, but these deletions were not observed in peripheral blood cells and oral mucosa. Of them all deletion points involved in whole mtgen region were identified, and none of them had identical short nucleotide sequences near the deletion points that have not been so far reported. These findings suggest that the onset of the CPEO in caused by accumulation of *de novo* deletions and it may lead to solution why he has the unique symptoms.

Molecular analysis of mitochondrial DNA in children with vomiting cyclic syndrome

S. Cara[1], *F. Pugliatti*[1], *C. Di Bella*[1], *V. Procopio*[1], *M. Fuoti*[2], *S. Martinazzi*[2], *A. Ravelli*[2], *V. Salpietro*[1], *C. Salpietro*[1], *L. Rigoli*[1];
[1]*Department of Pediatrics, Medical School, Messina, Italy,* [2]*Department of Pediatrics, Children's Hospital, Brescia, Italy.*

Cyclic vomiting syndrome (CVS) is a disabling condition affecting mostly children characterized by recurrent attacks of unremitting nausea and vomiting, often associated with lethargy and separated by asymptomatic intervals. Neuromuscular disease manifestations are present in approximately 25% of cases. In CVS children with a family history of migraine, migraine was identified on the maternal side only in 63% versus the paternal side only in 16% . Therefore, it has been suggested that at least some of the predisposing genetic factor is located on the maternally-inherited mitochondrial DNA (mtDNA). In order to further study the relationship between mtDNA sequences and CVS, we screened the entire mtDNA D-loop in 37 Italian children (23 males and 14 females) (age 11.9±4.8 years) with CVS, in their first-degree relatives and in 103 control subjects. The subjects included in our study had mtDNA haplogroup H.
Over 1200 bp of mtDNA, including the D-loop region, were amplified by nested PCR using primers L15990-H617. Four overlapped nested PCRs were performed using primers L15990-H16434, L16431-H162, L039-H407, and L361-H617. PCR products were analyzed by automatic sequencing. Excluding insertions in the ultravariable 302-315 region, 22 different mtDNA variants were identified in two or more CVS subjects. Most prominently, one of the SNPs, 16519C>T, was found to be highly associated with CVS vs. controls ($p<0.001$). Another, 73A>G SNP was found to be highly associated with CVS in subjects with 16519T vs. in controls ($p>0.01$) with 16519T. Our findings provide further evidence that there is a component of mitochondrial dysfunction in CVS.

DHTKD1 mutations cause 2-aminoadipic and 2-oxoadipic aciduria and suggest a therapeutic strategy for glutaric aciduria type 1

Glutaric aciduria type 1, caused by mutations in GCDH, results in a severe neurological phenotype for which the only available treatment is a lysine reduced diet. However, the identification and characterisation of novel metabolic disease genes together with the elucidation of their physiological function can provide guidance for therapeutic interventions.
Recently, by exome sequencing of individuals with 2-aminoadipic and 2-oxoadipic aciduria we identified mutations in DHTKD1. This gene encodes for dehydrogenase E1 and transketolase domain-containing protein1. The accumulation metabolites argued that this enzyme acts upstream of GCDH in the L-lysine-degradation pathway. Elevated levels of 2-oxoadipate in individual-derived fibroblasts could be restored upon lentiviral complementation using wild-type DHTKD1 mRNA. Moreover, experiemts with deuterium-labeled 2-oxoadipate showed accumulation in DHTKD1-deficient cells, indicating that DHTKD1 mediates the last unresolved step in the L-lysine-degradation pathway.
Since patients with DHTKD1 mutations showed only a mild phenotype with developmental delay, this opened the posibility to treat glutaric aciduria type1 patients with DHTKD1 inhibitors. An existing GCDH- mouse is known to develop a severe phenotype upon lysine-rich diet. To clarify whether inhibition of DHTKD1 activity can rescue the severe phenotype of GCDH deficiency we are creating a DHTKD1-/GCDH- double KO mouse by using a TALENs (transcription activator-like effector nucleases) approach. These nucleases bind to the desired DNA sequence and disrupt gene function by small insertions or deletions with high specificity, which has been verified in an in vitro system. This approach mimics the condition of a Glutaric Aciduria Type 1 patient, who receives an inhibitor for DHTKD1 activity.

Exploration of the impact of low-frequency and rare coding variation in the genetic architecture of type 2 diabetes susceptibility

A. Mahajan[1], *C. Fuchsberger*[2], *D. Pasko*[3], *J. Flannick*[4], *N. Robertson*[1], *X. Sim*[2], *N. Burtt*[4], *A. Morris*[1], *for the GoT2D study;*
[1]*Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom,* [2]*University of Michigan, Ann Arbor, MI, United States,* [3]*Institute of Biomedical & Clinical Science Peninsula Medical School, Exeter, United Kingdom,* [4]*The Broad Institute, Cambridge, MA, United States.*

Custom genotyping arrays, like the Illumina HumanExome Beadchip, provide a cost-effective alternative to sequencing to explore the role of low-frequency (LF; 1-5% MAF) and rare (<1% MAF) coding variants in type 2 diabetes (T2D) susceptibility.We studied 12,778 cases and 24,474 controls of European ancestry from the UK, Finland and Sweden, genotyped on this array to uncover novel T2D loci and examine whether LF and rare coding alleles could explain established common variant GWAS associations. We combined summary statistics (single-variant and gene-based) of up to 109,227 high-quality autosomal variants across studies by meta-analysis. We identified two LF nonsynonymous (NS) variants achieving study-wide significance ($P<2.5 \times 10^{-7}$) in genes not mapping to established T2D loci: *KRTAP4-3* (P152S; $P=1.7 \times 10^{-17}$; 0.3% MAF) and *DOCK6* (R430H; $P=6.2 \times 10^{-8}$; 0.4% MAF). One additional NS variant in *PSORS1C1* approached significance (E34K; $P=6.4 \times 10^{-7}$, 9% MAF). We found no evidence of LF or rare coding variants with large effects (Odds ratio>1.5) in established T2D risk loci that could explain common SNP GWAS associations. Gene-based analysis (SKAT-o) of rare NS variants in four genes *C16orf91*, *IL22RA2*, *FAM63A*, and *GSG2* met the gene-based significance threshold ($P< 5 \times 10^{-6}$), but each is driven by association in a single study and further confirmation is required.Our results indicate that the genetic landscape of T2D susceptibility is not dominated by LF and rare coding variants of large effect. In an effort to provide power to identify variants of weaker effect, we are expanding the sample size to >80,000 subjects.

Humans have an active endogenous D-lactate dehydrogenase

A. van Eerde, K. Lichtenbelt, K. Duran, G. Monroe, M. van Roosmalen, M. Oostendorp, G. Visser, I. Nijman, J. Jans, N. Knoers, E. Cuppen, N. Verhoeven-Duif, ***G. van Haaften****;*
UMC Utrecht, Utrecht, Netherlands.

Lactate exists as two stereo-isomers, the L and the D form. In human cells L-lactate is produced from pyruvate during the anaerobic metabolism of carbohydrates, mammals are not believed to produce and metabolize D-lactate. Increased levels of bacterial produced D-lactic acid are only occasionally seen in patients that underwent gastrointestinal surgery.
Here we present a patient with mental retardation and a normal intestine length. He was found to have chronic increased D-lactic acid levels in urine, which did not decrease after repeated antibiotic treatment, indicating an inborn metabolic defect in D-lactate metabolism.
Because his parents were consanguineous, we performed homozygosity mapping and identified several large stretches of homozygosity. The third largest homozygous stretch contained a gene with homology to D-lactate dehydrogenases from lower organisms. Sanger sequencing subsequently identified a homozygous missense variant Thr463Met in human lactate dehydrogenase D (LDHD), the variant is predicted to have a damaging (Sift) and deleterious (Polyphen) effect on protein function. Currently we are performing functional studies to assess the effect of the mutation on protein function.
We conclude that contrary to common textbook knowledge the human body does require endogenous D-lactate dehydrogenase activity for proper D-lactate clearance.

Clinical Exome Sequencing Leads to the Diagnosis of Mitochondrial Complex I Deficiency in a family with global developmental delays, ataxia, and cerebellar and pons hypoplasia

P. Gray[1], W. Zeng[1], S. Tang[1], J. Wei[1], K. Gonzalez[1], X. Li[1], H. Lu[1], H. Lu[1], E. Chao[2], V. Kimonis[2];
[1]Ambry Genetics, Aliso Viejo, CA, United States, [2]Division of Genetics & Metabolism, Department of Pediatrics; University of California, Irvine, Irvine, CA, United States.

Exome sequencing was performed on a 14 year-old female with familial ataxia, global developmental delays, and cerebellar and pons hypoplasia. The family history was remarkable for a 3 year-old sister with a similar phenotype. Nearly a decade of molecular, cytogenetic, and biochemical testing was uninformative. Exome sequencing revealed compound heterozygous alterations of the NUBPL gene (c.311T>C; p.L104P & c.815-27T>C). The c.311T>C missense alteration is located at a highly conserved amino acid. The c.815-27T>C alteration is located at a highly conserved nucleotide and previous in vitro analyses demonstrated splicing defects. The affected sister manifested both alterations; each parent carried one alteration. Alterations within the NUBPL gene occur in an autosomal recessive fashion in association with mitochondrial complex I deficiency syndrome (CI deficiency) (MIM_252010). The NUBPL gene was first discovered in association with disease in 2010 and has only been reported in two other families, both of which displayed remarkable clinical overlap with the family herein. Exome sequencing is an especially powerful tool to aid in the diagnosis of CI deficiency given the extreme clinical and genetic heterogeneity making establishing a clinical diagnosis exceedingly difficult. Further, the underlying mutation has not been discovered in about half of patients with CI deficiency, thought to be due to yet undiscovered associated genes. Diagnostic exome sequencing led to the successful identification of the NUBPL alterations and, after years of unsuccessful analyses, led to a molecular diagnosis for the family.

Pro-oxidant state and effect of anti-oxidants in Fanconi anemia and Down syndrome patients

M. M. Thomas[1], R. M. Kamal[2], H. H. El-Gebaly[2], H. H. Afifi[1], S. A. Abd El-Maksoud[1], H. T. El-Bassyouni[1], M. M. Eid[1], G. S. M. El-Saeed[1];
[1]National Research Centre, Cairo, Egypt, [2]Ain Shams University, Cairo, Egypt.

Background: Fanconi anemia and Down syndrome are two genetic disorders caused by chromosomal aberrations. Oxidative stress is an important pathological factor in both disorders.
Objective: Evaluation of the effect of antioxidant treatment on the level of oxidative stress and DNA damage in Fanconi anemia and Down syndrome patients.
Patients and methods: Seventeen Egyptian patients diagnosed to have Fanconi anemia, and Fifteen Egyptian patients diagnosed to have Down syndrome were recruited from the outpatient clinic of Clinical Genetics Department, National Research Centre. Fifteen healthy children were used as controls. Oxidative stress parameters including total antioxidant capacity (TAC), Superoxide dismutase (SOD) enzyme activity and Malondialdehyde (MDA) biomarkers were estimated. DNA damage was determined using the alkaline comet assay. Diepoxybutane (DEB) test was used for Fanconi anemia patients. Re-estimation of these parameters was done after six months of antioxidant intake.
Results: In Fanconi anemia patients after antioxidants intake, there was an improvement of DEB ($p< 0.01$), and DNA damage levels, ($p< 0.01$). Improvement in oxidative stress parameters occurred with significant lowering of MDA levels ($p< 0.01$) and significant elevation in TAC ($p< 0.01$) and SOD levels ($p< 0.01$). DNA damage levels in Down syndrome patients improved after antioxidants administration ($p< 0.01$). Also, improvement in oxidative stress parameters occurred after antioxidant administration with lowering of MDA ($p< 0.01$) and SOD levels ($p< 0.05$) and elevation in TAC levels ($p< 0.01$).
Conclusion: Improvement in oxidative stress parameters and DNA damage after giving antioxidants occurred in each of Fanconi anemia and Down syndrome patients.

P10.25

Haplotype-based regulation of frataxin by microRNAs in Friedreich Ataxia

***S. Bandiera[1,2]**, M. Girard[1], E. Hatem[1], A. S. Jannot[1], L. Rifai[1], A. Munnich[1], S. Lyonnet[1], A. Henrion Caude[1,2];*
[1]Inserm U781, Paris, France, [2]Institut Imagine, Paris, France.

MicroRNAs (miRNAs) are small non-coding RNAs that can modulate gene expression by interfering with translation or stability of messenger RNAs (mRNAs). The differential expression of miRNAs in patients with Alzheimer disease or various ataxia suggest a crucial role of miRNAs in neurodegeneration. We hypothesized a differential regulation of frataxin by miRNAs that could affect protein levels in patients with Friedreich ataxia (FRDA). To this end, we searched for miRNA binding sites in the frataxin gene using various computational tools, and identified a subset of target sites. By sequencing the 3'-UTR of frataxin in our cohort of patients with FRDA (n = 57), we were able to identify single nucleotide polymorphisms (SNPs) defining several haplotypes with one reaching 89% of homozygosity in patients versus 24% in controls. This result was confirmed in another cohort of FRDA Reunionese patients, with 94% patients who were found homozygous for this haplotype. Finally, by evaluating the potential regulator of those 3'-UTR haplotypes, we established differential regulation, and specifically demonstrated the involvement of miR-124 in the down-regulation of the FRDA haplotype. Our results suggest for the first time that post-transcriptional regulation of frataxin occurs through the 3′-UTR and involves miRNA targeting. We propose that the involvement of miRNAs in a FRDA-specific regulation of frataxin may provide a rationale to increase residual levels of frataxin through miRNA-inhibitory molecules.

Mucopolysaccharidosis IVA is an autosomal recessive inborn error of metabolism caused by the mutations in the N-acetylgalactosamine-6-sulfatase (GALNS) gene and manifests with a spondyloepiphyseal dysplasia. Bidirectional sequencing of all the coding region was performed in 60 patients from 58 families. In silico analysis was carried out for novel missense mutations to peredict the effect of mutations on protein function. We identified 37 different mutations, 26 of which had not been previously described. The 26 novel mutations consisted of 22 missense mutations (p.MlI, p.N32T, p.L36R, p.P52L, p.P77S, p.C79R, p.S82P, p.L86P, p.H142P, p.G188S, p.Y191D, p.N204T, p.F216S, p.W230C, p.R251Q, p.A291S, p.T313M, p.G317R, p.H329P, p.R386S, p.E450G, p.C501S), one nonsense mutation (p.Q414X), 3 intronic variations (c.120+1G>C, c.1003-3C>G and c.1139+1G>A) that affect the splice sites and 11 previously reported mutations. The missense mutations p.S287L and p.A291S account for 9.1 % (10/111) and 7.3 % (8/111) of the cases respectively and were the common mutations in Indian patients. This is the first report of screening for mutations in GALNS gene in the Indian population and the largest number of patients studied in the literature till date. The identification of these mutations has helped 5 families for prenatal diagnosis.

Increased level of alpha-synuclein oligomers in blood plasma in Gaucher disease

T. Usenko[1,2], *A. Emelyanov*[1,2], *E. Nuzhnyi*[2], *T. Boukina*[3], *E. Zakharova*[3], *S. Pchelina*[1,2];
[1]*Petersburg Nuclear Physics Institute, Saint-Petersburg, Russian Federation,* [2]*Pavlov's State Medical University of Saint-Petersburg, Saint-Petersburg, Russian Federation,* [3]*Research Centre for Medical Genetics, RAMS, Moscow, Russian Federation.*

At present alpha-synuclein is regarded as the key pathological molecular in pathogenesis of Parkinson's disease (PD). Oligomeric alpha-synuclein, the form of the protein most likely causing neuronal death, has been found in brain tissues of PD patients. Gaucher disease (GD) is the most common lysosomal storage disorders (LSD). Mutations in the glucocerebrosidase (GBA) gene result in lysosomal dysfunction and glucosylceramide accumulation. The carriers of GBA mutations are at an increased risk for PD. Dysfunctions in alpha-synuclein cellular degradation may link PD and LSD.
The aim of our work was to estimate the level of alpha-synuclein oligomers in blood plasma in GD patients.
We generated blood plasma of 22 GD patients (mean age 14, range1-42, 9 males) and 24 individuals of control group (mean age 20, range 1-41, 13 males). Diagnosis of GD is based on assay of glucocerebrosidase activity and genetics genotyping of mutations in the glucocerebrosidase (GBA) gene. We present a quantitative measurement of blood plasma alpha-synuclein oligomers in healthy control subjects and GD patients using enzyme-linked immunosorbent assay ELISA (Human Synuclein OLIGO kit aj Roboscreen, Germany).
The level of oligomeric alpha-synuclein was significantly elevated in blood plasma of GD patients (median 4.75 ng/ml, range 0.80-36.3 ng/ml) compared to controls (median 1.22 ng/ml, range 0.00-40.10 ng/ml), $p < 0.02$.
This is the first report of elevated level of alpha-synuclein oligomers in blood plasma in GD patients. Our results allow to suggest that GBA mutations promote alpha-synuclein aggregation in GD, which might explain the pathological mechanisms underlying GBA-associated PD.

GCK mutations are not common cause for MODY2 and Gestational Diabetes in Turkey

Ö. Yalcın Capan[1], *I. Sozen*[1], *A. Lembet*[2], *N. Aydin*[3], ***E. Berber***[1];
[1]*Istanbul Arel University, Istanbul, Turkey,* [2]*Memorial Hospital, Istanbul, Turkey,* [3]*Turkish Diabetes Foundation, Istanbul, Turkey.*

Maturity-onset diabete of the young (MODY) is an early-onset non autoimmune form of diabetes with an autosomal-dominant mode of inheritance. MODY has at least 10 subtypes associated with distinct genes. MODY2 associated with glucokinase (GCK) gene mutations is the second most common type of MODY. It accounts for 20-30% of all MODY cases. MODY2 is characterized by a glucose sensing defect and mild chronic hyperglycemia. In addition GCK gene mutations have been asssociated with increased risk of gestational diabetes. Studies have demonstrated that heterozygous GCK mutations are associated with mild fasting hyperglycemia and gestational diabetes while homozygous and compound heterozygous mutations are associated with mutations cause more severe clinical phenotypes like Permanant Neonatal Diabetes Mellitus. The purpose of the study is to determine the genetic profile of MODY2 and Gestational diabetes in the Turkish patient population by analyzing GCK gene. In order to identify GCK gene mutations, GCK gene exonic sequences, exon-intron boundaries and the promoter sequence was analyzed by direct DNA sequencing in 35 MODY suspected and 15 gestational diabetes patients. Studies have revealed presence of one novel mutation (c.765delC) and two previously known mutations (c.3G>A and c.686delC) in the MODY suspected patients. On the other hand, no pathogenic alteration in the GCK gene was detected in the gestational diabetes patients. This study demonstrated that GCK gene mutation is not a common cause of MODY and gestational diabetes in Turkey.

P10.29

Genome-wide association study of 10,947 type 2 diabetes cases and controls from five ancestry groups provides novel insights into the genetic architecture of the disease

A. P. Morris[1], *X. Sim*[2], *P. Fontanillas*[3], *on behalf of the T2D-GENES Consortium;*
[1]*Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom,* [2]*University of Michigan, Ann Arbor, MI, United States,* [3]*Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, MA, United States.*

We undertook genome-wide association studies (GWAS) of type 2 diabetes (T2D) in five ancestry groups: African American (AA), East Asian (EA), European (EU), Hispanic American (HA) and South Asian (SA). We performed trans-ethnic meta-analysis (MANTRA) of GWAS, imputed up to the 1000 Genomes Project Phase I reference panel (~32.3 million variants), in 5,464 T2D cases and 5,483 controls. We identified three novel T2D susceptibility loci at genome-wide significance, defined by $\log_{10}$ Bayes' factor (BF)>6 (equivalent to $p<5\times10^{-8}$ under a fixed-effects model), mapping near *PDGFRL* ($\log_{10}$BF=6.43), *CLDN10* ($\log_{10}$BF=6.37) and *LEP* ($\log_{10}$BF=6.36). The lead variant near *PDGFRL* is common (MAF≥5%) in all ancestry groups and has homogeneous allelic effects on T2D susceptibility across ethnicities (OR = 1.20 [1.13-1.28]). The lead variant near *LEP* is also common in all ancestry groups, but the allelic effect is heterogeneous between ethnicities ($\log_{10}$BF=5.07), and is specific to EA populations (MAF=10.5%, OR=1.85 [1.50-2.27]). At *CLDN10*, the lead variant is monomorphic or rare (MAF<1%) in EA, EU, HA and SA populations, so that the effect on T2D appears specific to AA populations (MAF=8.7%, OR=1.98 [1.58-2.49]). We identified no low-frequency variants (1%≤MAF<5%) at novel or established loci at genome-wide significance. The common lead SNPs are specific to one ancestry group, or are polymorphic across ethnicities with predominantly homogenous allelic effects. Our results highlight the benefits of trans-ethnic meta-analysis for discovery and characterisation of complex trait loci, and emphasize the opportunity to extend insights into the genetic architecture of human disease. across diverse populations.

Diabetes associated endothelial dysfunction begins in utero

S. Cvitic[1], *L. Gordon*[2], *U. Hiden*[1], *R. Saffery*[2], *G. Desoye*[1];
[1]*Medical University of Graz, Graz, Austria,* [2]*Murdoch Children´s Research Institute and Department of Pediatrics, Melbourne, Australia.*

The 'Developmental Origin of Health and Disease (DOHaD)' paradigm proposes that environmental factors in pregnancy act *in utero* to program the risk for adverse diseases, i.e. gestational diabetes mellitus (GDM) that confers an increased risk for vascular and endothelial dysfunction.
The feto-placental compartment is also affected by the maternal diabetic environment. We hypothesized that primary human arterial endothelial cells isolated from term placentas after healthy pregnancies (normal AEC) and pregnancies complicated with GDM (diabetic AEC) would differ in their intrinsic biological program. We focused on two key endothelial processes i.e., proliferation and angiogenesis.
Viable and dead cells were counted to determine proliferation of normal and diabetic AEC. *In vitro* angiogenesis (2-D network formation) was studied in media containing 2% normal or diabetic cord blood serum (CBS). In addition, the DNA methylation profile was determined by 450k methylation arrays and global gene expression profile by Human GeneChip 1.0ST arrays. Biological interpretation of the candidate genes was assessed using IPA.
Diabetic AEC had reduced proliferation (ANOVA $p<0.003$) after 96h culture than normal AEC. In the presence of normal CBS total tube length was increased in diabetic vs. normal AEC (ANOVA $p<0.001$). Diabetic CBS did not influence network formation potential. Thus the difference in proliferation and tube formation is the result of an intrinsic program of the cells. In fact principal component analysis revealed differences in the global methylation and expression pattern between normal and diabetic AEC. IPA identified that differentially methylated and expressed genes clustered to cell growth and proliferation related processes.

Purpose: Glycogen storage disease type III (GSD III) is a rare autosomal recessive disorder caused by a deficiency of the glycogen debranching enzyme, amylo-1, 6-glucosidase (AGL). GSD III is characterized by the storage of structurally abnormal glycogen, termed limit dextrin, in both skeletal and cardiac muscle and/or liver, with great variability in resultant organ dysfunction. Here, we present the molecular and enzymatic analyses of 22 Tunisian GSD III patients.
Methods: To examine the heterogeneity Glycogen Storage Disease Type III, we genotyped the AGL gene and sequenced all its exons in 22 Tunisian patients with a clinically and biochemically confirmed diagnosis.
Results: Molecular analysis revealed three novel mutations; a nonsense (Tyr1148X) and two deletions (3033_3036del AATT and 3216_3217del GA), and five known mutations; three nonsense (R864X, W1327X and W255X), a missense (R524H) and an acceptor splice-site mutation (IVS32-12A/G). Each mutation is associated to a specific haplotype.
Discussion: This is the first report of screening for AGL gene mutations in the Tunisian population. We concluded that Glycogen Storage Disease Type III is a highly heterogeneous disorder in our population, requiring full gene sequencing to identify commun or specific mutations.

Genomic, transcriptomic, and lipodomic profiling demonstrates the benefits of extreme phenotype approach and highlights the role of inflammation in individuals low HDL-cholesterol

P. Laurila[1], *I. Surakka*[1], *A. Sarin*[1], *L. Yetukuri*[2], *S. Söderlund*[3], *J. Naukkarinen*[1], *J. Tang*[4], *J. Kettunen*[4], *J. Soronen*[1], *T. Lehtomäki*[5], *V. Salomaa*[6], *O. Raitakari*[7], *M. Järvelin*[8], *A. Palotie*[9], *M. Oresic*[2], *M. Jauhiainen*[6], *M. Taskinen*[3], *S. Ripatti*[4];

Low HDL-C is a major risk factor for CVD. To elucidate novel pathways behind low HDL-C, we have employed 3 different omics:genomics, transcriptomics,and lipidomics.
We performed GWAS on 450 Finns with extreme HDL-C-phenotypes(90th percentiles). We obtained subcutaneous fat biopsies for transcriptome-analysis, and isolated plasma HDL particles for MS-lipidome analysis.
We first conducted network analysis for low-HDL-C-associated loci observing that SNPs within inflammatory pathways(e.g.antigen-presentation) were enriched among low-HDL-C-associated genes (p=10^-5). Also,these inflammatory pathways were over-expressed in SC-fat of low-HDL-subjects(p=10^-10). We then calculated genetic risk scores based on low-HDL-C-associating SNPs from these pathways,observing that high risk score resulted in both decreased HDL-C-levels and increased expression of these inflammatory pathways. Moreover, individual genes of these pathways (e.g. HLA-DRB1[p=10^-7],TAP2[p=10^-27]) exhibited cis-eQTLs, their expression inversely correlating with HDL-C.
Consistent with this,the inflammatory and potentially less vasoprotective nature of the HDL-particle of low-HDL-C-subjects was further highlighted by the elevation of proinflammatory ceramides and reduction of anti-oxidative plasmalogens in the lipidomic analysis, which was also GRS/genotype-dependent.
Interestingly,in a replication meta-analysis of 5 Finnish population-cohorts(n=11,211) we demonstrate that the genes found are indeed 'low-HDL-genes';the SNP-effects get stronger and more significant using more extreme low/high-HDL-C-criteria (e.g.HLA-DRB1; OR for low HDL-C<25%/high HDL-C>75%=1.11,OR(10%/90%)=1.38,OR(5%/95%)=1.77), but not observed for HDL-C as quantitative trait.
Here we demonstrate the following novel phenomena in cardiovascular genetics: extreme phenotype-approach may detect additional novel rare or common variants not detected in population-GWAS; and the major effect of HDL-C associated variants on cardiovascular phenotypes may in fact result from their association with impaired lipoprotein quality rather than quantity.

Autosomal Dominant Hypercholesterolemia (ADH) is characterized by high LDL levels, high risk of premature cardiovascular disease and is due to LDLR, APOB or PCSK9 mutations. Through the analysis of a large ADH family which excluded these three genes, we localized a fourth gene (HCHOLA4) at 16q22 (Marques-Pinheiro, Eur J Hum Genet 2010). Functional candidate genes in the locus were sequenced but no causal mutation was detected.
In parallel to the genetic approach, we searched for specific intermediate metabolic traits that could point out a metabolic pathway. Several analyses were performed for two members of the HCHOLA4 family. In vivo kinetic studies of apo B-100-containing lipoproteins showed a decreased LDL catabolism. At the cellular level in primary fibroblasts, the repression of the gene expression in response to a LDL overload was delayed in time for two sterol-dependant genes (HMGCoAR and LDLR), the LDL binding to their receptor is increased, indicating a likely increased receptor recycling. Immunohistochemistry analyses showed alterations of LDL endosomal transport, and larger early endosomes (EE) than in control cells. Labeled LDL-Dil, or labeled Shiga toxine B subunit, do not concentrate around the nucleus as seen in control cells, pointing out a delayed traffic between EE and Golgi. And, this was also observed for the intracellular distribution of the small GTPase Rab6a known to regulate the transport of vesicles into the Golgi compartment. Altogether, these observations indicate impaired endosomal sorting machinery. These results provide more insight into the alterations associated with mutations within the still unidentified HCHOLA4 gene.

LDLR and APOB gene analysis in the Slovene population of the children and adolescents with hypercholesterolemia

G. Klancar[1], *U. Groselj*[1], *N. Bratina*[1], *K. Trebusak Podkrajsek*[2], *T. Battelino*[1];
[1]*UMC Ljubljana, University Children's Hospital, Department of Endocrinology, Diabetes and Metabolic Diseases, SI-1000 Ljubljana, Slovenia,* [2]*UMC Ljubljana, University Children's Hospital, Unit for special laboratory diagnostics, SI-1000 Ljubljana, Slovenia.*

Introduction: Hypercholesterolemia (HCH) is a major risk factor for atherosclerosis and its premature cardiovascular complications. HCH can be multifactorial or less frequently monogenic. Monogenic form leads to Autosomal Dominant Hypercholesterolemia (ADH) and is most frequently associated with mutations in the LDLR gene, while much rarer with mutations in the PCSK9 or APOB gene.
Objective: To analyze the LDLR and APOB gene in the Slovene population of the children and adolescents with the probable or definite HCH according to the clinical criteria.
Methods: We have used various molecular genetic methods (PCR, dHPLC, HRM and sequencing). We analyzed all 18 exons of the LDLR gene and most common missense mutation p.Arg3527Gln in APOB gene in 98 patients.
Results: 44 patients have had 21 known and 3 novel (p.Asp100Glu, c.1587-1G>C and c.1706-1G>C) causative mutations in the LDLR gene. 13 patients have had mutation p.Arg3527Gln in APOB gene.
Conclusions: In addition to the known pathogenic LDLR and APOB mutations, 3 novel LDLR gene mutations were identified. Remaining 41 patients without identified causative mutation will be subsequently analysed for PCSK9 mutations. The genetic characteristics of the Slovene HCH population were comparable as in neighbouring and/or related populations.

P10.35

After LDLR, APOB and PCSK9, APOE is another major gene of autosomal dominant hypercholesterolemia

*J. P. Rabès[1,2,3], M. Marduel[1], K. Ouguerram[4], V. Serre[5], D. Bonnefont-Rousselot[6], K. Berge[7], G. Luc[8], J. Lecerf[8], **M. Abifadel**[9,10], T. Leren[7], C. Boileau[1,3,2], M. Varret[1,11];*
[1]INSERM U698, hopital Bichat, PARIS, France, [2]AP-HP, Hôpital A. Paré, Boulogne Billancourt, France, [3]Université Versailles Saint-Quentin-en-Yvelines, Guyancourt, France, [4]INSERM U915, Institut du Thorax, NANTES, France, [5]INSERM U781, hopital Necker, PARIS, France, [6]AP-HP, CHU Pitié-Salpêtrière, PARIS, France, [7]Oslo University Hospital Rikshospitalet, Oslo, Norway, [8]Institut Pasteur de Lille, Lille, France, [9]INSERM U698, hopital Bichat, Paris, France, [10]Université St-Joseph, Beirut, Lebanon, [11]Université Paris Denis Diderot, Paris, France.

Autosomal Dominant Hypercholesterolemia (ADH) is characterized by high LDL levels, high risk of premature cardiovascular disease and is due to LDLR, APOB or PCSK9 mutations. We found further genetic heterogeneity of ADH through a genomewide scan in a large French family with a new disease locus at 19q13.31-13.32. Whole exome and candidate genes sequencing showed an unique APOE mutation: p.Leu167del. This finding was unexpected since APOE mutants are essentially associated with familial combined hyperlipidemia (FCHL). APOE p.Leu167del was not detected in over 440 control chromosomes and two other APOE mutations (p.Arg235Trp, p.Arg269Gly) were found in three unrelated ADH probands.
In silico structural prediction of the mutant protein p.Leu167del showed an alpha-helix disruption within the receptor-binding domain that could affect apoE affinity for its receptors. In vivo apo B-100 kinetics from one APOE p.Leu167del carrier, showed: an increased LDL pool, which was the consequence of both an increased LDL production and a decreased LDL catabolism. These findings are similar to those from patients with a LDLR mutation. Together, these observations indicate a decreased catabolism of LDL-bearing the mutant apoE, explaining ADH, and underscoring the hypothesis that some APOE mutations may be responsible of ADH and should be looked for.
The APOE p.Leu167del was also reported in FCHL. Conversely, hypertriglyceridemia is sometimes observed with ADH, mainly because of the many genetic/environmental factors contributing to triglyceride elevation. Thus, mutations in LDLR or APOE may amplify the effects of these factors, and thus, could be associated with FCHL or ADH.

P10.36

A new homozygous frame shift mutation of the leptin receptor-(LEPR)-gene identified by SNP array analysis is causing an early onset of a severe form of generalized obesity that is also associated with intellectual disability and general psychomotor retardation.

*C. **Windpassinger**[1], A. Noor[2], E. Fröhlich-Reiterer[3], U. Gruber-Sedlmayr[3], K. Wagner[1], E. Petek[1], J. B. Vincent[2], P. M. Kroisel[1];*
[1]Medical University of Graz, Institute of Human Genetics, Graz, Austria, [2]Neurogenetics Section, Centre for Addiction and Mental Health, Toronto, ON, Canada, [3]Medical University of Graz, Department of Pediatrics, Graz, Austria.

Extreme obesity in children of less than a year of age is rare and in nearly all cases a genetic basis can be established. In the majority of these patients a mutation of the leptin gene can be found. Involvement of further genes like the melanocortin-4 receptor gene, the leptin receptor gene, and the Proopiomelanocortin gene (POMC) has recently been shown, however, additional genes might be of importance as well. In association studies and in particular in affected patients born to consanguineous parents SNP-array analysis can be helpful to identify candidate gene loci which could be of relevance. Homozygous or compound heterozygous mutations of the leptin receptor (LEPR) gene are infrequent but represent a very important cause of this disorder. Since sequencing of a number of these large genes is challenging and the probability that another new gene might be responsible the mentioned strategy was chosen. Here we describe a patient with a very severe obesity, and the use of SNP-array analysis to identify a homozygous frameshift mutation, c.461dupA[p.N154Kfs*3] in exon 5 of the LEPR-gene, leading to a loss of function of the membrane and leptin binding domains. Since this also the first report describing a severe form of intellectual disability associated with LEPR-gene mutations, this aspect is discussed as well.

Next generation sequencing technologies had revolutionized genomic research. While whole genome sequencing has been used several times to identify successfully physical breakpoints of apparently balanced *de novo* chromosome translocations, here it allowed us to characterize a *de novo* 7q32 duplication in an index-case with unexplained precocious anorexia and ponderal growth retardation. The whole-genome sequencing revealed that the duplication was a direct tandem duplication. The exact identified breakpoint suggested a gene fusion and was validated by Sanger sequencing. In addition the DNA combing approach was used to confirm the structure of the duplication.
The 5' part of the gene-fusion is unknown in current human gene databases. This potential pseudogene is paralogous to the *TLK2* gene. The 3' part of the gene-fusion includes the whole coding region of the *LEP* gene, coding for the well-known adipokine protein involved in the regulation of appetite. Several fusion transcripts by alternative splicing were detected by RT-PCR on patient's fibroblasts and lymphocytes.
In parallel, real-time quantitative RT-PCR revealed that the 7 genes included in the duplication were over-expressed in patient's fibroblasts compared with controls. Despite of the gene *LEP* over-expression in the patient's fibroblasts and lymphocytes, his leptinemia was normal.
We will present the exact nature of the gene fusion and the preliminary molecular characteristics of any fusion protein possibilities. Several hypotheses trying to explain the phenotype from the *de novo* duplication will be discussed, however these studies provide insight into the current ways to characterize a duplication.

Wolman Disease: the importance of early diagnosis. A review of 7 cases with complete lysosomal acid lipase deficiency.

P. Benlian[1,2], *A. Pagnier[3], K. Mention[4], F. Feillet[5], C. Sevin[6], S. Mary[1], M. Voicu[7], D. Plantaz[3], T. Levade[8], P. de Lonlay[9], V. Valayannopoulos[9];*
[1]Université Lille 2 - European Genomic Institute for Diabetes, LILLE, France, [2]Molecular Medicine of Metabolic Diseases (U4M) - CHRU Lille, Lille, France, [3]Reference Center for Rare Diseases - CHU Grenoble, GRENOBLE, France, [4]Reference Center for Rare Metabolic Diseases - CHRU Lille, LILLE, France, [5]Reference Center for Rare Metabolic Diseases - CHU Nancy, NANCY, France, [6]Pediatric Endocrinology - CHU Cochin/St Vincent de Paul - APHP, PARIS, France, [7]Molecular Medicine of Metabolic Diseases (U4M) - CHRU Lille, LILLE, France, [8]Biochemistry - CHU Toulouse, TOULOUSE, France, [9]Reference Center for Rare Metabolic Diseases - CHU Necker - APHP, PARIS, France.

Background. Wolman disease (WD) is a recessively inherited disease (<60 cases since 1961) resulting from complete lysosomal acid lipase (LAL) deficiency (OMIM#278000). Although normal at birth following normal pregnancy, Wolman infants die by age 6-mo of multiorgan failure caused by generalized lysosomal neutral lipid storage. Despite secure biochemical and genetic diagnosis and potential for curative therapy, WD remains largely underdiagnosed.
Aim. Identify early clinical, imaging and biological signs from 7 WD cases.
Results. Parental consanguinity was present in 5 cases. All had <0.08N leucocyte LAL activity, resulting either from severe homozygous or compound heterozygous gene mutations (c.193C>T, c.419G>C, c.429-1G>C, c.482del, c.538G>A, c.676-2A>G, c.1024G>T, c.1055_1057del). In all cases, between 1 & 3 wks of life, alerting signs were persistent regurgitation/vomiting and abdominal pain, fast followed by hepato-splenomegaly, gut distension and

growth failure (<-1SD) by age 4 wks; low grade fever was unusual (2/7 cases). By age 8wks, bilateral adrenal calcification and mesenteric adenomegaly were constant on ultrasound or MRI imaging. Fasting TG and TC were moderate-high; liver cytolysis with anicteric cholestasis, very low HDLC (<0.5N), and inflammation (CRP>10N, Ferritin >5N) associated with foamy leucocytes were constant. Serum and stool bile acids and sterol precusors were high. Untreated cases died by age 16wks of malnutrition, liver and multi-organ failure.
Conclusion. Wolman disease a lethal condition of infancy may be underdiagnosed because early signs are unspecific after a 4wk lag phase. Abdominal imaging, serum liver, lipids and inflammation profiling combined with enzyme activity and genotyping may early identify infants amenable to curative therapy.

Expanding the mutation spectrum in beta-mannosidosis: Identification of two novel beta-mannosidosis associated sequence variants

H. M. F. Riise Stensland[1], *G. M. Hansen*[2], *G. H. Bruun*[3], *G. Evjen*[4], *T. Levade*[5], *B. S. Andresen*[3];
[1]*Department of Medical Genetics, Division of Child and Adolescent Health, University Hospital of Northern Norway, Tromsø, Norway,* [2]*Tumor Biology Research Group, Department of Medical Biology, Faculty of Health Sciences, University of Tromsø, Tromsø, Norway,* [3]*Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark,* [4]*Molecular Cancer Research Group, Department of Medical Biology, Faculty of Health Sciences, Tromsø, Norway,* [5]*Center for Cancer Research, INSERM, Toulouse, France.*

Beta-mannosidosis (OMIM #248510) is a rare lysosomal storage disorder caused by deficient activity of the enzyme beta-mannosidase (MANBA, E.C. 3.2.1.25). The disorder has been reported in goats, cattle and man. It is a severe autosomal recessive neurological disease in animals, but the human disorder is generally milder, and the clinical spectrum is heterogeneous. So far, only 21 cases and 15 disease associated sequence variants have been reported, indicating substantial genetic heterogeneity in beta-mannosidosis. By sequence analysis of genomic DNA from an African patient with demyelinating peripheral neuropathy, but without apparent mental retardation (Graber *et al.* 1994 *Ann Neurol* 35:116-119), heterozygosity for a 2-bp deletion in exon 17 in the *MANBA* gene was the only obvious disease associated variant detected. However, RNA analysis revealed a heterozygous frameshifting deletion of exon 15 from the transcript. A mutation located outside the splice site sequences in exon 15, and originally believed to be silent, was shown by use of hybrid splicing reporter minigenes to cause aberrant splicing. Bioinformatics analyses predicted that the mutation weakens a potential binding site for splicing stimulatory protein SRSF1, and our preliminary results from RNA affinity binding studies corroborates this. Studies are in progress to evaluate this further. The present study provides a new and interesting example on how translationally silent substitutions can be deleterious by disrupting the finely tuned balance between splicing regulatory elements in constitutive exons.

Megdel syndrome in two Turkish siblings: a novel SERAC1 mutation

D. Yücel Yılmaz[1], *Ö. Ünal*[1], *R. Özgül*[2], *A. Dursun*[1];
[1]*Hacettepe University Department of Pediatrics, Metabolism Unit, Ankara, Turkey,* [2]*Hacettepe University, Institute of Child Health, Department of Pediatrics, Metabolism Unit, Ankara, Turkey.*

MEGDEL syndrome was described as a distinct entity with association of 3-methylglutaconic aciduria with impaired oxidative phosphorylation, deafness, encephalopathy, Leigh-like lesions on brain imaging, progressive spasticity and dystonia. It is an autosomal recessive disorder and, recently, it has been reported that SERAC1 (Serine Active Site Containing 1) gene mutations cause this syndrome.
Here we present two siblings with 3-methylglutaconic acid and 3-methylglutaric aciduria, microcephaly, growth retardation, dysmorphic features, severe sensorineural deafness, progressive spasticity, dystonia, seizures, basal ganglia involvement and degeneration consistent with leigh-like syndrome.
Other types of methylglutaconic acidurias were excluded by enzymatic analysis and clinical findings. Since the clinical pictures of our affected siblings are very comptible with reported patients with MEGDEL syndrome, SERAC1 gene was selected as a candidate gene for mutation screening. Sequencing analysis of SERAC1 gene in patients showed novel homozygous c.799_800delC (p.Pro267Leu fs*10) mutation in exon 9.
It is the first report of MEGDEL syndrome due to SERAC1 gene mutation after the report of Wortmann et.al. (2012) that describes a novel mutation ,its molecular effects and clinical correlation in the literature.
This study was supported by the Scientific and Technology Research Council of Turkey (TÜBİTAK-SBAG-111S217).

P10.41
Reduction of mutated mitochondrial DNA in MERRF cells by Peptide Nucleic Acids modified twice

M. Lamla[1], *K. Mellert*[2], *R. N. Lightowlers*[3], *H. Seliger*[4], ***D. Kaufmann***[2];
[1]*Institute of Organic Chemistry III, Ulm, Germany,* [2]*Institute of Human Genetics, Ulm, Germany,* [3]*Mitochondrial Research Group, Institute for Ageing and Health, Newcastle University, Newcastle upon Tyne, United Kingdom,* [4]*Research Group Chemical Function in Biosystems, Ulm, Germany.*

The intracellular number of mutated mitochondrial DNA (mtDNA) can increase during life resulting in cellular dysfunctions, e.g. in patients with the mitochondriopathy MERRF. We developed a method using peptide nucleic acids (PNA) modified twice to inhibit the replication of mutated mtDNA specifically. For this purpose, PNAs targeting the coding strand were modified C-terminal with a cell penetrating peptide and N-terminal with a mitochondrial targeting peptide. Transfection of a MERRF cybrid cell line with these PNAs results in a highly specific and efficient inhibition of replication of mutated mtDNA. The inhibition of replication strongly depends on the length of the PNAs, their concentration and the duration of treatment. The dramatic reduction of mutated mtDNA after 4 PNA treatments persists for at least 60 additional days in the MERRF cell line. We suggest that the used PNA modifications and the choice of the targeted strand are crucial for the successful inhibition of mtDNA replication by PNAs.

Background: Metabolic syndrome is a prevalent disease characterized by concurrent manifestation of 3 symptoms (elevated waist circumference, triglycerides, reduced HDL cholesterol, hypertension, elevated fasting glucose). We preformed genome-wide association and linkage study of major metabolic syndrome components in recombinant inbred strain panel PXO.
Methods: Adult male rats of 14 PXO strains and two progenitor strains SHR-Lx a BXH2 (n=183) were subjected to one-week of high-sucrose diet feeding. We established morphometric and metabolic profile of the whole PXO panel including glucose tolerance and triacylglycerol (TG) and cholesterol (C) concentrations in 20 lipoprotein fractions were determined. The association and linkage analyses utilizing > 20,000 SNPs were performed using MapManager, the significance validated by 2000 permutations per trait.
Results: In most of the phenotypes we identified substantial gradient among the strains (e.g. area under the glycemic curve from 237±25 to 606±35 mmol/l/180 min). Using interval mapping, we have identified 14 loci showing suggestive or significant linkage to studied traits. Except for linkage signals of LDL-TG on chromosomes 3 and 12, PXO strains carrying the SHR allele displayed significantly higher values of the lipid linked traits, e.g. LDL-C (21.2±0.4 vs. 12.5±0.4 mg/dl in PXO strains with SHR allele vs. BXH2 allele in D3Rat50-D3Got19 block). C concentrations in large, medium and very small LDL particles were significantly associated to a single gene (Lrp1b).
Conclusion: Using genome-wide linkage and association we have identified new genetic determinants of glucose tolerance, TG and C distribution into lipoprotein fractions.

Molecular diagnosis of mitochondrial diseases in Egyptian pediatric patients : A two year study

D. Mehaney[1], *L. Selim*[2], *M. Shaarawy*[3];
[1]*Chemical Pathology department,Faculty of Medicine-Cairo University, Cairo, Egypt,* [2]*Pediatrics department,Faculty of Medicine-Cairo University, Cairo, Egypt,* [3]*Ophthalmology department,Faculty of Medicine-Cairo University, Cairo, Egypt.*

Mitochondrial diseases (MCDs) are an important cause of morbidity and mortality in both adults and children. MCDs are caused by mutations in both nuclear and mitochondrial encoded genes. This report is the first one to describe the screening and diagnostic molecular service for MCDs routinely started at the Inherited Metabolic Disease Unit laboratory at Cairo University Children's hospital from January 2011.

DNA was extracted from whole blood samples of 62 Egyptian Pediatric patients using standard protocol. Eight patients were clinically and radiologically suspected to have Myoclonus epilepsy and ragged-red fibers (MERRF), 17 patients with mitochondrial encephalomyopathy , lactic acidosis and stroke-like episodes (MELAS), 31 patients with and Leigh's syndrome/Neuropathy Ataxia Retinitis Pigmentosa syndromes (LS/NARP), 3 with Leber's hereditary optic neuropathy (LHON), 2 patients with Mitochondrial Neurogastrointestinal Encephalopathy (MNGIE) and one with chronic progressive external ophthalmoplegia (CPEO).

Common mtDNA point mutations were screened using Polymerase Chain Reaction-Restriction Fragment Length Polymorphism and confirmed by direct sequencing. Sequencing analysis of the nuclear Thymidine hosphorylase (TP) gene was done in MNGIE patients.

The A3243G mutation was detected in one patient with MELAS and the T14484C was detected in two patients with LHON. The c.3371A>C and c.4183G>A in TP gene were detected in MNGIE patients.

As Egypt is a country with high rate of consanguineous marriage, the molecular pathogenesis of MCDs is suspected to be of nuclear genetic origin. Mitoexome and whole exome sequencing represents an appealing approach for detection of disease causing variants.

P10.44

Interest of exome sequencing in prenatal diagnosis of mitochondrial disorders.

S. Ait-El-Mkadem, *A. Chaussenot, C. Rouzier, K. Fragaki, S. Bannwarth, V. Paquis-Flucklinger;*
Nice Hospital - Medical Genetics Department , National Center for Mitochondrial diseases - IRCAN UMR7284 / INSERM U1081 / UNS, NICE, France.

Mitochondrial dysfunction is a major cause of metabolic disorders and accounts for a large variety of clinical symptoms in both childhood and adulthood. Genetic diagnosis is complex and challenging because of the involvement of mitochondrial or nuclear DNA and of primary or secondary nature of respiratory chain (RC) dysfunction. While mutations in nuclear genes underlie the vast majority of RC deficiencies, in most patients, genes and molecular mechanisms responsible remain unknown. Here, we report three consanguineous families with two affected siblings born from healthy parents suggesting an autosomal recessive transmission. Affected children presented with severe symptoms from the mitochondrial disease spectrum, beginning before 2 months of age, and associated to a RC deficiency. No mutation was found in mtDNA nor in known nuclear genes possibly involved regarding phenotypes and affected RC complexes. By using Whole Exome Sequencing (WES), we identify causative genes in all cases with mutations in *SERAC1*, *COQ2* and *SIAT9* encoding the GM3 synthase (GM3S). In the last family, we showed that GM3S deficiency was responsible for a secondary RC defect with a decrease of mitochondrial membrane potential leading to apoptosis in patients' fibroblasts. Moreover, our findings allow direct benefit for parents since prenatal diagnosis was performed in the 3 families and mutation analysis showed the non affected status of the fetus. In conclusion, our work highlights the importance of WES in prenatal diagnosis of mitochondrial disorders.

Background. Mitochondrial DNA (mtDNA) diseases are rare disorders whose prevalence is estimated around 1/5000. Patients are usually tested only for deletions and for common mutations of mtDNA which account for 5-40% of cases depending on the studies. However, the prevalence of rare mtDNA mutations is totally unknown.

Methods. We analysed the whole mtDNA in a cohort of 743 patients, suspected of manifesting a mitochondrial disease, after excluding of deletions and common mutations. Both heteroplasmic and homoplasmic variants were identified using two complementary strategies (Surveyor and MitoChip). Multiple correspondence analyses followed by hierarchical ascendant cluster process were used to explore relationships between clinical spectrum, age at onset and localisation of mutations.

Results. A total of 7.4% of deleterious mutations and 22.4% of novel putative mutations were identified. Pathogenic heteroplasmic mutations were more frequent than homoplasmic mutations (4.6% *versus* 2.8%). Patients carrying deleterious mutations showed symptoms before 16 years of age in 67% of cases. Early-onset disease (<1 year) was significantly associated with mutations in protein-coding genes (mainly in complex I) while late-onset disorder (>16 years) was associated with mutations in tRNA genes. *MTND5* and *MTND6* genes were identified as "hotspots" of mutations, with Leigh syndrome accounting for the large majority of associated phenotypes.

Conclusions. Rare mitochondrial DNA mutations probably account for more than 7.4% of patients with respiratory chain deficiency. This study shows that a comprehensive analysis of mtDNA is essential, and should include young children, for an accurate diagnosis that becomes now accessible with the development of Next-Generation Sequencing technology.

P10.46

The effect of citrulline and arginine supplementation on lactic acidemia in MELAS syndrome

A. W. El-Hattab[1], *L. Emrick*[2], *K. Williamson*[2], *W. Craigen*[2], *F. Scaglia*[2];
[1]*King Fahad Medical City, Riyadh, Saudi Arabia,* [2]*Baylor College of Medicine, Houston, TX, United States.*

Background: Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS) syndrome is a common mitochondrial disorder in which nitric oxide (NO) deficiency can play major roles in the pathogenesis of several complications including stroke-like episodes, myopathy, and lactic acidosis. Arginine and citrulline act as NO precursors and their administration can restore NO production in MELAS. Lactic acidemia in MELAS results from an inability of dysfunctional mitochondria to generate sufficient ATP, leading to shunting of pyruvate to lactate. Hypoperfusion may result in lactic acidosis. Therefore, NO deficiency in MELAS can result in decreased blood perfusion and therefore aggravates lactic acidosis.

Methods: We measured plasma lactate concentrations in 10 adults with MELAS before and after 48-hour supplementation of oral L-arginine at a dose of 10 g/m^2 body surface area/day. The study was subsequently repeated before and after L-citrulline.
Results: The average plasma lactate concentration was lower after arginine (3.16→2.99 mmol/L) and citrulline (3.17→2.94 mmol/L) supplementations. This reduction was statistically significant after citrulline ($p<0.05$), but not after arginine.
Conclusions: The reduction in lactate after arginine and citrulline supplementations add more evidence to their potential therapeutic utility in MELAS. Previous study showed that both arginine and citrulline supplementations increase NO production in MELAS with citrulline resulting in higher increment. In this study the lactate reduction was more significant after citrulline supplementation which can be due to the superiority of citrulline in increasing NO leading to a better perfusion and lower lactate levels. These results also suggest that citrulline can have a better therapeutic effect.

Mitochondrial diseases are common and symptoms range from isolated presbyacusis, to loss of vision, to catastrophic neurodegeneration. Treatments are ineffective but mitophagy, mitochondrial recycling which is important in mitochondrial quality control, has been suggested in studies to have a role in neurodegeneration. We have generated a transgenic mouse strain (RedMIT mouse) expressing the dsRed-monomer targeted to mitochondria to follow mitochondrial turnover.
We confirmed that dsRed is targeted to mitochondria in tissues section and in MEFs from this mouse. We used Imagestream (Amnis) to investigate the co-localisation of mitochondria and the autophagic marker LC3; an increase in co-localisation with a chloroquine treatment validated the system.
We identified two populations of mice with either low or high proportion of blood cells expressing dsRed. Interestingly the low expressing population shows the most LC3 labelling. Similarly MEFs with more LC3 have less dsRed. These observations suggest that dsRed expressing mitochondria could be removed by mitophagy and thus that dsRed might impair the mitochondrial functions.
Oxygen consumption measurements of RedMIT tissues and MEFs showed a slightly affected function compared to wild-type. A lower mitochondrial potential in RedMIT MEFs than wild-type MEFs is also found.
Finally we monitored the blood level of dsRed in mice and showed a drop with time. This latter result recapitulates the age-dependent fall in level of 3243 mutant mtDNA in mitochondrial disease patients.
In conclusion we have a mouse model with dsRed targeted to mitochondria that mildly impairs mitochondrial functions. This RedMIT mouse may usefully recapitulate features of heteroplasmic mtDNA disease.

P10.48
Identification of the first nonsense mutation in the *PDX1* gene in a family with diabetes mellitus

P. J. Laitinen-Forsblom[1], *T. Kröplin*[2], *C. Nevinny-Stickel-Hinzpeter*[1];
[1]*synlab MVZ Humane Genetik, Munich, Germany,* [2]*Diabetes Schwerpunktpraxis, Elmshorn, Germany.*

Maturity onset Diabetes of the Young type 4 (MODY4) is a monogenic form of diabetes mellitus caused by mutations in the *PDX1* homeobox gene. *PDX1* encodes a pancreatic beta-cell specific transcription factor essential for the embryonic development of the pancreas.
The index patient presented with a gestational diabetes at the age of 28 years (1-hour-OGTT 192mg/dl). No insulin therapy was necessary. The pregnancy ended at a spontaneous full term delivery (birth weight 3530g). Three months after the pregnancy the patient showed impaired glucose tolerance (1-hour-OGTT 148 mg/dl) but no other symptoms of diabetes. Her habitus is slender (BMI 19). Currently, she shows normal blood sugar levels (fasting glucose 98 mg/dl) and slightly elevated C-peptide level (1,42 nmol/l).
Direct sequencing of the *PDX1* gene revealed the heterozygous mutation c.204C>G resulting in a preliminary stop codon (p.Tyr68*). Sequencing and MLPA analysis of *HNF1A*, *GCK*, *HNF4A*, and *HNF1B* revealed no pathogenic mutations.
We analysed the maternal family of the index patient and detected the mutation in her mother (suffering from non-insulin dependent diabetes mellitus) and aunt (showing elevated blood sugar levels but no diabetes). In her grandmother with type 2 diabetes requiring insulin therapy the mutation was not detected. The diseased grandfather, known to have diabetes, is thus an obligate carrier of the mutation.
Until the year 2013, altogether 13 mutations in the *PDX1* gene have been described. Here we describe the first nonsense mutation in the *PDX1* gene. In a heterozygous state, this mutation is associated with a mild form of MODY.

P10.49
HNF1A gene analysis in the MODY suspected Turkish patients

O. Yalcin Capan[1], *M. Sargin*[2], *E. Berber*[1];
[1]*Istanbul Arel University, Istanbul, Turkey,* [2]*Kartal Education and Research Hospital, Istanbul, Turkey.*

Maturity-onset diabetes of the young (MODY) is an early-onset non autoimmune form of diabetes with an autosomal-dominant mode of inheritance. MODY has at least 10 subtypes associated with distinct genes. MODY3 associated with hepatocyte nuclear factor- 1 alpha (HNF1A) gene mutations is the most common type of MODY. It accounts for 12-65% of all MODY cases in Europe. MODY3 is dignosed during adolescence or early adulthood. MODY3 requires pharmocological treatment and late-onset microvascular complications are frequently observed in the patients. More than 300 different mutations were identified in the MODY3 patients. Functional studies revealed that they cause insulin deficiency by the loss of function or by the dominant negative effect. The purpose of the study is to determine the genetic profile of MODY3 in the Turkish patient population by analyzing HNF1A gene. To identify HNF1A gene mutations HNF1A gene exonic sequences, exon-intron boundaries, the promoter sequence was analyzed by direct DNA sequencing in 35 MODY suspected patients. One novel (p.Ser345Tyr) and two previously known (p.Thy10Met, p.Arg263Cys) mutations were identified. In addition 6 of the patients were heterozygous for p.Ile27Leu polymorphism that was associated with insulin resistance. Besides,a common haplotype (p.459Leu, p.487Asn, and IVS7+7G>A polymorphisms) was identified in 38 percent of the patients. Case control association study revealed that it was not assssociated with MODY3.In conclusion, this study revealed that the frequency of MODY3 in the Turkish MODY suspected patients is 8.5 percent. Future studies will reveal whether there are other genes responsible for the MODY phenotype in the Turkish population.

P10.50
Genetic heterogeneity of patients with Familial Young-Onset Diabetes: data from the Slovak nation-wide survey in years 2003-2012

D. Gasperikova[1,2], *J. Stanik*[1,3], *M. Huckova*[1,2], *L. Valentinova*[1], *I. Masindova*[1], *D. Stanikova*[1,3], *J. Michalek*[4];
[1]*Institute of Experimental Endocrinology, SAS, Bratislava, Slovakia,* [2]*Centre for Molecular Medicine, SAS, Bratislava, Slovakia,* [3]*First Dep. of Pediactrics, Children`s University Hospital, Bratislava, Slovakia,* [4]*National Instituten of Diabetes and Endocrinology, Lubochna, Slovakia.*

INTRODUCTION: Maturity Onset Diabetes of the Young (MODY) is a heterogeneous group of monogenic diabetes with early onset, familiar appearance, and autosomal dominant inheritance. Familial Young-Onset Diabetes (FYOD) represents a part of MODY caused predominantly by mutations in the genes for transcription factors.
THE AIM of this study was to identify the etiology of the Slovakian families with the clinical suspicion on the Familial Young-Onset Diabetes by the DNA analysis of the known MODY genes.
METHODS: 399 patients from 184 families were recruited from outpatient clinics throughout Slovakia. Relevant genes responsible for FYOD (HNF1A, HNF1B, HNF4A, NEUROD1, KCNJ11, insulin, ABCC8) were sequenced and MLPA analyzed.
RESULTS: 66 patients from 28 families had a mutation in one of the target genes: 24 probands and their 37 family relatives had a mutation in HNF1A gene; one family (2 pts) had a mutation in the HNF4A gene, one proband had a mutation in insulin gene, one proband had a HNF1B whole gene deletion

and one proband had a novel mutation in ABCC8 gene. No KCNJ11 and NEUROD1, gene mutation carriers were found. In 44 families no mutations in the analyzed genes were found (MODY-X).
CONCLUSIONS: Among 399 from 184 families with clinical suspicion on FYOD the monogenic diabetes was confirmed in 66 patients from 28 families. 20 different mutations (from which 8 are novel) were found in 4 out of 6 analyzed genes. These results indicate a high heterogeneity of etiology of the Familial Young-Onset Diabetes in Slovakia.

P10.51
Mutational spectrum of glucokinase (GCK) gene and prevalence of monogenic diabetes type GCK-MODY in Slovakia

L. Valentínová[1], *J. Staník*[2,1], *M. Hučková*[1,3], *M. Balogová*[1], *I. Mašindová*[1], *I. Klimeš*[1,3], *D. Gašperíková*[1,3];
[1]*Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*First Dept. of Paediatrics, Comenius University, Bratislava, Slovakia,* [3]*Centre for Molecular Medicine, Slovak Academy of Sciences, Bratislava, Slovakia.*

Heterozygous inactivating glucokinase (GCK) mutations cause a subtype of maturity-onset diabetes of the young (GCK-MODY) characterised by familial mild stable fasting hyperglycaemia. Over 600 GCK mutations have been reported, nevertheless none of them prevails between GCK-carriers. The aim of the study was 1) to determine the GCK mutation spectrum and 2) to disclose the prevalence of GCK-carriers among the Slovakian population.
Patients and methods: 369 unrelated probands with clinical suspicion on MODY were referred for genetic testing to our laboratory between 2004 - 2012 from >100 clinical diabetologists and endocrinologists across Slovakia. Following the proband's clinical phenotype consistent with GCK-MODY, direct sequencing and MLPA analyses of pancreatic GCK gene were carried out.
Results: DNA analyses identified 31 different GCK mutations in 55 probands and 90 relatives located in promoter, coding and intronic regions. Missense mutations occurred most frequently - 77% (24/31), followed by deletions 10% (3/31), splice-site substitution 6% (2/31), promoter substitution 3% (1/31) and intronic variant 3% (1/31); no exon deletion was detected. Different exon mutations were scattered along the entire GCK length, no hotspot region was found. The most frequent GCK mutation in Slovakia (promoter -71G>C) occurred in 27% (15/55) of unrelated families. In Slovakia with population of 5,4 millions the minimum prevalence of GCK-MODY was estimated to 27 cases/million inhabitants.
Conclusion: We have determined the GCK mutation profile with the Slovakian prevailing mutation (-71G>C). The minimum prevalence of GCK-MODY in Slovakia is 27 cases/million inhabitants, which is higher than our previously published data.

P10.52
A comparative transcriptome analysis identifies FGF23-regulated genes in HEK293 cells stably expressing KLOTHO

S. Diener[1], *T. Schwarzmayr*[1], *A. Walther*[1], *T. Wieland*[1], *B. Lorenz-Depiereux*[1], *T. M. Strom*[1,2];
[1]*Helmholtz Zentrum München, German Research Center for Environmental Health, Institute of Human Genetics, Munich, Germany,* [2]*Klinikum Rechts der Isar der Technischen Universität München, Institute of Human Genetics, Munich, Germany.*

Phosphate is the most abundant anion in the human body and is crucial for various biological functions like cellular activity and bone mineralization. A key regulator of phosphate homeostasis is fibroblast growth factor 23 (FGF23). It is mainly secreted from osteocytes, circulates in the blood and binds to receptor heterodimers composed of FGF receptor 1 (FGFR1) and KLOTHO in the kidney. As elevated FGF23 levels are the main cause of hypophosphatemia in monogenic disorders of phosphate homeostasis (XLH (MIM 307800), ADHR (MIM 193100), ARHR1 (MIM 241520) and ARHR2 (MIM613312)), further studies on the regulation of phosphate metabolism are necessary to identify possible therapeutic targets. FGF23 activates KLOTHO/FGFR1 to inhibit renal phosphate reabsorption and to suppress 1,25-dihydroxyvitamin D3 synthesis. Little is known about FGF23/KLOTHO/FGFR1 signalling and downstream targets of FGF23 contributing to its phosphaturic action. For this purpose, we established an in vitro cell system of FGF23-inducible HEK293 cells that stably express KLOTHO (HEK293-KL). To find early expressed FGF23-induced transcripts, we performed whole transcriptome analysis. We used the technology of RNA-Seq, which is a massively parallel sequencing approach to allow genome-wide analysis of gene expression profiles at a far higher resolution than is available with microarray-based methods. Genome-wide transcriptional changes in HEK293-KL cells specifically caused by FGF23 were defined by comparing the transcriptome of FGF23-induced HEK293-KL cells with the transcriptomes of not induced HEK293-KL cells and mock-treated HEK293 cells. We tried to identify new FGF23-responsive genes that might belong to a network of factors involved in the regulation of phosphate homeostasis.

P10.53
Clinical and Genetic Spectrum of Mucopolysaccharidosis Type VI (Maroteaux-Lamy Syndrome) at Eastern Province of Saudi Arabia

N. A. Al-Sanna'a[1], *R. P. Mathew*[2];
[1]*Dhahran Health Center, Dhahrab, Saudi Arabia,* [2]*Vanderbilt Children Hospital, Vanderbilt, TN, United States.*

Mucopolysaccharidodis (MPS) type VI or Maroteaux-Lamy Syndrome (MIM#253200) is an autosomal recessive lysosomal storage disease caused by deficiency of the enzyme N-acetylgalatcosamin-4-sulfatase or Arylsuulfate B. This will lead to a progressive intracellular accumulation of the glyacsosaminoglycans, dermatan sulfate resulting into a wide range of multi-systemic dysfunction. It is a clinically heterogeneous disorder ranging from a mild to moderate and severe phenotype. So far, more than 130 different mutations in the ARSB gene have been identified. However, most are unique to individual families making population screening is difficult. Here we report 16 Saudi Arab affected patients from 6 unrelated families from the Eastern Province of Saudi Arabia presented with a severe phenotype. All of the tested patients were found to be homozygous the nonsense mutation c.753C>G (p.Y251X) at ARSB gene. This is a good reflection of the high consanguinity rate among this population. We propose that this mutation could be utilized for screening individuals at risk within this region of the country.

P10.54
Prenatal diagnosis of Mucopolysaccharidosis by two-dimentional electrophoresis of amniotic fluid glycosaminoglycans: An Egyptian experience.

M. M. Ibrahim[1], *A. L. Aboulnasr*[2], *K. Gaber*[1];
[1]*National Research Centre, Cairo, Egypt,* [2]*College of Medicine - Cairo University, Cairo, Egypt.*

Abstract: Objective: Prenatal diagnosis of Mucopolysaccharidosis(MPS) in pregnancies at risk by means of two-dimensional electrophoresis for analysis of glycosaminoglycans(GAGs) in amniotic fluid. Subjects and methods: This study included 53 pregnant females having previously affected child or more with one of the MPS types. Those cases came from allover Egypt during the period from 2000 till 2012. Consanguineous marriages was present in 39 cases (73.6%) and gestational age at time of amniocentesis ranged between 15-19 weeks. All the pregnant females were subjected to history taking, pedigree construction, clinical examination, amniocentesis guided by ultrasound scan. Two-dimensional electrophoretic separation of GAGs was done in amniotic fluid of all cases.
Results: 18 cases (34%) out of the 53 pregnant females were affected. Eight cases showed electrophoretic pattern of MPS type-I with dermatan and heparin sulfate spots, 4 cases MPS type-II with small dermatan and heparan spots, one case showed pattern of MPS type-III with heparan and heparan sulfate spots and 5 cases showed pattern of MPS type-VI with big dermatan spots.
Conclusion: Prenatal diagnosis of MPS for women with previously affected child or more using two-dimensional electrophoretic separation of GAGS in amniotic fluid is a sensitive, rapid and reliable method for diagnosis. It helps those families to have healthy infants and prevent having another affected child in the family.

OBJECTIVE: To study the association between genes codifying for mitochondrial respiratory chain (MRC) subunits and BMI and obesity as well as the impact on the risk to develop type 2 diabetes in the general population from Spain.

RESEARCH DESIGN AND METHODS: Three thousand seven hundred and thirty-one subjects (age range 21 to 89) from three different population-based studies of Spain, were studied. Forty-eight single nucleotide polymorphisms (SNPs) of chromosomal genes which codify MRC proteins were selected and processed by the SNPlex method.

RESULTS: Significant associations were observed between polymorphisms rs4600063 (SDHC gene), rs11205591 (NDUFS5 gene), rs10891319 (SDHD gene) and BMI (p-value= 0.04, 0.0011 and 0.0004, respectively) and obesity risk (OR=0.72, p-value=0.0072; OR=0.72, p=0.039; OR=1.25, 0.0038, respectively). In addition, polymorphisms rs11205591 and rs10891319, showed a significant epistatic interaction for BMI levels and obesity risk. Finally, the GG genotype of rs11205591 polymorphism significantly reduced the risk of being diabetic after including age and sex as covariables (OR= 0.32, 0.17-0.62; p-value =0.0001), and BMI (OR=0.37, 0.19-0.72; p-value =0.0008).

CONCLUSIONS: Polymorphisms of genes codifying MRC can be involved in BMI variation and can be related to the risk for being obese in the Spanish general population. Furthermore, the rs11205591 (NDUFS5 gene) polymorphism might contribute to the risk to develop type 2 diabetes.

Dysmorphic features in Niemann-Pick type C disease: Blurring the frontiers between dysmorphology and biochemical genetics

C. M. Lourenco[1], *V. van der Linden*[2], *E. Ribeiro*[3], *M. Santos*[4], *W. Marques Jr*[1];

[1]*University of Sao Paulo, Ribeirao Preto, Brazil,* [2]*Hospital Barão de Lucena, Recife, Brazil,* [3]*Albert Einstein Hospital, Fortaleza, Brazil,* [4]*Pequeno Principe Hospital, Curitiba, Brazil.*

Background: Niemann-Pick type C disease (NP-C) is a rare lysosomal disorder whose presentation in early infancy is usually nonspecific and may be overlooked, specially because at this age, the classical neurological features of the disease - as the vertical supranuclear gaze palsy - are absent. Facing this challenge, it is important to develop tools and to recognize clinical clues that can lead to an early diagnosis. Here we report, for the first time, a cohort of NPC patients whose facial features point out to a similar "facial gestalt" that could help both the non-specialist clinician and the clinical geneticist to a early recognition of the disease or at least to raise a clinical suspicion. Discussion: In an apparent opposition to other lysosomal storge disorders (LSDs), NPC was generally considered a non-dysmorphic inborn error of metabolism, nevertheless there are some facial features that can make possible to recognize a facial phenotype in infants with NPC. This fact is not surprising since dysmorphic manifestations can be expected as a result of disorders which affect the synthesis, traffic or early steps in the degradation of the large molecules. Conclusion: Identification of some dysmorphic features can add one more 'layer' in the investigation of NPC in early infancy, although that there is still a need to further development of screening tools in a effort for a better and earlier recognition and management of the disease.

Mutation Screening in NPC1 and NPC2 Genes in 37 Turkish Patients Suspected with Niemann-Pick disease Type C: Six Novel Mutations

R. K. Özgül[1], *D. Yücel Yılmaz*[2], *A. Yüce*[3], *A. Dursun*[2];

[1]*Hacettepe University Institute of Child Health, Department of Pediatrics, Metabolism Unit, Ankara, Turkey,* [2]*Hacettepe University , Department of Pediatrics, Metabolism Unit, Ankara, Turkey,* [3]*Hacettepe University, Faculty of Medicine, Department of Pediatrics, Gastroenterology Unit, Ankara, Turkey.*

Niemann-Pick disease Type C (NPC) is a rare autosomal recessive lysosomal lipid storage disorder with probable minimal incidence of 1/120,000 live births. Clinical presentation of NPC is extremely heterogeneous, featuring a range of systemic and neurological signs that are not specific for the disease progression and prognosis. As a result, the diagnosis of NPC can be a prolonged and complicated. NPC is caused by mutations in the NPC1 (in 95% of cases) or in the NPC2 (in around 5% of cases) genes. To date more than 300 disease-causing mutations have been reported.

In this study, mutation screening of 25 exons in NPC1 gene and 5 exons of NPC2 was performed in 37 unrelated Turkish patients suspected with NPC. Twelve different mutations in NPC1 and NPC2 gene were detected in 13 of 37 patients. In regard to novel mutations in NPC1 gene, c.2229_2230delTG, p.Trp949Gly, p.Asn906Tyr were detected as homozygously and c.3246-2delAG¬¬_¬3246-3247delTG mutation was detected with p.Pro1007Ala mutation in compound heterozygously. In addition, two novel mutations p.Ala181Thr and p.Thr375Pro were detected in patients as heterozygously in NPC1 gene.

NP-C diagnosis in these individuals were confirmed by this molecular genetic analysis study. The mutation detection rate which resulted in confirmed molecular genetic diagnosis, is found 25% in this selected group of patients. This study would be helpful for to raise the awareness and improve the early diagnosis and therapy of the disease in Turkish patients.

P10.58

Characterization of the human ornithine carbamoyltransferase promoter

O. Luksan[1], *L. Dvorakova*[2,3], *M. Jirsa*[1];

[1]*Institute for Clinical and Experimental Medicine, Prague, Czech Republic,* [2]*Institute of Inherited Metabolic Disorders, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [3]*General University Hospital, Prague, Czech Republic.*

Full transcriptional activity of human ornithine carbamoyltransferase (OTC, EC 2.1.3.3; MIM#300461) promoter depends on an upstream enhancer. The promoter-enhancer interaction contributes to tissue specific expression of OTC in the liver. The aim of our study is a detailed characterization of basic OTC regulatory elements in human.

Using the luciferase reporter assay with constructs containing a series of truncated promoter variants, we specified the 173 bp core promoter region carrying three positive and a negative *cis*-acting element. The *Cis*1+ positive regulatory element reaching 80% of the promoter activity was found in a short sequence of 35 base-pairs located close to the transcription start site. Another regulatory elements *Cis*2+, *Cis*3- and *Cis*4+ were localized within the positions 128-179 bp, 180-219 bp and 220-269 bp upstream the initiation codon.

We set up an innovated DNase I footprinting method based on the capillary electrophoresis of fluorescently labeled fragments after DNase I cleavage. The comparative analysis of electrophoreograms revealed protected regions corresponding to *Cis*1+ and *Cis*2+ elements.

Introducing the electromobility shift assay we demonstrated DNA-protein interaction in all investigated *cis*-acting elements. Two of them, *Cis*1+ and *Cis*2+, contained short sequences recognized by HNF-4, a transcription factor playing an essential role in the *OTC* gene regulation in rodents. A binding site for COUP-TF, an antagonist to HNF-4 in rat was found in the *Cis*3- region. The nature of the *Cis*4+ element remains unknown; however it contains a conserved TATA-like domain and could serve as a binding site to the TBP transcription factor.

P10.59

Fatal Outcome of Iron-Sulfur Cluster Scaffold *NFU1* Gene mutations in a Neonatal Patient.

S. SENECA[1,2], *J. Smet*[3], *A. Vanlander*[3], *R. Van Coster*[3], *D. Roland*[4], *B. De Paepe*[3], *W. Lissens*[1,2], *M. Bonduelle*[1,2], *L. De Meirleir*[5,2];
[1]*UZ Brussel, Center for Medical Genetics, Brussels, Belgium,* [2]*REGE, Vrije Universiteit Brussel (VUB), Brussels, Belgium,* [3]*Ghent University Hospital, Department of Pediatrics, Division of Pediatric Neurology and Metabolism, Ghent, Belgium,* [4]*Centre Agréé des Maladies Héréditaires du Métabolisme, Institut de Pathologie et de Génétique, Gosselies, Belgium,* [5]*UZ Brussel, Pediatric Neurology, Brussels, Belgium.*

Mitochondrial diseases are a heterogeneous group of disorders characterized by a variety of clinical symptoms and a defect of the OXPHOS system, but only part of the genes involved in these pathways have been identified. The NFU1 protein is implicated in the iron-sulfur (Fe-S) cluster biogenesis. The latter are conserved protein co-factors with an essential role in a wide variety of enzymatic processes, including the e-transfer of complexes I to III of the respiratory chain. Recently, mutations in the *NFU1* and *BOLA3* genes were identified in patients with a multiple mitochondrial dysfunction syndrome.

Here we report on a patient with lactic acidosis, tubulopathy, failure to thrive and cardiac hypertrophy who died at 3 months of age. He is compound heterozygous for the common c.622G>T (p.Gly208Cys) missense mutation and a novel c. 62G>C (p.Arg21Pro) mutation changing a completely conserved arginine residue into a proline. Both parents are heterozygous carriers. His metabolic profile was largely characterised by an enzymatic complex II defect in lymphocytes, fibroblasts, muscle and liver tissue. Preliminary observations by BN-PAGE analysis concord with the conclusions of Ferrer-Cortès et al. 2012. They also observed a profound complex II deficiency as the main molecular signature of a pNFU1 malfunction and patients surviving the first months of life as compared to patients with an *NFU1* null allele. Today, only a small number of patients with Fe-S cluster protein defects, most of them compound heterozygous for the p.Gly208Cys mutation in the NFU1 gene, have been identified.

P10.60

Association between dyslipidaemia and mutations in the genes *PCSK9, LDLR*

A. Zarina[1], *L. Piekuse*[1], *M. Kreile*[1], *D. Juhnevica*[2], *K. Trusinskis*[2], *A. Erglis*[2], *A. Krumina*[3];
[1]*Riga Stradins university Scientific laboratory of molecular genetics, Riga, Latvia,* [2]*Pauls Stradins Clinical University Hospital, Latvian Cardiology Center, Riga, Latvia,* [3]*Latvian Biomedical Research and Study Center, Riga, Latvia.*

Introduction: Coronary heart disease (CHD) is the main cause of death in developed countries. One of the main causes of CHD is atherosclerosis, in which pathogenesis dyslipidemia is a crucial factor. There are several genes involved in cholesterol metabolism, e.g. *PCSK9* and *LDLR*. Mutations and polymorphisms in these genes can be associated with hyper- or hypocholesterolemia, and can cause Familial hypercholesterolemia.
Aim: To determine the association of the polymorphism E670G in the gene *PCSK9* with dyslipidemia and to test patients with dyslipidemia for seven mutations in the gene *LDLR*.
Material and methods: The study population included 38 patients with dyslipidemia and 66 healthy individuals served as a control population.
The E670G polymorphism was detected by RFLP analysis, but the mutations: D374Y, P664L, L458P, R329X, E207X, D200G, E80K in the gene *LDLR* were detected by ELUCIGENE FH20 (*Tepnel Molecular Diagnostics*).
Results: Polymorphism E670G - the G allele's frequency in affected individuals was 0.3947, in control population - 0.1339 ($p=3.9x10^{-5}$, OR 4.217, CI95% 2.069-8.587). After linear regression analysis there was not found significant association ($p>0.05$) with any of biochemical markers. Mutation E80K in the gene LDLR was found in two individuals with dyslipidemia.
Conclusions
1) Polymorphism E670G in the gene PCSK9 is one of the genetic risk factors in development of dyslipidemia, but it is not associated with specific biochemical markers;
2) Mutation E80K in the *LDLR* gene suggests that two patients have Familial hypercholesterolemia, but to make precise diagnosis, the mutations should be confirmed by other molecular method.

Background: Permanent neonatal diabetes mellitus (PNDM) is a rare monogenic form of non-autoimmune diabetes. Genetic defects have been identified in ~60% of cases, with mutations in *ABCC8*, *KCNJ11* and *INS* being the most frequent causes of PNDM. Recognition of genetic subtypes strongly impacts on both patients care and family counselling.
Objective: To identify the genetic aetiology of PNDM in a diabetic child born from consanguineous parents of Egyptian origin.
Methods: DNA samples from both the proband and non-diabetic parents were analysed for homozygosity mapping using the Illumina 660K-SNP chip. We then focused on the runs of homozygosity (ROHs) over 2.5 Mb, which were detected only in the patient. Sanger sequencing of candidate genes (*MNX1* and *GATA6*) present in those ROHs was subsequently performed, as well as expression analyses on human embryonic and adult pancreatic islet samples.
Results: We identified a putatively causal homozygous mutation in the transcription factor gene *MNX1* (c.816C>A/p.Phe272Leu) in the PNDM patient, who was clinically diagnosed as a typical case of PNDM without any pancreas developmental defects or other clinical features. The probably deleterious mutation is located within MNX1 homeodomain helix 2 that is highly conserved between species. In human embryonic pancreatic islet samples, we showed that *MNX1* expression was significantly enriched in pancreatic epithelium compared to mesenchyme, suggesting a role of MNX1 in human pancreatic beta-cell development.
Conclusion: We report a new putative cause of PNDM from a consanguineous family. Replication in other cohorts would be helpful to draw the clinical spectrum of *MNX1*-mutated PNDM patients.

P10.62

LC-MS/MS Analysis of Peroxisomal Biogenesis Disorder (PBD) Patients' Plasma Bile Acids (BA) Implicate Cytosolic BA-CoA:amino acid N-acyltranferase (BAAT) Activity in BA Reconjugation and Homoeostasis

D. Oglesbee, *C. T. Turgeon, P. Hall, M. Magera, D. Gavrilov, S. Tortorelli, K. Raymond, D. Matern, P. Rinaldo;*
Mayo Clinic, Rochester, MN, United States.

Bile acids (BA) are required for lipid and vitamin absorption, and cholesterol elimination among other functions. BA synthesis originates in the liver, and requires thirteen enzymatic steps, including cholesterol nucleus modification and side-chain oxidation. Glycine- and taurine-conjugation via BAAT is the last step before BA excretion into bile. Intestinal bacteria deconjugate BAs, but 95% of the BA pool is reabsorbed within enterohepatic circulation. BAAT is mostly peroxisomal, implying that deconjugated BAs must circulate to peroxisomes for reactivation and reconjugation via a currently unknown mechanism. As investigations with PBD patients are indispensible for the elucidation of the peroxisome's role in BA synthesis, we used an LC-MS/MS method to measure 18 conjugated and unconjugated plasma BAs (all primary, secondary, glycine-, and taurine-conjugates) alongside BA precursors, dihydroxycholestanoate (DHCA) and tetrahydroxycholestanoate (THCA), in PBD patients (n = 52) and controls (n = 279). Whereas PBD plasma contained elevated BA precursors, DHCA and THCA (median: 379x and 19x > controls, respectively), indicating BA synthesis impairment, taurine-conjugated primary BAs (taurocholate and taurochenodeoxycholate) were also markedly elevated (median: 136x and 26x > controls, respectively). In addition, the percentage of glycine-conjugated BAs in PBD specimens was half that of controls (42% vs. 89%, respectively), suggesting preferential taurine-reconjugation of BA pools. In summary, the analysis of BA levels in PBDs demonstrates the existence of BAAT activity without functional peroxisomes. Moreover, the reduction of the proportion of glycine-conjugated BAs suggests a cytosolic localization of BAAT activity in PBD hepatocytes and questions the functional purpose of peroxisomal BAAT in BA reconjugation.

Perrault syndrome is a genetically and clinically heterogeneous autosomal recessive condition characterized by sensorineural hearing loss and premature ovarian failure. By a combination of linkage, homozygosity mapping and exome sequencing in three families, we identified mutations in *CLPP* as the cause of this phenotype. In each family, affected individuals were homozygous for a different pathogenic *CLPP* allele: the missense mutations c.433A>C (p.Thr145Pro), c.440G>C (p.Cys147Ser), and an experimentally demonstrated splice donor site mutation c.270+4A>G.
CLPP encodes a highly conserved endopeptidase, a component of a mitochondrial ATP-dependent proteolytic complex that forms an element of the evolutionarily ancient mitochondrial unfolded-protein response (UPR^{mt}) stress signaling pathway. Protein modelling studies indicate the pathogenic nature of the mutations. Our findings define biallelic variants in *CLPP* that cause a strikingly variable phenotype of profound pre-lingual sensorineural hearing loss and ovarian failure/ovarian dysgenesis. This expands the understanding of the contribution of mitochondrial proteins to health and disease and allows accurate risk assessment and counselling in families with Perrault syndrome.

P10.64

The spectrum of mutations PAH gene in patients with phenylketonuria in Kazakhstan

D. N. Salimbaeva, ***G. S. Svyatova****, G. M. Berezina, I. G. Horoshilova;*
The Scientific Center of the obstetrics, gynecology and perinatology, Almaty, Kazakhstan.

In 2007, in the Republic of Kazakhstan has been introduced the State program of genetic screening of newborns for phenylketonuria (PKU). With the introduction this program, 54 patients with PKU were identified. The national register of patients with PKU in Kazakhstan includes information about 106 patients. 57 children with PKU were studied by molecular genetic method. The average frequency of PKU in Kazakhstan is equal of 1:18593. The aim of our study was detection in genome of PKU patients known mutations in PAH gene.
Molecular genetic analysis of mutations in PAH gene (R408W, R261Q, R252W, IVS10-11, IVS12 +1, R158Q, P281L, IVS14 +5) carried out using PCR technique.
The most widespread R408W mutation was detected in 20 patients (frequency was 0.538), 4 patient were homozygous and 16 heterozygotes. R261Q mutation was found in 5 patients with a frequency 0.096 in heterozygous state. 5 patients had P281L mutation with a frequency of 0.096. IVS12+1 was detected in getorozigous state in 2 patients (frequency 0.038). IVS10-11 mutation identified only 1 patient with a frequency 0.019. Other patient with PKU had unknown mutation, which requires a whole genome sequencing RAH gene. 2 patients had a whole genome sequencing RAH gene. It was found Arg243Glu (c.728g.a.) and R243Q/R243Q in 7 exon of PAH gene.
Application of molecular genetic techniques provided opportunities for diagnosis of hereditary diseases including ethnicity. Molecular genetic study of patients allows PKU prenatal diagnosis and detect heterozygous carriers. To date, this is the most adequate prevention of PKU in Kazakhstan.

Characterization of PMM2 mutations: identification of target mutants for specific pharmacological chaperone therapy

P. Yuste-Checa[1], *P. Sierra-González*[1], *A. Gámez*[1], *M. Martinell*[2], *L. R. Desviat*[1], *M. Ugarte*[1], *C. Pérez-Cerdá*[1], *B. Pérez*[1];
[1]*Centro de Diagnóstico de Enfermedades Moleculares, CBMSO, CIBERER, IDIPaz., Madrid, Spain,* [2]*Minoryx therapeutics, Barcelona, Spain.*

Congenital Disorders of Glycosylation (CDG) are a group of multisystemic, inherited, metabolic diseases resulting from defects in the protein N-glycosylation pathway. Phosphomanomutase 2 (PMM2) is the affected protein in CDG-PMM2 disorder, the most common CDG, for which there is currently not an effective treatment. PMM2 is a cytosolic enzyme which converts mannose 6-phophate to mannose 1-phosphate. The screening of target mutations for specific therapies was performed through the functional analysis of nine PMM2 mutations. All the studied mutations presented lower amounts of PMM2 protein detected by western blot from crude bacterial extracts and purified proteins. The analysis of the oligomerization pattern showed an oligomeric profile similar to the wild-type protein with abundance of dimers for several mutations others showed increased levels of aggregates while one mutation, p.Pro113Leu, did not present any oligomeric state. Protein stability, studied by differential scanning fluorimetry, showed that all mutants are more unstable than wild-type shifting the Tm from 2 to 7 °C. Finally, the specific activity of mutants from pure protein and bacterial crude extracts showed a reduction from 50 to 100% compared to the wild-type protein. Based on this results and the localization of residues in the PMM2 crystal structure, we have classified the mutations as catalytic, destabilizing and mutations affecting the dimerization. The destabilizing mutations pV44A, p.D65Y, p.R162W, p.C241S, p.F207S and p.T237M are promising candidates for testing the 15 pharmacological chaperones previously selected by high-throughput screening from 100 000 library´s compounds using the wild-type protein.

POLG1 is the most commonly gene involved in mitochondrial disorders with mitochondrial DNA instability and causes a wide range of diseases with recessive or dominant transmission. More than 170 mutations have been reported. Most of them are missense mutations but nonsense, splice-site mutations and small deletions and insertions have also been identified. However, to date, only one large-scale rearrangement has been described in

a child with Alpers syndrome. Herein, we report a large cohort of 160 patients with clinical, molecular and/or biochemical presentation suggestive of POLG deficiency. Using sequencing, we identified POLG1 variants in 25 patients including 5 novel pathogenic mutations. Two patients with novel mutations had unusual clinical presentation: one patient exhibited an isolated ataxic neuropathy and one child presented with endocrine signs. We completed sequencing step by QMPSF analysis in 40 patients with either only one POLG1 heterozygous variant or a family history suggesting a dominant transmission. We identified a large intragenic deletion encompassing part of intron 21 and exon 22 of POLG1 in a child with refractory epilepsia partialis continua. In conclusion, we describe the first large French cohort of patients with POLG1 mutations, expanding the wide clinical and molecular spectrum observed in patients with POLG1 mutations. We also show that large deletions are probably less rare events than previously thought and the great interest of using QMPSF in patients with a single heterozygous POLG1 mutation, particularly in severe infantile phenotypes.

Genetic variants of organic cation transporters (Octs) in patients with polycystic ovary syndrome (PCOS) and their association with glucose metabolism

N. Schweighofer, *E. Lerchbaum, H. Warnkross, O. Trummer, T. R. Pieber, B. Obermayer-Pietsch;*
Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University, Graz, Austria.

Metformin, a well-known oral insulin-sensitizing drug, is commonly used in the treatment of polycystic ovary syndrome (PCOS). It decreases also hepatic lipogenesis and activates hepatic SHBG production. There is a great variability in the clinical response to metformin, mainly due to genetic variances influencing the pharmacokinetics/dynamics of metformin or its action. Metformin is a substrate of organic cation transporters (Octs), especially Oct1 (liver) and Oct2 (kidney).
We investigated the pattern of metformin response mediating genotypes in PCOS patients to identify potential "bad responders" and "non responders" and determined their relation to glucose metabolism prior to metformin treatment.
We genotyped R61C, G465R, S14F, S189L, G220V, P160L and M408V (Oct1), A270S (Oct2) and rs11212617 (ATM) variants in 676 PCOS and 90 control women and performed oral glucose tolerance tests in 422 patients and 88 controls prior to metformin treatment.
In PCOS women, we found 30% with non-functioning alleles and 50% with decreased metformin response alleles. Oct variants were associated with elevated C-peptide levels at baseline (p=0.006) and following oral glucose load (AUC C-peptide p=0.005). A high percentage of our PCOS patients might be "bad responders" or "non-responders" due to their Oct genotypes. Oct genotypes are able to modulate the pharmacokinetic and pharmacodynamic profile of metformin, thus contributing to differences in metformin efficacy. In addition, Oct genotypes might have effects on glucose metabolism which are independent from metformin.

P10.68

The effect of Mediterranean diet and exercise on insulin resistance in the presence of PPARG2 rs1801282 polymorphism in a central Romanian population

K. Csep, *C. Banescu, A. Todoran Butila;*
University of Medicine and Pharmacy, Tg Mures, Romania.

As the environment has a role in modifying the relationship between genetic variants and clinical measures of disease, consideration of gene-environment interactions (GxE) is mandatory. Based on the Nutritional Phenotype Database initiated to facilitate GxE GWAS or single-gene studies, we proposed to follow the role of lifestyle and rs1801282 on insulin resistance in a non-diabetic population from central Romania.
In 210 subjects (median age 52) living in an urban environment, insulin resistance has been estimated by QUICKI (Quantitative Insulin Sensitivity Check Index, IRI=1/QUICKI), while genotyping was done by PCR-RFLP using BstUI. Lifestyle has been evaluated by the PhenX Toolkit and DataShaper questionnaires.
In case of an increased calorie intake, low fiber ingestion and sedentary lifestyle, IRI was found to be significantly higher (3.1 vs 2.71, p=0.003). Differences have been maintained and reproduced in the presence of the unmodifiable inherited factor (PP vs PA+AA), in subjects following (2.76 vs 2.68, p=0.02) or not (3.06 vs 2.93, p=0.03) a healthy lifestyle.
In conclusion, diet and physical activity may have beneficial effects even in the presence of risk alleles contributing to insulin resistance. Given the complex nature of GxE, minor effect of rs1801282 complicated by population differences and contradictory data reported in the literature, extension of analysis on a high number of subjects is necessary. Efforts, though, are motivated by insight that could directly facilitate a more active intervention through lifestyle choices to reduce cardiometabolic risk.

Propionic acidemia (PA) is characterized by neonatal or infancy-onset metabolic decompensation. The vast majority of patients develop long-term complications including progressive encephalopathy, cardiomyopathy and seizures in spite of adapted clinical management. We report an unusual late-onset PA diagnosis in an adult female patient.
The patient was referred to our department of genetics at the age of 28 years in the context of premature ovarian failure (POF). At the age of 17 years, she had presented acute heart failure secondary to a dilated cardiomyopathy which had required cardiac transplantation. Clinical examination, serum creatine phosphokinase concentration and karyotype were normal. No episode of metabolic acidosis nor neurocognitive impairement has been reported. Nevertheless, her personal history prompted us to perform metabolic investigations, which revealed an abnormal urine organic acid profile with elevated methylcitric acid. Acylcarnitine analysis showed an important increase of propionyl-carnitine. Enzymatic analysis showed no detectable PCC activity on cultured fibroblasts. Sequence analysis revealed two mutations within the PCCB gene: c.1218_1231del14ins12 and c.1514T>C. Both parents were shown to be heterozygous for one PCCB mutation. This observation is the second description of POF in a patient with PA, suggesting that POF is a complication of the disease. Dilated cardiomyopathy is commonly described as a long term complication in PA, but to our knowledge, only three other cases of PA revealed by DCM have been reported. This observation illustrates that a systematic metabolic evaluation should be performed in patients with dilated cardiomyopathy.

Transient expression of ATIC and ADSL restore affected purinosome assembly in cultured skin fibroblasts from patients with ADSL deficiency

M. Zikanova, *V. Baresova, V. Skopova, S. Kmoch;*
Charles University in Prague, First Faculty of Medicine, Institute of Inherited Metabolic Disorders, Prague 2, Czech Republic.

De novo purine synthesis (DNPS) is one of the basic processes in eukaryotic cells. Purinosome is multienzyme complex composed by enzymes of DNPS that cells transiently assemble in their cytoplasm upon depletion or increased demand of purines. Dysfunction of DNPS is represented by two genetic diseases: AICA-ribosiduria and adenylosuccinate lyase deficiency (dADSL). We hypothesized that some of the mutations may affect formation or stability of the purinosome.
We investigated purinosome formation in cultured skin fibroblasts from one AICA-ribosiduria patient and nine dADSL patients representing three groups of the disease - neonatal form, type I form and type II form. Skin fibroblasts cultured in purine depleted medium were immuno-labeled with

various combinations of DNPS proteins. We observed correlation between purinosome formation and the disease severity : no creation of purinosome in neonatal and type I forms and reduced formation in type II form of dADSL and AICA-ribosiduria.
Then we investigated the possibility of the purinosome formation recovery in AICA-ribosiduria skin fibroblasts transfected with wtATIC; and dADSL skin fibroblasts transfected with wtADSL. We observed renovation of purinosome formation in transfected dADSL fibroblasts comparable to control fibroblasts in the purine depleted medium. In contrast, no purinosome formation was observed in transfected AICA-ribosiduria fibroblasts.
These results indicate that genetic defects of DNPS affect not only activity and structure of the individual enzymes, but according to disease severity, also functionality of the DNPS pathway by purinosome complex destabilization.

Background
Peroxissomal biogenesis disorders (PBD) include Infantile Refsum disease (IRD), a rare autosomal recessive disorder, belonging to the mild end of the Zellweger spectrum disorders (ZSDs). Mutations in *PEX* genes, coding for peroxins, result in general impairment of peroxisomal functions. We report a fifth Portuguese patient with IRD, establishing a comparison with the remaining Portuguese patients.
Case report
A 3 years-old girl born from consanguineous parents was referred to the Medical Genetics consultation for retinitis pigmentosa, bilateral sensorineural hearing loss, developmental delay and dysmorphic cranio-facial features. Hypotonia was observed at birth. She had had neonatal jaundice and increased hepatic enzymes. Nystagmus, detected at 3 months, prompted ophthalmologic evaluation that later documented retinal dystrophy. Pyramidal syndrome was evident at 16 months. Plasma levels of very long chain fatty acids were slightly increased, which in combination with increased phytanic acid and pristanic acid levels supported the hypothesis of a peroxisomal disorder, either a ZSD or a D-bifunctional protein deficiency. The deficient activity of dihydroxyacetone-phosphase acyltransferase in fibroblasts is in accordance with diagnosis of ZSD.
Discussion
When comparing to the other Portuguese patients with IRD, biochemical abnormalities in the present patient were found to be milder. Hearing and visual impairment should prompt a comprehensive investigation of PBD, as the onset and severity of manifestations is variable and numerous clinical differential diagnoses exist. Since the ZSDs are a continuum of at least 3 phenotypes (Zellweger syndrome, neonatal adrenoleukodystrophy, IRD), to name a specific profile of ZSDs is useful when discussing prognosis and counselling families.

Common g.1541G>A SCO2 gene mutation carriership among Polish patients with negative molecular testing for spinal muscular atrophy.

S. Łuczak[1], *D. Piekutowska-Abramczuk*[1], *J. Zimowski*[2], *P. Kowalski*[1], *E. Ciara*[1], *M. Borucka-Mankiewicz*[1], *D. Jurkiewicz*[1], *M. Pelc*[1], *J. Trubicka*[1], *M. Krajewska-Walasek*[1], *E. Pronicka*[1], *J. Zaremba*[2];
[1]*The Children's Memorial Health Institute, Warsaw, Poland,* [2]*The Institute of Psychiatric and Neurology, Warsaw, Poland.*

Introduction
Spinal muscular atrophy (SMA) is one of the most frequent among rare diseases in Poland (1:7000-10000 births). Direct molecular testing for *SMN/NAIP* deletions is a routine diagnostic approach. About 80-100 such tests are performed per year.
Muscle histology and EMG records in *SCO2*-related encephalomyopathy (with g.1541G>A as a common mutation) are similar to these observed in SMA, which may suggest necessity of *SMN/NAIP* testing.
The aim of this study was to determine frequency of g.1541G>A mutation in a cohort of 468 archive DNA samples negative for *SMN/NAIP* deletions.
Material and Methods
We examined samples of DNA isolated from peripheral blood leukocytes. Genotyping with Taqman's probe (based on Real Time equipment) was used for specific mutation identification. Presence of the mutation in selected samples was confirmed by direct sequencing.
Results
The study revealed nine g.1541G>A positive samples: three g.1541G>A carriers , in addition to six finally established non-SMA diagnoses (5 cases of *SCO2*-related encephalomyopathy and one SMARD). The carrier frequency in the studied group was finally established as 1:156 (3/468).
Conclusion
It remains to be clarified if the number of g.1541G>A carriers identified in this study corresponds to the true population frequency or may be associated with a neurogenic muscle pathology.
The study was supported by the National Science Centre project no. 1154/B/P01/2011/40 and CMHI project no. S126/12

P10.73

The effects of the (TAAAA)n VNTR on serum SHBG and lipid levels in men with coronary heart disease

Ö. Kurnaz Gömleksiz[1,2], *B. Akadam Teker*[2], *Z. Bugra*[3], *B. Omer*[4], *H. Yilmaz Aydogan*[2];
[1]*Haliç University, Faculty of Arts and Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey,* [2]*Istanbul University, Institute DETAE Department of Molecular Medicine, Istanbul, Turkey,* [3]*Istanbul University, Istanbul Faculty of Medicine, Department of Cardiology,, Istanbul, Turkey,* [4]*Istanbul University, Istanbul Faculty of Medicine, Department of Biochemistry, Istanbul, Turkey.*

HDL-C levels are inversely associated with the CHD risk. Serum SHBG concentration is partially under genetic control and positively associated with the HDL-C levels. In our study, the possible relation between SHBG (TAAAA) n VNTR and low HDL-C were investigated in 75 men with CHD and in 50 healthy men by analyzing this polymorphism and also measuring SHBG levels. In CHD patients who had SHBG>35nmol/l, the possibility of having a HDL-C levels >0.90mmol/l was observed significant (p=0.004;OR:6.319). The frequency of six repeats allele was higher in controls (p=0.002;OR:0,293). Six repeats allele in patients and short repeats (≤8) in controls were found to be associated with higher SHBG ($p<0.05$ and $p<0.01$, respectively). In patients with eight repeats allele, HDL-C/LDL-C was observed lower than in non-carriers ($p<0.05$). Triglycerides were lower in controls with six repeats allele and short repeats and higher in controls with nine repeats allele ($p<0.05$). HDL-C/LDL-C was lower in controls with nine repeats allele. Our findings indicate six repeats allele has a positive effect on SHBG levels in both patients and controls. Consequently, this is a preliminary study to establish the link among (TAAAA)n VNTR, SHBG and HDL-C levels in CHD pathogenesis in a Turkish population. It was demonstrated 6 repeat allele may protect against CHD risk. Additional studies with larger sample sizes are needed to define the influence of SHBG (TAAAA)n VNTR on clinical outcomes. Finally, we suggest a positive correlation between SHBG and HDL-C levels in CHD patients, and this association might be affected by SHBG gene variations.

Study of an asymptomatic mother heterozygous for X-linked creatine transporter defect

A. Philippe[1], *N. Boddaert*[2], *A. Mazery*[3], *C. Fournier*[3], *J. Steffann*[1], *J. Bonnefont*[1], *A. Chabli*[4], *A. Tanet*[5], *L. Colleaux*[6], *V. Valayannopoulos*[7];

[1]*Inserm U781 & Département de Génétique, Hôpital Necker, Paris, France,* [2]*Département de Radiologie Pédiatrique, Hôpital Necker, Paris, France,* [3]*Département de Génétique, Hôpital Necker, Paris, France,* [4]*Service de Biochimie Métabolique, Hôpital Necker, Paris, France,* [5]*Service de Psychiatrie de l'enfant et l'adolescent, Hôpital de la Pitié-Salpétrière, Paris, France,* [6]*Inserm U781, Hôpital Necker, Paris, France,* [7]*Centre de référence des maladies héréditaires du métabolisme, Hôpital Necker, Paris, France.*

Female carriers of SLC6A8 mutations may have learning disabilities or be asymptomatic. Therefore, X-linked creatine transporter defect is likely to be under diagnosed in females and almost all of female carriers reported in the literature are related to an affected boy.

An increased creatine/creatinine ratio in urine or a relatively low cerebral creatine signal in 1H-magnetic resonance spectroscopy (MRS) compared to other metabolic peaks (choline-containing compounds, myo-inositol, N-acetylasparate) is used to detect the creatine transporter defect in females.

We report two female carriers of SLC6A8 mutations (c1006-1008 delAAC), aunt and mother of an affected boy: the aunt has mild cognitive impairment, the mother is asymptomatic.

Interestingly, the aunt has normal urinary creatine/creatinine ratio but low cerebral creatine signal in MRS whereas her sister has increased urinary creatine/creatinine ratio but normal cerebral creatine signal.

The cognitive evaluation of the asymptomatic mother shows IQ scores in the range of low average intellectual functioning with inter-scale heterogeneity. However, it represents a 35-40 point deficit when compared to her two healthy brothers' IQ scores.

In the same way as it is necessary to take into account the urinary creatinine or cerebral metabolic peaks to interpret respectively the urinary creatine and the cerebral creatine peak of individuals, we suggest considering cognitive levels of family members to assess effects of SLC6A8 mutations on IQ female carriers in further research.

Screening based on urinary creatine/creatinine ratio and MRS could be proposed to females with learning difficulties after global cognitive evaluation.

In the last two decades, several genetic defects affecting different steps of the cholesterol biosynthesis pathway were described and nine inherited errors of the distal part of cholesterol biosynthesis have been recognized. Affected patients present complex malformation syndromes involving different organs and systems.

We report on the biochemical data, genotype and evolution, since young life till adulthood, of three patients with enzymatic defects at three distinct, steps of cholesterol biosynthesis pathway, namely: Smith-Lemli-Opitz syndrome (SLO); X-linked dominant chondrodysplasia punctata type 2 (CDPX2) and congenital hemidysplasia with ichthyosiform erythroderma and limb defects (CHILD) syndrome in order to contribute for a better knowledge of the natural history of these genetic disorders. The differences on clinical manifestations depended on several factors: the step in cholesterol synthesis that is blocked, the type of mutation and its impact in the structure and function of the enzyme, and the amount of exogenous cholesterol that the patient received either via placenta during embryonic development or later by oral intake.

None of our patients showed life threatening episodes and their phenotypes actually improved over time probably due to the fact that the western adult diet became progressively enriched in cholesterol (due to the increased amount of animal products ingested), which may partially compensate for the deficiency after birth. In order to diagnose such disorders it is important to look for malformations, minor dismorphic features and chronic skin changes in patients with low or borderline cholesterol levels at any age.

P10.76

Discovery of new potentially associated loci from pathway analysis of known influencing genes for Type 2 Diabetes

L. Marullo[1,2], *A. Antonov*[3], *A. Morris*[2], *C. Scapoli*[1], *I. Prokopenko*[2,4];

[1]*The Department of Life Sciences and Biotechnologies, University of Ferrara, Ferrara, Italy,* [2]*The Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [3]*Medical Research Council, Toxicology Unit, Leicester, United Kingdom,* [4]*Department of Genomics of Common Disease, School of Public Health, Imperial College London, Hammersmith Hospital, London, United Kingdom.*

Genome-wide association studies have contributed to the description of 71 loci that influence susceptibility to T2D; however, our understanding of the underlying pathophysiological processes is still limited.

We explored the mechanistic basis of T2D associations assuming their functional dependence and, therefore, connectivity via non-interrupted gene networks.

We considered 84 T2D-associated genetic variants within 71 known loci (Jan 2013) and explored their gene network connections using the LocusSpider tool, enabling interrogation of functional gene-gene relations from KEGG, Reactome and PPI pathways. LocusSpider prioritised genes having: (i) maximal connectivity within the 71 input loci; and (ii) located most closely to the associated variants.

The LocusSpider gene network model (p_{model}=0.01) connected variants from 62 T2D-associated loci (41 genes were <50kb distant from the SNP) and suggested 44 additional genes required to connect genes from the input loci. The most represented pathways included signal transduction (WNT/EGFR-signaling), transcription, cell cycle and insulin secretion regulation. At 22 known loci, pathway analysis suggested a gene different from the previously assigned locus label, underscoring a need for further functional characterisation. We observed at least nominal associations (p-value<0.05, FDR q-value<0.20) with T2D in DIAGRAMv3 meta-analysis (Morris et al. 2012) within 25 loci (+/-50kb regions) surrounding the 44 suggested genes, with strongest signals at rs9270986 (*HLA-DQA1, p*=2.7x10^{-7}), rs7169735 (*p*=4.7x10^{-5}) at *RASGRF1* as *ARAP1-CAMK2B* inter-link, and rs603939 (*p*=5.7x10^{-4}) at *PRKACB* connecting *ADCY5* and *KCNJ11*.

Our findings suggest that novel pathway analysis methods may underscore important biological mechanisms of T2D pathogenesis and highlight biologically relevant associations for subsequent follow-up.

Congenital Disorders of Glycosilation: Antisense therapy in TMEM165 deficiency

P. Yuste-Checa[1], *C. Medrano*[1], ***L. R. Desviat***[1], *M. Ugarte*[1], *C. Pérez-Cerdá*[1], *G. Matthijs*[2], *B. Pérez*[1];

[1]*Centro de Diagnóstico de Enfermedades Moleculares, CBMSO, CIBERER, IDIPaz, Madrid, Spain,* [2]*Center for Human Genetics, University of Leuven, Leuven, Belgium.*

Deficiency of glycosyltranferases, glycosidases or nucleotide-sugar transporters involved in protein glycosylation leads to Congenital Disorders of Glycosylation (CDG), a rare group of diseases characterized by multisystemic phenotype. Recently, others proteins implicated in Golgi trafficking and Golgi pH homeostasis have been identified as CDG causing genes. In this work, we describe the functional analysis of the intronic change c.792+182G>A identified in TMEM165 causing new CDG type II. The protein function is unknown, but points to an important role in Golgi glycosylation and Golgi morphology maintenance. Using a functional in vitro splicing assay based on minigenes and transcriptional profile studies in patient-derived fibroblasts, we have validated its pathogenic effect. Once functionally analyzed the deep intronic change we have applied a mutation specific therapy. We have designed a specific antisense oligonucleotide targeted to rescue the abnormal splicing process. After transfection we have detected normal transcript mRNA which is efficiently translated into a well localized protein. We have observed a protein recovery (3-fold) detected by double inmunofluoresce using TMEM165 and the Golgi-specific marker GM130 antibodies. The recovery was dose and sequence specific with no effect on patient-derived fibroblasts harboring missense changes. The results show the efficiency of the antisense therapy targeted to intronic changes, which are detectable by combined DNA and RNA studies. Up to now, five TMEM165-CDG patients have been described and three of them are homozygous for the intronic change c.792+182G>A which makes antisense morpholino therapy an excellent candidate treatment for this new CDG type II.

Disruption of *NUBPL* due to balanced translocation [t(3;14)(q26.33;q14)] increases severity of a family-specific PGK1 mutation

D. David[1], *I. Haltrich*[2], *B. Marques*[1], *C. Fernandes*[1], *S. Malveiro*[1], *G. Fekete*[2];
[1]*Department of Human Genetics, National Institute of Health Dr Ricardo Jorge, Lisboa, Portugal,* [2]*2nd Department of Paediatrics, Semmelweis University, Budapest, Hungary.*

An intriguing group of familiar translocations are those which not always segregate with the "associated" disorder. Here we report the genetic alterations underlying a clinical phenotype characterized by haemolytic anemia and neuro-myopathy, seemingly associated with the familial translocation [t(3;14)(3q26.33;q14)]. Two affected probands and two unaffected relatives have been identified as carriers. The 3q26.33 breakpoint was mapped about 40 kb from the *TTC14* 5' end, at position 180.28 Mb and the 14q14 breakpoint within IVS 6 of *NUBPL*. The latter has been implicated in the aetiology of mitochondrial complex I deficiency (OMIM 252010). The most important additional possible candidate gene identified in this region is *DNAJC19* causing an autosomal recessive disorder (OMIN 610198) that partially overlaps the reported phenotype. The recognition that a deceased relative most likely suffered from a similar disorder suggested the possibility of an X-linked disorder. Exclusion of additional genomic alterations within the breakpoint regions or elsewhere in the genome, familial X-chromosome segregation analysis and whole exome sequencing identified a novel missense mutation, c.358G>A, p.Glu120Lys, in exon 4 of phosphoglycerate kinase 1 (*PGK1*). Segregation analysis confirmed the association of this mutation with the disease phenotype. Re-evaluation of clinical data indicates that myopathy is considerably more severe in PGK1 deficient patients carriers of the translocation. The confirmation of this observation is currently underway. In conclusion, we have identified a novel *PGK1* mutation whose clinical phenotype is exacerbated by co-inheritance of the disrupted *NUBPL* and/or by alterations affecting the genes in the breakpoint regions.

Novel mutations in HPD causing tyrosinemia type III in Northern Israel

T. C. Falik-Zaccai[1,2], *D. Raviv Shay*[1], ***N. Nasser Samra***[1], *L. Kalfon*[1], *O. Dementyev*[1], *M. Baydany*[1], *F. Fares*[3], *A. Shaag*[4], *S. Almashanu*[5], *H. Mandel*[6,7];
[1]*Western Galilee Hospital-Naharia, Naharia, Israel,* [2]*The Galilee Faculty of Medicine, Bar Ilan University, Safed, Israel,* [3]*Department of Human Biology, Faculty of Natural Sciences, University of Haifa, Mount Carmel, Haifa, Israel,* [4]*Monique and Jacques Roboh Department of Genetic Research, Hadassah, Hebrew University Medical Center, Jerusalem, Israel,* [5]*Newborn Screening, National Center for Newborn Screening, Tel-Hashomer Hospital, Tel Aviv, Israel,* [6]*Meyer Children's Hospital, Metabolic Unit, Rambam Medical Center, Haifa, Israel,* [7]*Rappaport Faculty of Medicine, Technion, Haifa, Israel.*

Impaired tyrosine catabolism result in elevated plasma tyrosine concentrations. Malfunction enzymes along the tyrosine catabolic pathway results in hereditary tyrosinemia. Tyrosinemia type III is caused by deficiency in 4-HPPD. To date, only 14 cases have been described, showing a wide clinical spectrum. Reported patients have either presented with mental retardation and neurological symptoms while others, detected by neonatal screening, have been asymptomatic.
We report 4 new patients, 3 from a highly consanguineous Druze family, presenting elevated blood tyrosine levels with normal development and intelligence. Clinical evaluation revealed novel eye and skin phenotype not previously described in tyrosinemia type III. The fourth patient, from a Muslim origin consanguineous family, was diagnosed with hypertyrosinemia in the neonatal metabolic screen. Her psychomotoric development is normal for her age. Sequencing revealed two novel splicing mutations in HPD. Healthy control screening from two Druze villages detected 3:100 carriers in one village and none in the second.
We suspect tyrosinemia type III to be under-diagnosed and more common than is currently known. With neonatal metabolic screen becoming more widespread, more patients are likely to be diagnosed. Molecular analysis is the gold standard for diagnosing tyrosinemia type II and III. In light of the minute number of patients with tyrosinemia type III worldwide, clinical characterization of new patients is highly significant, determining the natural history of the disease, and describing the treatment and its contribution to normal growth and development of the patients.

A homozygous *UQCRC2* mutation cause a neonatal onset metabolic decompensation due to complex III deficiency.

N. Miyake[1], *S. Yano*[2], *Y. Goto*[3], *N. Matsumoto*[1];
[1]*Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan,* [2]*Genetics Division, Department of Pediatrics, LAC+USC Medical Center, Keck School of Medicine, University of Southern California, Los Angeles, CA, United States,* [3]*Department of Mental Retardation and Birth Defect Research, National Institute of Neuroscience, NCNP, Tokyo, Japan.*

The mitochondrial respiratory chain generates energy as adenosine triphosphate (ATP) by means of the electron-transport chain and the oxidative-phosphorylation system. The mitochondrial respiratory chain, located in the inner mitochondrial membrane, is composed of five complexes: I, II, III, IV, and V. Among them, mitochondrial complex III (CIII) comprises 11 subunits encoded by one mitochondrial and 10 nuclear genes. Until now, mutations in four genes have been known to cause autosomal recessive CIII deficiencies: *UQCRB*, *UQCRQ*, *BCS1L* and *TTC19*. *UQCRB* and *UQCRQ* encode components of CIII itself, while *BCS1L* and *TTC19* produce mitochondrial assembly factors. Here, we report three patients from a consanguineous Mexican family presenting with neonatal onset of hypoglycemia, lactic acidosis, ketosis, and hyperammonemia. By whole exome sequencing combined with linkage analysis, we successfully found a homozygous missense mutation in *UQCRC2* that encodes mitochondrial ubiquinol-cytochrome c reductase core protein II. In its native state, the CIII monomer is quickly converted into a catalytically active homodimer that is incorporated into a supercomplex, and this supercomplex functions as a single enzyme. Based on structural modeling, the mutation (p.Arg183Trp) was predicted to destabilize the hydrophobic core at the subunit interface of the core protein II homodimer. In vitro studies using fibroblasts from the index patient clearly indicated CIII deficiency, as well as impaired assembly of the supercomplex consisting of complexes I, III, and IV. This is the first described human disease caused by *UQCRC2* abnormality.

Association and molecular analysis of 3' UTR polymorphisms of the WFS1 gene

Z. Ronai, *N. Nemeth, A. Somogyi, M. Sasvari-Szekely;*
Semmelweis University, Budapest, Hungary.

Wolframin is a major protein of the endoplasmic reticulum, loss of function mutations of the WFS1 gene result in the monogenic Wolfram-syndrome, characterized by optic atrophy, diabetes insipidus, diabetes mellitus and deafness, whereas polymorphisms of the gene are putative risk factors of diabetes. Our aim was the association and molecular analysis of two SNPs (rs1046322 and rs9457) in the 3' UTR of the WFS1 gene, which are supposed to alter the miRNA binding according to in silico data.
Association analysis was carried out by case-control study. 617 patients and 1147 healthy controls particiapted. Genotype analysis was carried out using PCR based methods, functional analysis was done by luciferase reporter system.
Our results showed that rs9457 "C" allele was significantly more frequent among patients with type 2 diabetes, whereas the rs1046322 variant showed a significant association with the type 1 form of the disease. Luciferase reporter experiments suggested that the rs1046322 and the rs9457 SNPs altered the binding of miRNA-668 and miRNA-185, respectively.
Our results suggest that the rs9457 and rs1046322 polymorphisms are the genetic components of diabetes mellitus. Earlier studies showed an association between WFS1 rs1046320 and diabetes, however no biological function of the SNP could be observed. We suggest that this result is due to the strong linkage disequilibrium between rs9457 and rs1046320, thus the latter polymorphism can be a genetic marker of rs9457.
This work was supported by the Hungarian grant OTKA K83766 and by the Bolyai János Scholarship (BO/00089/10/5) of the Hungarian Academy of Sciences.

X-linked adrenoleukodystrophy: Two manifesting heterozygotes in a cohort of Czech and Slovak patients

K. Peskova[1], *L. Dvorakova*[1], *H. Vlaskova*[1], *H. Treslova*[1], *H. Jahnova*[1], *M. Magner*[2], *P. Jesina*[1], *P. Hornik*[1], *P. Bartova*[1], *H. Waterham*[3], *R. Wanders*[3], *M. Hrebicek*[1];
[1]*Institute of Inherited Metabolic Disorders, General University Hospital in Prague, Prague 2, Czech Republic,* [2]*Department of Pediatrics and Adolescent Medicine, General University Hospital in Prague, Prague 2, Czech Republic,* [3]*Academic Medical Center, Amsterdam, Netherlands.*

The most common peroxisomal disorder, X-linked adrenoleukodystrophy (X-ALD; MIM# 300100), is a recessive neurodegenerative disease. The major phenotypic forms are
childhood cerebral (ccALD) and adrenomyeloneuropathy (AMN). The diagnosis of X-ALD was established in 25 Czech and Slovak families. All patients had elevated concentration of C26:0, elevated ratios of C26:0/C22:0 and C24:0/C22:0 and a mutation in *ABCD1* gene.
In the cohort there are two symptomatic females. The first presented with AMN symptoms from the age of 27 years. She is a carrier of previously published mutation c.887A>G (p.Tyr296Cys). Sequencing of cDNA showed a strong prevalence of the peak corresponding to the mutated allele.
The second female patient was a two-year-old girl with microcephaly, psychomotor delay, hearing and vision disorder, seizures, and leukodystrophy. Pathological VLCFA profile and a previously found a pathogenic mutation c.1553G>A (p.Arg518Gln) in a heterozygote state was identified. Sequencing of cDNA showed 70 - 80% prevalence of the mutated allele. However, the sequencing of the patient's asymptomatic mother revealed very similar results (including biochemical findings). HUMARA analysis confirmed the unfavorable X-inactivation skewing in the mother blood sample.
These data show that molecular diagnostics in heterozygous females is not straightforward. It may reflect at least three possible explanations: 1) The X-inactivation status does not correspond to the phenotype in X-ALD heterozygotes in all cases. 2) The genotype-phenotype correlation is poor. 3) Clinical picture of heterozygotes may result from a combination of X-ALD and other factors, like severe perinatal risks.

Arrested leukodystrophy in a young man with adrenomyeloneuropathy (AMN)

D. L. Renaud*, J. D. Port, K. M. Welker, M. R. Trenerry;*
Mayo Clinic, Rochester, MN, United States.

Background X-linked adrenoleukodystrophy (X-ALD) is a peroxisomal disorder which presents with progressive leukodystrophy in boys or as progressive spasticity and neuropathy in men (AMN).
Case Report A 30 year old male presented to the Neurometabolic Clinic with worsening stiff gait and paresthesias, suggestive of AMN, and a recent diagnosis of X-ALD. He was diagnosed with Addison's Disease at age 4. He was a gifted student until high school when he had a change in personality, decreased attention and executive functioning. This was progressive during high school and then stabilized. IQ testing at age 16 years revealed a verbal IQ of 115 and performance IQ of 92.
At the time of his evaluation, neuropsychological testing revealed a verbal IQ of 115 and an improved performance IQ of 110. MRI of the spine revealed generalized atrophy of the spinal cord and the EMG revealed sensorimotor neuropathy.
The MRI scan revealed abnormal signal in the white matter of the parieto-occipital, temporal and cerebellar white matter bilaterally which has remained stable. There was no enhancement or restricted diffusion to suggest active demyelination. MR spectroscopy was normal.
Conclusion This case demonstates a rare arrested form of leukodystrophy in a young man with AMN.

Mabry syndrome (hyperphosphatasia with developmental disability) was first described in 1970 (OMIM#239300). At first considered rare, improved syndrome identification has led to recruitment of more than twenty families world-wide. Salient features of the disorder include:
characteristic facial dysmorphology (hypertelorism, a broad nasal bridge and a tented mouth); variable shortening of middle and distal phalanges; and neural abnormalities on biopsy (plaques disrupting Schwann cells). Like many infantile metabolic storage disorders, seizures associated with Mabry syndrome have an onset in the first year of life. Persistently elevated serum alkaline phosphatase (ALP) levels are now known to be associated with abnormalities of the phosphatidylinositol glycan (GPI) anchor due to mutations in the PIGV, PIGO and PGAP2 genes. Lysosomal storage material detected in some patients with Mabry syndrome. It has been putatively identified as glycolipid in nature - possibly resulting from changes in lipid raft functions that result from GPI anchor disruption. Not all patients with a clinical diagnosis of hyperphosphatasia with neurologic deficit result from known GPI disruptions. We present data on patients that suggest there are further subtypes of the disorder.

Newborn screening for X-linked adrenoleukodystrophy

S. Tortorelli[1], *C. T. Turgeon*[1], *M. J. Magera*[1], *A. B. Moser*[2,3], *F. Lorey*[4], *P. Rinaldo*[1], *D. Matern*[1];
[1]*Mayo Clinic, Rochester, MN, United States,* [2]*Kennedy Krieger Institute, Baltimore, MD, United States,* [3]*Johns Hopkins Universitty, Baltimore, MD, United States,* [4]*California Department of Public health, Richmond, CA, United States.*

Objective: X-ALD is the most common peroxisomal disorder (incidence 1:21,000 males). It is a progressive and fatal disorder that affects nervous system, adrenal cortex and testis. Adrenal insufficiency is totally prevented by presymptomatic therapy, while the cerebral phenotype, affecting 40% of all male patients, can be prevented by hematopoietic cell transplantation. However, this intervention has a narrow window of opportunity to be effective. Lysophosphatidylcholine species (lyso-PC) on blood spots have been shown to be abnormally elevated in newborns affected with X-ALD and peroxisomal biogenesis disorders (PBD), allowing identification of presymptomatic patients.
Methods and Results: Using a flow injection analysis MS/MS (FIA-MS/MS) method, we have measured lyso-PC species (C26:0 to C20:0) on dried blood spots from 16 male patients with X-ALD (12 adults and 4 newborns), 12 XALD adult heterozygotes, and 6 patients with PBD (4 adults and 2 newborns). Data were compared with 340 controls (NBS dried blood spots).
Results are shown in the table
Conclusions: The data of the present study strongly indicate that our method is analytically suitable as a screening tool for X-ALD. Patients affected with peroxisomal biogenesis disorders and 70 - 85 % of XALD female carriers will be detected by this assay. With support from NICHD and the NBSTRN, a pilot study on 100,000 leftover NBS sample is ongoing to test the clinical validity of this approach.

Concentration of C26 Lyso-PC species in peroxisomal cases and controls

	C26 (ug/ml) 1 percentile	C26 (ug/ml) 99 percentile
XALD (16)	0.28	0.75
XALD H (12)	0.15	0.51
PBD (6)	0.25	1.06
controls (340)	0.07	0.28

P11.001

Intellectual disability and cancer susceptibility in a family with inherited 14q32.13q32.2 deletion

A. Jacquinet, *J. H. Caberg, V. Bours, F. G. Debray;*
1. Department of Medical Genetics, CHU Sart-Tilman, Liège, Belgium.

Located in 14q32.13, *DICER1* codes for an RNase III endoribonuclease essential in the processing of microRNAs. These microRNAs are functional non-coding RNAs that regulate gene expression at a post-transcriptional level by interfering with translation and degradation of target messenger RNAs. Their deregulations have been implicated in several human diseases and cancers. Germline mutations in *DICER1* are associated with a low susceptibility risk to tumor development. Inactivating mutations have been identified in patients and families with various benign and malignant tumors, especially pleuropulmonary blastoma, cystic nephroma and ovarian Sertoli-Leydig tumors. Germline *DICER1* deletion has not been reported so far. We report a 7-year-old girl with an inherited *DICER1* deletion. She was referred for mild intellectual deficiency, a medical history of cystic nephroma and dysmorphic features. Her father, two paternal uncles and the paternal grandmother had mild to moderate intellectual disabilities. The deceased grandmother had presented uterin and ovarian tumors. Array-CGH analysis identified a 5041kb deletion in 14q32.13-q32.2 in the patient, the father, the two uncles and the paternal grandmother. The deletion contained 50 coding genes and led to *DICER 1* haploinsufficiency which was responsible for cancer susceptibility. Moreover, transmission of the deletion was related to intellectual disability in this family. The 14q32.13q32.2 locus has been previously associated with autosomal recessive mental retardation, suggesting the presence in the region of genes implicated in cerebral development and cognitive functions.

P11.002

MiRNA related polymorphisms as susceptibility markers of childhood Acute Lymphoblastic Leukemia

A. Gutierrez-Camino[1], *E. Lopez-Lopez*[1], *I. Martin-Guerrero*[1], *P. Garcia-Miguel*[2], *J. Sanchez-Toledo*[3], *A. Carbone*[4], *M. A. Piñan*[5], *J. Uriz*[6], *A. Navajas*[7], *A. Garcia-Orad*[1];
[1]*University of Basque Country, Bilbao, Spain,* [2]*University Hospital La Paz, Madrid, Spain,* [3]*Hospital Materno Infantil Vall d'Hebron, Barcelona, Spain,* [4]*Hospital Miguel Servet, Zaragoza, Spain,* [5]*University Hospital Cruces, Bilbao, Spain,* [6]*University Hospital Donostia, San Sebastian, Spain,* [7]*University Hospital Cruces, Bilbao, Spain.*

Acute Lymphoblastic Leukemia (ALL) is the most common malignancy in children. ALL is developed in early life, and consequently, a strong genetic influence could be expected. In fact, previous Genome-Wide Association Studies (GWAS) have provided evidence of this fact. Nevertheless, most of these studies are focused in coding regions.

MicroRNAs (miRNA) are non-coding RNAs that act as negative regulators of the expression of other genes. Up to 171 deregulated miRNAs have been reported in pediatric ALL, showing their importance in the disease.

Recent studies have shown that SNPs in miRNAs-related genes might be associated with risk of cancer. These polymorphisms could affect miRNA function. Nevertheless, there are no studies in ALL risk.

The aim of this study was to evaluate the role of SNPs in miRNAs-related genes in ALL susceptibility and to determine their functional implication.

We analyzed 213 childhood B-ALL patients in complete remission and 387 healthy controls. We studied 118 SNPs in pre-miRNAs and genes of miRNA biogenesis pathway. The implication of these SNPs in miRNA function was evaluated by qRT-PCR.

We found 11 polymorphisms significantly associated ($p<0.05$) with ALL risk. Of them, 8 SNPs were in processing machinery genes and 3 in pre-miRNA genes. The functional effect of each SNP was evaluated.

Our results suggest that SNPs in miRNAs and miRNA biogenesis pathway may affect childhood ALL susceptibility.

Cytogenetic abnormalities and monosomal karyotypes in a large series of adult Greek patients with acute myeloid leukemia

A. Daraki[1,2], *P. Diamantopoulou*[1], *M. Kalomiraki*[1], *V. Patriarcheas*[1], *M. Margariti*[1], *D. Pantelia*[1], *D. Koumbi*[1], *G. Pantelias*[1], *C. Sambani*[1], ***K. N. Manola***[1];
[1]*Laboratory of Cytogenetics, NCSR Demokritos, Athens, Greece,* [2]*Department of Genetics & Biotechnology, Faculty of Biology, National and Kapodistrian University of Athens, Athens, Greece.*

Cytogenetic abnormalities constitute one of the most important prognostic factors in Acute Myeloid Leukaemia (AML). We performed a conventional cytogenetic study in AML patients in order to define the chromosomal abnormalities and their frequencies in *de novo* and secondary AML (*s*-AML). Our study includes 619 patients of whom 503 had *de novo* AML and 116 *s*-AML. Chromosome studies were performed on unstimulated bone marrow cells. The sex ratio (males/females) was 1.2/1. The median age of *de novo* AML and *s*-AML was 59.46 and 68.9 years respectively. The most common FAB subtype was M4 in 23.5% of patients followed by M2 in 22.6%, M3 in 19.7% and M5 in 15.3%. A successful karyotypic result was achieved in 98.2% of patients. Among them, normal karyotypes were found in 183 (30.1%) patients; 165 with *de novo* AML (33.5%) and 18 with *s*-AML (15.6%). Complex karyotypes had 32.6% of *de novo* and 34.5% of *s*-AML patients, while monosomal karyotypes were observed in 19.9% and 27.8% respectively. The most common chromosome aberrations in *de novo* AML patients were +8 (25.5%), -7/del(7q) (15.7%), -5/del(5q) (11.2%), abnormalities of 11q23 (6.5%), inv(16) (5.9%), t(15;17) (5.9%), t(8;21) (5.7%) and +21 (3.3%). In *s*-AML the most common abnormalities were +8 (27.4%), -7/del(7q) (28.7%), -5/del(5q) (28.7%), t(9;22) (6.1%), +21 (6.1%), -Y (4.3%) and abnormalities of 11q23 (3.5%). In conclusion the most common abnormality in AML was +8 followed by -7/del(7q). Secondary AML occurred in older adults and showed a higher frequency of abnormal karyotypes and monosomal karyotypes than *de novo* AML.

P11.004

Association of $A^{313}G$ glutathione S-transferase P1 germline polymorphism with the susceptibility of *de novo* acute myeloid leukemia

A. Daraki[1,2], *F. Rosmaraki*[1,2], *S. Zachaki*[1], *K. Kakosaiou*[1,2], *K. Stavropoulou*[1], *C. Sambani*[1], *G. Pantelias*[1], *P. Kollia*[2], *V. Aleporou*[2], *K. Manola*[1];
[1]*Laboratory of Cytogenetics, NCSR Demokritos, Athens, Greece,* [2]*Department of Genetics & Biotechnology, Faculty of Biology, National and Kapodistrian University of Athens, Athens, Greece.*

Genetic approaches for understanding the etiology of Acute Myeloid Leukemia (AML) comprise polymorphic variants in xenobiotic metabolizer loci. Glutathione S-transferases (GSTs) are phase II detoxification enzymes, involved in the metabolism of carcinogens and anticancer drugs. *GSTP1* gene is subjected to a single nucleotide polymorphism ($A^{313}G$) that decreases the catalytic activity, and consequently, the detoxification capacity. Individuals homozygous for the mutant allele (G/G) have a lower conjugating activity than individuals homozygous for the wild type allele (A/A), while heterozygotes (A/G) display intermediate activity. This study investigates the possible implication of *GSTP1* polymorphism in AML susceptibility and AML-specific chromosomal abnormalities. PCR-RFLP assay was applied to detect the *GSTP1* polymorphism in 184 primary AML patients and 370 unrelated healthy donors. Abnormal karyotypes were found in 62.6% of patients and among them, 32.1% and 20.5% had complex and monosomal karyotypes, respectively. A significantly higher incidence of the mutant *GSTP1* genotypes (A/G and G/G) was observed in AML patients as compared to the controls ($p<0.0001$). No association was found between the *GSTP1* polymorphism and gender or age. Stratification of patients according to karyotype revealed an increased frequency of G/G homozygotes with normal karyotypes as compared to the abnormal karyotypes (19.5% vs 8.9% respectively, $p=0.056$). Furthermore, a higher frequency of heterozygotes A/G was observed in patients with -Y, -7/del(7q) and +22. Our results suggest that the *GSTP1* $A^{313}G$ polymorphism may be a predisposing factor for the development of AML. Moreover, homozygosity of the *GSTP1* polymorphism seems to be associated with development of AML with normal karyotype.

P11.005

Immunophenotypic and clinical features of acute myeloid leukemia patients with normal cytogenetics and mutation of FLT3 gene

E. Petrova, *I. Martynkevich, M. Kozlovskaya, L. Martynenko, M. Ivanova, N. Cybakova, S. Gritsaev, K. Abdulkadyrov;*
Russian Research Institute of Hematology and Transfusion, St.-Petersburg, Russian Federation.

The goal of the research was to determine distinctive features of de novo acute myeloid leukemia (AML) with FLT3-ITD mutation. Objects: to review the variability of morphological and cytogenetic characteristics of AML patients with FLT3-ITD; to identify homogeneity of the group of AML patients with normal karyotype (NK) with FLT3-ITD based on haematological data and immunophenotype of blast cells. The investigation group included 101 AML patients. FLT3-ITD mutation were detected by PCR method in 21 cases (20,8%). Meanwhile 13 patients (61.9%) from this group had NK. The group of patients with expression of several antigens more than 20% (diagnostically significant number) were analyzed. There were no significant difference in number of patients with high expression of CD34 in control group and group with FLT3-ITD: 83,3% against 90,0%; *p=0,635.* At once, the number of patients with high expression of HLA-DR and CD7 were significantly higher in group with NK and FLT3-ITD: 6,2% against 50,0%; *p=0,007* and 55,6% against 100,0%; *p=0,014*, respectively. Correlation analysis showed FLT3-ITD to be determined significantly often in patients older 51 years in comparison with young*; r=0,400; p=0,034.* Received data allowed to make a conclusion that AML with NK and FLT3-ITD represent the group, homogeneous on a number of haematological data and biological characteristics of leukemic cells. Thereby such markers as leukocytosis in combination with aberrant expression of HLA-DR and CD7 on blast cells allowed to prognosticate the probability of detection FLT3-ITD mutation in AML patients with NK.

P11.006

Detection by array-based comparative genomic hybridization in a case of adenoid cystic carcinoma of an unbalanced translocation t(6;9)(q23;p22.3~23) which generates a MYB-NFIB fusion oncogene.

S. TOUJANI[1,2], *E. MONTEIRO*[3], *P. FOURET*[4,5], *A. BERNHEIM*[6,5];

Background: adenoid cystic carcinoma (ACC) has been shown as a histologically distinctive neoplasm for nearly 150 years. It is among the most common carcinomas of the salivary glands. A recurrent t(6;9)(q23; p22.3~23) translocation was reported in ACC. Recently, it has been shown that the ACC-specific t(6;9)(q23;p22.3~23) translocation results in a MYB-NFIB fusion oncogene which is the hallmark of ACC. Array comparative genomic hybridization (aCGH) is a suitable method for studying oncogenomic imbalances.
Results: a 44k aCGH analysis was performed on 17 frozen ACC. In one tumor, genomic imbalances involved only 6q and 9p. A 35.24 Mb deleted region was detected on 6(q23q27) and a gain segment of 13.87 Mb was observed on (9)(pterp23) <0.20-14.08 Mb>. Genomic mapping indicated that breakpoints lied within MYB/6q22.3~23 sequence and NFIB/9p23 gene. The unbalanced form of t(6;9)(q23;22.3~23) translocation: der(6)t(6;9) was hence suspected. The MYB-NFIB chimeric transcript was detected by RT-PCR. The latter fusion gene link MYB exon 9b to NFIB exon 11.
Discussion and conclusion: Analysis of 17 frozen ACC by aCGH has allowed the suspicion -of an unbalanced t(6;9)(q23;p23p24) translocation in one case. This tumor displays the der(6)t(6;9) as the sole cytogenomic imbalances, indicating that it is a primary rearrangement in this carcinoma. The der(6) is the critical derivative chromosomal of the t(6;9) translocation because the MYB-NFIB transcript was detected by RT-PCR. In cancer, the aCGH data should be analysed carefully and the chimeric fusion gene should be looked for because this type of abnormality may change the prognosis and the treatment.

Background: In up to 50% of families with colorectal adenomatous polyposis no germline mutation in the currently known genes APC causing familial adenomatous polyposis (FAP) or MUTYH causing MUTYH-associated polyposis (MAP) can be identified. Missense mutations in polymerase genes have recently been found as rare cause of multiple colorectal adenomas/carcinomas. Methods: To uncover new causative genes, the exomes of ten unrelated APC and MUTYH mutation negative polyposis patients were sequenced (Illumina HiSeq platform). For data analysis and variant filtering the GATK software and in-house tools were applied. Results: Altogether, 66 genes affected by biallelic truncating variants (recessive model) in at least one patient and 63 genes affected by truncating heterozygous variants (dominant model) in at least two patients were found. After detailed manual investigations of the variants and data mining according to functions and pathways seven genes of high interest remained (three for the recessive, four for the dominant approach), some of which are involved in cell adhesion, proliferation, or recombination repair. Moreover, we found a missense variant in the polymerase gene POLD2 in one patient, which is predicted to be damaging by in-silico analysis. In another patient, an APC nonsense mutation in mosaic state below the detection threshold of Sanger sequencing (10% of reads) was recognised. Conclusions: Using exome sequencing we identified new potentially causative genes for adenomatous polyposis. The clinical relevance of the genes is presently clarified in a validation sample of 200 polyposis patients. (Supported by German Cancer Aid and BONFOR programme of the University of Bonn)

We report a familial BWS presented with a benign hypersecretant adrenocortical tumor (ACT) which proved to be isolated in a 2 months old baby girl. Family history revealed a paternal aunt who developed at 60 years a benign ACT. Our patient was managed surgically and tumoral tissue so as blood sample and skin tissue underwent molecular analysis using MS-MLPA (Methylation-sensitive multiplex ligation probe analysis) in order to detect epigenetic alterations associated with BWS.
Genetic investigations noticed in blood sample a methylation mosaic pattern at imprinted domain 2 (IC2) encompassing KCNQ1, KCNQ1OT1, and CDKN1C genes. This mosaicism was associated in tumoral tissue to a complete loss of methylation at IC2, however skin tissue analysis showed a normal methylation profile.
This rare epigenetic constellation may explain the mild phenotype observed in both patient and her aunt. However appropriate genetic counseling to the affected patient and her family members should be provided and clinicians should be aware that patients may develop isolated benign ACT in the context of hereditary syndromes.

Megakaryoblastic leukemia in children is almost exclusively associated with Down Syndrome (DS) - trisomy 21 and acquired mutations in GATA1. Up to 10% of DS neonates develop Transient Myeloproliferative Disorder (TMD), which is self-regressing in the majority of cases, but in 20-30% it progresses to malignant acute megakaryoblastic leukemia (AMKL). Currently there is no evidence of a genetic component underlying the progression of the disease. In this study we have performed exome-sequencing of 7 megakaryoblastic leukemias in DS-children to test the hypothesis that somatic genetic variants contribute to the progression of TMD to AMKL.
In four out of seven studied AMKL/TMD cases we have observed somatic mutations, additional to GATA1, occurring in genes with established function in different types of leukemia (EZH2, APC, FLT3 and JAK1). In addition, the AMKL genomes were characterized by genomic instability which was not observed in the TMDs. In one patient we have detected two putative driver mutations, a frameshift indel in EZH2, and a hemizygous loss of APC in AMKL which were absent at the TMD stage of disease in this patient. Our findings favor a three-hit hypothesis, where transition of TMD to AMKL requires a 3rd genetic event additional to T21 and GATA1 mutation. These additional driver mutations were observed in genes of WNT, JAK-STAT and MAPK/PI3K pathways, aberrant activation of which may enhance the effect of GATA1 mutation resulting in overexpression of MYC therefore facilitating transition towards malignancy.

Array CGH analysis of acute myeloid leukemia patients with normal and complex aberrant karyotype.

D. Koczkodaj[1], *S. Zmorzynski*[1], *M. Michalak*[1], *E. Wasik-Szczepanek*[2], *A. A. Filip*[1];
[1]*Department of Cancer Genetics, Medical University of Lublin, Poland, Lublin, Poland,* [2]*Department of Hematooncology and Bone Marrow Transplantation, Medical University of Lublin, Poland, Lublin, Poland.*

Acute myelogenous leukemia (AML) is the most common type of leukemia affecting adults, and is responsible for a large number of cancer-related deaths. Lymphocytes of approximately 55% of AML patients show various chromosomal aberrations, including structural and numerical alterations. Such changes may not only correlate with morphological and clinical data, but also serve as prognostic factors.
In our study we analyzed bone marrow samples of 60 AML patients with normal (18 patients) or complex (42 patients) karyotype by conventional cytogenetics. We then assessed the genomic changes by the array CGH (aCGH) method. Genomic losses were found more frequently than gains. The most frequent losses affected 5q (25%), 7q (20%) and 3p (18%), and the most frequent genomic gains included 11q (20%) and 21q (17%).
In patients with initially normal karyotypes it was possible to determine single or multiple aberrations by means of aCGH. In this group losses were also more frequent than gains. Changes detected using aCGH were verified by FISH analysis in all cases.
In the second part of this study we analyzed the prognostic effects and interactions of the nucleophosmin (NPM1) gene mutation and fms-like tyrosine kinase-3 internal tandem duplication (FLT3-ITD) in patients with normal-karyotype (AML-NK).
Identification of all possible rearrangements is valuable for better understanding of the mechanisms of leukemogenesis, as well as for more precise stratification of patients into appropriate risk groups.

Hospital Clínico Universitario de Salamanca., Salamanca, Spain,* [5]*Servicio de Ginecología y Obstetricia. Hospital Clínico Universitario de Salamanca, Salamanca, Spain.*

Endometrial carcinoma (EC) is the most common gynaecological tumor in developed countries. There are several common mutated genes depending on the type. PTEN, PI3K, K-RAS and B-RAF genes are frequently altered in endometrioid carcinomas and P53, E-Cadherin, p16 and PPP2R1A genes in non endometrioid.
ARID1A is a recently identified tumor suppressor which participates in chromatin remodeling, specifically, in forming switch/sucrose non-fermentable chromatin remodeling complexes. It has been reported that ARID1A gene is mutated in ovarian clear cell, endometrioid carcinomas and in uterine endometrioid carcinomas. Most ARID1A mutations are nonsense, frameshift or in-frame, leading to loss of expression of the protein which encodes.
The aim of our study has been the analysis of the ARID1A gene in order to determine the incidence of mutations in the different types and grades of EC.
We extracted DNA from a set of 48 fresh tumor from patients diagnosed with EC (33 endometrioid carcinoma: 17 grade I, 13 grade II and 3 grade III; 15 non endometrioid: 7 mixed carcinoma; 6 serous carcinoma; 1 carcinosarcoma; 1 clear cell carcinoma. We studied the ARID1A gene by PCR, CSGE, cloning and automatic sequencing.
The results are showed in the annexed table. We found 21 ARID1A pathogenic mutations including some deletions, insertions and base substitutions.
Our results confirm that ARID1A gene mutations are a frequent event in EC.
Supported by FIS PI 10/000219

Tumor type	Patients mutated (%)
Endometrioid carcinoma	57.57
-I grade	27.27
-II grade	27.27
-III grade	3.03
Non endometrioid carcinoma	40

Molecular profile of low- and high-grade astrocytomas: a multivariate approach

I. Rodríguez-Hernández[1], *J. García*[2], *A. Santos-Briz*[3], *J. Gómez-Moreta*[4], *J. González-Valero*[2], *R. González-Sarmiento*[1];
[1]*Molecular Medicine Unit, Department of Medicine, University of Salamanca, Salamanca, Spain,* [2]*Institute for Health Science Studies of Castilla y León, Salamanca, Spain,* [3]*Department of Pathology, University Hospital of Salamanca, Salamanca, Spain,* [4]*Department of Neurosurgery, University Hospital of Salamanca, Salamanca, Spain.*

Malignant astrocytomas are the most common and aggressive primary brain tumors in adults with a dismal prognosis. In an attempt to better understand the biology of astrocytomas, we have performed a molecular analysis of TP53, IDH1, EGFR, PI3KCA, PTEN and BRAF genes in a set of 105 astrocytomas (24 low-grade astrocytomas and 71 high-grade astrocytomas).
Nineteen low-grade (79.2%) and 71 high-grade astrocytomas (87.7%) had at least one alteration in these genes, and more than 50% of cases showed two o more alterations. Mutations in TP53, IDH1 and BRAF genes were more frequent in low-grade astrocytomas while alterations in EGFR, PTEN and PI3KCA genes were more represented in high-grade astrocytomas (Table 1).

Table1. Alterations in low- and high-grade astrocytomas

	TP53 mutation	EGFR amplification	EGFRvIII expression	PI3KCA mutation	LOH 10q23	PTEN mutation	BRAF mutation	IDH1 mutation
Low-grade Astrocitomas	13(56.5%)	0(0.0%)	1(4.3 %)		4(33.3%)		2(8.7%)	15(65.2%)
High-grade Astrocytomas	17(22.7%)	26(35.1%)	23(33.3%)	5(6.7%)	49(75.4%)	19(25.3%)	1(1.3%)	3(4.0%)
Total	30(30.6%)	26(35.1%)	24(26.1%)	5(6.7%)	53(68.8%)	19(25.3%)	3(3.1%)	18(18.4%)

43.3% of tumors with TP53 mutation carried IDH1 mutation; 26.7% of cases showed both EGFR amplification and PTEN loss; 20.3% of tumors displayed PTEN deletion and mutation, and 14.3% of tumors carried TP53 mutation and PTEN mutation/deletion. However, mutations in PTEN and PI3KCA genes were mutually exclusive.

Multivariate analysis by logistic biplot and hierarchical clustering classified high-grade tumors in proneural subtype distinguished by TP53 and IDH1 mutations and EGFRvIII expression; classical subtype defined by EGFR amplification and PTEN deletion along with EGFRvIII expression and PTEN mutation; and mesenquimal subtype characterized by PTEN deletion with TP53 and PTEN mutations. Furthermore, proneural subtype patients demonstrated improved survival over the proliferative or mesenquimal groups.

P11.014

The malignant transformations in Ewing's sarcoma cells are correlated with beta arrestin1 level

D. Nedelcu[1], *N. Cucu*[2], *M. Puiu*[1];
[1]*University of Medicine &Pharmacy Victor Babes, Timisoara, Romania,* [2]*Bucharest University, Faculty of Biology, Bucuresti, Romania.*

Ewing's sarcoma is a malignant tumor which can have mesodermal and ectodermal origins. It appears most frequently in children and adolescents and in most of the cases is the result of a translocation between chromosomes 11 and 22 which affect Ewing's sarcoma and Friend leukemia integration 1 transcription factor genes. Beta arrestin1 and insulin-like growth factor receptor has an important role in the activation of a signaling cascade in MAPK pathway which is involved in the initiation and transformation of the malignant phenotype.
The aim of this study was to experience proper cell culture techniques in order to mimic pathological characteristics of Ewing sarcoma and provide adequate experimental model for drug screening. It is known the fact that cell culture lines represent an actual experimental study model of epigenetic and genetic mechanisms involved into the initiation of pathological processes. Many of these new research activities are based on genetic reprogramming of the patient derived cell lines. The experiment envisaged to evaluate the effect of beta-arrestin1 concentratons in two types of ES cell line, genetically modified by B-arr1 shRNA. Quantifying cell proliferation and estimation of cellular viability were used for the correlation between Beta arrestin level and its tumorigenicity. Results indicate that malignant transformations are connected with beta-arrestin1 level and the malignant phenotype is modified when the intracellular levels of beta-arrestin1 decrease. The protein beta-arrestin 1 play an important role in IGF1R signaling and also in the initialization process of tumorigenicity in ES cells.

Fanconi anemia (FA) is characterized by progressive bone marrow failure, congenital anomalies, and predisposition to malignancy. A small proportion of FA is due to biallelic FANCD1/BRCA2 mutations which is associated with earlier onset and increased incidence of leukemia and solid tumors. Here we describe the clinical and molecular features of a family in which the diagnosis of FA was unexpectedly made from a female proband with early onset breast cancer. Remarkably, she and her sister, also diagnosed with FA, had uneventful childhoods and no morphological anomalies. Both patients presented colorectal adenocarcinomas (microsatellite stable) with either gastric lymphoma or breast cancer around the age of 30. Another sibling died at the age of 5 of acute myeloid leukemia. Biallelic FANCD1/BRCA2 mutations were identified: one frameshift mutation (c.1845_1846delCT, p.Asn615LysfsX6) and one missense mutation (c.7802A>G, p.Tyr2601Cys) with a frame-shifting splicing anomaly leading to both a truncated protein and a residual point-mutant protein. This protein, predicted to be deleterious, is presumably partially active and might explain the clinical spectrum with delayed FA diagnosis. Spontaneous and mitomycin-induced chromosomal instability was pathognomonic of FA and only the molecular investigations permitted the diagnosis. The lack of other symptoms in the two older siblings and the occurrence of colon cancers raise the hypothesis that variations in spliceosomal proteins might participate in subtle defects in the splicing machinery and thus lead to constitutional and tissue-specific variability of the phenotype. An interaction between BRCA2 and the MMR pathway could also be questioned in presence of early colorectal adenocarcinomas.

P11.016

Genetic variants involved in specialized DNA replication and their relation with bilateral breast cancer

A. C. Brandalize[1,2,3], *L. Schuller-Faccini*[1,2,3], *P. Ashton-Prolla*[1,2,3];
[1]*Hospital de Clinicas de Porto Alegre, Centro de Pesquisa Experimental, Porto Alegre, Brazil,* [2]*Universidade Federal do Rio Grande do Sul, Programa de Pós -Graduaçao em Genética e Biologia Molecular, Porto Alegre, Brazil,* [3]*Instituto de Genética Médica Populacional - INAGEMP, Porto Alegre, Brazil.*

One of the hallmarks of cancer is the occurrence of high levels of chromosomal rearrangements as a result of inaccurate repair of double-strand breaks (DSB). Germline mutations in *BRCA* and *RAD51* genes, involved in DSB repair, are strongly associated with bilateral breast cancer. Pol θ, a "DNA repair" polymerase specialized in the replication of damaged DNA may also be involved in DSB repair and could act in this pathway with *BRCA* and *RAD51.* It is noteworthy that *POLQ* is highly expressed in breast tumors and this expression is able to predict patient outcome. Here we analyzed *POLQ* variants in hereditary (HBC) and sporadic (SBC) breast cancer. We recruited 229 breast cancer patients (94 SBC and 135 HBC) and 206 controls. In this case-control study seven SNPs (rs61757736, rs55748151, rs41545723, rs1381057, rs587553, rs13065220, rs3806614) were analysed using Taqman Real Time PCR. The rs581553 SNP located in a promoter region of POLQ was strongly associated with HBC (g.121265913C>T; HBC TT=18, Control TT=8; OR=2.30, CI95%= 1.47-3.55; p<0.0001). Interestingly, all of the homozygous for this polymorphism fulfilled criterions for HBOC (Hereditary Breast and Ovarian Cancer) syndrome, where 16 of them developed bilateral breast cancer and one had familial history of bilateral breast cancer. The age at diagnosis (> or < 50 years) did not show statistic differences when compared patients with or without this polymorphism. Considering the evidences that *POLQ* may be involved in DBS repair our study suggest that this polymorphism may contribute to the etiology of bilateral breast cancer in our population.

DNA repair gene polymorphisms involved in bladder cancer development

L. Akhmadishina[1], *G. Korytina*[1], *O. Kochetova*[1], *M. Urmantsev*[2], *A. Izmailov*[2], *S. Izmailova*[2], *G. Kunsbaeva*[3], *V. Pavlov*[2], *T. Viktorova*[1,2];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation,* [3]*Bashkir State University, Ufa, Russian Federation.*

To assess c.839G>A and c.1196A>G XRCC1, g.45854919T>G XPD, c.-4A>G XPA gene polymorphisms contribution in the development and severity of bladder cancer we carried out a study 306 DNA bladder cancer patients samples and 271 healthy individuals DNA samples. It was shown c.839 G>A XRCC1 associated with bladder cancer development in several models, but significantly in log-additive (p<0.0001, OR=2.40, AIC=765.9). Second polymorphism c.1196G>A XRCC1 associated with disease in recessive (p=0.03, OR=1.61, AIC=784) and overdominant (p=0.02, OR=0.66, AIC=782.7) models. No association with bladder cancer was observed for c.-4A>G XPA and

g.45854919T>G XPD. In order to estimate the contribution of studied polymorphisms in the development of invasive and non-invasive bladder cancer sample of patients with these forms were compared separately with control cohort. Interestingly, c.839 G>A XRCC1 contributes to the development of both non-invasive and invasive bladder cancer (p = 0.0017, OR= 2.06, CI (1.31-3.26) and p<0.0001, OR= 2.70, CI (1.78-4.10), respectively). Thus we can assume XRCC1 polymorphisms make a definite contribution to the development and severity of bladder cancer. However, the results should be confirmed in independent studies.

Expression of B7-H4 gene polimorphisms in transitional cell carcinoma of the bladder

H. Samli[1], *M. Samli*[2], *A. Sahin*[2], *U. Ince*[2], *F. Balci*[1], *Y. Saglican*[2];
[1]*Uludag University, School of Veterinary Medicine, Bursa, Turkey,* [2]*Acibadem University, School of Medicine, Istanbul, Turkey.*

B7-H4 is one of the most recently identified members of B7 superfamily of costimulatory molecules serving as an inhibitory modulator of T-cell response. The expression of B7-H4 has been observed in various types of human cancer tissues and its soluble form has been detected in blood samples.

In this study B7-H4 gene rs10754339, rs10801935 ve rs3738414 SNPs were studied by PCR-RFLP method in paraffin embedded tumor specimens from 62 transitional cell bladder cancer (TCC) patients and in the control group including 30 patients without bladder cancer. Both groups were in the similar age interval (patient group 63.34+12.5 vs control group 60.8+11.1; p>0.05). Male gender was more frequent among cancer patients (55 male vs 7 female) and the same gender distribution was detected in non-bladder cancer patients (28 male vs 2 female) (p>0.05).

According to WHO 2004 bladder cancer classification system 19 non-muscle invasive low-grade carcinomas, 20 non-muscle invasive high-grade carcinomas and 23 high-grade invasive carcinomas were included. We detected rs3738414 and rs10754339 polimorphisms were more frequent in cancer patients when compared with control group (p<0.05). Only rs3738414 polimorphism showed statistically significant difference in frequency between pathologic diagnostic groups (p<0.04).

In both rs10754339 and rs3738414 polymorphisms, AA and GG genotype distributions were found to have higher frequencies in the cancer group when compared with control group (p<0.05). None of the genotype distributions showed statistically significant difference from the control group in rs10801935 polimorphism.

We conclude that B7-H4 has the potential to be a useful prognostic marker for patients with TCC.

Background: Cancer of the bladder is a disabling disease with multifocality, frequent recurrence and growing incidence in the economically developed countries. The majority of tumors at presentation are low grade, non muscle-invasive, papillary tumors. The aim of our study is investigation the expression levels of the genes responsible for sensitivity and resistance to known chemotherapeutic agents.

Materials & Methods: Tumor sample of 40 patients with bladder neoplasia in different stages: precancerous, pTa, pT1 and pT2 were analyzed. 168 genes from two panels for Cancer drug resistance and metabolism (84 genes) and Cancer drug targets (84 genes) were investigated.

Reaults: Our results reveal a 3-5 times up-regulation of five genes for drug response related to xenobiotic metabolization, degradation of aromatic compounds, polycyclic aromatic hydrocarbons and the anti-cancer drug taxol. A more than 10 fold up-regulation of PPARG, CYP3A5 and ABCC3 genes related to metabolism of cyclosporine and steroid hormones was observed in a tumor stage dependent manner (pTa, pT1 and pT2).

The results from Cancer drug targets panel show up-regulation of TOP2A and genes from MRP subfamily (ABCC1 and ABCC5), involved in resistance to thiopurine anticancer drugs in the muscle invasive versus non-invasive bladder tumors.

Acknowledgements: This study was supported by contract № ДМУ 03/48 of the Ministry of Education and Science, Bulgaria and by contract № 13-Д/2012 of the Medical University of Sofia, Bulgaria.

Prediction of recurrence in bladder cancer by real-time quantitative PCR analysis: cDNA microarray results

J. Mares[1], *V. Soukup*[2], *J. Duskova*[2], *A. Horinek*[2], *M. Klabanova*[3], *M. Babjuk*[1];
[1]*2nd Faculty of Medicine, Prague 5, Czech Republic,* [2]*1st Faculty of Medicine, Prague 2, Czech Republic,* [3]*Diana Lucina, Prague 4, Czech Republic.*

The aim of the study was to define specific genetic profile in Ta and T1 urinary bladder carcinoma patients with and without recurrence by gene expression microarrays. Eleven patients with the time to recurrence shorter than one year (patients with recurrence) and 11 patients with time to recurrence longer than 4 years (patients without recurrence) were enrolled.

Data from microarrays were subjected to a panel of statistical analyses to identify bladder cancer recurrence-associated gene signatures. Initial screening revealed a putative set 47 genes differing in gene expression in both groups. After the validation, 33 genes manifested significant differences between both groups. The significant expression was observed in the group of patients without recurrence by 30 genes of which the highest differences were detected by ***ANXA1***, ***ARHGEF4, FLJ32252, GNE, NINJ1, PRICKLE1, PSAT1, RNASE1, SPTAN1, SYNGR1, TNFSF15, TSPAN1,*** and ***WDR34***. These genes code for signal transduction, vascular remodeling and vascular endothelial growth inhibition mainly. In the group with recurrence, 3 genes had significant differences, the highest differences were identified by two genes ***(PLOD2*** and ***WDR72)***. We have selected and validated 15 genes that are differentially expressed in superficial bladder cancer. We hope that this cohort of genes will serve as a promising pool of candidate biomarkers for early stage bladder cancer. Our results indicate that it may be possible to identify patients with a low and high risk of disease recurrence at an early stage using a molecular profile. . Introduction: Bladder carcinoma is the most common malignancy of the urinary tract. Analysis of p53 gene and mtDNA mutations might be useful to monitor the prognosis of bladder carcinoma. Therefore the aim of this study is to investigate the relation between mtDNA and p53 gene mutations in bladder carcinomas.

Methods: 30 patients and 27 controls were recruited to the study. Bladder cancer tissues were obtained by radical cystectomy or transurethral resection. Genomic DNA was extracted from peripheral blood. ATPase6, Cytb, ND1, and D310 regions of mtDNA as well as the exon 5,6,7 and 8 regions of p53 gene were amplified by PCR and sequenced directly. Results were evaluated statistically.

Results: In patient group, 33 mtDNA mutations and 3 p53 gene mutations were found in which 3 of them are novel and 15 of them cause amino acid substitutions. A15607G mutations in Cytb gene and 12570 A-insertion in p53 gene were found statistically significant in patient group whereas C12570A was found statistically significant in control group. Additionally, 8 different 100% correlations between mtDNA mutations and 3 different positive correlations between p53 gene and mtDNA mutations were detected.

Conclusion: High incidences of A15607G mutation and 12570 A-insertion may be important markers for the detection of bladder tumors. Despite that,

C12570A mutations may have a protective effect against the disease. Additionally, based on correlation values, it has been suggested that there is a relation between p53 gene and mtDNA gene mutations and this relationship could play an important role in bladder carcinogenesis.

Bortezomib Induces Apoptosis by Interacting with JAK/STAT Pathway in K-562 Leukemic Cells

N. Selvi[1], *B. Kaymaz*[1], *Ç. AKTAN*[1], *C. GÜNDÜZ*[1], *H. D. KİPER*[2], *F. ŞAHİN*[2], *B. KOSOVA*[1], *G. Saydam*[3];
[1]*Ege University Medical Faculty Dept. of Medical Biology, Izmir, Turkey,* [2]*Ege University Medical Faculty Dept. of Hematology, Izmir, Turkey,* [3]*Ege University Medical Faculty Dept. of Haemotology, Izmir, Turkey.*

In the current study, we aimed to identify the cytotoxic and apoptotic effects of Bortezomib (BOR) on human K-562 chronic myelogenous leukemia cells and to evaluate the potential roles of JAK/STAT pathway members STAT3, STAT5, JAK2 and IL-6 on BOR induced cell death of leukemic cells.
Cell viability was assessed via Trypan blue dye exclusion test and cytotoxicity of the BOR treated cells was conducted by XTT [2,3-Bis (2-methoxy-4-nitro-5-sulphophenyl)-2H-tetrazolium-5-carboxanilide inner salt] assay. The relative mRNA expression levels of STAT3, -5A -5B, JAK2 and interleukin- 6 were analyzed by quantitative reverse transcriptase-polymerase chain reaction (qRT-PCR). On the other hand, their protein expression levels were detected by western-blot method.
The obtained results indicated that, BOR treatment reduced cell viability and induced leukemic cell apoptosis in a dose and time-dependent manner as compared to untreated control cells. While mRNA expression levels of STAT5A, STAT5B and STAT3 were significantly
reduced following BOR treatment when compared to untreated controls; it had no effect upon JAK2 and IL-6 mRNA expressions. As for protein levels, STAT expressions were downregulated after BOR treatment especially at 72th and 96th hours.
Our results pointed out that, BOR treatment had a significant potential of being an anticancer agent for chronic myelogenous leukemia therapy; and this effect could be due to the expressional downregulations of JAK/STAT pathway members.

Splicing functional assays of a RCA1 minigene with exons 15-19

H. H. M. Cristina, *C. Álvaro;*
IBGM-Valladolid, Valladolid, Spain.

Deleterious mutations in BRCA1 and BRCA2 increased up to 20-fold the risk of developing breast cancer. Previously published data of our group showed that a third part of pathogenic mutations affected pre-mRNA processing so that splicing could be one of the most relevant etiopathogenic mechanism in hereditary breast/ovarian cancer. We constructed a hybrid minigene with BRCA1 exons 15 to 19 in the new splicing vector pSAD (Spanish patent: P201231427). Bioinformatics studies of DNA variants in exons 16 and 17 of BRCA1 were performed with NNSplice and Human Splicing Finder, to select them according to the following criteria: disruption of canonical splice sites, broken branch points or creation of de novo silencers. Functional assays performed either in lymphocyte RNA from patients or in hybrid minigenes in MCF7/HeLa cells. We investigated the impact on splicing of pre-selected variants listed in the international databases and to correlate these results with those obtained in lymphocyte RNA of patients from Castilla y Leon (Spain).
All the RT-PCR products were sequenced to characterize all the splicing outcomes. Splicing functional assays allow a better molecular characterization of DNA variants of unknown clinical significance. The ultimate goal of this research is to improve the quality of life of patients and their families that will benefit from new preventive measures, surveillance and prophylaxis.

Intronic sequence variants in BRCA genes among breast and ovarian Romanian patients

L. Negura[1], *D. Azoicai*[1], *Y. Bignon*[2], *N. Uhrhammer*[2], *A. Negura*[3];
[1]*Gr. T. Popa Medicine and Pharmacy University, Iasi, Romania,* [2]*Centre Jean Perrin, Clermont-Ferrand, France,* [3]*Alexandru Ioan Cuza University, Iasi, Romania.*

Molecular diagnosis in cancer predisposition is mainly targeting *BRCA1* and *BRCA2* genes, involved in hereditary breast and ovarian cancer syndrome (HBOC). Carriers of deleterious mutations are at significantly higher risk of developing cancer than general population. Screening for BRCA mutations is now standard practice in Europe, and permits medical follow-up and adapted genetic counselling.
Currently, most laboratories performing diagnostic analysis of the *BRCA* genes use direct Sanger sequencing of exons and intron-exon boundaries. Thousands of BRCA sequence variations have already been reported, but not all variants can be considered pathological. Deleterious mutations and common non-pathogenic SNPs are usually detected, but almost a half of the observed variations are of uncertain clinical significance. *In-silico* analysis is therefore essential for understanding possible effects on protein function and pathogenicity.
While completely sequencing *BRCA1* and *BRCA2* genes in routine molecular diagnosis, we found a total of 14 intronic variants, equally distributed to *BRCA1* (7 variants) and *BRCA2* (7 variants). Half of these variants were novel, not known in BIC, UMD or NCBI databases. By *in-silico* analysis, one variant showed to be pathogenic, by completely destroying a splicing site, while two other variants have an unclassified status (type 3 in the UMD 5-levels pathogenicity classification). Eight variants proved to be benign SNPs, and were used to define novel BRCA1 haplotypes.
This proves that a better investigation of intronic regions can bring useful information, either from pathogenic variants responsible for the predisposition to the disease, or form rare benign SNPs defining haplotypes important for population studies.

Breast cancer in men is extremely rare, less than 1% of all breast cancers. The presence of germline mutations in the *BRCA2* gene increases the risk of developing breast cancer and prostate cancer during man's lifetime.
Objectives: To describe breast and other cancers in men with deleterious mutation of the *BRCA1/BRCA2* genes and to investigate correlations between type of mutation, age and cancer phenotypes.
Materials and Methods: The study population included males participants in the French National cohort study GENEPSO of *BRCA1/2* carriers recruited at 33 cancer genetic clinics. This cohort study was initiated in 2000 to estimate breast and other cancer risk and to assess risk-modifying factors in *BRCA1/BRCA2* mutation carriers.
Results: To date, the GENEPSO cohort study has included 376 men, 60% of them carrying a *BRCA1* mutation. 24 breast cancers were observed. Mean age at breast cancer diagnosis was 62.4 years (range: 45-77). All the 3 *BRCA1* mutation positive male breast cancer (MBC) were invasive ductal carcinoma, RE+, RP+ and grade 3 for 2 men. 52% of *BRCA2*-related MBCs (n=21) were grade 2 or 3, 71% were RE+, 66% RP+ and 3 of them (14%) presented an invasive lobular carcinoma. Prostate cancers ranked second in this cohort: 5 *BRCA1* and 10 *BRCA2* mutation carriers. Median age at prostate cancer diagnosis was 64 years (range: 53-77).
Conclusion: In men, breast and prostate cancers are mainly associated with *BRCA2* mutation and breast cancer phenotypes seem to be different according to sex and type of gene.

Next-generation sequencing and analysis of the BRCA1 and BRCA2 genes in 95 Bulgarian women

S. Ivanov[1], *L. T. Balabanski*[1], *M. Nacheva*[2], *I. Gavrilov*[3], *D. Nesheva*[4], *B. Rukova*[4], *S. Hadjidekova*[4], *I. Dimova*[4], *M. Malinov*[1], *D. Toncheva*[4,1];
[1]*Malinov Clinic, Sofia, Bulgaria,* [2]*National Oncology Centre, Sofia, Bulgaria,* [3]*Oncology Hospital, Sofia, Bulgaria,* [4]*Medical University, Sofia, Bulgaria.*

Background: Breast cancer is the most common type of cancer in women. Most of its hereditary forms are caused by mutations in the *BRCA1* and *BRCA2* genes, the main function of which is DNA repair of double-stranded breaks. Genetic testing in women with familial history is recommended to determine whether they have a hereditary predisposition to this type of cancer.
Methods: After giving their informed consent, blood samples from 25 women diagnosed with cancer and 70 controls were collected, from which genomic DNA was isolated. Sequence-targeted *BRCA1/2* libraries were then prepared using the TruSeq Custom Amplicon technique, which were then sequenced on an Illumina MiSeq system.
Results: A wide range of mutations were found, of which 55 were in *BRCA1* and 69 in *BRCA2.* In total, 5 (4%) were categorised as deleterious, including a donor splice-site mutation in intron 2 of *BRCA2,* 11 (9%) supposed deleterious, e.g. an in-frame trinucleotide deletion in exon 17 of *BRCA1* within the BRCT functional domain and non-synonymous mutations within other functional domains of *BRCA1* and *BRCA2,* 28 (23%) variants with unknown significance, 21 (17%) favoured polymorphisms and 59 (48%) benign polymorphisms.
Conclusion: This is the first genetic study, in which the *BRCA1* and *BRCA2* genes of women from the Bulgarian population were sequenced paving the way for finding local founder mutations as well as polymorphisms typical for this region.

S. Ivanov: None. **L.T. Balabanski:** None. **M. Nacheva:** None. **I. Gavrilov:** None. **D. Nesheva:** None. **B. Rukova:** None. **S. Hadjidekova:** None. **I. Dimova:** None. **M. Malinov:** None. **D. Toncheva:** None.

P11.027

Women with sporadic breast cancer between age 36 and 41 should be offered BRCA1/BRCA2 testing

C. Tlemsani*, P. Benusiglio, M. Guillaud-Bataille, V. Byrde, M. Di Maria, O. Cabaret, D. Wehrer, B. Bressac-De Paillerets, S. Delaloge, O. Caron;*
Institut Gustave Roussy, Villejuif, France.

BACKGROUND: *BRCA1* and *BRCA2* are the two best-known breast cancer predisposition genes. Gene analysis is warranted in women with both a personal and family history of the disease, or with sporadic breast cancer at a very young age (≤35). There is however no consensus regarding testing in women with sporadic breast cancer between ages 36 and 41, as the probability of finding a mutation might be too low to justify a long and expensive procedure.
METHODS: We offered *BRCA* testing to all women with sporadic breast cancer ages 36-41, without other personal or familial history, and treated between 2006 and 2012 in our hospital. We searched for point mutations (Sanger sequencing) and large rearrangements (MLPA).
RESULTS: Out of 99 tested women, 11 (11%) carried a mutation, 7 in *BRCA1* and 4 in *BRCA2*. Four and four carriers had triple-negative (*BRCA1* only) and bilateral disease, respectively.
DISCUSSION: There is a consensus within the Cancer Genetics community that genetic testing should be performed when the probability of finding a mutation exceeds 10%. According to this large single-center study, women with sporadic breast cancer between ages 36-41 fit in this category, and should therefore be offered *BRCA1* and *BRCA2* analysis, especially if their tumour is triple-negative or bilateral. The identification of a mutation in a substantial proportion of these women would lead to a personal management, resulting in decreased morbidity and mortality.

P11.028

Haplotype analysis and ancient origin of the BRCA1 c.4035delA Baltic founder mutation

R. Janavicius[1], *V. Rudaitis*[2], *L. Tihomirova*[3], *D. Goldgar*[4], *L. Griskevicius*[1];
[1]*Vilnius University Hospital Santariskiu Clinics, Hematology, oncology and transfusion medicine center, Vilnius, Lithuania,* [2]*Vilnius University Hospital Santariskiu Clinics, Dept. of Oncogynecology, Vilnius, Lithuania,* [3]*Latvian Biomedical Research & Study Center, Riga, Latvia,* [4]*Department of Dermatology, University of Utah School of Medicine, Salt Lake City, UT, United States.*

Uncertainty exists about the origin of BRCA1 c.4035delA mutation which is prevalent in Baltic countries, with the highest frequency being in Lithuania (53% of all BRCA1 mutations), although formal founder mutation analysis by haplotype has not yet been undertaken. In this study we genotyped 78 unrelated BRCA1 c.4035delA mutation carriers families from Lithuania, Latvia, Poland and Russia. The results from the haplotype analyses were used to estimate the age of the mutation. Using maximum likelihood methods we estimated that the mutation arose approximately 1550 years (62 generations of 25 years) ago (ca. 5th century) somewhere in the present territory of Lithuania, in the area inhabited by ancient Baltic tribes at that time. Our results show that this mutation gradually entered the gene pool in the neighbouring countries.

Design of a multiplex PCR panel for semiconductor sequencing of the *BRCA1* and *BRCA2* genes on the Ion Torrent PGM

A. R. Mensenkamp[1], *J. L. Costa*[2], *H. Ouchene*[1], *M. Tychon*[1], *A. Justino*[2], *S. Sousa*[2], *J. C. Machado*[2], *M. J. Ligtenberg*[1];
[1]*Radboud University Medical Centre, Nijmegen, Netherlands,* [2]*IPATIMUP Diagnostics, Porto, Portugal.*

The introduction of benchtop massive parallel sequencing machines enables the development of methodologies that are faster and more cost-effective than conventional sequencing. In this study we describe a collaborative effort for the validation of a strategy for the screening of the breast cancer susceptibility genes *BRCA1* and *BRCA2*, making use of the most recent advances on Ion AmpliSeq multiplex PCR technology combined with Ion PGM System.
Strict criteria were set to the design of the amplification primers, including 100% coverage of all coding exons and exon-intron boundaries and the absence of recurrent SNPs in the last five nucleotides of primer. Twenty-five Dutch and twenty-five Portuguese mutations were selected for this analysis. The first 20 cases were used to test and optimize the methodology and were selected based on the presence of mutations in or within close proximity to homopolymeric regions. The additional 30 cases were used for an independent evaluation of the new methodology. These samples included common mutations in Portugal and the Netherlands. In all these cases all SNPs and mutations that were previously identified by capillary electrophoresis sequencing were detected with our multiplex-based approach. The mutations identified included missense, nonsense and indel mutations. The number false positive results were consistently less than five per sample and reproducible. This work demonstrates the potential for mutational screening of *BRCA1* and *BRCA2* using the AmpliSeq technology combined with the Ion Torrent PGM.

Gabon, [12]Hôpital Cochin, AP-HP, Paris, France, [13]Hôpital La Pitié Salpétrière, AP-HP, Paris, France, [14]Hôpital européen Georges Pompidou, AP-HP, Paris, France, [15]Institut Claudius Régaud, Toulouse, France, [16]Institut Curie, Saint-Cloud, France, [17]Centre Hospitalier Universitaire de Nancy, Nancy, France, [18]Institut Gustave Roussy, Villejuif, France, [19]Hôpital Edouard Herriot, Lyon, France, [20]Hôpital La Timone, AP-HM, Marseille, France, [21]Institut du Cancer, Boulogne Billancourt, France.

Background: Based on nationwide data from the French national cancer institute (FNCI), we analyzed the evolution of cancer genetics consultations and testing over time, and the uptake of targeted tests in relatives of families carrying BRCA1/2 or MMR gene mutations.
Methods: All French cancer genetics centers completed annually a survey collecting standardized parameters for the FNCI from 2003 to 2011. We report on the analysis of a total of 240·134 consultations and 134·652 genetic tests that identified 32·494 mutation carriers.
Results: From 2003 to 2011, 141·639 (59 %) and 55·698 (23·2 %) patients were referred for a breast or a colorectal cancer predisposition syndrome, respectively. During this period, we found a dramatic and steady increase in genetic tests performed for the *BRCA1/2* genes (from 2095 to 7393 tests/year, P<0·0001) but not for the MMR genes (from 1144 to 1635/year, P=NS). The percentage of deleterious mutations identified in the probands tested was 13·8 % and 20·9 % in BRCA1/2 and Lynch syndromes, respectively. In families with a *BRCA1/2* or a MMR identified mutation, there was an average number of 3·03 relatives performing target tested.
Conclusion: This nationwide study shows a lack of referral and genetic testing in Lynch syndrome as compared to BRCA1/2 syndrome. Only a third of relatives of a proband carrying a BRCA1/2 or MMR gene mutations performed a targeted test. Enhanced information about benefit of genetic testing is crucial in Lynch syndrome and for relatives of a proband carrying an identified BRCA1/2 or MMR genes mutation.

BRCA1 missense mutation p.Met18Lys detected in 11 Czech high-risk hereditary breast cancer families: segregation analysis and clinical data

***E. Machackova**, M. Mikova, E. Stahlova Hrabincova, J. Hazova, P. Vasickova, L. Foretova; Masaryk Memorial Cancer Institute, BRNO, Czech Republic.*

Identifying women who carry pathogenic mutation in BRCA1 is important for cancer prevention and individualised treatment. Many of tested women are discovered to have variant of unknown clinical significance. One of them, which is nearly exclusively detected in Czech population, is BRCA1 missense variant c.53T>A, p.Met18Lys located 6 aminocids upstream of the highly conserved C3HC4 - RING zinc finger domain. The p.Met18 is highly conserved residue where p.Met18Lys substitution represents replacement of non-polar hydrophobic methionine to a polar charged lysine with highest value of Align-GVGD prediction: C65; likely to induce distortion of helical bundle. Functional tests of p.Met18Lys exhibits loss of ubiquitin ligase activity (Morris 2006) and significantly resulted in a reduction of BRCA1/BARD1 complex formation (Sarkar 2008).
Here we present available segregation data and clinical data of 11 Czech high-risk hereditary breast/ovarian cancer families. In six families segregation with cancer diseases were apparent and in 4 families only insufficient data were available to make any conclusion. Out of these 10 families: 12 women with breast cancer (diagnosed from age of 26 to 64) and 4 women with ovarian cancer (diagnosed from age of 41 to 65) were carriers of BRCA1 p. Met18Lys; whereas only 2 individuals diagnosed with cancers were not carriers (glans penis cancer diagnosed at 53 and breast cancer diagnosed at 61).
Two mutations were segregating in the last family where 2 affected woman were double heterozygote for BRCA1 p. Met18Lys and BRCA2 p.Arg3052Trp (IARC class 5).

BRCA1 Splicing

***D. Baralle**[1], L. Smith[2], J. Blaydes[3];*
[1]Wessex Genetics, University of Southampton, Southampton, United Kingdom, [2]Human Development and Health, University of Southampton, Southampton, United Kingdom, [3]Cancer Sciences, University of Southampton, Southampton, United Kingdom.

BRCA1 is integral for maintaining genome integrity and correct cellular function. It has been shown to play a pivotal role in DNA damage repair, cell cycle control, and gene expression regulation. Importantly, BRCA1 function has been shown to be altered through alternative splicing of BRCA1 pre-mRNA, leading to the expression of BRCA1 splicing isoforms which exhibit diminished function. Two key BRCA1 splicing isoforms have been identified in both breast cancer tissue and cell lines: BRCA1 Δ11 and 11Q. The BRCA1 Δ11 splicing isoform, generated through skipping of exon 11, is associated with dramatic loss of BRCA1 function, particularly in DNA repair. The 11Q isoform is produced through use of an internal 5' splice site in exon 11, generating an mRNA containing a partial section of exon 11. This isoform has a relatively unconfirmed function, exhibiting a contextual effect of promotion or inhibition of cancer cell growth. Developing an understanding of the mechanism involved in the expression of these splicing isoforms in breast cancer, which also utilizes patient identified point mutations, helps us to understand how to regulate their expression for therapeutic benefit. Antisense oligonucleotide's (ASO's) can be used to alter the pattern of splicing, leading to either stimulation or suppression of particular splicing isoforms. ASO's can be applied to alter the splicing pattern of BRCA1 exon 11, and in turn alter the function of the wild-type protein. Endogenously altering BRCA1 splicing isoform expression in this way allows us to explore novel avenues for the development of new breast cancer therapeutics.

Identification pathogenic regulatory and non-coding variants in the 5' region of *BRCA1* and *BRCA2* genes

***M. Beault**[1], A. Briaux[1], C. Andrieu[1], C. Lefol[1], F. Lallemand[1], R. Lidereau[1], S. Caputo[1], M. Brown[2], E. Rouleau[1];*
[1]Institut Curie - Service de Génétique, Paris-St Cloud, France, [2]School of Chemistry and Molecular Biosciences, The University of Queensland, Brisbane, Australia.

BACKGROUND : *BRCA1* and *BRCA2* are major breast/ovarian cancer susceptibility genes, deleterious mutation increase in risk of breast/ovarian cancer. More than 60% of families with a significant cancer history do not have any coding deleterious mutation identified. The hypothesis is there are some variants in the non-coding variants which can have an impact in the risk of breast/ovarian cancer.
METHODS : 384 breast/ovarian cancer probands, *BRCA1/2* negative with the routine screening process, have been explored in four non-coding regions with qPCR-HRM approach and Sanger sequencing: *BRCA2* exon 1, *BRCA1* exon 1a, *BRCA1* exon 1b, *BRCA1* intron 2.
RESULTS : In *BRCA2* exon 1, 4 families with variants were identified (c.-277_-272dup in two families, c.-273G>T, c.-213T>G). All variants were related to very conserved interspecies regions, typical family histories (ovarian cancer, male breast cancer and several breast cancer under 60 year-old) and with several transcription factor sites. In *BRCA1* exon 1, no medium size deletion was identified in a 1.5kb fragment. Only one variant could have an impact (c.-20+279 G>A) close to the Alu sequence. In *BRCA1* intron 2, one variant was detected (c.81-3985A>T) in a family with breast cancers under 40 years-old and which have a potential interaction with the promoter.
DISCUSSION/CONCLUSION: As expected, those variants are very seldom in those regions (1.5% -6/384). Further analyses are needed to confirm any implication in the cancer predisposition (RNA allelic imbalance and luciferase assays). Currently, in the ENIGMA consortium, a database has been created to initiate collaborative work in their classification.

Confirmation of cancer family history: Impact on models predicting *BRCA1/BRCA2* germ-line mutations

***V. Viassolo**[1], A. Ayme[1,2], A. E. Murphy[1], V. Membrez[3], G. Benais-Pont[4], M. Rebsamen[4], P. O. Chappuis[1,3,5];*
[1]Oncogenetics and Cancer Prevention Unit, Division of Oncology, Department of Medicine Specialities, University Hospitals of Geneva, Geneva, Switzerland, [2]Department of Genetic and Laboratory Medicine , University Hospitals of Geneva, Geneva, Switzerland, [3]Division of Genetics, Institut Central de l'Hôpital du Valais, Sion,

Switzerland, [4]Laboratory of Molecular Oncology, Department of Genetic and Laboratory Medicine, University Hospitals of Geneva, Geneva, Switzerland, [5]Division of Genetic Medicine, Department of Genetic and Laboratory Medicine, University Hospitals of Geneva, Geneva, Switzerland.

Background: *BRCA1* and *BRCA2* mutations are responsible for 5 to 10% of all breast and ovarian cancer. Risk assessment tools based on personal and family history are used to evaluate the probability of identifying *BRCA1/BRCA2* germ-line mutations. To provide accurate counselling, gathering a detailed family history is important. The aim of this study is to evaluate the importance of confirming all familial cancer cases before using risk assessment tools.
Methods: Clinical and histopathological characteristics of cancer affecting index cases, 1st and 2nd degree-relatives and cousins, have been extracted from medical files for 204 families with *BRCA1/BRCA2* screening performed between 1998-2009. BRCAPRO, BOADICEA and Manchester Scoring System have been retrospectively applied with 3 distinct criteria: 1) using information collected during the 1st consultation; 2) integrating histopathological characteristics for index cases; 3) integrating clinicopathological features for all available cancer diagnoses after the confirmation process. Receiver operating characteristics (ROC) curves were generated to evaluate the performance of each risk assessment tool within these 3 situations.
Results: Histopathological characteristics were validated for all (n=189) affected index cases. Overall confirmation rates among affected relatives were 39% (144/372) for breast cancer and 51% (19/37) for ovarian cancer. Only 7% (27/396) diagnoses changed after the confirmation process. All risk assessment tools showed a statistically significant better performance ($p \leq 0.05$) when all cancer features were taken into account after the confirmation process.
Conclusion: Confirmation of cancer diagnosis among affected index cases and close relatives is associated with a significantly better evaluation of the likelihood of *BRCA1/BRCA2* mutations.

Fifteen years of *BRCA1/BRCA2* screening in a Swiss diagnostic laboratory: Issues with unclassified variants (UVs)

A. Ayme[1,2], *V. Viassolo*[1,3], *B. Pardo*[4], *M. Rebsamen*[4], *P. O. Chappuis*[1,3,5], *f. the SAKK Network for Cancer Predisposition Testing*[3];
[1]*Oncogenetics and Cancer Prevention Unit, Division of Oncology, Department of Medicine Specialities, University Hospitals of Geneva, Geneva, Switzerland,* [2]*Department of Genetic and Laboratory Medicine, University Hospitals of Geneva, Geneva, Switzerland,* [3]*Network for Cancer Predisposition Testing and Counseling, Swiss Group for Clinical Cancer Research (SAKK), Bern, Switzerland,* [4]*Laboratory of Molecular Oncology, Department of Genetic and Laboratory Medicine, University Hospitals of Geneva, Geneva, Switzerland,* [5]*Division of Genetic Medicine, Department of Genetic and Laboratory Medicine, University Hospitals of Geneva, Geneva, Switzerland.*

Introduction: *BRCA1* and *BRCA2* testing has moved from research to clinical setting some years ago. Analytical performance improvement of screening methods has added complexity in interpreting genetic results due to an increased detection of unclassified variants (UVs). We extensively reviewed all *BRCA1/BRCA2* UVs identified between 1996-2009 in a diagnostic laboratory in Geneva, Switzerland.
Methods: Various techniques [SSCP, HA, PTT (1996-1999); DHPLC prescreening, Sanger sequencing confirmation (1999-2007); HRM prescreening, Sanger sequencing confirmation (2007-2009); MLPA (since 2005)] were successively used to identify *BRCA1/BRCA2* germ-line modifications. Significance of all UVs was re-evaluated as follows: 1) referring to gene-specific databases (BIC, LOVD, UMD); 2) using *in silico* tools (Align-GVGD, SIFT, PolyPhen); 3) reviewing literature. BRCAPRO scores, as well as family history characteristics, were collected and compared to *BRCA1/BRCA2* testing results.
Results: 1'163 complete *BRCA1/BRCA2* analyses were performed: 218 (18.7%) index cases were identified as carriers of pathogenic mutations (*BRCA1*: n=134; *BRCA2*: n=84) and 127 (10.9%) as carriers of UVs. Among 114 distinct UVs (*BRCA1*: n=45; *BRCA2*: n=69), 77 were missense variants, 33 intronic variants and 4 in-frame deletions. Before 2009, 3 (2.6%) UVs were reclassified as pathogenic. Distribution of BRCAPRO scores and family history were not statistically different between families with UVs or non informative testing results. Higher BRCAPRO scores ($p<0.0001$) and some particular familial phenotypes, such as ovarian cancer or multiple early-onset breast cancer cases, were significantly associated with identification of *BRCA1/BRCA2* pathogenic mutations.
Conclusion: In our cohort, most *BRCA1/BRCA2* UVs were associated with similar features as non informative testing results.

P11.036

Spectrum of mutations in predisposing genes to hereditary breast and ovarian cancer in Czech Republic

A. Panczak[1], *P. Pohlreich*[2], *J. Stříbrná*[2], *J. Kotlas*[1], *M. Janatová*[2], *J. Soukupová*[2], *I. Tichá*[2], *K. Veselá*[1], *M. Zimovjanová*[3], *P. Kleiblová*[2], *Z. Kleibl*[2];
[1]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University, Prague, Czech Republic,* [2]*Institute of Biochemistry and Experimental Oncology, First Faculty of Medicine, Charles University, Prague, Czech Republic,* [3]*Department of Oncology, First Faculty of Medicine, Charles University, and General teching Hospital, Prague, Czech Republic.*

BRCA1 and *BRCA2* are major predisposition genes to hereditary breast/ovarian cancer (BOC) but germ-line mutations in these genes account for only 24.1% of inherited BOC cases in Czech Republic. Mutations in additional susceptibility genes, i.e. *CHEK2*, *ATM*, *TP53*, *NBN1*, and *PALB2* were studied in families at high risk of BOC negatively tested for *BRCA1/2* mutations.
Coding sequences of both *BRCA1* and *BRCA2* were analyzed by protein truncation test (PTT) and direct sequencing; patients negative for point mutations and small deletions/insertions were screened for large genomic deletions and rearrangements (LGRs) at *BRCA1/2* by MLPA, long range PCR and genomic sequencing. In patients negative for *BRCA1/2* mutations, the coding region of *TP53* was sequenced using cDNA, two most frequent Czech *CHEK2* alterations (c.1100delC and a 5395 bp deletion comprising exons 8 and 9) were detected by MLPA, and the coding region of *PALB2* was sequenced via cDNA; all mutations were confirmed by direct DNA sequencing.
The four most frequent mutations in *BRCA1* (c.300t>G, c1806C>T, c3819_3823del5, and c 5385dupC) accounted for 69.1% and LGRs for 11.4% of all *BRCA1* mutations. In *BRCA2*, the eight most frequent mutations accounted for 43% and no LGRs were found. Mutations in *PALB2* were present in 2% and two most frequent *CHEK2* mutations tested in 1.2% of our patients. Mutations in *TP53*, *ATM*, and *NBN1* genes were rare.
Mutation testing of other predisposing to BCO genes with moderate risk would help in clinical genetic consulting in Czech families at high risk of BCO negative for *BRCA1/2* alterations.

Evaluation of *ERBB2*, *C-MYC* and *CCND1* gene status and its association with tissue aluminum concentration in breast cancer

R. M. Rodrigues-Peres[1], *J. K. Heinrich*[1], *L. O. Z. Sarian*[2];
[1]*CAISM – Women´s Hospital, State University of Campinas - UNICAMP, Campinas, SP, Brazil,* [2]*Department of Obstetrics and Gynecology, Faculty of Medical Sciences, Sate University of Campinas - UNICAMP, Campinas, SP, Brazil.*

Introduction: It has long been hypothesized whether body tissue uptake of aluminum may have biological or clinical implications in breast cancer. *In vitro* and a few *in vivo* studies have shown that aluminum may trigger genomic instability by interfering directly on the assembly of DNA strands. **Objective:** to examine the relationship of aluminum concentration in peripheral and central areas of breast tumors with the instability of key genes in breast cancer, *ERBB2*, *C-MYC* and *CCND1*, and aneuploidy of chromosomes harboring these genes. **Subjects and Methods:** For this study, 118 samples of breast cancer tissue were obtained. Evaluation of tissue aluminum content was carried out using Graphite Furnace Atomic Absorption Spectrometry. A tissue microarray slide containing the samples was used in FISH assays to assess *ERBB2*, *C-MYC* and *CCND1* and the respective chromosomes 17, 8 and 11 centromere status. Clinicopathological data were obtained from patient records. **Results:** Levels of aluminum >2.0mg/kg were found in 20.3% and 22.1% of the central and peripheral areas, respectively. The amplification and/or aneuploid status for the *ERBB2/CEP17*, *C-MYC/CEP8* and *CCND1/CEP11* were detected in 24%, 36.7% and 29.3% of the tumors, respectively. We found that aluminum concentration was not related to any of these altered gene statuses. **Conclusions:** Recent lines of evidence, including our findings, suggest that aluminum concentration may not directly affect genomic stability in breast tissues. Tissue microenvironment modifications due to the presence of aluminum compounds seems more appealing as possible targets to current and future studies on the implications of aluminum in breast carcinogenesis.

P11.038

Mutation spectrum and prevalence of BRCA1 and BRCA2 genes in patients with familial and early-onset breast/ovarian cancer from Tunisia : Novel and high proportion of recurrent germline mutations

*A. Riahi[1], F. Khomssi[2], M. Kharrat[1], K. Rahal[2], A. Gammoudi[2], A. El May[2], **H. Chaabouni-Bouhamed**[1,3];*
[1]Faculte de medecine University Tunis Elmanar, Tunis, Tunisia, [2]Institut Salah Azaiez, Tunis, Tunisia, [3]Charles Nicolle hospital, Tunis, Tunisia.

Background: Hereditary factors are the most significant risk causing breast cancer and many of these are depending on mutations in BRCA1 or BRCA2 genes. Estimate of pathogenic mutations prevalence of BRCA1/2 genes varies within different populations. The contribution of BRCA1 and BRCA2 mutations to hereditary breast cancer in the Tunisian population has not been accurately estimated.
Methods: We studied 48 unrelated Tunisian high-risk cases selected for their family history of breast /ovarian cancer . Coding regions of BRCA1, BRCA2 and exon-intron boundaries were screened using direct sequencing.
Results: We identified five different pathogenic mutations in twelve families, three in BRCA1 and tow in BRCA2 with a prevalence of 25%. We also identified 20 distinct polymorphisms and unclassified variants. Among BRCA1 mutation carriers, four unrelated families shared the c.211dupA deleterious mutation which seems to be Tunisian specific mutation, since it was described for the first time in Tunisia and was not reported elsewhere. Morover analysis of twelve microsatellite markers in the BRCA1 locus has shown a common haplotype associated with this mutation in all carriers, suggesting a new Tunisian founder mutation.
Conclusion: This study indicates that our population has a spectrum of prevalent BRCA mutations which account for a high proportion of hereditary breast/ovarian cancer, and demonstrated a predominance of BRCA1 germline recurrent mutations, accounting for more than 66% of all identified alterations and appears as founding mutations. Identification of a recurrent mutation could reduce the cost of mutation analysis, for genetic counseling and cancer risk assessment.

The SWEA study - an extended analysis of hereditary breast cancer in Sweden

***H. Ehrencrona**[1], B. Arver[2], Z. Einbeigi[3], Y. Karlsson-Pålsson[4], A. Kvist[5], A. Lindblom[6], B. Melin[7], M. Stenmark Askmalm[8], T. Törngren[5], Å. Borg[5];*
[1]Clinical Genetics, Lund University, Lund, Sweden, [2]Oncology-Pathology, Karolinska University Hospital, Solna, Stockholm, Sweden, [3]Oncology, Göteborg University, Göteborg, Sweden, [4]Genetics and Pathology, Uppsala University, Uppsala, Sweden, [5]Oncology, Clinical Sciences, Lund University, Lund, Sweden, [6]Molecular Medicine and Surgery, Cancer Genetics, Karolinska University Hospital, Solna, Stockholm, Sweden, [7]Radiaton Sciences, Oncology, Umeå University, Umeå, Sweden, [8]Division of Clinical Genetics, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, County Council of Östergötland, Linköping, Sweden.

The SWEA study (The SWE-BRCA Extended Analysis) is a national collaborative study involving all cancer genetics clinics in Sweden. Within the SWEA study, index cases from breast cancer families are screened for mutations in 17 known breast cancer susceptibility genes: BRCA1, BRCA2, TP53, PTEN, STK11, CDH1, CDKN2A, CHEK2, PALB2, BRIP1, ATM, RAD50, RAD51C, RAD51D, BARD1, NBN and MRE11A. In addition, we screen the protein coding exons of 47 candidate susceptibility genes, selected based on the functional networks in which the known 17 genes exert their effect. Putative risk alleles will be followed up with segregation analysis. All patients who undergo clinical BRCA1/2 screening in Sweden are offered participation in SWEA. The study opened for inclusion in April 2012. In the first nine months over 400 index individuals were screened, and we estimate that over 1200 prospective families will be included within the first two years of the study. We will also perform pooled mutation screening in 5000 healthy controls, 5000 consecutive breast cancer patients and 4000 familial high-risk cases. Preliminary results will be presented.

P11.040

Detection of copy number variations on oncogenes and tumor suppressor genes by multiplex ligation probe amplification analysis

***I. Maleva**[1], K. Kubelka-Sabit[2], D. Jasar[2], A. Arsovski[3], L. Stojanovska[3], D. Plaseska-Karanfilska[4];*
[1]Macedonian Academy of Sciences and Arts, Research center for Genetic Engineering and Biotechnology „Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of, [2]„Adzibadem-Sistina", Private hospital, Skopje, Macedonia, The Former Yugoslav Republic of, [3]„Re-Medika", Private hospital, Skopje, Macedonia, The Former Yugoslav Republic of, [4]Macedonian Academy of Sciences and Arts, Research center for Genetic Engineering and Biotechnology, Skopje, Macedonia, The Former Yugoslav Republic of.

Copy number variations (CNVs) on chromosomes 8p, 11q and 17q are among the most common aberrations in breast cancer (BC). Several oncogenes and tumor suppressor genes involved in development and progression of the tumor are located on these chromosomes. Some of them are proposed to predict and guide therapy, but their prognostic value is still a subject of intense study and controversy. The aim of the study was to examine the CNVs in 21 BC related genes and to couple the data with pathological features of tumor that are currently used for prognosis and treatment selection. We analyzed 71 female invasive breast cancers with multiplex ligation-dependent probe amplification kit P078 (MRC Holland). We identified PRMD14 amplification in 42.2% of the patients, MTDH in 35.2%, CCND1 in 31%, MYC in 28.1%, ERBB2 and CDC6 in 22.5%, FGFR and MED1 in 21.2%, IKBKB, TOP2A and AURKA in 19.7%, BIRC5 in 16.9%, CDH1 in 15.5%, ADAM9 in 14.9%. Co-amplification of ERBB2/TOP2A, ERBB2/CCND1, ERBB2/MYC, MYC/CCND1 and MYC/TOP2A genes were observed in 15.5%, 8.5%, 5.6%, 12.7% and 7% of the tumors. Significant association was observed between HER2 positive tumors and high level amplification of 17q genes: MED1, ERBB2 and TOP2A (p=1.63x10-6, 3.52x10-4 and 0.001); between IKBKB gain and increased p53 expression (p=0.003); and CDH1 loss and lobular type of tumor (p=0.036).
In conclusion, MLPA is fast, simple and accurate method for detection of CNVs and can contribute to better understanding of the role of oncogenes and tumor suppressor genes in development and progression of BC.

P11.041

Qualitative analysis of the CTC levels in Bulgarian patients with metastatic breast cancer

***D. R. Dacheva**[1], S. Valev[2], M. Taushanova[2], V. Mitev[1], K. Timcheva[2], R. Kaneva[1], A. Mitkova[1];*
[1]Department of Medical Chemistry and Biochemistry, Molecular Medicine Centre, MU- Sofia, Sofia, Bulgaria, [2]Medical Oncology Clinic, Specialised Hospital for Active Treatment in Oncology, Sofia, Bulgaria.

Background: The vast majority of cancer-related death is due to the metastatic spread of the primary tumour. Circulating tumour cells (CTC) detection has been considered as a reliable biomarker for overall survival and assessment of the therapeutic response in patients with metastatic breast cancer (MBC).
Materials and methods: We have analyzed the CTC levels in 18 MBC patients at three specific points: before therapy, after three and after six cycles of chemotherapy, by commercial AdnaGen diagnostic tests based on CTC isolation from 5 ml blood samples with immunomagnetic separation and RT-PCR of three BC-associated expression markers GA733-2, Her-2 and Muc-1. Samples from 12 healthy women were used as negative controls. The PCR products were analysed by 4% agarose gel electrophoresis and Agilent Bioanalyzer 2100.
Results: CTC were detected in 44.4% (8/18) of MBC patients before therapy. All of the initially negative CTC patients remained negative in the course of treatment. All CTC positive patients lost their expression markers after three cycles of chemotherapy, but one of them became positive after the sixth course. Two patients died and could not be followed. The frequencies of the studied expression markers were 44.4% (8/18) for GA733-2, 33.3% (6/18) for Muc-1 and 11.1 % (2/18) for Her2. Interestingly two of the patients with Her2 negative primary tumor demonstrated positive Her2 expression in CTC.
Conclusions: Our results demonstrated that CTC levels determined by RT-PCR can be used as reliable surrogate biomarker of the clinical outcome and treatment response in Bulgarian patients with MBC.

Breast cancer risk prediction using the novel germline signatures in epigenome regulatory pathways.

C. Adaniel[1], J. Rendleman[1], J. Smith[1], R. Klein[1], Y. Shao[1], F. Schnabel[1], K. Offit[2], T. Kirchhoff[1];
[1]New York University School of Medicine, New York, NY, United States, [2]Memorial Sloan-Kettering Cancer Center, New York, NY, United States.

Epigenetic regulatory pathways are intensely studied for their involvement in breast tumorigenesis, however little is currently known about the genetic variation in epigenome components contributing to the risk and/or prognosis of breast cancer. In this study we have tested how novel germline genetic signatures identified in epigenetic regulatory genes (ERGs) may potentially contribute to clinical prediction of breast cancer risk. We have genotyped 711 SNPs tagging 87 ERGs in 1985 breast cancer cases and 1609 controls. The samples were of white European origin with a fraction of Ashkenazi Jewish (AJ) ancestry (n=1642). Associations with risk were assessed using logistic regression, adjusted by age and AJ status. The strongest associations were observed for RUNX1 (rs7280097, OR=0.83, CI 95%: 0.71-0.94, p=0.006) and PRDM16 (rs12135987, OR=1.22, CI 95%: 1.06-1.42, p=0.007). The predictive ability of SNP signatures was tested by ROC curves using logistic regression models, and the area under the curve (AUC) was used to assess their utility in the classification of breast cancer risk. A signature of 20 SNPs tagging 13 ERGs (20-SNP-ERG) was significantly associated with breast cancer risk. The inclusion of predictor variables (age, AJ status) and 20 associated SNPs in the ROC analysis yielded a best fitting model involving 10 SNPs tagging 8 ERGs with AUC of 0.723, compared to 0.660 with predictor variables alone (p=0.003). These results suggest the promising clinical potential of 20-SNP-ERG signature in identification of high-risk individuals in the population, and point to possible biological implication of germline patterns in epigenetic enzymes in breast tumorigenesis.

Prognostic and predictive significance of HOXB13:IL17BR expression ratio in breast cancer

E. Demirdogen[1], *U. Egeli[1], G. Tezcan[1], G. Cecener[1], B. Tunca[1], S. Gokgoz[2], I. Tasdelen[2], S. Tolunay[3];*
[1]Department of Medical Biology, Faculty of Medicine, Uludag University, Bursa, Turkey, [2]Department of General Surgery, Faculty of Medicine, Uludag University, Bursa, Turkey, [3]Department of Pathology, Faculty of Medicine, Uludag University, Bursa, Turkey.

Breast cancer progression is directly related to estrogen hormone (ER) status of patients. Although most of ER (+) cases benefit from adjuvant endocrine treatment with tamoxifen, almost 40% of these patients are not respond to this therapy. Recent studies have shown that *HOXB13* and *IL17BR* have both significant prognostic and predictive utility. The aim of this study was to investigate the significance of *HOXB13*: *IL17BR* ratio in recurrence/distant metastasis potential of ER (+) primary Turkish breast cancer patients.
HOXB13 and *IL17BR* gene expression levels were determined by quantitative RT-PCR analysis from formalin-fixed paraffin-embedded tissues of 40 tumor and 40 normal primary breast cancer patients receiving adjuvant tamoxifen. ΔCt values were used to build a *HOXB13: IL17BR* index. All statistical analyses were performed using MedCalc 12.4.0 Statistical software.
The expression level of *HOXB13* was 12,2 fold higher and *IL17BR* was 0,0006 fold lower in tumors. Although there was no significant correlation, *HOXB13* and *IL17BR* demonstrated opposing patterns of expression (r=-0.03465, *P*=0.8341). According to two sample T test, the ratio of *HOXB13*:*IL17BR* significantly different between metastatic and non-metastatic tumors of patients ($P < 0.0001$). Also, ROC Curve analysis validated to this significancy (AUC: 0.725, *P*=0.017). In addition, hormonotherapy was associated with longer disease-free (P =0,0166) and median (P =0,0101) survival in the entire cohort.
Even further studies needed, a higher *HOXB13*:*IL17BR* expression may be a candidate biomarker of recurrence /distant metastasis in breast cancer in the setting of adjuvant tamoxifen therapy.

The Importance of MIR-126 in Breast Cancer

C. Oner, ***D. Turgut Cosan****, S. M. Erkasap, I. Degirmenci, H. V. Gunes, F. Sahin Mutlu; Eskisehir Osmangazi University, Eskisehir, Turkey.*

There are many effective mechanisms in cancer development. Breast cancer is the most seen cancer type in women on the World. The effect of microRNAs in cancer and its mechanisms haven't been fully elucidated. Therefore, micro-RNAs are important because of the possibility of as a biomarker of cancer.
In this study, we have investigated and the effect of miR-126, which is thought to play a role in vessel development and the cell movements control like metastasis and invasion in breast cancer cases. Furthermore, in this study, we have also researched the gene expression of miR-126*, the complementary of miR-126, and the Epidermal Growth Factor Like-7 (Egfl-7) mRNA expression, which includes miR-126/126* in breast cancer patients. The decrease of miR-126 gene expression caused an increase in gene expression of Egfl-7, which was inhibited by miR-126.
Firstly we collected peripheral blood samples of breast cancer patients and isolated mononuclear cells. Then, we isolated RNA from these mononuclear cells and determined gene expression levels by using Real Time PCR method.
In our study, we observed a decrease in miR-126 gene expression and an increase in Egfl-7 gene expression when compared to that of healthy people. The decrease of miR-126 gene expression caused an increase in Egfl-7 gene expression, which is then inhibited by miR-126.
Our results supported that miR-126 can be a tumor suppressor in breast cancer.

Analysis of miR-195 Expression and Role in Breast Cancer

G. Cecener[1], *E. Demirdogen[1], E. Erturk[1], B. Tunca[1], U. Egeli[1], S. Gokgoz[2], G. Tezcan[1], S. Ak[1], T. B. Hayal[1], V. Polatkan[1], S. Tolunay[3], I. Tasdelen[2];*
[1]Department of Medical Biology, Faculty of Medicine, Uludag University, Bursa, Turkey, [2]Department of General Surgery, Faculty of Medicine, Uludag University, Bursa, Turkey, [3]Department of Pathology, Faculty of Medicine, Uludag University, Bursa, Turkey.

Because of the utility of currently available tumor markers is limited by disappointing sensitivities and specificities, the discovery of novel classes of molecular markers in cancer has provided exciting, potentially viable biomarkers that may have utility in early cancer detection. The potential of microRNAs (miRNAs) as novel tumor markers has been the focus of recent research because of their tissue specificity, stability, and association with clinicopathological parameters. The objective of this study was to investigate expression and potential role in prognosis of miR-195 in breast cancer.
miR-195 expression levels were determined by quantitative RT-PCR analysis from fresh frozen tissues of 72 tumor and 72 normal primary breast cancer patients not receiving neoadjuvant chemotheraphy. The Statistical analysis were performed to clarify the correlation with miR-195 expression level and clinical features of breast tumor tissues.
The expression level of miR-195 was 0,283 fold lower in tumors than normal tissues. Although miR-195 expression levels were not significantly different between tumor and normal tissues of patients according to Independent Sample T test (*P*=0.217), Binary Logistic Regression Analysis demonstrated that there was a significant correlation between miR-195 expression levels and tumor grade (P = 0.023). Also, miR-195 expression levels were associated with tumor size and tumor type (*P*=0.020 and *P*=0.018, respectively).
A low miR-195 expression was related with increased tumor size and grade. So our data imply that miR-195 play role in breast cancer malignancy and may be the potential therapeutic target.

Segregation Analysis Offers a Mechanism for Variant Reclassification in a Small Subset of Cases but is Especially Powerful in Classifying Deleterious Mutations

J. Eggington[1], *J. Saam*[1], *K. Bowles*[1], *K. Moyes*[1], *S. Manley*[1], *L. Esterling*[1], *S. Sizemore*[1], *B. Robinson*[1], *C. Arnell*[1], *E. Rosenthal*[1], *J. Bennett*[1], *M. McKellar*[2], *B. Roa*[1], *R. Wenstrup*[1];
[1]*Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States,* [2]*Myriad Genetics, Inc., Salt Lake City, UT, United States.*

Accurate classification of variants in regards to their clinical significance is a critical challenge associated with gene sequencing tests. Thus, it is important to evaluate the effectiveness of various strategies for variant reclassification. This study compares the use of segregation analysis against other methodologies for the reclassification of variants in Hereditary Breast and Ovarian Cancer (*BRCA1/2*). Reclassification methods independent of additional family testing and powered by Myriad's extensive *BRCA1/2* variant database resulted in 61% of reclassifications, mostly downgrades. Determining if a novel variant segregates with cancer in a family is the classic genetic tool used to assess a variant's effect on hereditary cancer risk. Myriad Genetics' test reports of variant of unknown significance (VUS) and favor polymorphism (FP) are accompanied by an offer of research testing to additional family members. These data are then used to reclassify variants. In this study, we recorded family history submissions from 17% of the VUS/FP results. Research testing was offered to an average of 2.3 relatives per family history submission, with a 24.1% response rate. While we made a significant effort to collect segregation data, this effort resulted in only 3.5% of all variant reclassifications during a 13-month time period. However, of the 10 variant upgrades to deleterious or suspected deleterious, two (20%) were based on co-segregation data. These results illustrate the power of segregation analysis in identifying deleterious variants and suggest that the tailoring of family analysis to specific families may be the most productive use of laboratory and community resources.

A Clinical History Weighting Algorithm Accurately Classifies BRCA1 and BRCA2 Variants

K. Bowles[1], *B. Morris*[2], *E. Hughes*[3], *J. Eggington*[1], *L. Esterling*[1], *B. Robinson*[1], *A. Van Kan*[1], *B. Roa*[1], *E. Rosenthal*[1], *A. Gutin*[1], *R. Wenstrup*[1], *D. Pruss*[3];
[1]*Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States,* [2]*Myriad Genetics, Inc, Salt Lake City, UT, United States,* [3]*Myriad Genetics, Inc., Salt Lake City, UT, United States.*

Genetic testing, including full gene sequencing and large rearrangement analysis for germline BRCA1 and BRCA2 mutations, can identify individuals with Hereditary Breast and Ovarian Cancer syndrome. Current genetic analysis identifies BRCA1 and BRCA2 deleterious mutations as well as variants of unknown clinical significance. Reclassification of uncertain variants to more clinically interpretable categories is critical for patient management. We have developed a statistical algorithm that aids in the assignment of clinical classifications to uncertain variants. This algorithm is based on the premise that disease-associated mutations will be observed more often in individuals at high risk for carrying a mutation, as determined by personal and family history. Statistical analysis weights the family histories of each proband carrying the variant of interest and compares these histories to those of control probands carrying variants known to be benign or deleterious. Data from over 400,000 probands were utilized for algorithm development. This technique was validated by and used to analyze over 6000 BRCA1 and BRCA2 variants. The algorithm successfully classified well-documented variants such as BRCA1 c.181T>G (Deleterious), BRCA1 c.1065G>A (Polymorphism), and BRCA2 c.2808_2811del (Deleterious). The BRCA1 c.5096G>A (Suspected Deleterious with reduced penetrance) and BRCA2 c.7878G>C (Suspected Deleterious with reduced penetrance) mutations were classified as „Not Callable" by the algorithm, consistent with their previous hypomorphic interpretations. This 'history weighting' algorithm allows for the accurate reclassification of BRCA1 and BRCA2 uncertain variants and improved clinical management of at-risk patients. With modifications, this algorithm is expected to be applicable to other autosomal dominant cancer-associated and non-cancer-associated genes.

P11.048

Germline mutation in the *RAD51B* gene confers predisposition to breast cancer

L. Golmard[1,2], *V. Caux-Moncoutier*[1], *G. Davy*[1], *E. Al Ageeli*[1], *B. Poirot*[1], *C. Tirapo*[1], *D. Michaux*[1], *C. Barbaroux*[1], *C. Dubois d'Enghien*[1], *L. Castéra*[1], *M. Stern*[1,2], *C. Houdayer*[1,2,3], *D. Stoppa-Lyonnet*[1,2,3];
[1]*Institut Curie, Department of Tumour Biology, Paris, France,* [2]*Institut Curie, INSERM U830, Paris, France,* [3]*Université Paris Descartes, Sorbonne Paris Cité, Paris, France.*

Background. Most currently known breast cancer predisposition genes play a role in DNA repair by homologous recombination. Recent studies conducted on *RAD51* paralogs, involved in the same DNA repair pathway, have identified rare germline mutations conferring breast and/or ovarian cancer predisposition in the *RAD51C, RAD51D* and *XRCC2* genes. The present study analysed the five *RAD51* paralogs to estimate their contribution to breast and ovarian cancer predisposition.

Patients and Methods. The study was conducted on 142 unrelated patients with breast and/or ovarian cancer either with early onset or with a breast/ovarian cancer family history. Patients were referred to a French family cancer clinic and had been previously tested negative for a *BRCA1/2* mutation. Coding sequences of the five genes were analysed by EMMA (Enhanced Mismatch Mutation analysis). Detected variants were characterized by Sanger

sequencing analysis.
Results. Three splicing mutations and two likely causal missense variants were identified: *RAD51B* c.452+3A>G, *RAD51C* c.706-2A>G, *RAD51C* c.1026+5_1026+7del, *RAD51B* c.475C>T/p.Arg159Cys and *XRCC3* c.448C>T/p.Arg150Cys. No *RAD51D* and *XRCC2* gene mutations were detected.
Conclusions. This study identified *RAD51B* as a new breast cancer predisposition gene and is the first report of *XRCC3* mutation analysis in breast and ovarian cancer. It confirms that *RAD51* paralog mutations confer breast and ovarian cancer predisposition and are rare events. In view of the low frequency of *RAD51* paralog mutations, international collaboration of family cancer clinics will be required to more accurately estimate their penetrance and establish clinical guidelines in carrier individuals.

Germline copy number variations in BRCA1/2-negative Finnish breast and ovarian cancer families

K. M. Kuusisto[1,2], *O. Akinrinade*[1,2], *M. Vihinen*[3], *S. Laasanen*[4], *J. Schleutker*[1,2,5];
[1]*University of Tampere, Tampere, Finland,* [2]*Fimlab Laboratories, Tampere, Finland,* [3]*Lund University, Lund, Sweden,* [4]*Tampere University Hospital, Tampere, Finland,* [5]*University of Turku, Turku, Finland.*

BACKGROUND Breast cancer (BrCa) is the most common cancer among women in western countries, including Finland. Inherited factors are known to account for 5-10% of all BrCa cases. Several BrCa susceptibility genes have been recognized but the predisposing factors remain mostly unidentified in majority of the hereditary breast and ovarian cancer (HBOC) families. In recent years, copy number variations (CNVs) have been shown to have an important role in predisposition to several complex diseases. Our aim was to identify germline CNVs contributing to HBOC predisposition in the Finnish population.
METHODS A genome-wide SNP array was performed for 84 HBOC individuals, who have been tested negative for *BRCA1/2*-founder mutations and pre-screened for most common BrCa genes, and 36 healthy controls. Gene-affected CNVs were analysed by Gene Ontology term enrichment, pathway analyses, and database searches. Six potential CNVs were validated and genotyped in 209 additional healthy controls by qPCR.
RESULTS Intronic deletion at *EPHA3* receptor tyrosine kinase was enriched in HBOC individuals (8 of 81, 9.9%) compared with controls (7 of 185, 3.8%) (OR=2.7; *P*=0.05). EPHA3 was identified in several enriched molecular functions including receptor activity. A rare novel deletion affecting intronic region of tumor suppressor gene, *CSMD1*, was observed in 1 of 81 (1.2%) HBOC individuals but it was absent in healthy controls implicating a disease susceptibility.
CONCLUSION The study reveals new information about the germline CNVs that likely contribute to HBOC susceptibility in Finland.

DNA repair gene (XRCC2, XRCC4 and RAD51) polymorphisms and breast cancer in Saudi females

S. Tulbah[1], *M. Alanazi*[2], *N. Reddy*[2], *A. Pathan*[2], *W. Khan*[2], ***A. S. Warsy***[1];
[1]*Department of Biochemistry, College of Science, Center for Science and Medical Studies for Girls, King Saud University, Riyadh, Saudi Arabia,* [2]*Department of Biochemistry, College of Science, King Saud University, Riyadh, Saudi Arabia.*

Double strand breaks in DNA are repaired by different mechanisms, including homologous recombination and non-homologous end joining (NHEJ). We investigated seven SNPs in XRCC2 and RAD51 (homologous repair) and XRCC4 (NHEJ) in 100 Saudi breast cancer patients and 100 controls, to study the association between rs3218536 (G>A) in XRCC2; rs1801320 (G>C), rs1801321 (G>T) and rs2619681 (C>T) in RAD51; and rs2075685 (G>T), rs10474081 (C>G) and rs1120476 (A>G) in *XRCC4* and occurrence of breast cancer in Saudis. Genotyping was performed using genomic DNA obtained from peripheral blood, by TaqMan genotyping assay, PCR-RLFP and DNA sequencing. We observed a highly significant association between breast cancer occurrence and RAD51 rs1801321 (G>T) where the G allele (OR=7.93; p<0.0001) homozygocity (GG) was observed only in the patients and the T allele was significantly protective (OR=0.13; p<0.0001). For RAD51, rs2619681 (C>T) also showed a significant association, where the C allele increased breast cancer risk (OR=2.05; p<0.01) and the T allele was significantly protective (OR=0.49; p<0.01). rs1801320 in RAD51 and the SNPs in XRCC4 did not show any association with breast cancer. rs3218536 (G>A) in XRCC2 showed a marginal association where the OR for the mutant allele was 1.82 and for the wild type allele was 0.54. We will present the results of association between the genotypes and age of diagnosis, family history, disease severity and recurrence risk of cancer in Saudis.

P11.051
Two novel *RAD51C* mutations in families with breast and ovarian cancer

J. Hauke[1,2], *A. Becker*[1,2], *G. Schnurbein*[1], *G. Neidhardt*[1,2], *A. Meindl*[3], *E. Hahnen*[1,2], *B. Wappenschmidt*[1,2], *R. K. Schmutzler*[1];
[1]*Center for Familial Breast and Ovarian Cancer, University Hospital of Cologne, Cologne, Germany,* [2]*Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany,* [3]*Department of Gynaecology and Obstetrics, Klinikum rechts der Isar at the Technical University, Munich, Germany.*

Since its discovery by Meindl et al. in 2010, *RAD51C* is defined as a breast and ovarian cancer (BC, OC) susceptibility gene besides the two highly penetrant BC genes *BRCA1/2*. Heterozygous mutations in *RAD51C* are predominantly found in families with both BC and OC. While *BRCA1/2* mutations are found in 21% of the families that fulfill the inclusion critieria of the German consortium of hereditary breast and ovarian cancer (GC-HBOC), *RAD51C* mutations are only found in 1 - 1.5 % of theses families Seven distinct pathogenic *RAD51C* mutations have been described so far in 14 families by the GC-HBOC.
We here describe two novel *RAD51C* mutations segregating in one BC and one BC/OC family respectively. One large genomic deletion including exons 5 to 9 was discovered in a BC family by MLPA technique during screening of 168 non-BRCA BC and 151 BC/OC families. The genomic break point was determined by quantitative real-time PCR followed by Sanger-sequencing. The second mutation, an exonic splice site mutation affecting the last nucleotide of exon 2, *c.*404G>C, was found during clinical screening of *RAD51C* by Sanger-sequencing. RT-PCR revealed the activation of a cryptic splice site in intron 2 with subsequent inclusion of 27 nucleotides from intron 2, leading to a truncated protein *p.*Met136X. The finding of two novel deleterious *RAD51C* mutations supports previous findings that *RAD51C* mutations are prevalent in high risk BC/OC as well as BC only families in Germany and may be included in routine clinical diagnostic testing in selected high risk families.

P11.052
Identification of breast cancer susceptibility loci in genes unregulated in breast cancer gene-expression arrays

M. Loizidou[1], *I. Neophytou*[1], *K. Siontis*[2], *J. Ioannidis*[3], *K. Kyriacou*[1], *A. Hadjisavvas*[1];
[1]*The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,* [2]*Clinical Trials and Evidence-Based Medicine Unit, Department of Hygiene and Epidemiology, University of Ioannina School of Medicine, Ioannina, Greece,* [3]*Department of Health Research and Policy, Stanford University School of Medicine, Stanford, CA, United States.*

Breast cancer is a complex, multifactorial, polygenic disease. Some of the familial risk for breast cancer can be explained by rare mutations in high-penetrance genes such as BRCA1 and BRCA2. The failure of linkage studies to identify further susceptibility genes suggests that most familial clustering of cancer is due to a combination of multiple lower penetrance alleles. In an attempt to gain a further insight into the inherited basis of breast cancer we performed a meta-analysis of publically available gene expression profiling data for breast cancer and used this information for prioritizing candidate genes to be investigated. A total of 243 single nucleotide polymorphisms (SNPs) located within or in close proximity to the top 50 meta-analysis genes were selected and subsequently genotyped in the MASTOS study cohort (which consists of 1109 Cypriot breast cancer patients and 1177 healthy controls) using the Sequenom Mass-ARRAY platform. Of the 243 SNPs studied, eighteen were found to be statistically significantly associated with breast cancer risk. Of these eighteen SNPs, two are located in the HMMR gene, two in the NTRK2 gene and the rest in the FLJ10357, KIT, TGFBR3, TXNIP, ZBTB16, MME, GSN, CKS2, EGR1, PTRF, NEK2, SYNM, ANXA1 and MTHF02 genes. Our study demonstrates that this approach is useful for disease risk loci identification in genes which are upregulated in breast tissues and are thus potentially important in the carcinogenesis pathway. However, large-

scale replication in multi-ethnic cohorts is warranted in order to replicate our results and confirm the associations observed in our population.

Analysis of the BRCA1 promoter methylation in triple-negative sporadic breast cancer

J. Fernández Mateos[1], *J. Ceballos Viro*[2], *A. Gómez Bernal*[2], *T. Martín Gómez*[1], *J. J. Cruz Hernández*[2], *R. González Sarmiento*[1];
[1]*Unidad de Medicina Molecular, Departamento de Medicina. Universidad de Salamanca-IBSAL,, Salamanca, Spain,* [2]*Servicio de Oncología Médica. Hospital Clínico Universitario de Salamanca-IBSAL,, Salamanca, Spain.*

Background: Breast cancer is the most frequent neoplasia in women. Approximately 5% of them are hereditary, caused by inherited mutations in breast cancer susceptibility genes: BRCA1 and BRCA2. The 95% remaining are sporadic. Epigenetic regulation, especially promoter methylation, is an important mechanism for down-regulating tumour suppressor genes in human cancer cells. Methylation of the BRCA1 promoter has been reported in sporadic breast cancer with links to reduced mRNA and protein expression in tumours and cancer cell lines.
The aim of our study was to estimate the percentage of methylation in the promoter region of BRCA1 oncosupressor gene, in patients from Salamanca (Spain), diagnosed with sporadic breast cancer and to compare these results with their clinical data.
Patients and methods: Genomic DNA was extracted from paraffin blocks from triple-negative breast cancer samples of 98 women. After bisulphite conversion, DNA methylation was measured by quantitative analysis of methylated alleles (QAMA), to estimate the extent of methylation of 2 CpG sites in the promoter region of BRCA1 gene. Association between methylation and clinico-pathological features was evaluated using statistical tests with SPSS.
Results and conclusion: Preliminary analysis showed a big percentage of cases with BRCA1 methylation with an inverse relationship between C-KIT gene expression and BRCA1 methylation (p=0.017).
Our results show that BRCA1 promoter is an important mechanism of BRCA1 gene silencing in sporadic triple-negative breast cancer.

Breast cancer, IL6 gene polymorphism and infection with Torque teno virus: a pilot association study

S. Spandole[1], *D. Cimponeriu*[1], *M. Toma*[1], *M. Stavarachi*[1], *P. Apostol*[1], *I. Radu*[1], *G. Mihaescu*[2];
[1]*Department of Genetics, University of Bucharest, Bucharest, Romania,* [2]*Department of Microbiology, University of Bucharest, Bucharest, Romania.*

Inflammation leads to dysplasia and was associated with cancer development.
The -174C allele of interleukin 6 -174G>C gene polymorphism is assumed to confer breast cancer risk. Torque teno virus (TTV) was proven to increase production of IL6.
The aim of this study was to assess if the combination of IL6-174G>C genotypes and TTV infection represents a risk factor for breast cancer.
Blood samples were collected from 200 subjects (100 breast cancer patients and 100 healthy controls). Subsequent to total DNA extraction, genotyping of IL6 polymorphism and presence of TTV were assessed with PCR based methods.
IL6-174G>C genotype distribution respected the Hardy-Weinberg equilibrium (p>0.05). The IL6-174CC genotype was more frequent in cancer patients (p=0.7). In our study, the presence of the C allele was not associated with breast cancer (p=1.7).
The average prevalence of TTV was 77%, with a significantly higher value in cancer patients (p=0.001; OR=0.3). The presence of C allele was not associated with TTV infection (p=0.3) when both cohorts were analyzed. However, cancer patients carriers of C allele were prone to TTV infection (p=0.01).
TTV was more prevalent in cancer patients. Our results disagreed with other studies that reported IL6-174C allele as a risk factor for breast cancer. Nevertheless, the combination of IL6-174C allele and infection with TTV showed a modest association with breast cancer in our cohort.

P11.055

Genetic heterogeneity of amplification of ERBB2 status in breast invasive carcinoma with 2+ HER2 immunostaining:a challenge for genetic scoring.

A. VALENT, *M. Ferchiou, S. Delaloge, N. Auger, V. Koubi-Pick, M. Mathieu, A. Bernheim; Institut Gustave Roussy, Villejuif, France.*

The genetic heterogeneity of *ERBB2* gene amplification (GA) in breast cancer has previously been described, but its clinical significance remains unknown. We studied the genetic categories of a series of consecutive 4491 invasive breast carcinomas 2+ IHC, with a focus on cases with *ERBB2* GA detected in minor clone(s). We compared the *ERBB2* status in primary tumors and positive axillary lymph nodes (ALN) to test the hypothesis that HER2 amplified cells are more aggressive and metastase quicker than non amplified cells. Heterogeneous amplification was defined as the presence of 5-50% of amplified cells (ratio>2,2) within the tumors otherwise classified as not amplified or borderline.
The genetic heterogeneity of IHC 2+ tumors is a common event. FISH can classify these tumors into 5 genetic categories (monosomy, disomy, polysomy, ERBB2 gain and GA). 48 cases (10% of 2+ cases) declared as negative cases contained one or several *ERBB2* amplified clones. All types of clones (amplified and not amplified) have a metastatic capacity. We continue our work in collaboration to:
1) Find out a proportion of such patients in HER2 IHC 2+ group in other hospitals
2) Study a status of the gene in relapsed cases
Institut Gustave Roussy Guidelines for *ERBB2* FISH heterogeneous and difficult cases will be proposed in order to help to analyse the breast cancers and reach accurate conclusions.

Genetic polymorphisms and breast cancer risk

D. Fernández García[1], *E. Sánchez Tapia*[1], *T. Martín Gómez*[2], *R. Vidal Tocino*[2], *J. Cruz Hernández*[1,2], *R. González Sarmiento*[1,3];
[1]*Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Servicio de Oncología, Hospital Universitario, Salamanca, Spain,* [3]*Unidad de Medicina Molecular-Departamento de Medicina, Salamanca, Spain.*

Breast cancer risk in BRCA1/2 mutations carriers appears to be modified by different genetic or environmental factors. GWAS (genome-wide association studies) identified genome regions that contain SNPs that appear to be associated with breast cancer risk in high penetrance genes mutation carriers. Specific variations in this regions act as risk modifiers, however their mechanisms of action remain unknown.
The aim of the study was to determine if genetic variants could be associated with different phenotypes of cancer, segregated in function the presence/absence of BRCA mutations and whether risk modification by these genetic variants is associated to immunohistochemical characteristics.
Genomic DNA was extracted from peripheral blood by standard techniques. We selected 8 non-synonymous SNPs that are involved in risks modification. Studies were performed using TaqMan probes for the analysis of polymorphisms: rs2981582 (FGFR2), rs13281615 (8q24 region), rs2910164 (miR146), rs799917 (BRCA1), rs1042522 (TP53), rs16941 (BRCA1), rs16942 (BRCA1) and rs2279744 (MDM2).
Allelic distribution were studied in three group of patients: Familiar breast cancer patients with BRCA mutation, breast cancer patients without BRCA mutation and less than 3 relatives affected, and breast cancer patients without BRCA mutation and 3 or more relatives affected. Statistical analysis was performed using SPSS.
Preliminary analysis showed a strong association between rs2981582 and BRCA mutation carriers, the association of rs2910164 with breast cancer incidence according to age, and association of rs799917 with breast cancer incidence according to presence/absence of hormonal receptors. These results support the hypothesis that SNPs in high penetrance genes mutation carriers could act as risk modifiers.

P11.057

Determining a role for germline mutations in genes associated with an intermediate risk for breast cancer in the Belgian population

K. De Leeneer, *A. Dejaegher, W. Vermeesch, P. Schietecatte, J. Vandenhaute, F. Malfait, T. Van Maerken, B. Poppe, K. Claes;*
Center for Medical Genetics, Ghent University Hospital, Gent, Belgium.

In our patient population *BRCA1&2* germline mutations are identified in less than 15% of patients referred for genetic testing. In this study we evaluated the mutation prevalence of *PALB2* and *ATM* mutations in *BRCA1/2* mutation negative families referred for genetic testing.
We screened the complete UTR, coding and splice site regions of these genes with high resolution melting curve analysis followed by Sanger sequencing of the aberrant melting curves. *In silico* predictions of variants with an unclear clinical significance was performed with the Alamut software.
We identified 10 mutations predicted to lead to a premature stop codon or to affect splice sites: 4 *PALB2* mutations in 357 unrelated patients (1.1%) and 6 *ATM* mutations in 190 unrelated patients (3.2%). In case more family members were available, we confirmed segregation of the mutation with the disease. In addition, we detected 11 missense variants (4 in *PALB2* and 7 in *ATM*), which may also affect protein function, based on *in silico* prediction programs. Deleterious *PALB2* and *ATM* mutations were exclusively identified in familial and not in sporadic cases with early onset or bilateral breast cancer. Interestingly, the average age at diagnosis for the *PALB2* (62y; range 48-71) mutation carriers was higher compared to the average age at diagnosis of the *ATM* carriers (44y, range: 33-66) and the non carriers (39y, range: 25-78).
Cancer prevention guidelines have not been established for *PALB2* or *ATM* heterozygous carriers. Currently screening schedules are based on family history of breast cancer.

[1]*IBGM, Valladolid, Spain,* [2]*CIC, Salamanca, Spain,* [3]*CNIO, Madrid, Spain,* [4]*Complejo Hospitalario de Burgos, Burgos, Spain,* [5]*ICO-IDIBELL, L'Hospitalet de Llobregat (Barcelona), Spain,* [6]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* [7]*Hospital Clínico San Carlos, Madrid, Spain,* [8]*Hospital La Fe, Valencia, Spain,* [9]*VHIO, Barcelona, Spain,* [10]*Hospital de Cruces, Barakaldo (Bizkaia), Spain,* [11]*Hospital Clínico Lozano Blesa, Zaragoza, Spain,* [12]*ICO-IDIBELL, L'Hospitalet de Llobregat (Barcelona), Spain.*

BRCA2-c.2808_2811delACAA is one of the most reported germline mutations in non-Ashkenazi breast/ovarian cancer patients. We aimed to investigate its genetic origin in Spanish carrier families.
Mutation carriers of 51 families were genotyped with seven microsatellites and four intragenic *BRCA2* SNPs. Mutation age was calculated with the DMLE software. DNA secondary structure was predicted with Quikfold. Random mutagenesis experiments were performed over a 923-bp fragment of *BRCA2*.
Three independent founder haplotypes associated with c.2808_2811delACAA were clearly distinguished that accounted for 23 families (West Castilla y León/WCL), 20 families (East Castilla y León/ECL) and 6 families (South of Spain). Mutation age was estimated in a range of 45-68 and 45-71 generations for WCL and ECL haplotypes, respectively. The most prevalent variants of this DNA region, c.2808_2811delACAA and c.2803G>A, were located in a double-hairpin loop structure (c.2794-c.2825) that was proposed as a candidate mutational hotspot. To check this hypothesis, random mutagenesis was performed and a total of 86 DNA variants were characterized. Interestingly, three mutations reported in the mutation databases (c.2680G>A, c.2944delA and c.2957dup) were replicated in this experiment and 20 affected the same position with different nucleotide changes. Moreover, five variants were placed in the same hairpin-loop of c.2808_2811delACAA, and one of them (c.2808A>G) affected the same position.
Our results support that at least three different mutational events occurred to generate this mutation. A relevant fraction of DNA variants, including *BRCA1*-c.68_69delAG and *BRCA2*-c.5946delT and c.8537delAG, are preferentially concentrated in predicted hairpin-loops suggesting that these structures may represent mutational hotspots.

P11.059

A high rate of mutations is identified in a single exon of the *CHEK2* gene in Greek breast/ovarian patients

F. Fostira[1], ***P. Apostolou***[1], *A. Stavropoulou*[1], *I. Konstanta*[1], *A. Vratimos*[1], *I. Konstantopoulou*[1], *G. Fountzilas*[2], *D. Yannoukakos*[1];
[1]*NSCR Demokritos, Athens, Greece,* [2]*Aristotle University of Thessaloniki, Thessaloniki, Greece.*

CHEK2 gene encodes for a cell cycle checkpoint kinase that is activated by ATM in response to DNA damage and interacts with and phosphorylates BRCA1 and influences its role in DNA repair pathway by homologous recombination.
Certain mutations in CHEK2 are associated with increased risk of breast cancer in women, while 80% of CHEK2-associated breast cancers are ER and PR positive.
The aim of this study is to elucidate CHEK2 breast cancer susceptibility in Greek breast/ovarian patients.
We analyzed, 466 women with breast/ovarian cancer diagnosed with synchronous or metachronous cancer, or having at least one family relative diagnosed with breast and/or ovarian cancer and 223 women diagnosed with early onset breast/ovarian cancer (<45 years). All patients have been previously tested negative for BRCA1 founder and recurrent mutations.
Missense and loss-of function mutations were detected in 17/466 (3.6%, mean age 42,2 years) patients previously reported with family history and in 10/223 (4.85%, mean age 34,7 years) of early onset breast cancer patients. Remarkably, all the identified variants were located on exon 3 of the gene.
The present study demonstrates the existence of a large proportion of CHEK2 mutations within breast/ovarian cancer patients in Greece, all of which identified in exon 3. Women with early-onset breast/ovarian cancer should be considered for CHEK2 mutation testing, after a negative BRCA1 and BRCA2 result.
This research has been co-financed by theESF and Greek national funds through the Operational Program „Education and Lifelong Learning" of the NSRF - Research Funding Program of the GSRT: THALIS.

Identification of tumor microRNAS in plasma samples from hereditary breast cancer patients

K. Yanowsky[1], *N. Matamala*[1], *M. Tanic*[1], *I. Marquez-Rodas*[2], *A. Barroso*[1], *V. Fernandez*[1], *J. Benitez*[1], ***B. Martinez-Delgado***[3];
[1]*Spanish National Cancer Research Centre (CNIO), Madrid, Spain,* [2]*Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain,* [3]*Instituto de Salud Carlos III, Majadahonda, Madrid, Spain.*

There is increasing evidence that microRNAs (miRNAs) may be good biomarkers for diagnosis, prognosis or monitoring of various diseases. It has been observed that miRNAs are present in detectable levels in a variety of body fluids, and it has been shown that serum/plasma miRNAs are stable and resistant to degradation. We analyzed the expression of miRNAs in plasma samples from patients with hereditary breast cancer compared to the expression in blood plasma of healthy women to establish their role as disease markers with diagnostic utility.
Based on miRNA expression profile data of hereditary tumors previously set by microarray analysis, 19 miRNAs were selected because they were globally expressed at high levels in tumors, to study their presence in plasma of breast cancer patients. Expression in tumors was previously validated by quantitative PCR.
RNA from plasma samples was extracted (miRNeasy kit, Quiagen) in 20 women with hereditary cancer (BRCA1, BRCA2 and BRCAX) and 20 female controls. The expression level of the 19 tumoral miRNAs, 3 control serum miRNAs, 2 interplate calibrators, were analyzed by quantitative PCR (qPCR), using a customized designed Pick&Mix specific panel (Exiqon), and the detection system of miRNAs from Exiqon (LNA miRCURY miRNAs Universal RT PCR).
We were able to identify significant increased expression of 4 tumor specific miRNAs in plasma samples of women with breast cancer, compared to the control samples ($p<0.05$).

The detection of tumor-specific miRNAs in plasma support them as promising noninvasive biomarker with potential utility in the diagnosis or monitoring of these tumors.

P11.061
The common missense polymorphism rs2229742 in NRIP1 is associated with non-BRCA hereditary breast cancer risk

*A. Desrichard[1], A. Castet-Nicolas[2,3], A. Boulahtouf[2], Y. Bignon[1,4], V. Cavaillès[2], **N. Uhrhammer**[4];*
[1]Université d'Auvergne, EA 4677 ERTICa, Clermont-Ferrand, France, [2]IRCM, Institut de Recherche en Cancérologie de Montpellier, Montpellier, F-34298, Montpellier, France, [3]CHU Montpellier, Hôpital Lapeyronie, Pharmacie, Montpellier, France, [4]Centre Jean Perrin, Département d'Oncogénétique, Clermont-Ferrand, France.

Non *BRCA1* or *BRCA2* related hereditary breast cancer (HBC) represents 80-85% of all HBC families. Increasing evidence highlights the contribution of low-risk variants such as common polymorphisms to a polygenic HBC model. Many of the genes involved are related to either DNA repair or hormone metabolism. Several studies have suggested that a common polymorphism in the *NRIP1* gene, Arg448Gly (c.1342C>G; rs2229742) might be associated with pathologies involving estrogen signaling. In this case/control study, we investigated the contribution of this variant in 159 non-*BRCA* HBC cases and 416 unaffected controls. The frequency of the G allele (Gly448) was significantly higher in cases compared to controls (16.0% *vs* 9.7%; p = 0.0024). The risk of breast cancer increased in carriers of at least one copy of this allele (p < 0.001; 95% CI, 1.33-3.05) with an OR of 1.79 (95% CI, 1.23-2.61). Functional tests confirmed that the Gly448 variant reduced the intrinsic transrepression activity of the central NRIP1 repressive domain. Altogether, our data indicate that *NRIP1* Arg448Gly might influence the risk of HBC in the absence of *BRCA* mutations.

P11.062
Comprehensive and rapid approach detects the most frequent BRCA1 and BRCA2 mutations in Slovak HBOC population

***M. Konecny**, K. Zavodna, Z. Bartosova;*
Department of Clinical Genetics, St. Elizabeth Cancer Institute, Bratislava, Slovakia.

Detection of germline mutations in BRCA1/2 genes represents, according to many facts (e.g. lack of mutational hot spots, several types of mutations, genomic rearrangements, size and number of exons) serious methodical problem. Complex analysis of both genes by direct sequencing is also time-consuming and financially demanding and even after all this effort, approximately 70% of families remains negative for the presence of any causal mutation.
Here we describe a rapid and comprehensive approach for the detection of most frequent mutations in BRCA1 and BRCA2 genes in Slovak HBOC population. Currently, we are able to detect 77% of all BRCA1/2 mutations detected in our population, namely 13 mutations in BRCA1 (c.68_69delAG, c.181T>G, c.1938_1947del10, c.1953_1956del4, c.2068delA, c.2921T>A, c.3016_3019del4, c.3018_3021del4, c.3700_3704del5, c.3770_3771del2, c.4065_4068del4, c.4243delG, c.5266dupC) and 4 different mutations in BRCA2 gene (c.3076A>T, c.5645C>A, c.9098dupA, c.9403delC).
Altogether, methodology comprises only 3 multiplex PCR reactions, 2 of which serve as PCR templates for SNaPshot PCR and third is a multiplex fluorescently-labeled PCR. SNaPshot PCR analysis detects selected point mutations (substitutions as well as 1-2 bp deletions/insertions) and the fluorescently-labeled PCR detects frame-shift mutations in three large regions of exon 11 of BRCA1 gene.
This approach allows us to pre-screen all the samples, assign preliminary results and finally, in the case of mutation carriers, apply a preventive management to specific patients as soon as possible. This method represents very time and financially efficient approach with relevant sensitivity (77% of all HBOC positive families), which can be offered to a broad spectrum of women.

P11.063
Pharmacogenomic assessment of outcomes of cisplatin-based chemotherapy in ovarian cancer patients

***A. V. Khrunin**[1], D. V. Khokhrin[1], A. A. Moisseev[2], V. A. Gorbunova[2], S. A. Limborska[1];*
[1]Institute of Molecular Genetics, Russian Academy of Sciences, Moscow, Russian Federation, [2]N.N. Blokhin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation.

Background: Platinum drugs are among the most active and widely used chemotherapeutic agents. However, their effective clinical use is impeded by significant variations in both the response rate and the rate of adverse reactions and requires the identification of genetic markers that can be used to screen patients before treatment. Here, we have evaluated the associations between polymorphisms in approximately 100 genes, involved mainly in drug metabolism, DNA repair, cell cycle and apoptosis, and outcomes in ovarian cancer patients receiving cisplatin-cyclophosphamide chemotherapy. **Methods:** DNA was isolated from blood samples of 104 patients by proteinase K treatment. 228 single nucleotide polymorphisms were genotyped using the arrayed primer extension technology. Correlations between the polymorphisms and survival were assessed using the Kaplan-Meier product limit method and the log-rank test and $\chi 2$ test. To evaluate the associations between the genotypes and treatment toxicity, patients were classified as having good or poor tolerance. **Results:** SNPs in *GSTP1*, *TPMT*, *NQO1*, *COMT* and *GRPR* genes were significantly associated with progression free survival. Polymorphisms in *NAT2*, *GSTA4*, *GSTM3* and *CCNH* genes were associated with anemia. SNPs in *ERCC5*, *RAD52*, *MUTYH* and *LIG3* genes correlated with the occurrence of severe neutropenia. Thrombocytopenia, emesis, nephrotoxicity and neurotoxicity were associated with SNPs in *MSH3*, *MSH6*, *EPHX1* and *CYP1A1* genes, respectively. SNP in *ADH1C* gene correlated with complete tumor response. **Conclusions:** The obtained results suggest that polymorphisms in different genes involved in drug metabolism can be important in distinguishing subgroups of cancer patients who would have benefit from cisplatin-based treatment.

P11.064
RAD51D germline mutations in Greek ovarian cancer patients

*A. V. Stavropoulou, **I. Konstanta**, F. Fostira, P. Apostolou, A. Vratimos, I. Konstantopoulou, D. Yannoukakos;*
NCSR Demokritos, Athens, Greece.

Ovarian carcinoma is the most common cause of cancer death from gynecologic tumors. One in four ovarian cancer cases is now known to be attributed to germline mutations in at least 16 genes. Germline mutations in the BRCA1 and BRCA2 genes contribute to approximately 18% of hereditary ovarian cancers, 1% is associated with deleterious mutations in MMR genes, while 5% is associated with other genes of the Fanconi Anemia- BRCA DNA repair pathway.
Recent studies have shown that 0.8-0.9% of BRCA1 and BRCA2-negative ovarian cancer cases are positive for loss-of-function mutations in RAD51D. The aim of this study was to identify the prevalence of RAD51D mutations in Greek ovarian cancer patients, both in familial and sporadic cases that were previously found negative for the most common BRCA1 mutations. Subsequent analysis of the full BRCA1 gene in familial cases did not identify any mutations. We thus sequenced the full coding sequence and intron-exon boundaries of RAD51D in 235 sporadic and 60 familial cases. We identified one deleterious mutation and two probably damaging unclassified variants. The present data provide the first evidence for the existence of RAD51D mutations in hereditary ovarian cancers in Greece. Women with ovarian cancer should be considered for RAD51D gene testing after a BRCA1-BRCA2 negative test result, irrespective of ovarian cancer family history, or age at diagnosis.This research has been co-financed by the European Union (ESF) and Greek national funds through the Operational Program „Education and Lifelong Learning" of the NSRF - Research Funding Program of the GSRT: ARISTEIA.

Non-epithelial ovarian (NEO) tumours make up 10% of all primary ovarian cancers. They include germ cell tumours (GCTs), sex cord-stromal tumours (SCSTs), and other rare tumours. GCTs include dysgerminomas, embryonal carcinomas, yolk sac tumours, teratomas, and mixed GCTs. SCSTs represent 3-5% of ovarian malignancies and include granulosa cell tumours and Sertoli-Leydig cell tumours (SLCTs). SLCTs and juvenile granulosa cell tumours, like GCTs, usually occur in younger women.

DICER1 is involved in cleavage of dsRNA to miRNA. Somatic mutations in the *DICER1* gene have been found in various types of NEO tumours, specifically around the RNase IIIb domain metal-binding sites. These mutations reduce the number of miRNAs from 5p strands, leaving those from 3p strands to target mRNAs. Given that recent reports and unpublished data (Foulkes lab) suggest that deleterious somatic mutations outside of RNase III are uncommon, we focused on the RNase III domain. We have sequenced the RNase III regions of *DICER1* in 184 cases of NEO tumours, and 32 samples of lymphocyte DNA from affected patients (Tables below). Our study confirms that somatic mutations in *DICER1* are frequent in Sertoli-Leydig cell tumours (SLCTs) and could represent a therapeutic target. They are uncommon in other types of NEO tumours.

Table 1. Mutations found and Number of Samples Analyzed

Tumour Type	Mutations found/ Total Tumour Samples	Mutations found/ Total Lymphocyte DNA Samples
GCT		
Dysgerminoma (5 cases of Gonadoblastoma)	1/55	0/4
Mixed GCT	1/18	0/9
Yolk Sac Tumour	2/40	0/3
Embryonal Carcinoma	0/2	-
Immature Teratoma	0/29	0/5
Mature Teratoma	0/21	0/10
SCST		
Juvenile Granulosa Cell Tumour	0/2	-
SLCT	7/14	0/1
Unclassified SCST	0/3	-
Total	**11/184**	**0/32**

Table 2. Mutations found in *DICER1* RNase IIIb region

Tumour Type	Codon Change	Predicted Effect
Gonadoblastoma/Dysgerminoma	c.5429 A>G	Exon 25 Skip
Yolk Sac Tumour	c.5428 G>T	Cryptic Splice site
Yolk Sac Tumour	c.5438 A>G	Exon 25 Skip

P11.066

C1orf24 is negatively regulated by miR-106b-5p in thyroid tumorigenesis process.

***G. M. G. Carvalheira**, B. H. N. Nozima, J. M. Cerutti;*
UNIFESP, São Paulo, Brazil.

We have previously shown that the *C1orf24* geneis highly expressed in follicular thyroid carcinomas while is not expressed in benign lesions. However, little is known about the molecular mechanism involved in *C1orf24* expression. It is widely demonstrated that microRNAs (miRs) are potent regulators of gene expression. The miRs expression varies in according of tissue, development stage, and tumor types. In this study, employing three algorithms (miRBase targets, TargetScan and microRNA.org) we identified miR-17-5p and miR-106b as potential candidates to regulate the expression of *C1orf24*. We initially investigated the expression of miR-17-5p and miR-106b in 64 thyroid lesions by qPCR. Although both miRs showed lower expression in thyroid carcinomas, compared to benign lesions, the difference was considered statistically significant only for miR-106b ($p<0,01$). Then, miR106b was transiently transfected into the follicular thyroid carcinoma cell line (WRO). Ectopic expression of miR106b inhibited *C1orf24* mRNA and protein in WRO cells, when compared to negative control. To show that miR-106b directly interacts with *C1orf24* mRNA at 3' UTR, we then transfected PCCL3 cells with both *C1orf24* 3'-UTR mRNA wild type and mutated. We observed that miR-106b directly interacts with *C1orf24*. Our findings indicate that miR-106 acts as tumor suppressor gene and plays a role in thyroid carcinogenesis, at least in part by negatively regulating *C1orf24* expression. However, further analysis is needed to fully demonstrate the role of miR-106b in regulating *C1orf24* expression and, therefore, its role on thyroid carcinogenesis.

P11.067

A European OncoNetwork Consortium study to develop Ion AmpliSeq™ Colon and Lung Cancer Panel to detect most frequent somatic CRC or NSCLC mutations on FFPE samples.

*K. Henriette[1], E. Amato[2], D. Le Corre[3], A. Rachiglio[4], B. Tops[5], A. Mafficini[6], A. Reiman[7], O. Sheils[8], C. Noppen[1], I. Cree[7], M. Ligtenberg[5], N. Normanno[4], A. Scarpa[2], P. Laurent Puig[3], **L. Lacroix**[9];*
[1]VIOLLIER AG, Basel, Switzerland, [2]ARC-NET University of Verona, Verona, Italy, [3]Université Paris Descartes, Paris, France, [4]Centro Ricerche Oncologiche Mercogliano, Mercogliano, Italy, [5]Institut GustaveUniversitair Medisch Centrum St Radboud, Nijmegen, Netherlands, [6]2 ARC-NET University of Verona, Verona, Italy, [7]Warwick Medical School, Coventry, United Kingdom, [8]Trinity College Dublin, Dublin, Ireland, [9]Institut Gustave Roussy, Villejuif, France.

Several somatic mutations have been associated with therapeutic benefit in CRC or NSCLC. Thus, there is a need for simultaneous screening of multiple targetable gene mutations using small amounts of DNA. The OncoNetwork Consortium made up of 8 European Cancer Translational Research Labs developed an approach to identify hotspot mutations in 22 CRC or NSCLC related genes using IonAmpliSeq™ technology. The analyses were performed using the IonAmpliSeq™ workflow, with 10 ng of DNA amplified in a single multiplex PCR. Sequencing was carried out with the PGM™ Sequencer on Ion316 chip (8 samples per chip) and results were analyzed using the IonReporter™ Software. In phase 1, all labs tested the same 5 control FFPE samples. In phase 2, each lab sent 10 characterized FFPE samples for blind analysis by another lab. In phase 3, each lab tested 15 of their own FFPE samples. A total of 140 unique FFPE samples were screened. Overall, the percentage of on target reads was greater than 85 % with an average per base accuracy >98%. The 6 labs that completed all phases confirmed detection of all expected variants in both controls and blind samples, corresponding to a 100% true positive rate. For example, a sample of phase 3 with low allele frequency had a mean coverage of 6119, allowing detection of KRAS-G12D variant at 2%. The Ion AmpliSeq™ Colon and Lung Cancer Panel allows fast, highly sensitive and reproducible detection of frequent mutations from only 10ng of DNA from FFPE CRC or NSCLC samples.

Prognostic significance of IDH1 mutations and 1p/19q co-deletion in patients with gliomas

***G. Stancheva**[1,2], T. Goranova[2], M. Laleva[3], S. Petkova[2], M. Kamenova[4], A. Mitkova[1,2], N. Velinov[3], R. Kaneva[1,2], G. Poptodorov[3], V. Mitev[1,2], N. Gabrovsky[3];*
[1]Department of Medical Chemistry and Biochemistry, Medical University-Sofia, Sofia, Bulgaria, [2]Molecular Medicine Center, Medical University-Sofia, Sofia, Bulgaria, [3]Department of Neurosurgery, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria, [4]Department of Pathology, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria.

Background:

Somatic mutations in IDH1, which encodes cytoplasmic isocitrate dehydrogenase 1, were reported to occur at high frequency in glial tumours. In astrocytomas these aberrations are commonly found together with loss of 1p and/or 19q. Chromosomal co-deletion of the short arm of chromosome 1(1p) and the long arm of chromosome 19(19q) are found most frequent in oligodendrogliomas. Both events, separately or combined, are associated with favourable prognosis and improved overall survival not only in oligodendrogliomas, but also in astrocytomas even though they are rarer in astrocytic tumours.

Methods:

We screened 65 gliomas (astrocytomas and oligodendrogliomas) by direct

sequencing of exon 4 of IDH1 gene and MLPA analysis of large genomic deletions within chromosome 1p and 19q performed using SALSA MLPA kit P088.
Results:
IDH1 abberations were found in 25 (38%) glial tumours of WHO grade II, III and IV. In 24 patients mutations were at position 395 causing amino acid substitution R132H and in one -amino acid substitution R132L. Mutations in IDH1 were associated with better overall survival (median survival 22.9 months vs. 9.1 in non-mutated cases; p=0.006). MLPA analysis showed loss of 1p and/or 19q in 28% of cases but no significant association with the overall survival of patients. However, the combination of 1p/19q co-deletion and IDH1 mutations were associated with increased overall survival (p=0.002).
Conclusion:
Our results indicate that IDH1 mutations combined with chromosomal co-deletions of 1p and/or 19q identify gliomas with better survival and may be used as specific prognostic biomarkers in patients with gliomas.

P11.069

A Functional Variant, rs967591G>A, in the 19q13.3 and Survival of Early-Stage Lung Cancer

H. Jeon, *M. Hong, H. Kang, Y. Choi, J. Choi, S. Do, J. Park;*
Kyungpook National University, Deagu, Korea, Republic of.

To define the causative functional SNP of the association, this study was conducted to investigate the associations between single nucleotide polymorphisms (SNPs) in 19q13.3 and survival of early-stage non-small cell lung cancer (NSCLC) patients.
A two-stage study design was used to evaluate five SNPs in relation to survival outcomes in 328 patients and then to validate the results in an independent patient population (n= 483). Luciferase assay and real-time PCR was performed to examine functional relevance of a potentially functional SNP. Of the five SNPs, three SNPs (rs105165C>T, rs967591G>A and rs735482A>C) were significantly associated with survival outcomes in a stage 1 study. The rs967591A allele had significantly higher promoter activity of *CD3EAP* compared with the rs967591G allele (*P* = 0.002), but the SNP did not have an effect on the promoter activity of *PPP1R13L* in promoter assay. The rs967591G>A was associated with the level of *CD3EAP* mRNA expression in lung tissues (*P* = 0.01). The rs967591G>A exhibited consistent associations in a stage 2 study. In combined analysis, the rs967591 AA genotype exhibited a worse overall survival (adjusted hazard ratio = 1.69, 95% confidence interval = 1.29-2.20, *P* = 0.0001). The rs967591G>A affects *CD3EAP* expression and thus
influences survival in early-stage NSCLC. The analysis of the rs967591G>A polymorphism can help identify patients at high risk of a poor disease outcome.

Background: Germline mutations in the *CDH1* gene are associated with hereditary diffuse gastric cancer. Large rearrangements in *CDH1* are now being reported as well. Because *CDH1* mutations can be associated with breast cancer, rearrangements could also impact susceptibility for this disease.
Methods: A zoom-in CGH array that covered exonic, intronic and flanking regions of the *CDH1* gene was used to screen a cohort of 148 *BRCA1/2* negative probands. *CDH1* intron 2, including several regulatory regions, was specifically targeted. Real-time RT-PCR has been used to assess *CDH1* expression in related lymphoblastoid cell line and also in breast tumors.
Results: Two large rearrangements of *CDH1* exon 3 causing a premature stop were detected. In both families, screened also for *BRCA1/2*, lobular breast and gastric cancers were reported. Two large rearrangements within intron 2, a deletion and a duplication, were also reported in probands with breast cancer and without any familial gastric cancer. Recurrent duplication copy number variations are found in this region. The deletion encompasses an expressed sequence tag and resulted in *CDH1* RNA downregulation. Two novel transcripts starting at the deleted region were characterized.
Conclusion: No germline rearrangements in the *CDH1* coding region were detected in families without gastric cancer and with a broad range of breast cancer susceptibility. This study confirms the diversity of large rearrangements in *CDH1*. The intron 2 deletion highlights a putative role for intron 2 in *CDH1* regulation. The four herein described *CDH1* rearrangements involving intron 2 could modulate the risk of breast cancer.

Genome-wide association study identifies multiple loci for cervical cancer

U. Gyllensten, *D. Chen, I. Juko-Percipep, E. Wilander, S. Enroth, S. Enroth, I. Gustavsson;*
Uppsala University, Dept of Immunology, Genetics, Pathology, Uppsala, Sweden.

Cervical cancer is caused by infection with human papillomavirus (HPV). Our understanding of the genetic basis of cervical cancer is still limited. We performed the first genome-wide association study (GWAS) by analyzing 731,422 single nucleotide polymorphisms (SNPs) in 1,075 cervical cancer cases and 4,014 controls, followed by replication in 1,140 cases and 1,058 controls. Three independent loci in the major histocompatibility complex (MHC) region at 6p21.3 were identified to be associated with cervical cancer; the first is adjacent to the MHC class I polypeptide-related sequence A gene (MICA) (rs2516448, odds ratio [OR]=1.42, Pcombined=1.6×10-18), the second is between HLA-DRB1 and HLA-DQA1 (rs9272143, OR=0.67, P-combined=9.3×10-24) and the third at HLA-DPB2 (rs3117027, OR=1.25, P-combined=4.9×10-8). Using imputed alleles at classic human leukocyte antigen (HLA) loci we confirmed previously reported associations of B*0702 and DRB1*1501-DQB1*0602 with susceptibility (OR=1.42, P=7.9×10-8; OR=1.39, P=3.8×10-7, respectively) and DRB1*1301-DQA1*0103-DQB1*0603 with protection (OR=0.47, P=8.8×10-10). However, none of them can account for the effects of the three novel loci. The nature of the new loci and their effect on the susceptibility will be discussed. The results demonstrate the presence of additional loci in the MHC region with a stronger effect on the disease susceptibility than those previously identified.

P11.072

Mitochondrial (mt)DNA D-loop region SNPs in human papillomavirus-related cervical neoplasia

C. D. Rusanu[1], *A. Botezatu*[2], *I. Iancu*[2], *I. Huica*[2], *G. Anton*[2];
[1]*Ixia Medica Research Centre, Bucharest, Romania,* [2]*Stefan S Nicolau Institute of Virology, Bucharest, Romania.*

Cervical cancer is the second most common malignant neoplasm in women and high risk human papillomavirus (hr-HPV) is known to be its etiological agent. On the other hand, alterations in the non-coding displacement (D) loop mtDNA are present in many cancers, suggesting that the extent of mtDNA mutations might be useful in the prognosis of cancer outcome.
In order to evaluate the role of T239C, A263G, C150T, T16189C and C16223T mtDNA polymorphisms in cervical lesions, 60 cervical specimens were investigated. Isolated DNAs from cervical cells were tested for HPV presence. TaqMan SNP Genotyping Assays were used for SNP detection.
In patients with normal cytology and ASCUS (Atypical Squamous Cells of Undetermined Significance), hrHPV was absent. 72.2% (13/18) LGSIL (Low-Grade Intraepithelial Lesion) and 93.3% (14/15) HGSIL (High-Grade Intraepithelial Lesion) patients presented infection with hrHPV in single or

co-infection represented mainly by HPV16,18,31 and 33. We detected a significantly greater incidence of mtDNA polymorphisms T239C, A263G and C150T and a lower incidence of T16189C, C16223T in cervical lesions. C150T and T239C polymorphisms were corelated with hrHPV-positive LGSIL and HGSIL lesions (P<0.05). HPV-positive individuals were more likely to carry the C150T, A263G and T16189C polymorphisms than HPV-negative controls (P<0.003). A positive corelation between HPV-positive HGSIL patients and A263G SNP was found. In all cancer subjects, an increased risk of HPV infection was associated with the selected polymorphisms.
These findings suggest that mitochondrial SNPs in the D-loop region may represent a cofactor in HPV-induced neoplasia but their carcinogenesis mechanism remains to be solved.

Molecular cytogenetic analyses of *hTERC* (3q26) and *MYCC* (8q24) genes amplifications in 30 patients with cervical carcinomas: correlations with clinical outcome

P. Kuglik[1], *V. Vallová*[1], *K. Kašíková*[1], *A. Laštůvková*[1], *H. Filková*[2], *L. Mouková*[3];
[1]*Laboratory of Molecular Cytogenetics, Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic,* [2]*Department of Medical Genetics, University Hospital, Brno, Czech Republic,* [3]*Department of Gynaecological Oncology, Masaryk Memorial Cancer Institute, Brno, Czech Republic.*

Cervical cancer remains one of the most common malignancies among women worldwide in both incidence and mortality. Although infection of high-risk human papilloma virus (HPV) is recognized as an essential initiating event in cervical tumorigenesis, this alone is not sufficient for the progression to invasive cancer. Some chromosomal aberrations have been associated with the progression of CIN to carcinoma, especially the amplification of *hTERC* (3q26) and *MYCC* (8q24) genes.
In this study, tumour samples of patients with cervical spino- or adenocarcinoma (stage IA-IVA) were studied using fluorescence in situ hybridization with the Cervical FISH Probe Kit and Agilent 244K or 180 K microarray. The results of molecular cytogenetic analyses were compared with clinical findings.
HPV infection was proven in 97 % (29/30) of patients, *hTERC* copy number changes were found in 26 from 30 patients (87 %). *hTERC* alteration were detected in 3/4 patients with IA, in 17/19 patients with IB, in all 5 patients with IIIB and in 1/2 patients with IVA TNM stage. Copy number changes of *MYCC* gene were found in 18/30 patients (60 %); in 1/4 patient with IA, 14/19 patients with IB, 2/5 patients with IIIB, and in 1/2 patient with IVA TNM stage.
No single amplification of *MYCC* was detected. Twelve patients with carcinoma were positive for lymfangioinvasion. All patients were in high risk group and had amplification of *hTERC* gene. In 13 cases, array CGH profiling revealed additional genomic alterations associated with the progression of cervical carcinoma.

Evaluation of circulating DNA as an alternative marker in multimodal care for patients with advanced colorectal cancer

L. Benesova[1], *B. Belsanova*[1], *J. Pudil*[2], *F. Pazdirek*[3], *D. Langer*[2], *J. Hoch*[3], *M. Ryska*[2], *M. Minarik*[1];
[1]*Genomac research institute, Prague, Czech Republic,* [2]*Surgical Clinic, 2nd Faculty of Medicine, Charles University in Prague and Military University Hospital, Prague, Czech Republic,* [3]*Department of Surgery, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, Prague, Czech Republic.*

Background: A presence of circulating cell-free DNA (cfDNA) has long been observed in patients with advanced colorectal cancer. It is expected that cfDNA may represent a useful biomarker, especially for monitoring course of therapy.
Aim: The main purpose of this work was to evaluate a feasibility of using cfDNA in process of monitoring patients with progressive colorectal cancer, namely the follow-up after the surgery and in between chemotherapy cycles.
Methods: A total of 21 patients in advanced stages (III and IV) were included in the study. Peripheral blood samples were collected at various stages of the disease management i.e. before and after the surgery and in some patients also in several time intervals during chemotherapy regimens. A mutation-based approach was applied for cfDNA detection in which a panel of genes was tested for presence of a mutation in peripheral blood-derived plasma samples. Mutations were tested by denaturing capillary electrophoresis (DCE) exhibiting detection sensitivity limit of 1% mutated alleles.
Results: Cell-free DNA was detected in 16 patients (76%). In most cases the cfDNA occurrence did not correlate with elevated levels of CEA or CA19-9. No correlation was found when comparing presence of the cfDNA mutation in primary tumor and/or metastatic tissue.
Conclusions: Presence of cfDNA in peripheral blood may be used for observation of disease development as an alternative to standard tumor markers. Apparently the kinetics of cfDNA release is defined by characteristics of both, primary as well as metastatic lesion.

Introduction: Choroidal melanomas are the most common primary, intraocular malignant tumors in adults. In these tumors, the presence of CD8+ T lymphocytes is associated with bad prognosis. In contrast, in most other solid tumors, the CD8+ T cell infiltrate is related to good prognosis.
Materials and Methods: The primary untreated choroidal melanomas were analyzed for gene expression using Affymetrix U133 plus 2.0 array (n=15) and by immunohistochemistry (n=89).
Results: Gene expression profile analysis led to the identification of a gene signature consisting of 39 upregulated genes in a subset of choroidal melanomas. These genes were associated with: antigen processing and presentation, cell adhesion molecules, interferon-gamma and chemokine signaling pathways. On immunohistochemistry, signature positive tumors displayed a dense intra-tumoral infiltrate of HLA-DRA+CD163+ macrophages and CD3+CD8+ T-cells. It was mild to moderate in tumors lakking the signature. On this basis, additional tumors were analyzed by immunohistochemistry. In total, 19 melanomas had high immune infiltrate and 70 low. Kaplan-Meier plots demonstrated tumors with high immune infiltrate had shorter disease-free survival (log-rank P < 0.001).
Conclusions: We identified in choroidal melanomas an interferon-gamma induced gene signature associated with infiltration of macrophages and CD8+ T lymphocytes. The presence of tumor-infiltrating immune cells correlated with higher risk of occurrence of metastases.

Aberrations of chromosome 5 are common findings in bone marrow cells of MDS patients. The most frequent is del(5q) occurring in 10-15% of them. Extent of deletion differ among patients, however region 5q31 is commonly deleted. Monosomy 5 is described in 3-8% cases. We performed genome wide analysis in MDS patients with monosomy 5 detected by G-banding with aim to determine real existence of total monosomy 5 in MDS.
Bone marrow cells of 67 patients with suspected monosomy 5 were analyzed by I-FISH (Abbott), mFISH/mBAND (MetaSystems) and array CGH (BlueGnome). All 67 patients presented a complex karyotype with confirmed del(5)(q31). In all cases the deleted 5 entered into unbalanced rearrangements with various partners (most frequently chromosomes 3, 7, 12 and 17). Chromosomes 8, 22 and Y were never included in these translocations. We confirmed our hypothesis that pure monosomy 5 does not exist in MDS

as separate cytogenetic entity, as declared in the literature and WHO classification. In all patients with suspected monosomy 5 we showed that at least part of chromosome 5 is retained elsewhere in the genome. Minimal common preserved region was assessed at 5p11.1-p14.2 (22.31Mb). Complex karyotypes involving chromosome 5 identified at diagnosis gave extremely poor prognosis (median OS 3 months).
We assume that del(5q) is arising in myeloid precursor cells as the primary event and subsequently leads to chromosome instability and higher susceptibility to the breakage and rearrangements. This process is resulting in increased genomic damage and fast disease progression.

P11.078

Characterization of a new rearrangement and identification of a novel fusion transcript, FNIP1/ETV6 in an uncommon chronic eosinophilic leukemia (CEL) with an atypical t(5;12).

M. Decamp[1,2], *N. Richard*[1], *C. Thuillier*[3], *N. Gruchy*[1,2], *H. Johnson-Ansa*[1], *J. Andrieux*[3], *G. Plessis*[1], *H. Mittre*[1,2], *M. Kottler*[1,2], *M. Leporrier*[2], *N. Leporrier*[1,2];
[1]*Centre Hospitalier Universitaire, Caen, France,* [2]*UFR médecine, Université de Caen Basse Normandie, Caen, France,* [3]*Centre Hospitalier Régional Universitaire, Lille, France.*

Chronic eosinophilic leukemia (CEL) is a clonal proliferation of eosinophil precursors with recurrent chromosomal rearrangements, such as del 4q- or t(5;12)(q33;p13), leading to *FIP1L1/PDGFRA* and *ETV6/PDGFRB* fusion genes respectively, enhanced tyrosine kinase activity, uncontrolled cellular proliferation.
We describe here a patient first referred to us in 1984 with a high eosinophil count (20.000/µL). A diagnosis of CEL was made and eosinophilia resumed incompletely with interferon-α. Later on, a t(5;12) was recognised, but subsequent TKI treatment remained ineffective. These atypical features (protracted course, resistance to TKI) prompted us to analyse breakpoints. BAC-FISH positional cloning showed that the breakpoints occurred at *ETV6* on chromosome 12 (p13) and at *FNIP1* on chromosome 5 (q23). A fusion transcript, ETV6/FNIP1 was identified on the der(5) whereas no fusion transcript was identified on the der(12) in which an interstitial deletion encompassing *ACSL6*, was found.
The underlying mechanism of leukemogenesis in this patient still remains elusive. However, *FNIP1* could be involved as this gene has been shown to interact with mTOR signaling pathway in Birt-Hogg-Dubé syndrome, predisposing to kidney tumors. On the other hand, we found that the IL-3 gene located near the breakpoint on chromosome 5 and ending up on the der(12) was overexpressed. The encoding eosinopoiesis cytokines IL-5 and GM-CSF genes, located in the vicinity of the translocation could also be involved. In sum, we describe a new rearrangement in CEL. The deregulation of key genes of eosinopoiesis, located near the rearrangement or implication of *ETV6/FNIP1* fusion transcript remains to be determined.

Automated cartridge based method for BCR-ABL detection in chronic myeloid leukemia patients achieved major and complete molecular response on tyrosine kinase inhibitors therapy

S. A. Smirnikhina[1], *G. A. Tsaur*[2], *A. V. Lavrov*[1], *Y. A. Yakovleva*[2], *E. Y. Chelysheva*[3], *O. A. Shukhov*[3], *A. G. Turkina*[3], *S. I. Kutsev*[1,4];
[1]*Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*Regional Children Hospital N 1, Research Institute of Medical Cell Technologies, Ekaterinburg, Russian Federation,* [3]*Federal State Budgetary Institution "Hematological Research Centre" of Ministry of Health of the Russian Federation, Moscow, Russian Federation,* [4]*State Budgetary Educational Institution of Higher Professional Education "Russian National Research Medical University named after N.I. Pirogov" of Ministry of Health of the Russian Federation, Moscow, Russian Federation.*

Introduction. Automated cartridge-based GeneXpert Dx System for detection of *BCR-ABL* level was recently developed. There is lack of findings concerning the results' concordance obtained by routine and automated methods. **Purpose.** To compare the results of *BCR-ABL* gene expression analysis obtained by GeneXpert and manual standardized RT-PCR in 45 CML patients on TKI therapy, most of them were in major molecular response (MMR, n=12) or complete molecular response ($CMR^{4.0}$, n=33). "Xpert BCR-ABL Monitor" assay was developed according to WHO reference standard and allows to present results in %IS. **Results.** Four patients demonstrated *BCR-ABL* >0.1%IS by both methods. MMR (0.01-0.1%IS) was detected in 8 patients, $CMR^{4.0-5.0}$(0.0001-0.01%IS) was revealed in one patient and negative results were obtained in 12 patients by both methods. Concordance rate was 56% (25 of 45 patients). In 15 cases (33%) GeneXpert results were more sensitive than manual ones: two cases of MMR by GeneXpert were CMR by conventional RT-PCR and 13 cases of CMR by GeneXpert were negative by manual. In 5 cases (11%) GeneXpert demonstrated less sensitive results than obtained by manual method: 2 cases of CMR by GeneXpert were MMR by manual method and 3 negative results by GeneXpert were one MMR and two CMR by manual. Probably it was closely related to samples' quality. **In conclusion**, the results have demonstrated appropriate concordance rate of GeneXpert Dx System and conventional RT-PCR for *BCR-ABL* transcript measurement. GeneXpert allows detecting fusion gene transcript in higher percentage of cases.

The role of VHL gene inactivation in sporadic clear cell renal cell carcinoma development.

I. Gilyazova[1], *L. Kutlyeva*[1], *A. Shafigina*[2], *V. Pavlov*[3], *A. Khaliullin*[3], *A. Zagidullin*[3], *E. Klimentova*[2], *E. Khusnutdinova*[1,3];
[1]*Institute of Biochemistry and Genetics,Ufa Science Centre, RAS, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation,* [3]*Bashkir State Medical University, Ufa, Russian Federation.*

Sporadic clear cell renal cell carcinoma (ccRCC) is the most common type of adult kidney cancer. It's often associated with aberrations on chromosomes 3p. Aberrations on chromosome 3p are associated with inactivation of tumor suppressor gene von-Hippel Lindau (VHL), which activates the hypoxia-inducible factors HIF1α and HIF2α. The goal of the study was to investigate inactivation of VHL gene by mutations, loss of heterozygosity (LOH) and methylation of its promoter in cancer tissues of ccRCC patients. We studied 93 paired DNA samples of tumor tissues and normal renal parenchyma in ccRCCpatients from Bashkortostan Republic of Russia. DNA extraction was performed by phenol-chloroform extraction. Analysis of mutations in the coding part of the VHL gene was performed by direct sequencing. Mutations in VHL gene were found in tumor tissues with the frequency of 22,6% (21/93). We found out 10 somatic mutations which hadn't been described in literature previously. Analysis of LOH was performed using D3S1038 and D3S1317 microsatellite loci. LOH at D3S1038 was detected in 25,3%, at D3S1317 - 28% (27/83 and 14/50, respectively) of informative cases. Besides, we analyzed VHL gene promoter methylation. In 5 cases hypermethylation of VHL gene promoter was identified (3,8%). VHL inactivation through promoter hypermethylation and through sequence alterations in tumor DNA didn't differ by histopathologic characteristics or occupational exposure. Thus, somatic inactivation of VHL gene is the main molecular event in most sporadic RCC and a number of drugs have been developed in the treatment of RCC that target HIF-responsive gene products and block angiogenesis.

P11.081

Assessment of microarray analysis as a prognostic clinical tool in chronic lymphocytic leukemia.

N. Prié, S. Bougeon, N. Kramer, L. Etter, D. Ernst, O. Bruzzese, S. Porter, D. Muehlematter, ***J. Schoumans****;*
Lausanne University Hospital, Lausanne, Switzerland.

Chronic lymphocytic leukemia (CLL) is a B-cell malignancy with a highly variable clinical course. In addition to the mutational status of the immunoglobulin heavy chain, recurrent genomic abnormalities are among the strongest prognostic markers. For risk classifications and clinical decision-making in CLL a standard panel of commercially available FISH probes is most often used to identify deletions at 11q22, 13q14 and 17p13, duplications of 6q, and trisomy 12 in the clinical setting. In order to assess the usefulness of CGH+SNP array analysis as an alternative to conventional karyotyping and iFISH in routine clinical use, 100 CLL patients were analyzed both by iFISH and CGH+SNP arrays. In addition, all cases in which no abnormalities were identified were subjected to G-band analysis. The iFISH panel included del(13)(q14)(DLEU1), del(11)(q22)(ATM), del(17)(p13)(TP53)

and trisomy 12. For array analysis a 180K custom-designed cancer focused array was used from OGT. The array was designed for the detection of single exon abnormalities in 17 selected genes (average coverage 1probe/100bp) as well as the simultaneous identification of CNLOH by adding 36000 SNP probes (12000 different SNPs across the genome). In addition, the array covers 1500 cancer-associated genes with an average resolution of 2kb, whilst retaining an average backbone resolution of 50kb. From this study we concluded that CGH+SNP array analysis is a robust, high resolution and sensitive screening method for routine clinical use in CLL with a higher diagnostic yield than iFISH. It also reliably detected genomic abnormalities present in only 10% of the cells.

P11.082

Exome sequencing during disease evolution in CML patients displaying an isochromosome 17q

N. E. Larsson[1], *H. Liljebjörn*[1], *M. Rissler*[1], *C. Högberg*[1], *J. Richter*[2], *T. Fioretos*[1];
[1]Department of Clinical Genetics, Lund University, Lund, Sweden, [2]Department of Hematology, Lund University Hospital, Lund, Sweden.

The acquisition of a Philadelphia chromosome in a hematopoietic stem cell, resulting in a constitutively active tyrosine kinase, BCR-ABL1 is a hallmark of chronic myeloid leukemia (CML). The P210 BCR-ABL1 fusion protein is critical and most likely sufficient for establishing the initial chronic phase (CP), but secondary genetic changes are likely to be important for disease progression in to the acute phase, referred to as blast crisis (BC). Here we describe the clinical features and mutation patterns in three CML patients exhibiting an isochromosome for the the long arm of chromosome 17, i(17)(q10), which is one the most common structural cytogenetic change at the disease progression of CML. Exome sequencing was performed at different stages of the disease to identify genomic changes critical for the disease progression. Exome enrichment was performed using the Truseq exome enrichment kit (Illumina) and paired end 100 bp sequencing was performed on a HiScanSQ (Illumina). Mutations in genes involved in DNA repair, cell cycle control and epigenetic regulation such as *TP53, ASXL1* and *EZH2* were detected, but no recurrent mutations were identified. Interestingly, the *TP53* mutation preceded the occurrence of an i(17q) in one patient, suggesting that that the loss of 17p-material as a consequence of i(17q)-formation, partly served to unmask the effect of the *TP53* mutation. However, no *TP53* mutations were detected in the other two patients, suggesting that i(17q)-formation leads to disease progression by causing dosage imbalances of several genes encoded by chromosome 17 rather than via specific gene mutations on this chromosome.

P11.083

Clonal evolution in chronic myeloid leukemia revealed by whole-exome sequencing

J. Menezes[1], *F. Acquadro*[1], *G. Gómez-López*[1], *S. Alvarez*[1], *M. Trujillo*[2], *J. Garcia-Talavera*[2], *D. G. Pisano*[1], *J. C. Cigudosa*[1];
[1]Spanish National Cancer Research Center - CNIO, Madrid, Spain, [2]Hospital N Sra La Candelaria, Tenerife, Spain.

CML is one of the best examples of a disease that can be targeted by molecular therapy however, the success is restricted to the chronic phase (CP) of the disease. If not cured at this stage, CML transforms into a blast crisis (BC). To investigate the genetic changes associated with CML progression we performed whole-exome sequencing (WES) of an individual patient at three different time points: CP, complete hematological remission (CHR) and BC.
We validated mutations in genes known to be involved in CML (*ASXL1* and *TP53*) as well as in genes that have not been described so far in the disease (*UBE2G2*, *ZEB2* and *IKZF3*). *TP53* mutation (p.E286K) was found in the three phases of CML progression. However, *ASXL1* (p.G679*), *UBE2G2* (p.D35V), *ZEB2* (p.L420R) and *IKZF3* (p.E272K) were present only in the CP and BC. The evaluation of the number of mutated reads allowed us to study clonality and clonal evolution : 93% of the selected SNSs that were present in the CP were also seen in BC. In fact, the percentages of reads of the mutant alleles were the same, both at CP and at BC.
WES allowed us to identify a large number of mutated genes, even at the chonic phase of CML, that harbour clear prognostic and predictive significance (*TP53*, *IKZF3*, absence of *ABL1* mutations). The study of the mutation profile through the disease progression indicated that, at least in this patient, the number and the type of mutations were rather similar at CP and BC.

[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]MVZ Dr. Eberhard & Partner, Dortmund, Germany, [3]Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany, [4]Division of Medical Genetics, University Children's Hospital and Department of Biomedicine, University of Basel, Basel, Switzerland, [5]University Hospital of the Ludwig-Maximilians-University, Campus Innenstadt, Munich, Germany, [6]MGZ - Medical Genetics Center, Munich, Germany, [7]Cologne Center for Genomics, University of Cologne, Cologne, Germany, [8]Institute of Pathology, University of Cologne, Cologne, Germany, [9]Department of Bonn-Aachen International Center for IT (B-IT), Algorithmic Bioinformatics, University of Bonn, Bonn, Germany.

Background: In up to 50% of patients with colorectal adenomatous polyposis, a tumour predisposition syndrome, no germline mutation in known genes (APC, MUTYH) can be identified. Loss-of-function copy number variants (CNVs) contribute significantly to the mutation spectrum of hereditary tumor syndromes and thus those CNVs might also be the underlying cause in yet unidentified genes responsible for adenomatous polyposis.
Methods: Genomic DNA from 222 unrelated mutation negative polyposis patients was genotyped (HumanOmni1-Quad BeadArray, Illumina). Putative CNVs were identified by QuantiSNP v.2.2, filtered according to various criteria by use of the Cartagenia Bench™ software, in-silico-analysis, comparison with data from 531 healthy in-house controls, and validated by qPCR. The expression of affected genes was examined by cDNA analysis of normal colonic mucosa. Candidate genes were prioritized by function, pathways, and segregation analysis.
Results: 33 unique deletions and 64 unique duplications, encompassing 151 protein coding genes, were found in 28 (13%) and 50 patients (23%), respectively. Each except one CNV occurred only once in the cohort. After expression analysis and data mining, the number of candidates could be further reduced to 23 deletions and 57 partial duplications, including protein kinases, transcription factors, and potential tumor suppressors. To identify pathogenic point mutations, 24 candidates are currently sequenced in the whole patient group.
Conclusions: By applying stringent filter criteria, we identified a group of rare and potentially causative loss-of-function CNVs. The clinical relevance of the most promising candidates will be verified by a target sequence approach. The study was supported by the German Cancer Aid.

P11.085

Expression of GA-733 gene family in colorectal cancer.

I. Mamaloudis[1], *P. Kollia*[2], *D. Zacharoulis*[1], *M. Samara*[3], *K. Hatzitheofilou*[1];
[1]Department of Surgery, University Hospital of Larissa, Larissa, Greece, [2]Laboratory of Human Genetics, School of Biology, University of Athens, Athens, Greece, [3]Department of Pathology, School of Medicine, University of Thessaly, Larissa, Greece.

Aim of study: Colorectal cancer is the third more frequent malignancy among the newly diagnosed cancer cases in the United States and the third cause of death from malignancy. It has been and being an object of study in regards to the mechanisms that promote oncogenesis as well as the implicated genes. Genomic and protein analyses in colon cancer have proved the significant participation of GA733 protein family. However, so far a small number of studies have been reported in human-tissue material.
Experimental Design: Cancerous and noncancerous tissues were obtained from 40 patients with colorectal cancer and RNA was extracted from each sample (cancerous - non cancerous tissue samples). In order to quantitate GA733-1 and -2 mRNA transcripts, we developed and evaluated real-time fluorescence PCR assays. Correlation of GA733-2 mRNA levels in noncancerous versus cancerous tissue with clinicopathologic parameters was performed in adenocarcinoma colon samples.
Results: mRNA expression of GA733-1 gene was almost undetectable in both noncancerous and cancerous tissues. This can be explained since no

metastasis was diagnosed before or after surgery. In noncancerous tissues the median ratio GA733-2/h-PBGD mRNA levels was 273.31 (range, 65.24-14862.41), while in cancerous tissues of the above patients, the median ratio GA733-2/h-PBGD was 115.64 (range, 11.58-1189.14) (p<0.05).
Conclusion: Our results reveal a strong correlation between reduced GA733-2 mRNA levels and lymph node perforation (p=0.0343) in contrast to GA733-1 gene expression which was almost undetectable in our samples. Therefore, GA733-2 mRNA measurement could be a potential predictive marker for metastasis and poor cancer prognosis.

P11.086
The allelic expression of the beta-catenin is polymorphic in the general population and allelic imbalance of the beta catenin constitutes a risk factor for colorectal cancer

*L. Ippolito[1], E. Houivet[2], C. Abadie[1], J. Mauillon[3], A. Killian[1], M. Bougeard[1], F. Charbonnier[1], D. Malka[4], J. Duffour[5], F. Desseigne[6], C. Colas[7], A. Cailleux[8], H. Sebaoui[9], J. Blot[9], J. Tinat[1,3], S. Baert-Desurmont[1,3], **T. Frebourg**[1,3];*
[1]Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France, [2]Department of Biostatistics, University Hospital, Rouen, France, [3]Department of Genetics, University Hospital, Rouen, France, [4]Institut Gustave Roussy, Villejuif, France, [5]Comprehensive Cancer Centre Val d'Aurelle, Montpellier, France, [6]Comprehensive Cancer Centre Leon Berard, Lyon, France, [7]AP-HP, Saint Antoine Hospital, Paris, France, [8]Clinical Investigation Centre, Inserm and University Hospital, Rouen, France, [9]Department of Clinical Research, University Hopital, Rouen, France.

In order to identify new genetic risk variations associated with colorectal cancer (CRC) risk, we conducted a prospective case-control study in 716 CRC patients without detectable germline mutations and highly selected on criteria suggestive of an increased genetic risk for CRC: (i) CRC before 61 years with a first degree relative presenting with CRC; or (ii) CRC before 51 years of age; or (iii) multiple primitive CRC, the first one diagnosed before 61 years. We recruited 550 controls that were CRC-free and had no familial history of CRC in their first-degree relatives. Analysis of the allelic expression of beta catenin and TCF4 revealed that, in controls, the ratio of allelic expression was dispersed for beta catenin, as compared to TCF4 (0.76 +/- 0.26 versus 0.91 +/- 0.07; interquartile range: 0.22 versus 0.09; p < 0.0001). Using cut-off values corresponding to the 5th and 95th percentiles, we observed, among the 355 informative patients and 274 informative controls, a beta catenin allelic imbalance in 73 patients (20.6%) and in 37 controls (13.5%) (p = 0.0208; OR = 1.66, CI [1.08; 2.55]). This difference was even more significant after taking into account age at blood sampling and sex (p = 0.0062; OR 2.07, CI [1.25-3,43]). This study reveals that allelic expression of the beta-catenin, the main regulator of the APC pathway, is polymorphic in the general population and that allelic imbalance of the beta catenin constitutes a risk factor for CRC.

P11.087
Association between microsatellite instability, BRAFV600E mutation and MLH1 promoter hypermethylation in sporadic and familial colorectal cancers

***M. Hiljadnikova-Bajro**[1], A. Kapedanovska-Nestorovska[1], A. Eftimov[1], N. Matevska-Geskovska[1], T. Josifovski[2,3], M. Panovski[2], N. Jankulovski[2], A. J. Dimovski[1];*
[1]Faculty of Pharmacy, Ss Cyril and Methodius University, Skopje, Macedonia, The Former Yugoslav Republic of, [2]University Clinic for Digestive Surgery, Ss Cyril and Methodius University, Skopje, Macedonia, The Former Yugoslav Republic of, [3]Clinical Hospital Acibadem Sistina, Skopje, Macedonia, The Former Yugoslav Republic of.

In our ongoing study investigating the genetic and epigenetic mechanisms of colorectal cancer (CRC) development among patients from the Republic of Macedonia, we have evaluated the microsatellite instability (MSI), BRAF-V600E mutation and methylation status of the MLH1-promoter in a total of 389 patients with histopathologically confirmed CRC. Fluorescent multiplex PCR followed by capillary gell electrophoresis; bidirectional DNA sequencing and quantitative methylation-specific PCR after bisulfite DNA-conversion were employed for the above analyses respectively. MSI was detected in 11.2% of all CRCs, acting as a mechanism that enables development of cancers with early phenotypic presentation (55 years on average) in the proximal colon (p<0.001) and lower tumor stage at diagnosis (p=0.046). Nearly one third of all MSI cancers (29%) were isolated from patients with a clinical diagnosis of Lynch Syndrome. MLH1 promoter hypermethylation was responsible for MSI in 54% of cancers with this type of genetic instability, suggesting sporadic character of the disease. The BRAFV600E mutation was significantly associated with MSI (p=0.03), being detected in 12% of MSI cases, and 2% of MSS cancers. All of the evaluated "BRAF+" cancers were MLH1 hypermethylated, and only half of the MLH1-hypermathylated cancers bear the BRAFV600E mutation, supporting the previous hypothesis that the gene- promoter-hypermethylated phenotype creates a permissive environment for the BRAFV600E mutant clones. A family with MSI cancers without defects in the mismatch repair genes, but bearing the BRAFV600E mutation and hypermethylated MLH1 promoter was identified, suggesting a role of the later two mechanisms in development of the currently unexplained familial CRC cases.

P11.088
Identification of cancer relevant variants by comparison with data from 200 healthy Danes using CLC Genomics Workbench

***A. Joecker**[1], K. Thorsen[2], L. Kahns[1], C. Lindbjerg Andersen[2], C. Boysen[1], N. Thomson[1], J. Grydholt[1], M. Bundgaard[1], J. Buur Sinding[1], A. K. Hein[1], M. Værum[1], R. Forsberg[1], B. Knudsen[1];*
[1]CLC bio, Aarhus, Denmark, [2]Department of Molecular Medicine (MOMA), Aarhus University Hospital Skejby, Aarhus, Denmark.

It is well known that people with a different native background respond differently to drugs and have different prepositions to develop rare diseases. Furthermore, the knowledge about common genetic variants in a population can be helpful to identify disease related variants in patients.
Projects like the HapMap and 1000 Genomes project have been proven to be excellent repositories to explore common as well as rare variants. However, not all different ethnic groups are part of these projects, yet. Also, if a lot of publicly available population data exists, the accurate identification of common and rare variants from this data is a difficult and often time-consuming step, which requires a lot of specialized knowledge.
In this presentation we will show how fast and easy common and rare variants can be identified using CLC Genomics Workbench and how they can be used to distinguish between common and disease related variants in a patient with a certain genetic disease. As examples we will use publicly available data from 200 healthy Danes and one cancer sample from a patient of Danish ethnicity.

P11.089
Stool DNA methylation markers suitable for colorectal cancer screening

***K. Rønlund**[1], J. Lindebjerg[2], D. Crüger[3], D. Morton[4], S. Kølvraa[1];*
[1]Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark, [2]Department of Pathology, Vejle Hospital, Vejle, Denmark, [3]Vejle Hospital, Vejle, Denmark, [4]the School of Cancer Sciences, University of Birmingham, Birmingham, United Kingdom.

Background: Colorectal cancer is the third most commonly diagnosed malignancy in the world. Research over the last decade has shown that population screening for CRC can reduce mortality by 15 - 33%. Until recently the method most often used to screen for early CRC has been based on the findings of faecal occult blood. The problem with this test is, however, that the sensitivity is only 50-60% when used as a single examination. Tumour specific DNA methylation in stool is a new method for detecting colorectal cancer and precancerous lesions at an early stage.
Materials and method: In order to define suitable markers for a DNA methylation based screening assay we have conducted analysis of normal colonic mucosa and adenoma tissue samples. First we used a DNA methylation

array platform based on immunoprecipitation and then we performed an Illumina Infinium 450K Methylation assay analysis. We have conducted various filtering analysis and performed statistical and bioinformatic analyses to define aberrant methylated candidate CpG sites suitable for a stool based screening test.
Results: We have identified these 21 candidate genes; ADAMTS5, DLX5, DMRTA2, DPP10, FAM19A4, GRIA4, HAND2, HPSE2, ITGA4, KCNA1, LRFN5, MEOX2, MIR129-2, PAX6, PRMT8, SLC6A15, TBX5, VCAN, ZIC1, ZNF568 and ZNF804B, p-value of <0.001, with more than one differential methylated CpG site by the Infinium 450K array.
Conclusions: Further work is necessary in order to develop „high-throughput" methods for each of the potential markers and hopefully it will result in a more sensitive screening tool for early diagnosis of colorectal cancer.

Colorectal cancer (CRC) occurs as consequence of a complex interplay between genetic and epigenetic alterations. Epigenetic modifications represent the dynamic link between the environment and the genome. DNA methylation is potentially reversible and therefore is a good target for research and therapy. One-carbon metabolism is necessary for DNA synthesis, repair and methylation and several studies reported its pivotal role in carcinogenesis. Folates may influence CRC risk either through dietary intake as well as by intrinsic factors. Our study is aimed to evaluate the methylation levels of APC, CDKN2A, hMLH1 and MGMT genes in CRC and healthy adjacent tissue specimens. The correlation among the methylation status of these genes and the clinical-pathological features of the patients and the association among MTHFR, TYMS, DNMT3B, RFC1, MTRR, MTR folate metabolism gene polymorphisms and the methylation levels of CRC key genes were assessed. Allele and genotype frequencies between CRC and healthy control subjects for the gene polymorphisms were evaluated. Some interesting correlations have been observed, such as an interaction between MTRR A66G polymorphism and CRC risk; a higher gene promoter methylation in CRC tissue with respect to the healthy adjacent tissue; a statistically significant positive correlation between age and hMLH1 and MGMT promoter methylation and between gender and hMLH1 promoter methylation. Moreover low folate levels were associated with an increase of hMLH1 and APC methylation while TYMS 1494 6bp ins/del polymorphism correlated with CDKN2A promoter methylation. All these data corroborate the critical role of folate metabolism in CRC.

P11.091
The VEGF/VEGFR pathway in advancing stage colorectal cancer

Y. A. Shelygin, *V. N. Kashnikov, S. I. Achkasov, O. I. Sushkov, A. S. Tsukanov, N. I. Pospekhova, V. P. Shubin;*
Ministry of Health / State Scientific Center of Coloproctology, Moscow, Russian Federation.

Angiogenesis as the process of new capillary formation plays an important role in colorectal cancer (CRC) development. The VEGF/VEGFR pathway is one of the most important regulators of angiogenesis. Vascular endothelial growth factor (VEGF) binds to its receptors (VEGFR1/2) and leads to cell proliferation and new vascular formation. VEGF is expressed by cancer cells after the activation of hypoxia-inducible transcription factors in response to hypoxia.
We analyzed the VEGF signaling on 17 samples of advancing stage CRC ($T_{3-4}N_{0-2c}M_{0-1}$) compared to normal adjacent tissue by RT-PCR. The VEGF expression level increased more than 3 times in 7 tumors. VEGFR2 was up-regulated in 8 samples (15-1000 times), VEGFR1 - in 14 samples (5-200 times). Co-expression VEGF/VEGFR1 and VEGFR2/VEGFR1 were observed always. High level of HIG2 (hypoxia-inducible gene 2) strongly correlates with VEGFR1 expression. Also we observed up-regulation the hypoxia-inducible CA9 (carbonic anhydrase 9) expression in 8-1300 times which correlated with VEGFR1. Up-regulation of VEGFR2 closely associated with availability of nodal metastasis or peritoneal carcinomatosis.
The expression of VEGF/VEGFR on tumor might be a prognostic marker for successful use anti-VEGF therapeutics.

P11.092
The EMT gene expression signature in advancing stage colorectal cancer

V. P. Shubin, *Y. A. Shelygin, V. N. Kashnikov, A. S. Tsukanov, O. I. Sushkov, S. I. Achkasov, N. I. Pospekhova;*
Ministry of Health / State Scientific Center of Coloproctology, Moscow, Russian Federation.

Colorectal cancer (CRC) has been considered to be a molecularly heterogeneous disease. Investigation of gene expression signature in CRC is an effective approach for prognosis of disease and its metastatic status. The analysis of EMT (epithelial- mesenchymal transition) program classifies colon tumors on two molecular subtypes: epithelial and mesenchymal.
The gene expression signature (45 genes) was investigated on 17 samples of colon and rectal cancers T3-4 N0-2c M0-1 by RT-PCR. 5 of 17 samples were characterized as mesenchymal subtype: high level of ZEB1, ZEB2, VIM and low level of CDH1. High level of PDGFR and TH were strongly correlated with this gene profiling. The EMT signature was found on 2 of 3 tumors with nodal metastases. 3 of 3 cancers with peritoneal carcinomatosis were demonstrated the EMT profiling also. Whereas the sample with MLH1 germline mutation (p.R100X) showed the epithelial gene signature.
Our data confirm the notion that the mesenchymal subtype of tumor is associated with poor prognosis, metastatic CRC and peritoneal carcinomatosis.

P11.093
3-phosphoglycerate dehydrogenase polymorphism in male patients with colorectal carcinoma

M. L. Ristanovic[1], *I. Novakovic*[1], *B. Rovcanin*[1], *J. Trifunovic*[1], *Z. Krivokapic*[2], *I. Dimitrijevic*[3];
[1]*Institute of Human genetics, University of Belgrade, Belgrade, Serbia,* [2]*First Surgical Clinic Clinical center of Serbia, Medical faculty,University of Belgarde, Belgrade, Serbia,* [3]*First Surgical Clinic Clinical Center of Serbia, Belgrade, Serbia.*

/>Introduction:. Colorectal cancer (CRC) is one of the most common malignant tumors and the second leading cancer in Serbia. Recent studies suggest important role of both environmental and genetic factors in cancerogenesis. 3-Phosphoglycerate dehydrogenase (3-PHGDH) gene overexpression is assosiated with patogenesis of human cancer and contributes to cell proliferation.
Aim: The objective of our study was to assess the association of PHGDH gene polimorphism in group of males with colorectal cancer and control group of healthy men.
Methods: The survey was carried out in the Department of Human Genetics-Medical School, University of Belgrade. The study has encompassed 63 man diagnosed with colorectal cancer in The First Surgical Clinic, Clinical Center of Serbia and 100 health males volonteers. The DNA was isolated from the periferal blood with solting out method. The genotypes 3-PHGDH polimorphism were determined by Polimerase Chain Reaction (PCR) and Restriction Fragment Lenght Polimorphism (RFLP). Gel-electrophoresis was used to separate DNA fragments.
Results: There was a statistically significant difference between frequences for genotypic distribution of rs541503 polymorfism in patiens with colorectal carcinoma and healthy volonteers ($p=0.00013$, $p<0.01$).
Conclusion: In the present study we found TT genopype as the most frequent in both of group of patients with colorectal carcinoma and control group. The results of our study also suggest that C allele might be factor of risk associated with colorectal cancer. It is necessary to undergo futher testing with more adequate test groups in order to get firm results.
Key words: PHGDH gene, colorectal cancer, PCR, RFLP

Colorectal Cancer Inherited Susceptibility in the Brazilian population: the first replication study in Latin America

I. Gomy[1], E. M. M. Santos[1], G. M. G. T. Spilborghs[1], S. R. A. S. Viola[1], S. Aguiar Jr[1], L. Carvajal-Carmona[2], S. R. Rogatto[1], B. M. Rossi[3];
[1]A.C. Camargo Hospital, São Paulo, Brazil, [2]University of California, Davis, CA, United States, [3]Barretos Cancer Hospital, Barretos, Brazil.

Background:
Colorectal cancer (CRC) is one of the most common and fatal cancers worldwide, including in developing countries. Genome-wide association studies have uncovered part of the CRC inherited susceptibility through genotyping common low-penetrant variants in individuals with European ancestry. Replication studies in genetic heterogeneous populations are scarce.
Aim: to identify SNPs previously known to be associated with CRC risk in the Brazilian population.

Methods:
Ten SNPs were genotyped in 1,467 individuals (727 cases and 740 controls) using TaqMan assays. SNPs with significant Hardy-Weinberg disequilibrium and genotypes with either poor clustering or call rates <95% were excluded. Effect sizes were calculated by logistic regression and p-values were corrected for multiple analyses.

Results:

Models SNP	Risk allele	Frequency	Allelic OR [95%C.I.]	p	Dominant OR [95%C.I.]	p	Recessive OR [95%C.I.]	p	Additive OR [95%C.I.]	p
rs4939827	C	0.47	**1.43 [1.23 - 1.66]**	**2.12 x 10^{-5}**	**1.67 [1.33 - 2.11]**	**0.0001**	**1.51 [1.18 - 1.93]**	**0.011**	**1.54 [1.20 - 1.98]**	**3.49 x 10^{-5}**
rs10411210	T	0.17	0.83 [0.68 - 1.00]	0.080	**0.75 [0.60 - 0.94]**	**0.040**	1.19 [0.70 - 2.01]	0.749	0.71 [0.56 - 0.90]	0.083
rs4444235	C	0.51	**1.26 [1.09 - 1.45]**	**0.011**	1.26 [1.00 - 1.60]	0.097	**1.45 [1.14 - 1.83]**	**0.012**	**1.38 [1.07 - 1.78]**	**0.012**
rs3802842	A	0.26	**1.29 [1.09 - 1.53]**	**0.010**	1.26 [1.02 - 1.56]	0.072	**1.85 [1.23 - 2.78]**	**0.009**	**1.69 [1.10 - 2.60]**	**0.011**
rs16892766	C	0.08	**1.39 [1.07 - 1.82]**	**0.038**	**1.49 [1.11 - 1.99]**	**0.035**	0.96 [0.40 - 2.27]	0.920	**1.55 [1.14 - 2.10]**	**0.049**

Conclusions:
We found significant association with half of SNPs in the first replication study carried out in Latin America. This study will proceed to increase sample size and stratify our population by ancestry in order to avoid type I and II errors. It is worth to replicate GWAS in admixed populations in order to help to uncover the missing heritability of CRC and narrow the boundaries of the genetic architecture of CRC susceptibility.

P11.096

HER2 gene status in KRAS positive/negative colorectal cancers

*J. K. Bar[1], A. L. Lis-Nawara[1], A. Lebioda[2], A. Jonkisz[2], M. Jeleń[1], **T. M. Dobosz**[2];*
[1]Department of Pathomorphology and Oncological Cytology, Wroclaw Medical University, Wroclaw, Poland, [2]Molecular Techniques Unit, Department of Forensic Medicine, Wroclaw Medical University, Wroclaw, Poland.

Mutation at codons 12 and 13 of the KRAS gene in patients with colorectal cancer has been shown to be predictive of cetuximab response in colorectal cancer. Fifty three paraffin-embedded colorectal cancer specimens were analyzed for KRAS mutation and HER2 overexpression/amplification. A high-resolution melting (HRM) assay and single-nucleotide polymorphisms (SNPs) were used to detect somatic mutation in exon 2 notably condons 12 and 13 of the KRAS gene. HER2 overexpression was detected using monoclonal antibody and confirmed by fluorescence in situ hybridization (FISH) analysis.
KRAS mutations for codons 12 and 13 were identified in 19/53 (35.8%) by SNP and in 17/53 (32.0%) of colorectal cancer by HRM technique. Colorectal cancers showed mainly heterozygous 35G>A and 38G>A KRAS gene mutations.
The concordance rate between the two methodologies was high at 89.4%. KRAS mutation was more frequently observed in poorly differentiated tumors and adenocarcinomas than in other histological types.
HER2 overexpression was observed in 42/53 (79.2%) of all colorectal cancers and in 62.1%, 61.5% of KRAS mutation-positive cases detected by SNP and HRM techniques respectively. HER2 overexpression was accompanied by amplification of HER2 gene.
In conclusions, the presence of HER2/KRAS positive immunophenotype of colorectal cancers suggests that HER2 might be the candidate gene for target therapy of patients with colorectal cancer.

P11.097

KRAS, BRAF and PIK3CA mutations and KRAS-LCS6 polymorphism in the binding site of let-7 microRNA to the 3´UTR region of KRAS gene in Czech patients with colorectal cancer

J. Simova[1,2], B. Kubova[1], M. Uvirova[1,2], I. Urbanovska[1,2], D. Konvalinka[1], I. Zebrakova[1], A. Hopenstokova[1], J. Mazurova[1], J. Dvorackova[1,2];
[1]CGB Laboratory Inc., Ostrava, Czech Republic, [2]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic.

Background: Personalised cancer medicine based on mutation profiling of tumours is now reality in the treatment of metastatic colorectal cancer (mCRC). KRAS mutations represents a predictive biomarker for resistance to anti-EGFR therapy. However, up to 65% of patients with KRAS wild-type tumours do not respond to this therapy. This fact suggest that additional markers (in the RAS-RAF-MAPK or PI3K-AKT-mTOR signaling pathways, functional polymorphism in the binding site of microRNA) may also contribute to resistance to anti-EGFR therapy.
Aim: Mutation profiling of selected mutations in KRAS, BRAF, PIK3CA gene and SNP (rs61764370) KRAS-LCS6 in the binding site of let-7 microRNA to the 3´UTR region of KRAS gene.
Method: In this study 503 DNA samples of tumours tissues of mCRC patients were tested for presence of selected mutations of KRAS,BRAF and PIK3CA gene. Analysis was performed by PCR, reverse hybridisation, real-time PCR and primer extension method. SNP (rs61764370) was analysed in 164 samples and was performed by PCR+RFLP method.
Results: Activating mutations were detected in 40% (KRAS), 5,6% (BRAF) and 9% (PIK3CA) of the tumours. Coexistence of mutations were detected in 4,8% (mutations in KRAS and PIK3CA gene) and 0,6% (BRAF and PIK3CA). T/G genotype of the SNP (rs61764370) was identified in 11% of 164 mCRC patients.
Conclusion: Frequency of mutations of KRAS, BRAF and PIK3CA is similar to frequency reported by other authors, respectively. KRAS and BRAF mutations were mutually exclusive. Additional predictive biomarkers may aid in the selection of mCRC patients which could profit from targeted cancer therapy.

P11.098

The evaluation of miRNA expression levels in LGR5 and SOX2 positive colorectal cancer tissues

B. Tunca[1], S. Ak[1], G. Tezcan[1], G. Cecener[1], U. Egeli[1], T. Yilmazlar[2], E. Ozturk[2], O. Yerci[3], A. Zorluoglu[4];
[1]Department of Medical Biology, Medical Faculty, Uludag University, Bursa, Turkey, [2]Department of General Surgery, Medical Faculty, Uludag University, Bursa, Turkey, [3]Department of Pathology, Medical Faculty, Uludag University, Bursa, Turkey, [4]Department of General Surgery, Acıbadem Hospital, Bursa, Turkey.

Colorectal cancer (CRC) is one of the leading causes of cancer deaths in the world. Cancer stem cell (CSC), suggested to responsible for tumor initiation, growth, and metastasis in CRC. The search for a reliable marker to identify these CSCs is ongoing as current markers, such as *LGR5* and *SOX2*. Additionally, according to recent studies, microRNAs (miRNAs), may also contribute to preserving stemness of human CSCs. However, the knowledge about the regulation of *LGR5* and *SOX2* positive CRC cells via miRNA expressions is very limited. Therefore, the aim of this study was to evaluate the significance of expression levels of CRC related miRNAs in *LGR5* and *SOX2* positive CRC tumors.
The expression profiles *LGR5* and *SOX2* genes and 38 CRC related miRNAs were analyzed in tumor tissues of 30 early-onset CRC patients, using RT-qPCR assays and miRNA PCR arrays respectively. Statistical analyses were performed using SABioscience PCR Array Data Analysis Software.
The expression level of miR-143 almost 2-fold reduced in normal tissues in compare to tumor tissues. Furthermore, reduction level of miR-143 was significantly increased in tumors with over-expressed *LGR5* and *SOX2* (P = 0.045 and P = 0.040, respectively).
Although miR-143 associated with *SOX2* previously, its association with *LGR-5* determined first time in this study. Even, further studies needed, we suggest that, miR-143 may has a potential to be candidate of new therapeutic target in advance therapy protocols of stemness CRC.

Easy-to-use online referral test detects most patients with a high familial risk of colorectal cancer

N. Hoogerbrugge, *N. Dekker, A. R. Mensenkamp, M. J. L. Ligtenberg, W. A. v. Zelst-Stams, R. P. Hermens;*
Radboud University Medical Center, Nijmegen, Netherlands.

Introduction: Currently, only 12-30% of individuals at high risk for Lynch syndrome, the most common hereditary colorectal cancer (CRC) syndrome, are referred for genetic counselling. We developed a new online referral test based on current guidelines, aimed at improving referral for genetic counselling, of those at high familial risk of CRC. This study focuses on sensitivity, usability and user experiences of this test, which is also available as cell phone App.

Patients and Methods:

Sensitivity was assessed by entering pedigree data from high-risk individuals (i.e., Lynch syndrome mutation carriers) into the referral test to determine whether genetic counselling was recommended. For usability, we assessed non-medical staff members' ability to determine referral according to guidelines in seven fictive clinical cases using the referral test after minimal training. Referral was also determined by medical specialists (surgeons, gastroenterologist, clinical geneticists) **NOT** using the referral test.

Results: Sensitivity of the referral test was 91% for mutation carriers with CRC (n = 164) and 73% for all mutation carriers (n = 420). Non-medical staff members (n = 20) determined correct referral according to guidelines in 84% of cases using the referral test. Without the use of the referral test Medical Specialists (n=312) correctly determined referral in 65%.

Conclusions: The referral test has a high sensitivity for detecting individuals with a high risk of Lynch syndrome and is suitable for use in clinical practice by cell phone. Widespread use of the online referral test will improve recognition of patients with high familial risk of colorectal cancer.

P11.100

Over expression of CK20 may has a potential to be a prognostic marker in MSS tumors of early-onset colorectal cancer patients

S. Ak[1], *B. Tunca*[1], *T. Yilmazlar*[2], *G. Tezcan*[1], *G. Cecener*[1], *U. Egeli*[1], *E. Ozturk*[2], *O. Yerci*[3], *E. Erturk*[1], *A. Zorluoglu*[4];
[1]*Department of Medical Biology, Medical Faculty, Uludag University, Bursa, Turkey,* [2]*Department of General Surgery, Medical Faculty, Uludag University, Bursa, Turkey,* [3]*Department of Pathology, Medical Faculty, Uludag University, Bursa, Turkey,* [4]*Department of General Surgery, Acıbadem Hospital, Bursa, Turkey.*

The association between microsatellite instability (MSI) status and gene expression profiles in tumorigenesis pathways causing early-onset sporadic colorectal cancer (CRC) has not clearly established. Since molecular targeting therapeutics are being used in clinical settings and trials, identifying differentially regulated molecular target genes depend on MSI status in early-onset CRC is required. The aim of this study was to evaluate the altered gene expressions depend on the MSI status of early-onset CRC to identify specific biomarkers that could provide novel therapeutic molecular targets in this population.

5 MSI markers were investigated in tumor and normal tissues of 36 early-onset CRC patients whose expression profiles of 114 CRC associated genes already examined using mRNA PCR arrays. Statistical analyses were performed to clarify the potential influence of MSI status and altered gene expression to clinical features. Prognosis was estimated with Kaplan-Meier analysis.

The frequency of MSI tumors was 41.66 % and microsatellite stabile (MSS) tumors were 58.33 %. The expression levels of *IMPDH2, CK20* and *MAP3K8* were up-regulated in MSS in compared to MSI patients ($P < 0.05$). Up-regulation of *CK20* was significantly associated with lymph node metastasis ($P = 0.026$), recurrence/distant metastasis ($P = 0.0008$) and short survival ($P = 0.0137$) in MSS.

Although validations are required, our findings supported that over expression of *CK20* gene might provide novel therapeutic molecular target related with MSI status for treatment of early-onset CRC, as well as new directions for the development of anticancer drugs.

MUTYH mutations and variants in Jews of Moroccan origin with or without minimal colorectal adenomatous polyposis

G. Rosner[1], *D. Bercovich*[2], *S. Pel*[1], *Z. Samuel*[1], *E. Santo*[1], *P. Rozen*[1];
[1]*Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel,* [2]*Human Molecular Genetics and Pharmacogenetics, Migal - Galilee Bio-Technology Center, Kiryat-Shmona, Israel.*

Background: Israeli-Jews of North-African origin were a low-risk population for colorectal cancer (CRC). This is changing. Little is known of contributing genetic susceptibility. **Objectives:** Evaluate frequency and types of *MUTYH* mutations and variants in a defined population of North-African Jews. **Methods:** Patients were of Moroccan origin having colonoscopy 2007-12 and volunteering for genetic evaluation. Excluding Familial Adenomatous Polyposis and Lynch Syndrome, patients with ≥3 colorectal adenomas and non-adenoma controls were examined for 6 *MUTYH* mutations & variants. **Results:** Seventy-five patients, 52 with adenomas, had *MUTYH* analysis; 17 (32.7%) had mutations or variants identified. In adenoma patients there were 8 (15.4%) Y179C, G396D homozygotes or compound heterozygous; all had >10 adenomas and 4 had familial neoplasia. Six others were heterozygotes, 4 with <10 and 2 with >10 adenomas; 5 had familial neoplasia and 3 a neoplasm. Other mutations were two S512F heterozygotes with <10 adenomas and familial neoplasms and one had a neoplasm; another had 1186_1187ins GG and >10 adenomas. Four heterozygotes had the Q324H variant. In 23 non-adenoma controls: 1 had the S512F another the L417M variant, another the R509C variant and 16 the Q324H variant. **Conclusions**: Jews of Moroccan origin can have *MUTYH* mutations associated with only few adenoma, family and personal history of cancer similar to sporadic CRC. The S512F mutation appears to be pathogenetic, the Q324H a frequent variant. The findings suggest *MUTYH* evaluation in these patients with even few adenomas, and need to follow-up heterozygotes and Q324H carriers for CRC.

Identification of potentially functional single nucleotide polymorphisms (pfSNPs) associated with fluorouracil / platinum drug response in colorectal cancer patients

S. S. Chong[1,2], *J. Wang*[1], *S. Y. K. Ong*[3], *L. L. Ooi*[4], *C. G. Lee*[1,3,5];
[1]*National University of Singapore, Singapore, Singapore,* [2]*National University Hospital, Singapore, Singapore,* [3]*National Cancer Centre, Singapore, Singapore,* [4]*Singapore General Hospital, Singapore, Singapore,* [5]*Duke-NUS Graduate Medical School, Singapore, Singapore.*

Colorectal cancer (CRC) ranks among the most common causes of cancer death worldwide. Approximately a third of patients are diagnosed at the metastatic stage (stage IV) and a third of curatively resected cases (stages I-III) relapse. Thus a substantial proportion of patients require drug treatment for metastatic/relapsed CRC. Two common combination drug regimes for this cancer are CAPOX (capecitabine and platinum-based oxaliplatin) and CAPIRI (capecitabine and topoisomerase-I inhibitor) but positive response to these regimes is only ~40-45%. Availability of a reliable early predictive biomarker of drug response in metastatic CRC can enable appropriate individualized tailoring of drug regimes for patients, moving personalized medical care closing to reality. Patients predicted to be non-responders to specific drug regimens can avoid ineffective drug treatments and their associated side-effects, and instead opt for novel treatments. Currently, no reliable tests exist for early prediction of response to chemotherapy in these patients. Single nucleotide polymorphisms (SNPs) in some genes have previously been shown to be associated with differences in drug response. A novel pathway-based approach was used to test potentially-functional SNPs (pfSNPs) in candidate genes that may serve as predictive biomarkers of drug response. Of >100 patients examined, three pfSNPs in strong LD with each other showed presence of the minor alleles only in non-responders. Their minor alleles are predicted to disrupt nonsense mediated decay, an exon-splice enhancer site, and miRNA binding. These 3 SNPs could thus serve as a useful biomarker for early response to standard anti-CRC drug regimens.

Carriership of pathogenic *BLM* alleles is associated with early-onset colorectal cancer

M. M. Hahn[1,2], *A. R. Mensenkamp*[1,2], *R. M. de Voer*[1,2], *W. A. van Zelst-Stams*[1], *L. Spruijt*[1], *C. Gilissen*[1], *M. Tychon*[1], *R. Derks*[1], *N. Wieskamp*[1], *L. Vreede*[1], *I. D. Nagtegaal*[1], *H. K. Schackert*[3], *A. Geurts van Kessel*[1], *N. Hoogerbrugge*[1], *M. J. L. Ligtenberg*[1], *R. P. Kuiper*[1];
[1]*Radboud University Nijmegen Medical Center, Nijmegen, Netherlands,* [2]*These Authors contributed equally to the presented work, Na, Netherlands,* [3]*Universitätsklinikum Carl Gustav Carus, Dresden, Germany.*

Around 5% of all colorectal cancer (CRC) cases are caused by known monogenic aberrations, but much of the genetic heritability of CRC is still unexplained. The known genetic causes of CRC predisposition include rare recessive RecQ-helicase deficiency syndromes: Bloom (*BLM*) syndrome and Werner (*WRN)* syndrome. Previous studies have led to conflicting conclusions as to whether carriership of pathogenic *BLM* and *WRN* alleles predispose to CRC. Here we assessed the carriership of pathogenic *BLM* and *WRN* alleles in early-onset CRC (<45 years of age) patients.
By performing whole exome sequencing in a cohort of 57 unexplained early-onset mismatch-repair proficient CRC patients we detected two carriers of a pathogenic *BLM* mutation and one carrier of a pathogenic *WRN* mutation. Screening of an additional cohort of 183 young CRC patients from the Netherlands and Germany resulted in 3 additional patients with a pathogenic mutation in *BLM* and one patient with a pathogenic *WRN* mutation. A comparison with data from 1,302 exomes in our in-house database (non-CRC) as well as with 6,503 exomes from a public database (http://evs.gs.washington.edu/) revealed a significant enrichment of pathogenic *BLM* mutations (both p-values <0.05), but not *WRN* mutations, in our CRC cohort. Moreover, in 1 out of 2 analyzed tumor samples from *BLM* carriers somatic loss of the wild-type allele was found.
In conclusion, we found that carriership of pathogenic *BLM* alleles is enriched in early-onset CRC patients suggesting that these alleles contribute to an increased CRC risk.

Background: Biallelic germline mutations in the *MYH* gene cause MYH-associated polyposis (MAP) disease, an autosomal recessive form of inherited colorectal cancer.
There have been many investigations into MAP that have been conducted in many different countries. Currently there is limited data on MAP in Morocco, and it is reasonable to think, that the prevalence of this form of genetic predisposition is as high as other autosomal recessive genetic diseases found in countries with high rates of consanguinity.
The aim of this study is to examine the frequency of MYH mutations in colorectal cancer and/or attenuated polyposis in Moroccan patients.
Patients and methods: We carried out DNA analysis in 62 patients to screen for the three recurrent mutations c.494A>G, c.1145G>A and c.1185_1186dup, whereas 40 subjects were screened for germline MYH mutations in the whole coding sequence of the MYH gene by direct DNA sequencing.
Results: Three patients with colorectal cancer and attenuated polyposis carried biallelic mutations in the MUTYH gene. One patient with 25 adenomas without colorectal cancer carried the c.1145 G>A mutation at a homozygote state and one patient with 3 polyps was heterozygote for the mutation c.1145 G>A.
Conclusion: We report the first biallelic MYH mutations in four Moroccan patients with clinical criteria of MAP. Despite the relatively small sample size of the current study, our findings suggest that the MAP is not a frequent cause of colon cancer in Morocco as we had expected.

P11.105

Investigation molecular and epidemiologic of polymorphisms Tyr113His gene EPXH1 and DraI-CYP2E1 in xenobiotics metabolism for treating patients with sporadic colorectal cancer.

G. M. M. Fernandes[1], *A. Russo*[1], *A. L. S. Galbiatti*[1], *R. B. Lelis*[1], *N. F. Gazola*[1], *S. P. Santos*[1], *M. A. Proença*[2], *A. E. Silva*[2], *G. S. Cunrath*[3], *J. G. Netinho*[3], *É. C. Pavarino*[1], *E. M. Goloni-Bertollo*[1];
[1]*Faculty of Medicine of São José do Rio Preto – FAMERP, São José do Rio Preto-SP, Brazil,* [2]*University Estadual Paulista – UNESP, São José do Rio Preto-SP, Brazil,* [3]*Department of Surgery - Coloproctology Service, Base Hospital, University Hospital, Faculty of Medicine of São José do Rio Preto - FAMERP., São José do Rio Preto-SP, Brazil.*

Colorectal cancer (CRC) is neoplasm malignancy that occurs in the large intestine (colon) and rectum and has a high incidence among Brazilian patients. The etiology of colorectal cancer includes age over 60 years and lifestyle habits (smoking and alcohol consumption). To analyze the frequency of polymorphism Tyr113His and DraI-CYP2E1 and the association between them and clinicopathological characteristics of the patients compared with controls. The study included a total of 231 individuals (57 patients and 174 controls) Coloproctology Service, Base Hospital, University Hospital, Faculty of Medicine of São José do Rio Preto - FAMERP. The variables analyzed were age, sex, primary site of occurrence. Molecular analysis was performed by Real Time. For the statistical analysis we used chi-square test, Hardy-Weinberg and multiple logistic regression. Statistical analysis showed that there significant differences between patients and controls in relation to sex (p = 0.001; OR = 0.27; CI95%= 0.12 to 0.60) and age (p= 0.035; OR= 3.16; CI95%= 1.08 to 9.25). Also found relation for the DraI-CYP2E1 polymorphism (p≥ 0.000; OR= 6.78; CI95%= 3.19-14.39). In the present study we observed a high frequency of males and in the older age of patients group in the control group. Only the polymorphic allele of *Dra*I-CYP2E1 appears to be associated with susceptibility to CCR. According to preliminary results, male gender, older age and the presence of the polymorphism DraI-CYP2E1*6 are being ratified as a risk factor. Results led us to extend for further study of these polymorphisms and others to a better understanding of RCC carcinogenesis.

P11.106

K-ras gene - possible correlations of its mutational status with the histopathological findings in metastatic colorectal carcinomas

F. F. Cionca[1], *G. Cardos*[2];
[1]*The National Institute for Research and Development in the Field of Pathology and Biomedical Sciences „Victor Babeş", Bucharest, Romania,* [2]*Personal Genetics - Medical Genetic Centre, Bucharest, Romania.*

Background: Gain-of-function K-ras point mutations, present in 30-50% of the metastatic colorectal carcinomas (CRC), maintain the active form of the ras p21 protein and lead to epidermal growth factor receptor (EGFR) independent activation of intracellular signaling pathways, making the anti-EGFR tumor therapy ineffective.
The aim of this study is to identify possible correlations between the mutational status of the K-ras gene and the histopathological findings in patients with CRC.
Methods: We studied 45 patients with CRC, 39 primary tumors and 6 metastases. The formalin-fixed paraffin-embedded tissue samples were analyzed using an indirect bistadial immunohistochemical (IHC) technique, performed with a Dako EnVision+ Dual Link System-HRP, with antibodies for the EGFR and the ras protein. Mutations in exon 2, codons 12 and 13 of the K-

ras gene were detected by PCR-Restriction Fragment Length Polymorphism analysis.

Results: K-ras mutations were present in 46, 66 % of the cases (21 cases), 19 adenocarcinomas and 2 metastases. EGFR was positive in 10 cases in tumor cells and in 11 cases in the vessels, with 3 cases of double positivity. Immunohistochemical overexpression of ras protein was detected in 14 samples. The relationship between the positivity of the K-ras mutation and the positive immunohistochemical reaction for EGFR and the ras protein did not reach statistical significance.

Conclusions: There were no significant correlations between the mutational status of the K-ras gene and the IHC reactions for EGFR and ras p21 protein, proving once more the major role of the molecular analyses in CRC anti-EGFR therapy.

Introduction Lynch syndrome is an inheritable cancer syndrome caused by mutations in one of the mismatch repair (MMR) genes. The clinical phenotype for mutations in the MLH1, MSH2 or MSH6 is comprehensively described, but the consequences of a PMS2 mutation are less well understood. We aim to establish the cancer risk for PMS2 mutation carriers in the largest cohort reported so far.

Methods Data were used from 107 PMS2 families, including approximately 378 mutation carriers and more than 2500 family members, assembled by our centre in cooperation with Dutch university hospitals and several genetic clinics in other European countries. A Kaplan Meier analysis calculating cancer risk in proven or obligated PMS2 carriers will be done.

Results The result Kaplan Meier analysis will be shown during the presentation.

In the 378 mutation carriers analyzed, CRC was most frequently diagnosed (n=112). In 208 female mutation carriers endometrial (n=29) and breast cancers (n=11) (after CRC) were most frequent. Other cancers than the colon or endometrium were reported in a total of 47 cases.

Discussion In this study we analyze the cancer risks in a large cohort of PMS2 mutation carriers.

The tumor spectrum in total group of family members is diverse and families seem less severely affected than other MMR deficient families, suggesting a lower penetrance for PMS2 mutation carriers.

DNA methylation changes in Lynch syndrome associated normal colonic mucosa

S. Valo[1,2], *S. Kaur*[2], *L. Renkonen-Sinisalo*[3], *H. Järvinen*[3], *J. Mecklin*[4], *M. Nyström*[1], *P. Peltomäki*[2];
[1]*Department of Biosciences, University of Helsinki, Helsinki, Finland,* [2]*Department of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland,* [3]*Second Department of Surgery, Helsinki University Central Hospital, Helsinki, Finland,* [4]*Department of Surgery, Jyväskylä Central Hospital, Jyväskylä, Finland.*

Colorectal cancer (CRC) develops via multiple steps which involve genetic changes, such as mutations in growth-regulatory genes, and epigenetic alterations, such as CpG island hypermethylation. These changes accumulate over time in the normal tissue, for example due to many environmental factors such as diet, and may result in pre-cancerous field defects. Lynch syndrome (LS) is associated with inherited defects of the DNA mismatch repair genes which together with other genetic and epigenetic changes accelerate tumorigenesis. The aim of this project is to gain new insights to the molecular mechanisms through which DNA methylation can affect colorectal carcinogenesis in predisposed LS mutation carriers and to define how CpG island methylation of CRC risk genes varies with age, mutation, CRC diagnosis and different colorectal regions.

Normal colonic mucosa biopsies from different colorectal regions were gathered from 38 Finnish LS mutation carriers during regular surveillance in addition with 11 matching normal-polyp pairs. Patient information was obtained from a nation-wide registry. CpG island methylation was studied with the methylation-specific multiplex ligation-dependent probe amplification test (MS-MLPA) which detects CpG methylation of selected genes. Of 15 CRC risk genes tested so far at least two show increased methylation already in normal mucosa which further increases in the vicinity of polyps and in polyps themselves. Our preliminary findings suggest that increased DNA methylation in normal colonic mucosa may indicate higher risk for developing CRC.

P11.109

Constitutional epimutation of *MLH1* is linked to the variants c.-27C>A and c.85G>T present on an ancestral haplotype

I. P. Vogelaar[1], *C. Kwok*[2], *W. A. G. van Zelst-Stams*[1], *A. R. Mensenkamp*[1], *M. J. L. Ligtenberg*[1], *R. W. Rapkins*[2], *R. L. Ward*[2], *N. Chun*[3], *W. C. McKinnon*[4], *M. S. Greenblatt*[4], *M. P. Hitchins*[2];
[1]*Radboud University Medical Center, Nijmegen, Netherlands,* [2]*University of New South Wales, Sydney, Australia,* [3]*Stanford University School of Medicine, Palo Alto, CA, United States,* [4]*University of Vermont, Burlington, VT, United States.*

Lynch syndrome, caused by germline heterozygous mutations of the DNA mismatch repair genes *MLH1*, *MSH2*, *MSH6* and *PMS2*, or deletions affecting the *EPCAM* gene upstream of *MSH2*, is characterized by a predisposition to early-onset colorectal and additional extracolonic cancers. An alternative but rare cause of Lynch syndrome is a constitutional epimutation of *MLH1*, which is characterized by promoter methylation and transcriptional silencing of a single allele in normal tissues.

Worldwide, five families with autosomal dominant transmission of a constitutional *MLH1* epimutation linked to an *MLH1* haplotype with two single nucleotide variants (c.-27C>A and c.85G>T) have been identified. To examine whether these families share a common ancestry, we performed SNP array-based genotyping in four of the families. The genotyping revealed a shared haplotype across a ≤2.6 Mb region of chromosome 3p22 encompassing *MLH1* and additional surrounding genes, indicating common ancestry.

This finding has two important implications. First, the candidate region for the genetic defect of this epimutation is now defined by the ≤2.6 Mb minimal region of haplotype overlap between the four families. Furthermore, regardless of the exact underlying mechanism, which might be driven by either the c.-27C>A or c.85G>T variants, these variants can serve as markers for this disease-causing genetic haplotype. Additional carriers of this founder haplotype could be spread across the globe. Our results can therefore improve the identification and diagnosis of (yet unexplained) Lynch syndrome cases.

[1]*Lille University Hospital, Department of Molecular Oncology, Lille, France,* [2]*UMR Inserm 837, Lille, France,* [3]*Lille North of France University, Lille, France,* [4]*Rouen University Hospital, Department of Genetics, Rouen, France,* [5]*Bergonie Institute, Bordeaux, France,* [6]*Inserm U916, Bordeaux, France,* [7]*Gustave Roussy Institute, Department of Genetics, Villejuif, France,* [8]*Lille University Hospital, Department of Clinical Genetics, Lille, France,* [9]*Eugene Marquis Center, Rennes, France,* [10]*Amiens University Hospital, Amiens, France.*

Lynch syndrome is characterized by genetic predisposition to colorectal, endometrial and other cancers due to germline mutations of the mismatch repair genes *MLH1*, *MSH2*, *MSH6* and *PMS2*. In a subset of patients without

genetic mutation, constitutional *MLH1* epimutations (i.e. germline *MLH1* promoter hypermethylation) have been identified as the cause of Lynch syndrome.
We first performed a retrospective study in a cohort of 134 unrelated patients (*Hum. Mutat. 2012; 33:180-8*), and identified the epimutation in two probands, with transgenerational transmission of the epigenetic defect in one case.
Starting fall 2009, we implemented *MLH1* promoter methylation testing on a systematic basis with *MLH1* gene analysis in our lab. Thus 160 patients were screened for germline epimutation, and 119 additional DNA samples from patients referred to other French institutions and tested negative for genetic mutation were sent to our lab for methylation analysis. Altered MLH1 and/or PMS2 protein expression was documented for 158 patients without deleterious genetic mutation. An epimutation was found for 8 patients (5 %, 8/158).
Somatic *MLH1* promoter hypermethylation is frequently observed in microsatellite unstable sporadic cancers and is commonly used to discriminate sporadic from hereditary cancers. However it can also reveal the presence of a germline epimutation, emphasizing the importance of methylation analysis in germline DNA, especially for patients with multiple or young-onset cancers. Additionally some patients with germline epimutation where not tested for somatic hypermethylation due to maintained MLH1 protein expression or lack of available tumor sample. Systematic constitutional epimutation testing proved to be useful in these cases.

P11.111
Functional identification of splicing mutations in the exon 10 of MLH1, a gene implicated in hereditary colorectal cancer

O. Soukarieh[1], *M. Hamieh*[1], *P. Gaildrat*[1], *S. Baert-Desurmont*[2], *T. Frébourg*[1,2], *M. Tosi*[1], *A. Martins*[1];
[1]*Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France,* [2]*Department of Genetics, Rouen University Hospital, Rouen, France.*

It's currently known that sequence variations identified in patients can be deleterious by affecting mRNA splicing: either by changing splice sites or by modifying splicing regulatory elements. Here, we analyzed the effect on splicing of all single-substitutions reported on the Leiden Open Variation Database in the exon 10 of *MLH1* (n=22), a gene implicated in hereditary colorectal cancer (also called Lynch Syndrome). *Ex vivo* splicing assays with representative minigenes revealed that only 5 out of the 22 tested mutations had no effect on splicing. Among the splicing alterations induced by the remaining 17 mutations, we detected the following events: (i) creation of internal splice site, (ii) increased exon inclusion, and (iii) increased exon skipping. Mutations located outside splice sites but inducing exon inclusion or skipping were further analyzed by using a completely heterologous minigene particularly sensitive to the presence of exonic splicing regulatory sequences. Results suggest that indeed those mutations alter splicing regulatory elements. We could confirm the drastic impact on splicing of one of these mutations by analyzing a RNA sample from a patient. Interestingly, in this case, we observed not only increased skipping of exon 10 but also of exons 9-10 and 10-11. Our results indicate that the exon 10 of *MLH1* is very sensitive to splicing mutations. Moreover, this study contributes to the molecular diagnosis of hereditary colorectal cancer.

P11.112
Elimination of pseudogene interference in a PMS2 mutation screen. Validation in patients at risk for Lynch Syndrome in Ontario, Canada.

J. M. Kelly[1], *C. Reith*[1], *A. J. Stuart*[1], *D. K. Driman*[2], *P. J. Ainsworth*[2];
[1]*London Health Sciences Centre, Mol Dx Lab., London, ON, Canada,* [2]*Dept. Pathology, LHSC/Western University., London, ON, Canada.*

Lynch Syndrome (LS) is characterized by mutations in the DNA mismatch repair genes MSH2, MLH1, MSH6, and PMS2. However the identification of PMS2 specific mutations is challenged by a wealth of pseudogenes, along with the allelic diversity of the 3' region of PMS2, a complexity which has probably lead to under-reporting PMS2 gene mutations as a cause of LS. We describe a technique to characterize the PMS2 gene which combines MLPA analysis utilizing SNP-specific probes, along with methodology, adapted from Clendenning et al, utilizing genomic LR-PCR enabled, and direct specific sequencing, of both PMS2 and PMS2CL exons.
The identification of LS in a panel of 30 patients, at risk of this disease by clinical history, was approached by examination of their tumour tissue/DNA (where available) using immunohistochemical analysis of the 4 MMR proteins, along with assessment of microsatellite instability of the tumour DNA. Using the PMS2 technique outlined above on leukocyte-derived genomic DNA, PMS2 gene mutations were identified in 6 unrelated individuals in the panel of 30 patients: (c.736_741delins [four unrelated families], c.1882C>T, and a deletion containing exons 5-7, i.e. 6/30). All 6 individuals demonstrated isolated imunohistochemical loss of PMS2. No PMS2 mutations were identified in 2 further individuals also showing isolated imunohistochemical loss of PMS2, and no PMS2 mutations were identified in any individuals (14) showing imunohistochemical loss of both MLH1 and PMS2.
Immunohistochemical analysis of the MMR proteins followed by blending MLPA with sequence analysis can effectively identify deleterious PMS2 gene mutations in individuals at risk of LS.

Lynch syndrome due to PMS2 mutations: one clinic's experience

T. Graham[1], *J. Cohen*[1], ***L. Velsher***[2];
[1]*Sunnybrook Odette Cancer Centre, Toronto, ON, Canada,* [2]*North York General Hospital, Toronto, ON, Canada.*

PMS2 is a mismatch repair gene that forms a dimer with MLH1. Whereas MLH1 mutations are found in almost 50% of Lynch syndrome cases, PMS2 mutations are a rare cause of this condition. Information regarding the spectrum of disease due to PMS2 mutations is limited. In our hereditary cancer clinic we have 3 PMS2 families from a total of 44 mutation-proven Lynch families. We discuss each case to show the variability of presentation. These cases add to the limited clinical information about Lynch due to PMS2 mutations. We also review some of the basic science evidence to support reduced penetrance of heterozygous PMS2 mutations.

Lynch Syndrome (LS) is caused by mutations in DNA mismatch repair genes. Diagnosis is not always trivial and may be costly. Knowledge of incidence, genotype-phenotype correlation, spectrum of mutations and genes involved in specific populations, facilitates the diagnostic process and contributes to clinical work-up. Aim: To report the unique features of LS, gene distribution, mutations detected and co-occurrence of related syndromes in Ashkenazi Jews. METHODS: Patients were studied in high risk clinics. Diagnostics followed a multi-step process. It included testing for founder mutations, tumor testing, gene sequencing and MLPA. LS was defined by positive tumor analysis and/or positive mutation testing. RESULTS: We describe a cohort of 120 carriers from 75 Ashkenazi families with LS. Mutations were identified in 51/75 (68%) families. 36 families harbored mutations in *MSH2*, 9 had mutations in *MSH6*, and 6 had mutations in *MLH1*. 37/51 (73%) families carried one of the 3 ‚Ashkenazi' founder mutations in MSH2 or MSH6. Each of the other 14 families carried a private mutation. 3 (6%) were large deletions. Only 25/75 (33%) families were Amsterdam Criteria positive, 62 (83%) were Bethesda positive and 13 (17%) did not comply with any clinical criteria. We report C-MMRD and co-occurrence of BRCA and LS in our cohort. CONCLUSIONS: Mutation spectrum and gene distribution among Ashkenazi

Jews are unique. Three founder mutations cause LS in 73% families with known mutations. *MSH2* and *MSH6* cause the majority of cases, while *MLH1* comes third. These features affect the phenotype, the diagnostic process, risk estimation, and genetic counseling.

One next generation sequencing panel for all patients suspected of hereditary cancer

Y. J. Vos, *B. Sikkema-Raddatz, K. K. v. Dijk-Bos, P. v. Norel, L. F. Johansson, E. N. de Boer, H. Westers, A. H. v.d. Hout, R. J. Sinke, R. H. Sijmons;*
University Medical Centre Groningen, University of Groningen, Groningen, Netherlands.

Phenotypes of many hereditary tumour syndromes are known to overlap. In addition, different genes may underlie one syndrome. Therefore the number of genes to examine in a particular clinical case can be large. In current diagnostic and reimbursement settings, the number of genes that can be analysed for one patient through Sanger sequencing is limited. Next generation sequencing offers novel possibilities to analyse large numbers of genes in parallel at relatively low cost. We developed a kit based on Agilent Sure Select Target Enrichment for simultaneous mutation detection in 73 genes that have previously been associated with tumour syndromes. The kit has been validated by two series of twelve patients with known variants identified through Sanger sequencing of the BRCA or the Lynch syndrome genes. In addition, a set of twelve breast or colorectal cancer patients was analysed anonymously for all 73 genes.
The samples were sequenced using 151 bp paired-end reads on an Illumina MiSeq sequencer and analysed using the Next gene software and Cartagenia. All pathogenic mutations, unclassified variants and polymorphisms previously detected were identified. Furthermore, 40 novel variants that were identified in twelve anonymous patients could be confirmed by Sanger sequencing.
The Cartagenia software allows blocking the analysis of certain genes. For diagnostic purposes genes within the panel have been defined for filtering, e.g. depending on the availability of preventive options. The genes to be analysed will be decided during genetic counselling prior to testing.

Influence of VEGF polymorphism -634 G/C on *VEGF* mRNA expression and susceptibility to sporadic colon cancer

T. Cacev, *J. Ponos, S. Kapitanovic;*
Rudjer Boskovic Institute, Zagreb, Croatia.

Angiogenesis is one of the six postulated hallmarks of cancer and Vascular endothelial growth factor (VEGF) is one of the key mediators of this very complex process. Thusfar no prognostic and predictive markers for *VEGF* expression have been established and therefore the prediction of VEGF production based on individual genetic background might be useful in the prediction of disease progression and/or the efficacy of anti-cancer treatment. *VEGF* gene is highly polymorphic, with many single nucleotide polymorphisms (SNPs) that may affect VEGF production and/or activity and possibly lead to inter-individual differences in tumor development and progression. In this study we have examined the influence of *VEGF* -634 G/C (rs2010963) polymorphism on *VEGF* mRNA expression as well as susceptibility to sporadic colon cancer.
VEGF mRNA expression analysis in tumour tissue was performed by real-time RT-PCR. VEGF -634 G/C genotyping was performed in 250 patients with sporadic colon cancer and 250 unrelated healthy volunteers by real-time PCR-SNP analysis.
A statistically significant correlation between *VEGF* mRNA expression and *VEGF* -634 G/C genotypes was found (p=0.019). Genotypes carrying the G allele (GG+CG) were associated with high *VEGF* mRNA expression, while the CC genotype was associated with low *VEGF* mRNA expression. However, there was no statistically significant association between *VEGF* -634 G/C genotypes and susceptibility to sporadic colon cancer.
Finally, we can conclude that although in our study VEGF -634 G/C polymorphism was associated with *VEGF* mRNA expression in sporadic colon tumours it was not associated with susceptibility to this type of cancer.

Copy Number Alterations in Small Intestinal Neuroendocrine Neoplasms Determined by Array Comparative Genomic Hybridization

J. Hashemi[1], *O. Foutohi*[1], *L. Sulaiman*[1], *M. Kjellman*[2,3], *A. Höög*[1], *J. Zedenius*[1,3], *C. Larsson*[1];
[1]*Department of Oncology-Pathology, Karolinska Institutet, Cancer Center Karolinska, Karolinska University Hospital, Stockholm, Sweden,* [2]*Department of Molecular Medicine and Surgery , Karolinska Institutet, Cancer Center Karolinska, Karolinska University Hospital, Stockholm, Sweden,* [3]*Department of Breast and Endocrine Surgery , Karolinska Institutet, Cancer Center Karolinska, Karolinska University Hospital, Stockholm, Sweden.*

Small intestinal neuroendocrine neoplasms (SI-NENs) are typically slow-growing neoplasms that have metastasized already at the time of diagnosis. To further define regions of recurrent copy number (CN) alterations (CNA), we applied array CGH on SI-NENs including 18 primary tumors and 12 metastases. The most frequent abnormality was loss on chromosome 18 observed in 70% of cases. CN losses were also frequently found on chromosomes 11 (23%), 16 (20%), and 9 (20%), with regions of recurrent CN loss identified in 11q23.1-qter, 16q12.2-qter, 9pter-p13.2 and 9p13.1-11.2. Gains were most frequently detected in chromosomes 14 (43%), 20 (37%), 4 (27%), and 5 (23%) with recurrent regions of CN gain located to 14q11.2, 14q32.2-32.31, 20pter-p11.21, 20q11.1-11.21, 20q12-qter, 4 and 5. Quantitative PCR analysis confirmed most CNAs detected by a-CGH as well as revealed CNAs in an extended panel of SI-NENs. Unsupervised hierarchical clustering of recurrent regions of CNAs revealed two important tumor groups and 5 chromosomal clusters. Loss in chromosomes 20, 18, 16 and 11 were found in both tumor groups. Tumor group II was enriched for alterations in chromosome cluster D, including gain on chromosomes 4, 5, 7, 17 and gain on 20 in chromosome cluster B. Gain on 20pter-p11.21 was associated with short survival. Statistically significant differences were observed between primary tumors and metastases for loss on 16q and gain on 7.In conclusion, our results revealed several CNAs in recurrent candidate regions with a potential role in SI-NEN development. Distinct genetic alterations and pathways are involved in tumorigenesis of SI-NENs.

Gallbladder Cancer Predisposition: A Multigenic Approach involving Inflammatory, Xenobiotic and Steroidal receptor genes

K. L. Sharma[1], *S. Misra*[2], *A. Kumar*[1], *B. Mittal*[1];
[1]*Sanjay Gandhi Post Graduate Institute of Medical Sciences (SGPGIMS), Lucknow, India,* [2]*CSMMU, Lucknow, India.*

Introduction: Gallbladder cancer (GBC) is a multifactorial disease with complex interplay between multiple genetic variants. We analyzed 15 polymorphisms in 9 genes involved in inflammatory, xenobiotic and steroidal receptor pathways to find out combinations of genetic variants contributing to GBC risk.
Methods: The genes included in the study were (MMP-2,7,9) TIMP-2, CYP1A1, CYP1B1, PLCE1, LXR-alpha and LXR-beta. Genotypes were determined by PCR-RFLP and Taqman probes. Statistical analysis was done by SPSSver16. Multilocus analysis was performed by Classification and Regression Tree Analysis (CART) and MDR to identify genetic variants in modifying GBC risk. In-silco analysis was performed using Bioinformatics tools (F-SNP, FAST-SNP).
Results: Single locus analysis by logistic regression showed association of MMP2 (-735 C>T, -1306 C>T), MMP7 -181 A>G, MMP-9 (P574R, R668Q), TIMP2-418 G>C, CYP1A1-MspI, CYP1A1-Ile462Val, PLCE1 (rs2274223 A>G, rs7922612 T>C) and LXR-beta T>C (rs3546355 G>A, rs2695121 T>C) polymorphisms with GBC risk (pA, rs2695121 T>C), MMP-2 (-1306C>T) and MMP-9 (R668Q) and PLCE1 rs2274223A>G to be key players in GBC causation (p<0.001, CVC=7/10). The results were further supported by independent CART analysis ((p<0.001). Sub-group analysis based on gender and gallstone status showed distinct subsets of genetic signatures in GBC susceptibility. Insilico analysis revealed variable change in splicing or transcriptional regulation.
Conclusion: The multigenic approach showed the importance of PLCE 1, LXR-beta and MMPs genetic variants and their interactions in contributing to GBC risk.

Whole genome and whole exome sequencing of gastric cancer samples

D. Esser[1], *P. Rosenstiel*[1], *J. Haag*[2], *N. Holze*[2], *S. Schreiber*[1,3], *C. Röcken*[2];
[1]*Institute for Clinical Molecular Biology, Christian-Albrechts-University, Kiel, Germany,* [2]*Institute for Pathology, Christian-Albrechts-University, Kiel, Germany,* [3]*3 Department of General Internal Medicine, University Hospital Schleswig-Holstein, Kiel, Germany.*

Gastric cancer is diagnosed in 8% of all cancer cases and causes 10% of the cancer deaths worldwide (Jemal et al., 2011). To further analyze the genetic basis of gastric cancer, we sequenced the whole genome of a microsatellite stable and a microsatellite unstable gastric carcinoma and the genome of the matched normal tissue samples on the Illumina HiSeq with an average coverage of 49x. In order to increase the read depth in the coding regions we performed whole exome capture using the Agilent SureSelect Human All Exon v2 kit followed by sequencing on the Solid 4 and received an additional average coverage of 55x.
Using a comprehensive filter strategy for single nucleotide variants (SNVs) and structural variants (SVs) we were able to identify a multitude of novel potentially damaging mutations that are followed up by functional assays. Recurrence is assessed in an independent cohort of gastric cancer patients. With help of the databases OMIM, HGMD and GWAS we could further detect a great number of known cancer associated SNVs. Pathway (KEGG) and functional (GO) analysis of SNVs and SVs were performed using 1087 samples from the 1000 Genomes project as a normal variant matrix.
The results highlight a strategy of an exemplary tumor genome analysis that combines both exome and whole genome sequence information with two different NGS platforms, uses population-based whole genome resources as a novel pathway-based filter and integrates SNV as well as SV analysis.

P11.120

Gastric cancer as a part of BRCA1-related syndrome

E. N. Suspitsin[1,2], *V. M. Moiseyenko*[1], *N. M. Volkov*[1], *G. A. Yanus*[1,2], *A. G. Iyevleva*[1], *A. V. Kornilov*[1], *E. N. Imyanitov*[1,2,3];
[1]*N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation,* [2]*St.-Petersburg State Pediatric Medical University, St.-Petersburg, Russian Federation,* [3]*I.I. Mechnikov North-Western Medical University, St.-Petersburg, Russian Federation.*

The risk of cancer disease in BRCA1 mutation carriers is believed to be restricted mainly to breasts and ovaries. We screened 65 patients with gastric cancer (GC) for Russian BRCA1 5382insC founder allele, and identified 2 (3%) heterozygotes. Both mutation-positive patients demonstrated unusually pronounced and durable response to platinum-containing therapy, and reported personal or family history of breast or ovarian cancer. Patient 1, 60 years old female, was treated by cisplatin/5-fluorouracil, and showed 66% reduction of tumor size with a time to progression 10.7 months; her mother was affected by ovarian cancer. Patient 2, 62 years old female, was treated by doxorubicin/cisplatin/5-fluorouracil; the reduction of tumor size was 93%, and the time to progression was 21.9 months; this patient had a personal history of successfully cured breast cancer at age 44. In accordance with the "two-hit" mechanism of inactivation of hereditary cancer gene, both BRCA1-associated gastric carcinomas showed the somatic deletion of the wild-type BRCA1 allele. The involvement of BRCA1 germ-line mutations in GC development may be somewhat related to regional attitudes, which until recently included frequent use of strong alcohol, low intake of fresh fruits and vegetables, excessive consumption of fat and salty food, etc. Thus, based on (1) the elevated frequency of BRCA1 mutations in GC patients, (2) the pronounced sensitivity of mutation-positive GC to platinum containing therapy, and (3) the somatic loss of the wild-type BRCA1 allele in the tumor tissue, we conclude that some cases of gastric carcinoma may be linked to BRCA1 syndrome.

P11.121

Somatic alterations of the E-Cadherin gene predict survival of gastric cancer patients mainly those presenting with familial history

J. Carvalho[1], *G. Corso*[2], *D. Marrelli*[2], *C. Vindigni*[3], *B. Carvalho*[4], *R. Seruca*[1], *F. Roviello*[2], *C. Oliveira*[1];
[1]*Institute of Molecular Pathology and Immunology of the University of Porto (IPATIMUP), Porto, Portugal,* [2]*Department of Human Pathology and Oncology, Unit of Surgical Oncology, University of Siena and Instituto Toscano Tumori (ITT), Siena, Italy,* [3]*Unit of Pathology, Azienda Ospedaliera Universitaria Senese, Siena, Italy,* [4]*Department of Pathology, VU University medical center, Amsterdam, Netherlands.*

The prognosis of gastric cancer (GC) is poor, the treatment ineffective, and the molecular pathogenesis players vastly unknown. As E-cadherin (*CDH1)* deregulation and Microsatellite Instability (MSI) define two major paths involved in GC, we characterized and stratified 246 GC cases according to alterations in these pathways.
We systematically analysed a GC series comprising distinct clinical settings (sporadic, familial) and tumour histological types (intestinal, diffuse), for the presence of *CDH1* structural alterations (mutations, LOH) and promoter hypermethylation. Independently of clinical setting and histotype, ~30% of all cases displayed *CDH1* somatic alterations. Familial intestinal GC (FIGC) and both histological types of sporadic GC showed methylation and structural *CDH1* alterations, whilst tumours from hereditary diffuse GC HDGC showed exclusively *CDH1* methylation. Importantly, the worst patient survival rate was seen for FIGC patients carrying *CDH1* structural alterations. MSI phenotype was significantly different between sporadic (19%) and familial (39%) GC and between intestinal (31.2%) and diffuse (12.8%) GC. MSI phenotype occurred preferentially in FIGC families. Notably, among FIGC families, we identified the group with the worst survival who presented MSS tumours and *CDH1* structural alterations (85.7%), and the group presenting the best prognosis with tumours carrying *CDH1* epigenetic alterations and MSI phenotype (77.8%).
In conclusion, this work pinpointed a somatic molecular landscape that determines clinical outcome in GC patients. Particularly for FIGC families, stratification at diagnosis, based on somatic *CDH1* alterations and MSI phenotype, may significantly improve clinical management.

Molecular classification of gastric cancers using an extended panel of gene amplifications

M. Minarik[1], *L. Dusek*[2], *B. Belsanova*[1], *P. Minarikova*[3], *I. Tuckova*[4], *M. Zavoral*[3], *L. Benesova*[1];
[1]*Genomac Research Institute, Prague, Czech Republic,* [2]*Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic,* [3]*Internal clinic, 1st Faculty of Medicine, Charles University in Prague and Military University Hospital, Prague, Czech Republic,* [4]*Department of pathology, Military University Hospital, Prague, Czech Republic.*

Introduction: Gastric cancer represents the third most common malignancy of the gastrointestinal tract in the Czech Republic. Recent advances in biological anticancer therapy revealed importance of understanding of tumor biology underlying its clinical behavior. The standard histopathology categorization into intestinal or diffuse type (lauren classification) is useful for assessing general prognosis, especially, uncovering hereditary origin of the tumor for subsequent CDH1 testing. It is clear, however, that in order to estimate therapy response, further evaluation of molecular profiles is highly desirable.
Aims: In this project we evaluated a large panel of gene amplifications in an attempt to classify gastric cancer tumors.
Methods: Formalin-fixed paraffin-embedded (FFPE) sections from a total of 85 patients were subjected to molecular analysis. Gene amplifications were analyzed by Multiplex Ligation-dependent Probe Amplification (MLPA). The final panel consisted of a total of 70 common oncogenes and tumor supressors. The complex patterns were statistically processed by hierarchical data clstering using Ward and farthest neighbor method.
Results: The overall success rate of DNA extraction from the gastric FFPE samples was at a level of 85%. Both statistical approaches delivered similarities in data clustering. The resulting dendrograms revealed comparably constituted subclusters of samples. As expected HER2, MYC, p16 and b-CAT genes were among the most frequently amplified.
Conclusions: Presence of specific gene amplification may indicate aberrant activation of various signaling pathways, hence, define characteristic tumor behavior. A correlation to monitoring parameters such as progression-free survival or overall survival is ongoing.
Supported by the Czech Ministry of Health grant no. NT13640

P11.123

Abnormal methylation of tumor-related genes in biopsies of the gastric mucosa from patients previously operated on gastric cancer.

N. Checunova, *T. Kchorobrich, D. Zaletaev, M. Nemtsova;*
First Moscow Medical Sechenov University, Moscow, Russian Federation.

Gastric cancer (GC) is one of the most common malignant tumors in the world. GC develops through the accumulation of genetic and epigenetic alterations. Epigenetic silencing of tumor-related genes, due to hypermethylation of the CpG sites in the promoter regions, has emerged as one of the main genetic alterations in cancer development. Aberrant methylation of tumor-related genes is one of the early events in carcinogenesis, it can be determined before the clinical manifestation of the tumor.
We investigated the clinical and prognostic importance of CpG-island hypermethylation in 6 tumor-related genes (*CDH1, RASSF1A, MLH1, N33, DAPK, RUNX,*) for gastric cancer patients. We examined hypermethylation of 6 tumor-related genes in 35 frozen biopsies of the gastric mucosa, obtained during endoscopic research, from patients previously operated on gastric cancer.
There was no hypermethylation of the CpG sites of *CDH1, RASSF1A, MLH1, N33, DAPK, RUNX3* genes in 29 biopsies. In 6/35 samples we have identified aberrant methylation of *CDH, N33, RUNX3* genes, in 1 patient we have identified aberrant methylation of three genes (*CDH1, N33, RUNX3*), in 2 patients - two genes (*CDH1, N33*), in 3 patients - of one methylated gene (*N33* or *RUNX3*).
The current study shows that the hypermethylation of tumor-related genes may be used as additional marker for postsurgical monitoring of gastric cancer patients.

Foveolar cells phagocytose apoptotic neutrophils in chronic active Helicobacter pylori gastritis.

F. Pugliatti[1], *L. Rigoli*[1], *C. Di Bella*[1], *F. Fedele*[2], *V. Procopio*[1], *S. Cara*[1], *R. Caruso*[2];
[1]*Department of Pediatrics, Medical School, Messina, Italy,* [2]*Department of Human Pathology, Medical School, Messina, Italy.*

The recognition and removal of apoptotic inflammatory cells by tissue macrophages and non-professional phagocytes, in a process called efferocytosis, is required for resolution of inflammation and is actively anti-inflammatory. Biopsy specimens from 28 subjects with or without H. pylori infection and active inflammation were examined and graded according to the updated Sydney system. Light microscopy, electron microscopy, and Terminal Deoxynucleotidyltransferase-Mediated UTP End Labeling staining were used to identify apoptosis. H. pylori infection was detected by histology and by molecular assay in 16 out of 28 cases. DNA from paraffin-embedded gastric biopsies was amplified using primers specific for cagA, for the cag „empty site" as well as for the s and m alleles of vacA. The more virulent cagA-positive strains were found in five out of nine patients with chronic active gastritis. The vacA s1/m1 and s2/m1 genotypes were more common in nine patients with chronic active gastritis, while the vacA s2/m2 genotype was more frequent in seven patients with chronic inactive gastritis. Apoptotic neutrophils were also detected within the cytoplasmic vacuoles of the foveolar cells of nine cases with chronic active gastritis. Transmission electron micrographs revealed further apoptotic neutrophils within spacious phagosomes of foveolar cells in a similar manner to those described in late-phase efferocytosis both in vivo and in vitro. These new observations expand the morphological spectrum of gastritis in patients infected with more virulent H. pylori strains, compatible with an anti-inflammatory role for the gastric epithelial cells in their removal of apoptotic neutrophils during active chronic gastritis.

P11.125
O-6-methylguanine-DNA methyltransferase variant in gastric cancer samples from Kashmiri population

T. N. Patel*, N. A. Chikan;*
VIT, Vellore, India.

Background and aims: The Kashmiri population under investigation is a non-migrant population with special social, personal and dietary habits. Gastric cancer along with esophageal cancer accounts more than 60% of all cancers in the region. O6-methylguanine methyltransferase (MGMT) the enzyme of our interest repairs, O6-Methylguanine (O6-meG), a DNA adduct. Genetic alterations and variants of MGMT gene impair the protein's ability to remove alkyl groups from the O6-position of guanine, thereby raising the mutation rate and increasing the risk of cancer.
Methods: We have analyzed fresh frozen gastric cancer samples for MGMT variation using conventional method followed by PCR product sequencing.
Results: Out of 30 samples we studied, 13 neoplastic tissue harbored somatic missense MGMT mutations in Exon 5, leading to S151I, which according to *in silico* analysis reduced MGMT function.
Conclusion: In summary, we found that there is variation in MGMT exon 5 in neoplastic tissue which may lead to impaired DNA repair and contributing to underlying molecular mechanisms in progression of cancer.

P11.126
Chromogenic In Situ Hybridization, a viable alternative to FISH, for detection the HER2neu gene amplification in gastric cancer

M. Neagu*;*
National Institute of Pathology Victor Babes, Bucharest, Romania.

Gastric cancer is one of the most common solid tumours, being the second leading cause of cancer death worldwide, after lung cancer.
Detection of Her 2 neu amplification, its useful to guide therapy for patients with gastroesophageal cancer, as patients with HER2 amplification may be candidates for Herceptin therapy and to confirm the presence of HER2 amplification in cases with 2+ HER2 protein overexpression by immunohistochemistry.
Methods: we collected 55 paraffin-embedded tissue sections of gastric cancer, for which the HER2 status had been predetermined using immunohistochemistry, for this cases determined HER2 gene and chromosome 17 copy numbers using the dual-color PathVysion HER2 DNA probe set (Abbott Molecular), respectively CISH and the scoring system and interpretation of CISH was from - Zytovision.
Immunohistochemistry alone is not sufficient, for determining HER2 status in gastric cancer, detection of Her 2 neu amplification it is a useful methodology for confirming ambiguous immunohistochemistry results.
CISH is a method for detection of gene amplification using a peroxidase reaction, is more practical alternative, due to lower cost, no requirement of fluorescence microscope, use of existing bright-field microscopy, archivable and quantitative results, it s easy to observe both the tissue morphology and the gene amplification evaluation
The CISH results were compared with dual-colour fluorescence in situ hybridisation (FISH) data, there was 98% concordance between CISH and FISH
The high concordance, indicates that CISH is a viable alternative to FISH, for detection of HER 2 NEU gene amplification in gastric cancer.

The correlation between polymorphism of Toll-Like Receptor 4 and cytokines TNFα, TLR4, TGFβ, CD14 AND CCR2 and bacterial infections in patients with pancreatic cancer in Polish population.

M. Durlik[1,2], *M. Zagozda*[1,2], ***M. Fic***[1,2], *M. Nowak-Niezgoda*[2], *W. L. Olszewski*[1,2];
[1]*Mossakowski Medical Research Centre Polish Academy of Science, Warsaw, Poland,* [2]*Central Clinical Hospital, Ministry of Internal Affairs, Warsaw, Poland.*

Introduction: Toll-Like Receptors, antigen CD14, pro- and anti-inflammatory cytokines and chemokines with their receptors are involved in the mechanism of innate response during bacterial infections. Polymorphism in these genes can cause that their products may be functionally inefficient and consequence of this may be tendency of some patient to the development of extensive inflammation and sepsis. The aim of study was to research markers of bacterial infections, surgical wound healing disorders or fistula anastomosis in patients operated on pancreatic cancer. Material and methods: Genetic polymorphisms was surveyed polymerase chain reactions - restriction fragment length polymorphism analysis technique in 62 patients with pancreatic cancer. A control group of 130 blood donors was ethnically matched to the study and randomly selected to comparing the study data. Results: We did not note statistical importance of polymorphic genotypes in TNFα (-308G/A), TLR4 (1363C/T), CCR2 (190G/A) and CD14 (-159C/T) genes. Compared with healthy volunteers we observed that polymorphisms of TLR4 (1063A/G) gene was statistically significant. Conclusions: Up to now we still searching for specific genetic marker for bacterial infection during pancreatic cancer. Despite of this we are able to determine that TLR4 (1063A/G) gene is crucial to pancreatic bacterial infections.

Constitutional mismatch repair deficiency syndrome in Israel caused by founder mutations in the MMR genes

*I. Barnes-Kedar[1], Z. Levi[2,3], H. Toledano[4,3], M. Halpern[5], I. Lerer[6], T. Peretz[7], R. Kariv[8], E. E. Half[9], N. Magal[1], K. Wimmer[10], Y. Goldberg[7], D. Berkovich[11], **H. N. Baris**[1,3];*
[1]The Recanati Genetic Institute, Beilinson Hospital, Petah Tikva, Israel, [2]Gastroenterology Division, Rabin Medical Center, Beilinson Hospital, Petah Tikva, Israel, [3]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, [4]Pediatric Oncology, Schneider Children's Medical Center, Petah Tikva, Israel, [5]Department of Pathology, Rabin Medical Center, Hasharon Hospital, Petah Tikva, Israel, [6]Department of Human Genetics, Hadassah-Hebrew University Medical Center, Jerusalem, Israel, [7]Sharett Institute for Oncology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel, [8]Department of Gastoenterology & Liver Disease, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [9]Gastroenterology Department, Rambam Health Care Campus, Haifa, Israel, [10]Division of Human Genetics, Medical University Innsbruck, Innsbruck, Austria, [11]GGA-Galil Genetic Analysis, Kazerin, Israel.

Heterozygous germline mutations in one of the four mismatch repair (MMR) genes, *MLH1, MSH2, MSH6* and *PMS2*, cause Lynch syndrome (LS) an autosomal dominant cancer predisposition syndrome conferring a high risk of colorectal, endometrial and other cancers in adulthood (HNPCC). Offspring of couples, both having LS, have a high risk to inherit biallelic MMR gene mutations. These cause constitutional MMR deficiency (CMMRD), a severe recessively inherited childhood cancer syndrome with a very broad tumor spectrum including mostly hematological malignancies, brain tumors and childhood colon cancer. Most of CMMRD children also present with café au lait spots and axillary freckling mimicking Neurofibromatosis type 1.
We describe our experience in Israel with five CMMRD families. The clinical presentation included: brain tumors at ages 2-19 years, colon cancer at ages 9-20 years and one patient with lymphoma at age 12 years. In two non-consanguineous Ashkenazi families, the common founder Ashkenazi mutations were detected: one family was homozygous for c.1906G>C in *MSH2* and the second family was compound heterozygous for c.3984_3987dupGTCA and c.3959_3962delCAAG in *MSH6.* In the three other consanguineous families, different homozygous mutations were identified: c.2192T>G (p.L731X) in *PMS2*, a recurrent mutation among Iranian Jews, *PMS2* c.686_687delCT and *MSH6*3606_3603 delAGTG were found in large pedigrees of Bedouin and Arab ancestries, respectively.
Given the prevalence of these mutations among the Israeli population, we want to raise the awareness of CMMRD syndrome and open a discussion regarding screening for MMR founder mutations among spouses of LS patients for the purpose of prenatal diagnosis.

Marcinkowski University of Medical Sciences,, Poznan, Poland, [5]Center of Cancer Prevention and Epidemiology, Poznan, Poland, [6]I Chair of Pediatrics, Department of Gastroenterology and Metabolism, K. Marcinkowski University of Medical Sciences,, Poznan, Poland.

Colorectal cancer (CRC) is the fourth most common cancer in the world, and it is also considered as the third most common cause of cancer-related deaths. On average, it affects 5-6% of people, and the risk depends on both factors related to heredity and lifestyle.
It is assumed that in 20-30% of cases, it is potentially possible to define genetic background and 3-5% develop genetically determined bowel syndromes associated with a high risk of CRC. The search for new genetic factors that increase the risk of the disease is the subject of extensive research in many laboratories. In our study we analyzed the frequency of polymorphisms in the BMPR1A gene in 200 patients with sporadic colorectal cancer and we compared them with their frequency in the control group. Rs7074064 showed a statistically significant increased frequency of allele C and genotype CC in patients with CRC. The frequencies of genotypes for the group of patients and for the control group were respectively TT (31%), TC (62%), CC (7%) and TT (65%), TC (33%), CC (2%). The different distributions of genotypes in both groups were statistically significant at P <0.0001. Odds ratio for occurrence of the disease for people with variant C of rs7074064 was estimated at 2.621. The study was financed by the Ministry of Education and Science, Poland, grant number N402431438

NCL/NPM and BRAF gene structure in metastatic cutaneous melanoma(CM)patients

***E. Zenit-Zhuravleva**, A. Lushnikova, I. Tsyganova, I. Mikhailova, E. Cheremushkin, H. Treshalina;*
N.N.Blokhin Cancer Research Center RAMS, Moscow, Russian Federation.

Background. Nucleolin/C23 and nucleophosmin/B23 are major nucleolar argyrophilic proteins involved in carcinogenesis and CM progression. There are none data on C23/B23 encoded genes NCL/NPM in CM. Material and methods. DNA samples from 23 CM patient (CMP)metastatic nodes were analyzed by PCR for NCL and NPM genes. Alterations in NCL/NPM gene structure(23 CM)and 2 human CM xenografts(X)+ BRAF mutations in exon 15(7/23 CM)were studied. Results. Genetic alterations in NCL/NPM were grouped in several types: (1) two simultaneous nucleotide substitutions (NS) IVS5-31G/A+IVS6+42G/A in NPM gene - in 13/23 (56%) CMPs and 1/2 X; (2) NS IVS8-63A/G in NPM - in 9/23 (39%) CMPs + two NS from the group (1); (3) germinal deletion p.D255delGAT (c. 763-765delGAT) + common polymorphism p.E149E in NCL gene + intron structure variant in 1 CMP with 4 CM relapses; (4) 1 NS IVS2+31G/A in NCL gene. Somatic mutation V600E BRAF (70% in CM cases) and K600E BRAF + AGT/AAA BRAF were revealed in 3/7 and 1/7 CMPs with 2-5 relapses, consequently. Mutation V600E BRAF in 1CMP was accompany by NS of the group (1) + group (2) in NPM gene; V600E BRAF in other 1CMP was accompany by analogous NS, except IVS6-39A/G+-42G/A. Conclusion. Some certain types of NPM and/or NCL gene alterations, including NS in NPM and germinal deletion in NCL were found in 17/23 CMPs. The data obtained indicate that alterations in NPM/NCL/BRAF genes likely to associate with numerous relapses in CMPs.

P11.131

A novel mutation in 3'-UTR of the growth factor independence 1 (Gfi-1) gene in the cutaneous T-cell lymphoma

***J. Bienertova Vasku**[1], V. Vasku[2], A. Vasku[1];*
[1]Faculty of Medicine, Masaryk University, Department of Pathological Physiology, Brno, Czech Republic, [2]University affiliated Hospital, Clinic of Dermatovenerology, Brno, Czech Republic.

Background: The growth factor independence 1 (Gfi-1) has recently attracted a lot of attention attention due to its pivotal effects in lymphopoiesis and myelopoiesis. The aim of the study was to investigate possible associations of variability in the Gfi-1 gene with cutaneous T-cell lymphomas (CTCL).
Methods: 63 patients with CTCL (30M/33F, median age 62y, 26-101y) diagnosed and treated at the 1st Department of Dermatology of the St Ann's Faculty Hospital Brno were sequenced for the Gfi-1 gene and the sequences were then compared to the database sequence and the sequency of sex- and age-matched controls (30M/33F, median age 58, age range 26-80y) without personal or family history of skin diseases and without signs of malignancy.
Results: A novel polymorphism 1765C/T in 3´-UTR region of the Gfi-1 gene was identified in several CTCL patients that was not present in the controls. No association of the identified polymorphisms with disease severity and/or survival of the patients was observed.
Conclusion: Our study indicates that a novel polymorphism 1765 C/T in 3'-UTR of Gfi-1 gene might be involved in CTCL ethiopathogenesis, adding Gfi-1 to the short list of potential CTCL susceptibility genes. More research into the role of this variation as well as replication of the observations on larger populations with different ethnicity is imperative.

University of Munich, Munich, Germany, [6]Heinrich-Heine-University Duesseldorf, Dresden, Germany.

Introduction: In the ongoing German multicenter Lemon5-study, the safety of lenalidomide monotherapy with special focus on leukemic transformation in IPSS low risk MDS patients with isolated 5q deletion is examined. Here we report on the current cytogenetic results from this study.
Methods: Cytogenetic investigations were performed using chromosome banding and FISH analyses of bone marrow aspirates and CD34+ peripheral blood cells. FISH analyses on blood cells are carried out every 2 to 3 months using 8 to 13 DNA probes to detect cytogenetic changes during treatment.
Results: We have already analyzed 146 suspected MDS patients. Only 84 patients could be enrolled in this study due to cytogenetic and/or morphologic screening failures in 62 patients. To date, follow-up data for 53 patients are available. A complete cytogenetic response could be observed in 35 patients (66%) after a median follow-up of 15.5 (2-36) months. In eleven patients (20%) 5q- clone size did not show any changes. Cytogenetic response could be observed within a median of 6 (2-12) months after start of therapy, lasting for a median duration of 10 (2-25) months.
Conclusion: FISH analysis on CD34+ pb cells allows a reliable frequent and relevant genetic monitoring of treatment response to lenalidomide and to identify cytogenetic non-response or progression as early as possible.

Dogs spontaneously develop many cancer types presenting the advantage to be homologous to human cancers, breed specific and frequent in the predisposed breeds. These features reflect the fact that predisposing genes could be tracked in these genetic isolates more easily than in humans. Faced to limitations in the use of classical rodent cancer models, Dog who offers a physiopathology closer to humans, gives the opportunity to decipher the natural steps of tumorigenesis from genetic predispositions to acquired abnormalities and to investigate new therapies.
We illustrate the power of this original model with the study of canine histiocytic sarcomas (HS). These tumours present striking breed specificity: HS mainly affects Bernese Mountain dogs (> 25%), while in Human, HS are extremely rare and poorly known.
Thanks to the collection of over 3000 DNA samples, we proposed an oligogenic transmission for this cancer (Abadie et al. 2009) and performed genome wide association studies which allowed us to identify 2 major loci involved in HS predisposition. These loci are under investigation: one of them is orthologous to the human region 9p21 (Shearin et al. 2012). To get a complete view of pathways involved in the tumorigenesis, CGH and RNA sequencing analyses are ongoing to identify tumour progression alterations. Recurrent alterations have been identified among which deletions of CDKN2a and PTEN (Hedan et al 2011).
All together, these genetic analyses are thought to gain a better understanding of the physiopathology and genetics of HS in dogs but also in humans.

P11.135
Detecting mutations in the EGFR gene in lung adenocarcinomas in order to guide personalized therapy with tyrosine-kinase inhibitors.

P. APOSTOL*, A. Grigore, M. Stoicea, V. Celmare, G. Cardos;*
Personal Genetics - Medical Genetics Center, BUCHAREST, Romania.

The EGFR gene codifies the Epidermal Growth Factor Receptor, a transmembrane tirosine-kinase glycoprotein, involved in cell growth and differentiation. Mutations in exons 18-21 of the EGFR gene - identified in 10-30% of Caucasian patients with non-small-cell lung carcinomas (NCSLC) - trigger constitutive activation of the EGFR receptor, playing a crucial role in tumor progression. The EGFR mutational status is a predictor of benefit for the new personalized therapy with anti-EGFR tyrosine-kinase inhibitors (TKI).
The aim of our study was to analyse the EGFR mutational status in exons 19 and 21 (cca 90% from all mutations) in NCSLC patients, in order to contribute to the selection of patients for the anti-EGFR TKI therapy.
DNA was extracted from formalin fixed, paraffin embedded lung adenocarcinomas sampled from 139 patients. The EGFR mutational status was analyzed by ARMS-PCR and sequencing.
Activating mutations were detected in the EGFR gene in 24 tumors (17,26%), of which 17 tumors with deletions in exon 19 (2 of them being less-common) and 7 tumors with L858R mutation in exon 21; the amount of tumor cells was variable, between 90% and 1%. Patients were between 49 and 86 year old, sex distribution was 1:1,66 (9M:15F); 18 of them were non-smokers.
Our results were in accordance with international data, contributing to an effective selection of patients with NSCLC for the anti-EGFR personalized therapy.
Further evaluation of the significance of some *EGFR* mutations is needed, including assessment of the functional importance (clinical and/or predictive significance) of the less-common activating mutations.

The importance of the P53, P16, CDH1 and PPP2R1A genes analysis in grade III endometrioid carcinomas

C. Cieza-Borrella[1], *M. Fernández-Prieto*[1], *M. Núñez-Casado*[1], *V. Streinu*[1], *M. Sancho-de-Salas*[2], *V. Sancho-de-Salas*[3], *Á. García-Iglesias*[3], *R. González-Sarmiento*[1];
[1]*Unidad de Medicina Molecular. Facultad de Medicina. IBMCC-IBSAL, Salamanca, Spain,* [2]*Servicio de Anatomía Patológica. Hospital Clínico Universitario de Salamanca, Salamanca, Spain,* [3]*Servicio de Ginecología y Obstetricia. Hospital Clínico Universitario de Salamanca, Salamanca, Spain.*

Endometrial carcinomas are classified in two groups based on clinical and pathologic characteristics: endometrioid (EC) (grade I, II and III) and no endometrioid (NEC) (grade III). EC usually show mutations in PTEN (35-50%), PIK3CA (36%), BRAF (5-20%), KRAS (15-30%) and CTNNB1 (20-40%) genes whereas there are other genes more associated with NEC but sometimes mutated in EC as well: P53 (10-20%), P16 (10%), CDH1 (10-20%) and PPP2R1A (5%) genes. We have analyzed these genes in a group of ECs in order to determine if the mutation frequency is associated to the tumor grade.
We extracted DNA, RNA and total proteins from 53 ECs: 23 grade I, 23 grade II and 7 grade III. We analyzed these 9 genes by PCR, CSGE-heteroduplex and sequencing. Moreover, we performed *in sílico* analysis, allelic pertenence and expression protein studies to characterize the novel mutations found.
Our results are showed in the annexed table. We found that 14.28% of grade III EC cases carry 4 or more mutated genes and that all cases show at least one of these genes mutated.
In conclusion, we report that there is a correlation between the number of mutations and the kind of mutated genes and EC tumor grade. Therefore, we suggest that P53, P16, CDH1 and PPP2R1A genes analysis could help in EC grade discrimination.
Funded by FIS PI 10/00219

Endometrial stromal tumors (ESTs) are the second most common mesenchymal tumors of the uterus. The current classification of ESTs divides these

tumors into three modalities: the most benign endometrial stromal nodules, low-grade endometrial stromal sarcomas (ESS) and undifferentiated uterine sarcomas (UES), which are characterized by the most aggressive clinical course. Over 50% of classical ESS cases carry characteristic chromosomal translocations that involve genes encoding polycomb group (PcG) proteins. On the other hand, UES do not show the evidence of specific chromosomal aberrations. Recently, a new t(10;17)(q22;p13) which results in YWHAE-FAM22A/B fusion formation has been reported in cases described as "high-grade ESS", due to clinicopathological features intermediate between classical low-grade ESS and UES.
In the present study, we performed gene expression microarray experiments on 11 ESTs cases using the Agilent Technologies platform, in order to investigate the genetic profiles of distinct ESTs subtypes. Our cohort included 4 classical low-grade ESS cases with typical translocations, 4 UES cases and 3 cases which were classified as high-grade ESS based on the histological features and the presence of YWHAE-FAM22A/B fusion. Hierarchical clustering analysis of our microarray data revealed that high-grade ESS formed a separate sub-cluster with a distinct molecular profile as compared with the low-grade ESS and UES cases. High-grade ESS cases were characterized predominantly by decreased expression level of a subset of genes related to immune response and cell adhesion. Our results support the notion that the current ESTs classification should discriminate high-grade ESS as a distinct subtype.

Background: Myelodysplastic Syndromes (MDS) and Acute Myeloid Leukaemia (AML) share common translocations, involving the 3q21-26 region, and suggesting that EVI1 and/or *MDS1/EVI1* rearrangements may be associated with an adverse prognosis. **The objective** of our study was to refine the chromosomal breakpoints in the 3q26-28 region with the use of Bacterial Artificial Chromosomes (BACs), and to determine whether the *EVI1* and *MDS1* genes were included in the breakpoints. **Material and Methods**: In 9 patients, with either AML(n=5), MDS (n=3) or chronic myelomonocytic leukaemia (CMML)(n=1), the following translocations: t(2;3)(p21;q26)(n=2), t(2;3)(p21;q27)(n=1), t(2;3) (p23;q26)(n=2), t(3;7)(q26;q21), t(3;8)(q27;q24), t(3;10)(q28;q23) ,t(3;12) (q26;p13) were observed. A set of 5 BACs were used to cover the 3q26.2 region, including the *EVI1*, *MDS* and *MYNN* genes, and the BAC RP44B17 to test the 2p21 region.
Results: The breakpoints were precisely established only for one translocation, t(2;3)(p21;q27), within the BAC RP11-415B12 at the 3q26.2 region, including the MDS gene and within the BAC RP 44B17 at the 2p21region with no genes described. The breakpoints in the 2p21 region for the other 4 translocations were located in regions more centromeric than the BAC RP 44B17.The breakpoints in the 3q26.2 region for the other 8 translocations included BACS involving the *MDS1* gene (n=2) the *MYNN* gene (n=1), regions more centromeric than the EVI1 gene (n=2) and regions more telomeric than the *MYNN* gene (n=3). **Conclusion:** BACs covering the 3q26.2 region revealed that the *EVI1* gene was not involved in any of the translocation breakpoints, while the *MDS1* gene was involved in 3.

Analysis of Ewing Sarcoma NGS Transcriptome Data Highlights Mechanisms of Cancer

J. Billaud, *S. Tugendreich, D. Toburen;*
Ingenuity Systems, Redwood City, CA, United States.

The Ewing Sarcoma family of tumors is a category of cancers that mostly affects adolescents of age 10 to 20. To understand the molecular mechanisms of tumorigenesis and metastatic processes in Ewing Sarcoma (ES), gene expression profiling of samples from Ewing Sarcoma patients was performed using Next Generation Sequencing (NGS) technology. In this study we present the results of combined statistical and biological analyses that demonstrate the differences between samples from primary and metastatic tissues from one patient with ES. Ingenuity Pathway Analysis (IPA) was used to analyze biological processes and to identify molecular mechanisms participating in the development of ES. We identified differentially expressed isoforms (CAV1, STAT3) and highlighted their potential roles in tumor progression and/or metastatic processes. We identified contributors to tumorigenesis, such as fatty acid metabolism and highlighted important enzymes in ES tumor progression (CDK1, AKT1). Subsequent IPA Upstream Regulator Analysis enabled prediction of the activity state of several other transcription factors (such as SREBF1, PPARGC1B) as well as activity of cytokines (IL1RN, IL6, EDN1) and growth factors (BMP4, FGF10) that altogether may contribute to the pathological context observed in this patient. We identified sets of connected upstream regulators (such as MBTPS1 that connects to SREBF1 and SREBF2) that can work together to elicit the gene expression changes observed in this dataset and induce key molecular changes for metastasis. The data presented here is from one patient, therefore similar studies are needed to understand if these insights are supported by data from other Ewing Sarcoma patients.

A novel full promoter 1B deletion of APC gene in Bulgarian Familial Adenomatous Polyposis Family

T. K. Kadiyska[1,2], *T. Todorov*[2], *S. Bichev*[3], *R. Vazharova*[3], *A. Nossikoff*[2], *A. Savov*[3], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemitry, Sofia Medical University, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*National Genetic Laboratory, University Hospital „Maichin Dom", Sofia, Bulgaria.*

Familial adenomatous polyposis (FAP) is an inherited condition causing multiple intestinal polyps and predisposition to colorectal cancer. Most cases are caused by mutations in the adenomatous polyposis coli (APC) gene. Over 1500 mutations have already been identified, however routine genetic testing fails to detect causative mutations in about 10% of classic FAP cases. Recently, it has been shown that a proportion of mutation negative FAP cases bear molecular changes in deep intronic and regulatory sequences, warranting targeted genetic testing of these regions.
In this study, we used direct sequencing, followed by MLPA of genomic DNA from a proband and his father, referred for genetic testing as both of them were affected by classic FAP. We found peak area decrease in two of the MLPA probes, corresponding to promoter 1B deletion in both patients. In order to determine the boundaries of the deletion, we conducted a whole-genome oligonucleotide array and long range PCR. The exact breakpoints of the above deletion were identified by direct sequencing as follows - genomic position: chr5: g.112,061,394_112,083,285del21,890 insTTGCTCTATGACCAATT. We performed Real-time PCR assay and Allele specific expression analysis to investigate the total APC expression levels. Thus, the APC promoter 1B deletion was associated with reduced expression of total APC mRNA levels in the patient's blood samples.
In this family, we found a novel deletion affecting the full sequence of promoter 1B. To the best of our knowledge such mutation has not been reported yet. Furthermore, the APC gene expression was clearly reduced, which indicates causative relationship.

Identification and characterization of miRNAs and mRNA targets in Glioblastoma multiforme

L. Muñoz Hidalgo[1], *E. Serna*[2], *T. San Miguel*[3], *R. Gil Benso*[4], *A. Andrés Bordería*[1], *D. Monleón*[1], *M. Cerdá Nicolás*[4], *C. López Ginés*[5];
[1]*Foundation for research HCU-INCLIVA,Valencia, Spain, Valencia, Spain,* [2]*Central Unit of Medical Research, University of Valencia, Valencia, Spain,* [3]*Department of Pathology, University of Valencia ,Spain, Valencia, Spain,* [4]*Department of Pathology ,University of Valencia, Spain, Valencia, Spain,* [5]*Department of Pathology University of Valencia, Spain, Valencia, Spain.*

MicroRNAs (miRNAs) are small 20-22 nucleotide-long members these act as regulators of gene expression, and have been implicated in the carcinogenesis oncogenetics of a variety of cancers. Glioblastoma multiforme (GBM) is the most common and most aggressive malignant primary brain tumor in humans. Molecular screening for gene amplification revealed frequent amplification of the EGFR, observed in about 35-70% of glioblastomas.
In this study, we analyzed miRNAs and mRNAs expression in glioblastoma multiforme into different groups according the status of EGFR amplification.

Forty human biopsies (GBM) were analyzed histopathological, and inmunohistochemical characteristics (GFAP, Ki-67, EGFR) and the status of *EGFR* amplification by FISH and differential PCR. We have used Genechip Human Gene Array containing 28.000 gene-level probe sets and Genechip miRNA Array containing 6703 miRNAs to profile mRNA and miRNA expression in tumors.Microarrays studies were obtained and normalized with the use of Gene Chip Operating Software and miRNA QC Tool and analyzed using Partek Genomics Suite 6.4 software.
We determined the expression levels of 145 filtered miRNAs in 40 GBM (16 GBM with amplification, 15 GBM with low amplification and 9 no amplification) . El 46, 2 % of miRNAs showed up-regulation and 53,8% of miRNAs were down-regulated in the relative analysis. Results indicate that miRNAs expression profiles distinguish between GBM into different groups according the status of EGFR amplification.
Our findings indicate that miRNAs are deregulated and changed their levels expression in the different groups suggesting a potential role for these molecules in the pathogenesis of this tumor.

Exon wise deletion status of tumor suppressor P16 gene in high grade glioma in the Indian population

G. K. Chetan, *M. K Sibin, C. h. Lavanya, M. Jeru Manoj, I. Dhananjay Bhat;*
National Institute of Mental Health and Neuroscinces, Bangalore, India.

Since its discovery as a CDKI (cyclin-dependent kinase inhibitor) in 1993, the tumor suppressor p16 (INK4A/CDKN2A) has gained widespread importance in cancer. High frequency of p16 gene alterations were observed in many primary tumors. In human neoplasms, p16 is silenced in at least three ways: homozygous deletion, methylation of the promoter, and point mutation. Gliomas are most common brain tumors occur in the central nervous system. Homozygous deletion of p16 gene deletion has been observed in different grades of glioma especially in high grade glioma. But, the detail Exon wise analysis is not done in correlation with patient survival.
Our study aimed to perform Multiplex PCR in 50 high grade glioma samples, to see status of homozygous deletion in Indian patients. 20% of the patients showed deletion of p16 as compared to world reports (33-74%) and in consistent with Asian reports (17-46%). The exon wise deletions status for 1, 2 and 3 is 10, 4 and 8 percentage respectively. Exon 1 and 3 deletion is found to be higher in the Indian patients, as compared to the world literature (exon 2 deletion is predominant) . We recommend to screen all 3 exons of p16 for Indian patients. The survival status of these patients in relation to the p16 deletions is underway to understand the prognostic value of our findings.

Genomic changes in 295 patients with diffuse gliomas

S. Ransdorfova[1], *Z. Zemanova*[2], *F. Kramar*[3], *L. Lizcova*[4], *Z. Krejcik*[1], *D. Bystricka*[4], *H. Buryova*[4], *P. Hrabal*[3], *K. Michalova*[1,4];
[1]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic,* [2]*Center of Oncocytogenetics,General University Hospital and 1st Faculty of Medicine,Charles University, Prague, Czech Republic,* [3]*Department of Neurosurgery, Central Military Hospital and 1st Faculty of Medicine, Charles University, Prague, Czech Republic,* [4]*Center of Oncocytogenetics, General University Hospital and 1st Faculty of Medicine, Charles University, Prague, Czech Republic.*

Diffuse gliomas form a heterogenous group of primary neuroepithelial brain tumors with non-random mutations, loss of heterozygosity, deletions and/or amplifications of chromosomal regions found in glial tumor cells. Identification of specific genomic changes by combination of I-FISH and SNP-A methods could help in assessment of diagnosis and predict of tumor progression.
During 2004-2012, we examined fresh non-fixed tissue specimens of 295 patients with histologically confirmed glial tumors (WHO grade I-IV). For detection of the most frequent cytogenetic changes (deletion of *TP53*, *CDKN2A, RB1*, 1p36/19q13.3, amplification of *EGFR*, trisomy 7 and monosomy 10) we used I-FISH with specific DNA probes (Abbott Molecular). Unbalanced changes in 60 cases were specified by whole genome SNP-A (HumanCytoSNP-12 BeadChip; Illumina). Results of molecular-cytogenetic analyses were correlated with morphological and clinical findings.
In WHO Grade II and III tumors, the risk of malignant progression was significantly higher in cases with specific aberrations (*EGFR* amplification, *CDKN2A* and *RB1* deletion, monosomy 10 and trisomy 7) compared to patients without these changes. In glioblastoma, monosomy 10 was linked to worse clinical course and shorter OS (8.4 months). In oligodendroglial tumors, a combined deletion 1p36/19q13 was shown as a powerful favorable marker, however prognosis was influenced by additional chromosomal aberrations (OS 80.6 vs. 60 months).
Analyses of genomic aberrations significantly contributed to diagnosis and prognosis of the disease in our patients. Therefore, detailed molecular cytogenetic analysis of tumor cells is recommended and should be an integral part of all gliomas examinations.
Supported by NT/13212-4 and PRVOUK-P27/LF1/1.

P11.144
Utility of OCT3/4, TSPY and β-catenin as biological markers for gonadoblastoma formation and malignant germ cell tumor development in dysgenetic gonads

I. Palma[1], *G. Nayeli*[2], *G. Aristi*[2], *G. Queipo*[3];
[1]*Instituto Politécnico Nacional, Mexico City, Mexico,* [2]*Hospital General de México-Facultad de Medicina UNAM, Mexico City, Mexico,* [3]*Hospital General de México, Mexico City, Mexico.*

Gonadoblastoma (GB) is regarded as an in situ form of germ cell tumor in dysgenetic gonads (type II GCTs). This type of tumor is thought to be a precursor to seminoma/dysgerminoma tumors. It almost exclusively affects a subset of patients with disorders of sex differentiation (DSD). In 35% of GB cases, overgrowth of the germinal component leads to dysgerminoma/seminoma . The TSPY gene (testis-specific protein, Y encoded) localized within the GBY locus (gonadoblastoma locus on the Y chromosome) has been shown to be involved in the multistep transformation of germ cells to GB. However, the precise role that TSPY plays in GB development and its involvement in the malignant transformation are not clear . OCT3/4 has been implicated in the GB oncogenic process, but the molecular details of OCT3/4 deregulation are still unknown. Analysis of OCT3/4, E-cadherin and β-catenin showed that the proliferation of immature germ cells in GB may be due to the interaction between OCT3/4 and accumulated β-catenin in the nuclei of the immature germ cells, leading to the development of invasive behavior and the progression of GB into dysgerminoma/seminoma in dysgenetic gonads. In the present study, to determine whether TSPY participates in the OCT3/4-β-catenin pathway in the dysgenetic gonad and whether OCT3/4 and β-catenin are expressed in the dysgenetic gonad, we analyzed 18 dysgenetic gonads from DSD patients with mixed gonadal dysgenesis and compared them with GB and dysgerminoma/seminoma tumors.

P11.145
No association between gr/gr deletion and susceptibility to Testicular Germ Cell Tumor in a Norwegian population

I. Holm[1], *S. Naderi*[2,1], *K. L. Eiklid*[1], *T. B. Haugen*[2], *W. Kristiansen*[2];
[1]*Department of Medical Genetics, Oslo University Hospital, Oslo, Norway,* [2]*Oslo and Akershus University College of Applied Sciences, Oslo, Norway.*

Introduction: Testicular germ cell tumor (TGCT) is the most common malignancy in young men, but the etiology is unclear. Development of TGCT is most probably multi-factorial and an underlying genetic predisposition has been suggested by family studies. The current age-adjusted incidence rate of TGCT in Norway is 11:100 000 male persons per year, and is the highest worldwide. In epidemiological studies male infertility has been shown to be associated with TGCT. Nathanson et al. (2005) found that presence of gr/gr deletion, a 1.6 Mb deletion on the Y chromosome strongly associated with infertility, was associated with a twofold increased risk of TGCT. Our aim was to investigate a possible association with gr/gr deletion and TGCT in our Norwegian dataset.
Material and methods: We investigated 616 Norwegian Caucasian men with TGCT, divided in 304 seminomas and 312 non-seminomas. 814 healthy blood donors were included as controls. Multiplex PCR with three different markers (SY1191, SY1206 and SY1291) in the AZFc- region were used to determine the presence of the gr/gr deletion.
Results: Preliminary results show that the prevalence of gr/gr deletion in TGCT patients was 2.6% (3% seminoma and 2.2% non-seminoma) compared to 2.9% in controls. No statistically significant difference in frequency of gr/gr deletion between patients and controls (OR=0.88, 95% CI=0.46-1.67,

p=0.69), or between seminoma and non-seminoma (OR=1.00, 95% CI=0.46-2.19, p=0.99 and OR=0.76, 95%CI=0.32-1.77, p=0.52, respectively) were found.

Conclusion: The presence of gr/gr deletion does not seem to influence risk of TGCT in a Norwegian population.

Ffrequency and spectrum of chromosome aberrations and micronuclei in peripheral blood lymphocytes of patients with head and neck tumors and relapse of breast cancer during the course of neutron therapy

A. Melnikov[1], *S. Vasilyev*[2], *L. Musabaeva*[1], *V. Velikaya*[1], *O. Gribova*[1], *L. Urazova*[1], *I. Lebedev*[2], *E. Choynzonov*[1];
[1]*Research Institute of Oncology SB RAMS, Tomsk, Russian Federation,* [2]*Institute of Medical Genetics, Tomsk, Russian Federation.*

Neutron therapy is an effective treatment for patients with radioresistant tumors, however cytogenetic monitoring of cancer patients during the course have not been performed. Cytogenetic aberrations in peripheral blood lymphocytes were investigated in 17 patients with head and neck tumors and 12 patients with relapse of breast cancer during the treatment by neutron therapy. The treatment course specified 5.5-8.4 Gy by 4 fractions with 1.3-2.4 Gy per first fraction for patients with head and neck tumors and 4.8-8.0 Gy by 3-4 fractions with 1.4-1.6 Gy per first fraction for patients with relapse of breast cancer. There were three time points: before treatment, 24 h after the first fraction and at the end of the neutron therapy. Chromosomal aberration analysis was performed according to standard protocol in the first mitosis of PHA-stimulated lymphocytes. Cytokinesis-blocked micronucleus test was performed in combination with FISH using a pancentromeric DNA probe. It was shown that chromosome-type aberrations were prevalent among cytogenetic abnormalities both before and after neutron therapy. Level of chromosome aberrations and micronuclei significantly increased in lymphocytes of patients from both groups during neutron therapy ($p<0.05$). This increase was mainly due to chromosome-type aberrations and centromere-negative micronuclei. The prevalent types of aberrations are in agreement with expected results based on theoretical mechanisms of neutron effects on cells. A Benign Vascular Tumor with a New Fusion Gene: EWSR1-NFATC1 in Hemangioma of Bone

E. Arbajian*, L. Magnusson, K. H. Nord, F. Mertens;*
Lund University, Department of Clinical genetics, Lund, Sweden.

Abstract: The *EWSR1* gene in chromosome band 22q12 is a promiscuous fusion partner involved in a vast array of tumors characterized by gene fusions. In this study, we report the finding of a new fusion gene, *EWSR1-NFATC1*, in a hemangioma of bone; genetic rearrangements have not previously been described in this tumor type. Chromosome banding analysis showed a t(18;22)(q23;q12) as the sole change. FISH mapping suggested the involvement of each of the two partner genes and RT-PCR revealed an in frame *EWSR1-NFATC1* transcript. *NFATC1* has not previously been shown to be involved in a fusion chimera. However, *NFATC2*, encoding another member of the same protein family, is known as a fusion partner for *EWSR1* in a subgroup of Ewing sarcoma. Thus, our findings further broaden the spectrum of neoplasms associated with *EWSR1* fusion genes, add a new partner to the growing list of EWSR1 chimeras, and suggest that chromosomal rearrangements of pathogenetic, and possibly also diagnostic, significance can be present in benign vascular bone tumors.

Hepatocellular carcinoma (HCC) is an aggressive hepatic neoplasm that most commonly affects adults. In contrast to adults, most paediatric HCCs arise without liver abnormalities or pre-existing cirrhotic diseases. So extremely rare, liver tumours such as HCC and also slightly more frequent hepatoblastoma, could occur in familial adenomatous polyposis (FAP), an inherited autosomal dominant disorder due to germline mutations in the adenomatous polyposis coli (*APC*) gene. To our knowledge, only 10 cases of HCC were so far reported in FAP patients. Because of its rarity, the pathogenesis of liver tumours in FAP patients remains undefined although biallelic inactivation of *APC* was already described unlike in sporadic cases. We report the case of a 16-year-old patient with an 18.5 cm encapsulated HCC occurring without underlying hepatic disease. Right hepatectomy was performed following by chemotherapy and sorafenib. A germline *frameshift APC* mutation (codon 1280) was identified in the proband, actually inherited from his mother suffering from a duodenal polyposis after coloproctectomy at 37 but with no contact anymore. Whereas an activating beta-catenin somatic mutation was found in the tumour, we discuss the role of APC/beta-catenin pathway in the hepatic carcinogenesis in this patient after sequencing *APC* and LOH analysis in the tumour. This report revived the debate of the mutually exclusive nature of *APC* and beta-catenin mutations.

Different pattern of RET proto-oncogene mutations in Iranian Patients with hereditary medullary thyroid carcinoma

M. Hedayati*, M. Zarif Yeganeh, S. Sheikholeslami, S. Kabiri, S. Farashi, G. Dehbashi;*
Cellular & Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of, Tehran, Islamic Republic of Iran.

Introduction: Thyroid cancer is the most common endocrine cancer and Medullary thyroid carcinoma is one of the most malignant thyroid tumors which occur in both hereditary (25%) and sporadic (75%) forms. Mutations of the RET proto-oncogene in MTC development have been well demonstrated.

Material and methods: To investigate the spectrum of the RET germline mutations in exons 3, 5, 10-16 in hereditary MTC in Iranian population, 319 participants were studied. Genomic DNAs were extracted from the leukocytes using the standard Salting Out/ProteinaseK method. Mutation detection was performed through direct DNA sequencing.

Results: Totally, from 319 participants (182Female, 137Male) 224individuals were patients (179MTC, 5MEN2A, 3MEN2B, 2Pheochromocytoma) and 95 individuals were their relatives. The germline RET mutations were found in 83.4% of participants (58.4%patients and 25% relatives), including exon 10, exon 11, exon 13, exon14, exon 15, and exon 16. The most common mutation in our population was C634Y (4.1%) on the other hand, C618R, C618S, C620G, L887L (0.3%) had rare allele frequency. Also the allele frequency of G691S/S904S haplotype was 36% in patients and 16.6% in their relatives. Moreover, a novel germline mutation R886Q was detected in exon 15 in two members of a family affected with MTC: 0.62%. The most frequent mutation in our population is haplotype G691S/S904S, and C634Y, whereas in the most population the frequent mutation is C634R. Altogether, further analysis needs to demonstrate the disease progress in individuals harboring multiple risk alleles.

Background: Hyperplastic polyposis (HP) is a rare condition characterized by multiple or large hyperplastic polyps in the large intestine, typically with

proximal localization, and associated with increased risk of colorectal cancer *via* the evolution of lesions through the serrated pathway of carcinogenesis. Some cases of familial hyperplastic polyposis have been described, but the familial transmission of this entity has not been elucidated by now.
Purpose: We sought genes potentially responsible for familial transmission of HP using whole-exome sequencing strategy.
Methods: Four patients were selected, who fulfilled the diagnostic criteria of hyperplastic polyposis according to the WHO Classification of digestive tumours (2000). They showed either family history of HP and/or colorectal cancer, or early onset at disease. We assessed the carcinogenesis pathway involved by morphological characterization and molecular biology analysis. Whole-exome sequencing was conducted on DNA derived from blood samples. Genomic DNA was enriched for coding region using SureSelectXT Human All Exon v4 (Agilent technologies, Inc., Santa Clara, USA), and paired-end sequencing was realized with Genome Analyzer IIX (Illumina, Inc., San diego, USA).
Results: We used KGGSeq software, that integrate pathways involved in diseases and pubmed references as filters. This analysis selected more than 300 genes, including 13 genes mutated in one patient only, which are in tight relation with the pathways of APC, STK11, MUTYH and BMPR1A, previously associated with forms of familial polyposis. This study enabled us to identify 13 candidate genes in the familial hyperplastic polyposis, and suggested a possible genetic heterogeneity in this syndrome.

Exome sequencing characterise the somatic mutation spectrum of early serrated lesions in a patient with BRAF negative hyperplastic polyposis syndrome

*S. Horpaopan[1], J. Altmüller[2], R. Hüneburg[3], P. Kahl[4], I. Spier[1], D. Drichel[5], H. Thiele[2], M. Odenthal[4], M. M. Nöthen[1,6], P. Hoffmann[1,6,7], S. Strassburg[3], H. Fröhlich[8], P. Nürnberg[2], R. Büttner[4], **S. Aretz**[1];*
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Cologne Center for Genomics (CCG), University of Cologne, Cologne, Germany, [3]Department of Internal Medicine I, University of Bonn, Bonn, Germany, [4]Institute of Pathology, University of Cologne, Cologne, Germany, [5]German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany, [6]Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany, [7]Division of Medical Genetics, University Children's Hospital and Department of Biomedicine, University of Basel, Basel, Switzerland, [8]Department of Bonn-Aachen International Center for IT (B-IT), Algorithmic Bioinformatics, University of Bonn, Bonn, Germany.

Background. Hyperplastic polyposis syndrome (HPS) is a yet poorly defined colorectal cancer (CRC) predisposition characterised by the occurrence of multiple and/or large serrated lesions throughout the colon. A serrated polyp-CRC sequence (serrated pathway) of CRC formation has been postulated, however, to date only few molecular signatures of serrated neoplasia (BRAF, KRAS mutations, CpG Island Methylation, MSI) were described in a subset of HPS patients and neither the etiology of the syndrome nor the distinct genetic alterations during tumorigenesis have been identified. Methods. To describe the mutational landscape of serrated polyps and the involved pathways we sequenced the exomes (Illumina HiSeq platform) of 11 early hyperplastic polyps without the BRAF V600E mutation obtained from a 41 year-old female patient with clinically confirmed HPS. For data analysis the VARBANK pipeline was used. Somatic mutations were identified by comparison with leukocyte DNA and are currently validated by Sanger sequencing. Results. We identified 25 unique rare somatic alterations of 25 different genes in the 11 serrated tumours. All variants are single basepair substitutions; all but two variants are present in one tumour only. The predominant mutation type are missense mutations (92%) caused by G>T transversions (75%). No known cancer genes are affected. Conclusions. Somatic mutations seem to be rare events in early hyperplastic lesions of HPS patients without BRAF mutation. No frequently affected genes or enrichment of specific pathways have been observed. Thus, other alterations such as epigenetic changes might be the major driving force of tumour progression.

Modulation of CDX2 expression by the RNA-binding protein MEX3A: impact on intestinal differentiation and stemness

B. Pereira[1], *S. Sousa[1], R. Barros[1], L. Carreto[2], P. Oliveira[1], C. Oliveira[1,3], N. T. Chartier[4], M. Plateroti[5], J. Rouault[6], J. Freund[7], M. Billaud[4], R. Almeida[1,3];*
[1]IPATIMUP - Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal, [2]Department of Biology and CESAM, RNA Biology Laboratory, University of Aveiro, Aveiro, Portugal, [3]FMUP - Faculty of Medicine, University of Porto, Porto, Portugal, [4]INSERM-UJF U823, Institut Albert Bonniot, Grenoble, France, [5]Centre de Génétique et de Physiologie Moléculaire et Cellulaire, Université Claude Bernard Lyon 1, UMR5534, Villeurbanne, France, [6]Institut de Génomique Fonctionnelle de Lyon, UMR5242 CNRS/INRA/UCBL/ENS Ecole Normale Supérieure de Lyon, Lyon, France, [7]INSERM UMR_S1113, Université de Strasbourg, Fédération de Médecine Translationnelle, Strasbourg, France.

Introduction: The homeobox transcription factor CDX2 is the key molecular mediator of intestinal development and homeostasis. Furthermore, multiple evidences substantiate its involvement in tumorigenic processes of the digestive tract encompassing intestinal reprogramming. The CDX2 regulatory network is intricate and it has not yet been fully uncovered. **Materials & Methods:** Through genome-wide screening of a 3D culture system, the RNA-binding protein MEX3A was identified as putatively involved in CDX2 regulation, so its biological relevance was addressed by setting up cell-based assays together with expression studies in murine intestine. **Results:** We demonstrate that MEX3A has a translational repressive function by controlling CDX2 levels in gastric and colorectal cellular models. This is dependent on the interaction with a specific binding determinant present in *CDX2* mRNA 3`untranslated region. We have further determined that MEX3A impairs intestinal differentiation and cellular polarization, affects cell cycle progression and promotes increased expression of intestinal stem cell markers, namely *LGR5*, *BMI1* and MSI1. Finally, we show that MEX3A is expressed in mouse intestine in a pattern that correlates with CDX2 modulation and stem cell properties. **Conclusion:** The recent identification of MEX3A as being part of an intestinal stem cell signature, together with our observations, support an association of MEX3A with the intestinal stem cell phenotype and a role in fine-tuning CDX2 expression. We describe a novel CDX2 post-transcriptional regulatory mechanism, through the RNA-binding protein MEX3A, with a major impact in intestinal differentiation, polarity and stemness, likely contributing to gastrointestinal homeostasis and carcinogenesis.

P11.153

Coexistence of inv(16) and Cryptic BCR/ABL1 rearrangement in the patient with AML

J. Y. Sohn, *J. H. Jang, S. Lee, S. Kim;*
Samsung Medical Center, Gangnam-gu, Seoul, Korea, Republic of.

Coexistence of inv(16) and t(9:22) has been described in chronic myelogenous leukemia in blast phase (CML-BP) and de novo acute myeloid leukemia (AML). Cryptic *BCR/ABL1* rearrangements were reported in 5% of CML patients, which are not visible under conventional cytogenetic analysis and so are detectable only with fluorescence in situ hybridization (FISH) or reverse transcriptase polymerase chain reaction (RT-PCR). Here we report the case with this rare coincidence of coexistence of inv(16) and cryptic *BCR/ABL1* rearrangement. A 65-year-old man presented with leukocytosis (18.2×10^9/L) with 72% blasts. Bone marrow blast cells showed cytogenetic abnormality with 46,XY,inv(16)(p13.1q22)[15]/46,XY[5], and Philadelphia chromosomes were not found. Metaphase FISH detected both the *CBFB* and the *BCR/ABL1* rearrangements, located on chromosome 9. Additional FISH study for *BCR-ABL1-ASS* gene showed no apparent deletion of flanking material of ASS gene on chromosome 9. These results prove that *BCR/ABL1* fusion signal resulted from an insertional translocation from the small part of *BCR* gene on chromosome 22, to the proximal of *ABL1* gene on chromosome 9. *CBFB/MYH11* (A type) and minor *BCR/ABL1* (e1a2, P190) fusion transcripts were both detected by real-time quantitative RT-PCR. The patient was treated with standard AML chemotherapy. Molecular remission was achieved at the end of the first chemotherapy and he remained in remission until the last follow-up (6 months after diagnosis). He wasn't received imatinib and stem cell transplantation. To our knowledge, this is the first reported case of de novo AML with inv(16) that has cryptic *BCR/ABL1* rearrangement.

Background: All non-CML MPN's have in common the presence of JAK2-V617F mutation. This is associated with leucocytosis, elevated platelet count and higher risk for thromboembolic events.
Objectives: To demonstrate the efficacy of Anagrelide and Antiplatelets Agents in TE JAK2-V617F positive patients with major thromboembolic events.
Patients and Therapy: 40 patients, ages between 33 and 45 years, no cardio-vascular risk, followed between 2010-2013; 26 (65%) women and 14 (35%) men; 24patients (60%) were JAK2-V617F positive. 8 patients(20%) arrived with major thromboembolic event: 3 patients(37,5%) had portal vein thrombosis,3 patients (37,5%) had ischemic stroke and 2 patients(25%) had acute myocardial infarction. They started Anagrelide (1,5-3 mg) +75mg Acetylsalicylic acid and they were followed monthly; 3 patients also received VKA's.
Results: During follow up-3 years, no other thromboembolic event occurred and the platelet count became in normal ranges. No bleeding events also.
Conclusions: The association between Anagrelide and Antiplatelets agents is a very effective treatment in TE- JAK2+ patients with major thromboembolic events.
Comment: Too few cases and too little follow up period; it needs to be studied further more.

Profile of DHFR gene expression in laryngeal carcinoma cell line (HEP-2) administered with different MTX chemoterapy doses

A. L. S. Galbiatti[1], *H. C. Caldas*[2], *R. Castro*[1], *J. Padovani Junior*[3], *É. C. Pavarino*[1], ***E. M. Goloni-Bertollo***[1];

Introduction: Studies have found varying degrees of success in patients with laryngeal cancer treated with methotrexate (MTX) chemotherapy. The varying degree depends on the dose received by patients and may lead to resistance mechanisms and collateral effects. MTX acts inhibiting dihydrofolate reductase (DHFR), key enzyme that is codified by DHFR gene involved in folate metabolism. **Objectives:** To investigate *DHFR* gene expression for MTX response in laryngeal cancer cell line (HEP-2) treated with three different concentrations of MTX chemotherapy. **Methods**: The 0.25 µM, 25 µM, and 75 µM concentrations of MTX chemotherapy were added separately in HEP-2 cell line plated in six-well culture plates for 24 hours at 37 °C. The Real-time quantitative PCR technique was performed for quantification of gene expression with TaqMan Gene Expression Assay. **Results:** We found that expression level for DHFR gene was higher in cells treated with 75 µM of MTX chemotherapy. There were significant effects of the expression in *DHFR* gene between control group and the three different concentrations evaluated. There was significant association between the control group and increased expression of the *DHFR* gene in 75 µM MTX application group. **Conclusions:** Chemotherapy treatment for laryngeal cancer with higher MTX dose may be associated with increased expression level of *DHFR* gene. These results on the mechanisms involved in the generation of drug resistance by gene expression opening new perspectives in pharmacologic regimens to the chemotherapy treatment.

Analysis of *HOX* genes in patients with laryngeal squamous cell carcinoma

R. de Barros e Lima Bueno[1,2], *D. Guariz Pinheiro*[1], *D. L. Zanette*[1,2], *R. C. Martins Mamede*[3], *W. Araújo de Silva Junior*[1,2];
[1]*Departament of Genetics - Medical School of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil,* [2]*National Institute of Science and Technology in Stem Cell and Cell Therapy - Regional Blood Center of Ribeirão Preto, Ribeirão Preto, Brazil,* [3]*Department of Ophthalmology, Otorhinolaryngology and Head and Neck Surgery - Medical School of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil.*

Laryngeal squamous cell carcinoma (LSCC) is one of the most aggressive neoplasms among head and neck cell carcinoma (HNCC). Besides advances in therapeutic treatment, the survival of HNCC patients wasn't significantly improved. Therefore, understanding of the molecular mechanisms involved in LSCC is important to identify predictive biomarkers. We investigated global gene expression patterns of 32 laryngeal HNSCC patients versus 13 samples of normal tissues surrounding tumors, using the Agilent microarray platform. The comparison of normal versus tumor tissues, revealed 81 differentially expressed genes ($p \leq 10^{-7}$), among these, 35 genes were overexpressed in tumor tissues and, within these; eight genes belonged to the *HOX* gene family. *HOX* genes are expressed during embryogenesis, but its re-expression has been reported to be associated with some tumors. The *HOX* genes overexpressed were *HOXA10*, *-A11-AS1*, *-C8*, *-C9*, *-C10*, *-C13*, *-D10* and *-D11*. The qPCR confirmed the overexpression of *HOX* genes in tumors samples and their almost absent expression in the normal tissue. We also investigated HOTAIR expression, a lincRNA located within *HOXC* locus associated with metastatic tumors. HOTAIR has an increased expression in tumors as compared to normal tissue. Also, there was a significant correlation (Spearman test) between the expression of HOTAIR and the expression of *HOXC13*, *-C10* and *–C9*. There was no significant difference in the expression of these *HOX* genes between the two different cancer stages, although there is trend for a higher expression of *HOX* genes in the early stage. These findings suggest an important role of *HOX* family in LSCC tumorigenesis.

The t(8;21) and inv(16)/t(16;16) rearrangements affecting the core-binding factors, RUNX1 and CBFB, respectively, are found in 15-20% of adult *de novo* AML cases and are associated with a favourable prognosis. Since the expression of the fusion genes *CBFB/MYH11* or *RUNX1/RUNX1T1* alone is not sufficient to cause leukemia, we performed exome sequencing of an AML sample with an inversion 16 to identify mutations, which may collaborate with the CBFB/MYH11 fusion during leukemogenesis. We discovered an N676K mutation in the ATP-binding domain (TKD1) of the *fms-related tyrosine kinase 3* (*FLT3*) gene. In a cohort of 84 *de novo* AML patients with a *CBFB/MYH11* rearrangement and in 36 patients with a *RUNX1/RUNX1T1* rearrangement, the *FLT3* N676K mutation was identified in 5 and 1 patients, respectively (5/84, 6%; 1/36, 3%). The FLT3-N676K mutant alone leads to factor-indpendent growth in Ba/F3 cells and confers resistance to the FLT3 PTK inhibitors PKC412 and AC220 together with a concurrent *FLT3* internal tandem duplication (ITD). Genes differentially expressed in AML patient samples with an inv(16) and a *FLT3* N676K mutation are signficantly enriched for genes involved in ubiquitin-mediated proteolysis, adherence junction and the JAK/STAT signaling pathway. Ours is the first report of recurring *FLT3* N676 mutations in CBF leukemias and suggests a defined subgroup of CBF leukemias. Although *FLT3* is a well known mutational target in AML, it appears that the spectrum of *FLT3* mutations is still not fully understood. Unbiased mutation screening by exome sequencing allows the detection of novel sequence variations even in extensively studied genes.

B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) is a heterogeneous disease consisting of subgroups with different and partly unknown genetic background as well as heterogeneous prognosis.
Deletions of ERG (ERGdel) were recently described as a recurrent abnormality in childhood ALL. However, a systematic evaluation of this aberration in the context of large clinical trials is missing. Therefore, we designed a multiplex PCR assay to screen ERGdel in 1323 childhood ALL patients enrolled into trial ALL-BFM 2000 and analyzed clinical/biological features of positive patients.
We identified 60 cases with ERGdel, exclusively within BCP-ALL. In more than 1/3 of cases the deletion was bi-/oligoclonal. The deletion was significantly associated with higher age, CD2-positivity and deletion of the IKZF1 gene. We found only a weak association of ERGdel alone with prognosis. However, when combined with CD2 status, the ERGdel/CD-positive patients demonstrated superior outcome. This effect was significant even within IKZF1-deleted cases, known to have a poor prognosis on ALL-BFM 2000. In addition, we analyzed the stability of ERGdel from diagnosis to relapse in all six ERGdel/CD2-negative patients. In 3/6 cases the ERG deletions were lost and in 3 cases the relapse deletions differed from those found at diagnosis.
In summary, we describe a high incidence of ERGdel in BCP ALL, suggesting that the ERG locus is prone to deletion in childhood ALL. However, the deletion does not seem to play a major driving role here. Nevertheless, combined with CD2-positivity, ERGdel confers superior prognosis overcoming the negative impact of IKZF1 deletions.

Cytogenetically unrelated clones in hematologic malignancies: ten years of experiences in a single institution.

M. S. Dencic Fekete*, J. Jovanovic, V. Djordjevic, A. Bogdanovic, M. Gotic;*
Clinic of hematology, Belgrade, Serbia.

We evaluated the frequency and clinical significance of cytogenetic polyclonality in patients with various hematologic malignancies. The study includes 2683 patients who had been diagnosed with: Acute myeloid leukemia (AML), Acute lymphoid leukemia (ALL), Myelodisplastic syndrome (MDS), Myeloproliferative disorders (MPD) and Chronic myeloid leukemia (CML). During the past ten years, karyotypically unrelated clones were found in 20 patients (0.75%): 1.11% (7/631) of AML, 1.01% (2/195) of ALL, 1.16% (3/257) of MDS, 0.25% (3/1200) of MPD and 1.25% (5/400) of CML. In four AML and one MDS patient, the presence of unrelated clones was confirmed by FISH analysis. Patients diagnosed with AML, ALL and MPD had various structural and numerical aberrations of which the most common were trisomies, affecting chromosomes 8, 9, 12, 18 and 22. Translocations [t(8;21), t(15;17), t(2;5), t(14;16)] and monosomies (-Y,-7, -15, -17) were observed in 4 patients, each, while deletions (del(6q), del(7q) and del(11q)) were detected in 3 patients. Del(5q) and +8 were detected in unrelated clones of one MDS patient, del(5q) and del(8q) were present in the other one, while the third patient with MDS had unrelated clones with del(20q) and t(7;20). Four patients with CML, treated with imatinib mesylate, had unrelated clone of +8 in Philadelphia negative cells. In one patient, diagnosed as CML de novo, del(7q) and der(20) were detected in the unrelated Ph negative clone. Karyotypically unrelated clones are rare events and may originate from the common malignant clone which could be revealed by molecular methods, needed to identify hidden primary aberrations.

SPRED1, the gene involved in a neuro-cardio-facial-cutaneous syndrome, Legius syndrome, is a leukemia predisposing gene

B. GILBERT-DUSSARDIER[1,2], *F. Brizard*[3], *P. Vabres*[4], *F. Millot*[5], *D. Vidaud*[6,7], *E. Pasmant*[6,7];
[1]*CHU, Poitiers, France,* [2]*Génétique, Centre de Référence Anomalies du Développement Ouest, Poitiers, France,* [3]*Hématoloigie CHU, Poitiers, France,* [4]*Dermatologie, CHU, Dijon, France,* [5]*Hématologie Pédiatrique, CHU, Poitiers, France,* [6]*UMR745 INSERM, PRES Sorbonne Paris Cité, Université Paris Descartes, Faculté des Sciences Pharmaceutiques et Biologiques, Paris, France,* [7]*Service de Biochimie et de Génétique Moléculaire, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris), Paris, France.*

Germline loss-of-function mutations in SPRED1 located on chromosome 15q14, have been reported to originate Legius syndrome, belonging to the overlapping neuro-cardio-facial-cutaneous (NCFC) syndromes, all caused by germline mutations in the Ras-mitogen-activated protein kinase (MAPK) pathway and are associated with predisposition to cancer in children, notably leukemia.
Until now, only one case of an 11-month-old boy with a SPRED1 germline mutation who developed an acute myeloblastic leukemia, had been reported.
Here, we present a girl who had multiple café-au-lait spots since the age of 2 years and developed an acute lymphoblastic leukemia at age of 3 years. Other members of the family in her paternal lineage had multiple café-au-lait spots too, but none of them developed any cancer. The patient was shown to have a germline loss-of-function frameshift mutation in the SPRED1 gene (c.395dupA NM_152591.2; p.Asn133fs P010194), when she was 11 years old. Going back to her hematologic file, we could find result of a medullar karyotype she had as part of the leukemia diagnosis : a somatic mosaicism of a heterozygous deletion on chromosome 15q was found in medullar leukemia blasts [46,XX(30)/45,XX,der(5),del(15)(q11q25),-20(3)] including the SPRED1 locus. At the time of remission, a normal karyotype was observed.
This is the first case where a loss of heterozygozity of SPRED1 is shown in leukemia, supporting the hypothesis of the involvement of this gene in a few forms of leukemia, as a tumor suppressor.
Furthermore, this observation highlights the usefulness of cancer cells karyotyping to detect somatic chromosomal anomalies.

Polymorphisms in microRNA-binding sites and risk of childhood acute lymphoblastic leukemia and myeloid leukemias in adults

A. Dzikiewicz-Krawczyk[1], *E. Mały*[2], *M. Fichna*[1], *M. Mosor*[1], *E. Strauss*[1], *D. Januszkiewicz*[1,3], *J. Nowak*[1];
[1]*Institute of Human Genetics, Poznan, Poland,* [2]*Department of Medical Diagnostics, Poznan, Poland,* [3]*Department of Oncology, Hematology and Bone Marrow Transplantation, University of Medical Sciences, Poznan, Poland.*

microRNAs (miRNAs) regulate diverse cellular processes by binding to the 3' untranslated regions (3'UTRs) of messenger RNAs. Polymorphisms in miRNA-binding sites (miRSNPs) may alter the strength of miRNA interaction with target transcripts thereby deregulating gene expression.
In this study we analysed with specialized algorithms (PITA, Partocles, polymiRTS, dbSMR, miRANDA) the 3'UTRs of 138 leukemia-associated genes and identified 111 putative miRSNPs. For further investigation 11 miRSNPs were chosen based on the accordance of at least three algorithms. Using TaqMan allelic discrimination and PCR-RFLP we genotyped patients with childhood acute lymphoblastic leukemia (ALL, n=101), acute myeloid leukemia (AML, n=86), chronic myeloid leukemia (CML, n=153) and healthy controls (n=471). Variant alleles of ETV6_rs1573613 and TLX1_rs2742038 were associated with increased ALL risk in recessive model (OR=1.9264, 95% CI=1.1762-3.1551 and OR=3.9893, 95% CI=1.4377-11.0692, respectively), while the PML_rs9479 variant allele was linked to decreased ALL risk in dominant model (OR=0.5470, 95% CI=0.3464-0.8639). In adult myeloid leukemias we found significant associations between variant alleles of PML_rs9479 and BCL11B_rs1152781 and decreased AML risk (OR=0.6010, 95% CI=0.3669-0.9846, dominant model and OR=0.2557, 95% CI=0.0781-0.8371, recessive model, respectively) and between the variant allele of IRF8_

rs10514611 and increased CML risk in recessive model (OR=2.8128, 95% CI=1.3470-5.8735). Differential allelic expression (DAE) showed that the variant alleles of ETV6_rs1573613, PML_rs9479, and BCL11B_rs1152781 are expressed at a significantly lower level than the wild-type alleles, while the variant allele of IRF8_rs10514611 is expressed at a higher level compared to the wild-type allele. The results suggest that these miRSNPs are a potential risk factor in leukemias.

Novel somatic mutations in large granular lymphocyte leukemia

E. I. Andersson[1], *H. L. M. Rajala*[1], *S. Eldfors*[2], *P. Ellonen*[2], *T. Olson*[3], *A. Jerez*[4], *M. J. Clemente*[4], *O. Kallioniemi*[2], *K. Porkka*[1], *C. Heckman*[2], *J. P. Maciejewski*[4], *T. P. Loughran Jr.*[3], *S. Mustjoki*[1];

[1]*Hematology Research Unit, Biomedicum Helsinki, Helsinki University Central Hospital (HUCH), Helsinki, Finland,* [2]*Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland,* [3]*Penn State Hershey Cancer Institute, Penn State Hershey College of Medicine, Hershey, PA, United States,* [4]*Translational Hematology and Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, United States.*

Large granular lymphocyte (LGL) leukemia is a clonal disease characterized by expansion of mature cytotoxic T-cells. Our recent findings suggest that 40% of LGL-leukemia patients harbor mutations in STAT3 (Koskela et al. NEJM 2012). To identify additional novel somatic mutations in STAT3-mutation negative LGL-leukemia patients, we performed exome sequencing from leukemic cells of three untreated patients.

Patient 1 harbored a missense mutation in PTPRT with a variant frequency of 14%. PTPRT has previously been found to reverse Tyr705 phosphorylation on STAT3, a modification associated with STAT3 deactivation. This novel V995M mutation occurs within the tyrosine-protein phosphatase 1 domain and may thereby affect STAT3 activity by reducing dephosphorylation of Tyr705, thus increasing the expression of STAT3 target genes.

Patient 2 had a missense mutation in ANGPT2 (variant frequency 34%). K436E occurs within the TIE2-binding domain and is likely to affect the binding of TIE2 by ANGPT2. Over-expression of ANGPT2 has previously been shown to confer an adverse prognostic factor in other forms of leukemia.

Exome sequencing of patient 3 revealed a H126R mutation in BCL11b (variant frequency 51%). BCL11B is required for T-cell survival and overexpression could effectively increase T-cell activation and proliferation.

While these mutations appear biologically relevant and exciting, they have not been found to be recurrent in the screening of large cohort of LGL-leukemia patients (n=170).

Somatic mutations in PTPRT, ANGPT2 and BCL11b may represent rare genetic causes for LGL-leukemia. Inactivating mutations in PTPRT may have the same functional consequence as activating mutations of STAT3 in LGL-leukemia patients.

Expression profiling with microarrays method in human leukemic cells after coumarins and furanocoumarins exposition

J. Kocki[1], *M. Cioch*[2], *A. Bogucka-Kocka*[3];

[1]*Dept. Clinical Genetics, Medical University, Lublin, Poland,* [2]*Dept. Haematology, Medical University, Lublin, Poland,* [3]*Dept. Pharmaceutical Botany, Medical University, Lublin, Poland.*

Coumarins are chemical compounds which can be found naturally in some plants. The subject of the study was to find the coumarin inhibitors of the pathogenetic mechanisms of human leukemic cells. We used Affymetrix GeneChips and quantitative RT-PCR technologies for the genes expression profiling in J45.01 human leukemic cells exposed on coumarins in Scan'R system. The apoptotic and cytotoxic effects of coumarins on leukemic cells were observed in FlowSight flow cytometer.

Moreover, we selected two coumarins with the lowest IC50 values. The analysis of transcriptomes with Ingenuity Pathways Analysis (IPA) showed differences in the genes expression in particular cells exposed on coumarins. There were some changes found in genes expression in the cells which were exposed on these coumarins. The genes with the highest coefficient of P were functionally classified as tumor markers, cell death, cell cycle and cell growth regulators and were associated with the cell organization.

The transcriptomes analyses revealed some specific features of the therapy responses depending on the exposition agents, which has increased our knowledge on leukemogenesis.

This work was funded by the Polish State Committee for Scientific Research (Project No: NN405162639) and was developed using the equipment purchased within the Project „The equipment of innovative laboratories doing research on new medicines used in the therapy of civilization and neoplastic diseases" within the Operational Program Development of Eastern Poland 2007 - 2013, Priority Axis I Modern Economy, Operations I.3 Innovation Promotion.

P11.164

Cytogenetic analysis of human liposarcomas by array-based comparative genomic hybridization

M. Koczkowska[1], *M. Iliszko*[1], *J. Ryś*[2], ***J. Limon***[1];

[1]*Department of Biology and Genetics, Medical University of Gdansk, Gdansk, Poland,* [2]*Department of Tumor Pathology, Center of Oncology, Krakow, Poland.*

Liposarcomas are the most common soft tissue sarcomas accounting for 20% of all mesenchymal malignancies. Morphologically, WHO classifies liposarcomas into four main subtypes consisting of: myxoid/round cell (M/RLPS), dedifferentiated (DDLPS), well-differentiated (WDLPS) and pleomorphic liposarcomas (PLPS). Characteristic cytogenetic features of WDLPS and DDLPS are supernumerary ring giant chromosomes and dmin (*double-minute chromosomes*), while MLPS are characterised by the presence of specific translocation: t(12;16)(q13;p11).

The aim of the study was to analyse genomic profile of 65 liposarcomas (WDLPS n=21, DDLPS=24 and MLPS n=20) using array-based comparative genomic hybridization at unprecedented resolution of ~10kb (*NimbleGen, Roche*). Additionally we analysed genomic profile of subsequent samples of tumors resected from an individual patient during disease progression.

DNA copy number aberrations were found in 60 tumors (92%). Loss of chromosomal segments was observed in 29% of WDLPS (n=6), 60% of MLPS (n=12) and in 71% of DDLPS (n=17). In MLPS the most frequently involved chromosomal region was 1q (30%) with minimal overlapping region of gain 1q25.1-q32.2 (34 Mbp). 42 (93%) of WDLPS and DDLPS had 12q gain, with minimal common region at 12q14.1-q21.1. In WDLPS, the other common aberration was gain at chromosome 5 with minimal common region of overlap 5p15.2-p14.1. In contrary to WDLPS, in DDLPS we identified aberrations at chromosome 13q.

The observed patterns of genomic aberrations in particular liposarcoma subtypes reflect biological differences between these tumors.

Objectives: Lung cancer is often a multistep, multifactorial disease involving both genetic and environmental components. Mitochondrial uncoupling protein 2 (UCP2), a negative regulator of mitochondrial reactive oxygen species (ROS) generation, was observed to be abundantly expressed in components of the immune system such as spleen, lung, and isolated macrophages. The purpose of this study was to investigate the relationship between the UCP2 gene variants and lung cancer susceptibility.

Methods: Seventy five lung cancer patients and 75 healthy controls were included in the study. The UCP2 gene variants (-866G>A and 45 bp insertion/deletion (I/D)) were determined by polymerase chain reaction and/or restriction fragment length polymorphism method.

Results: Distribution of genotype and allelic frequency of UCP2 45 bp I/D variant were significantly different between lung cancer and control groups. The distribution of II genotype was found significantly higher in the lung

cancer group (54.7%) than in the control group (8%) (p< 0.0001). In addition, the I allele frequency (68%) was higher than in controls (23.3%) (p< 0.0001). On the other hand, no statistically significant difference was found between UCP2 -866G>A variant and lung cancer susceptibility.
Conclusion: We suggest that both I allele and II genotype of UCP2 45 bp I/D variant are risk factors for susceptibility to lung cancer. Additional studies are needed to confirm the exact role of UCP2 variants on lung cancer.

Background: Lung cancer is a leading cause of death in Bulgaria. Somatic gain-of- function mutation in the epidermal growth factor receptor (EGFR) detected in patients with non-small cell lung cancer (NSCLC) has significance for assigning optimal disease treatment. 29 EGFR somatic mutations are associated with either sensitivity or resistance to gefitinib or erlotinib treatment.
Methods: We performed DNA analysis on 98 patients with NSCLC. All cases are histologically confirmed as NSCLC. Tumor sample materials are extracted from formalin-fixed paraffin-embedded NSCLC samples. DNA extraction was performed by QIAamp DNA FFPE Tissue Kit for genomic DNA purification. The samples are analysed by polymerase chain reaction (PCR), using EGFR RGQ Kit on Rotor-Gene Q instrument, and the results were processed by Rotor-Gene Q Series Software.
Results: Analyses were processed according to manufacturer's recommendation. EGFR-mutations were discovered in 10% of samples. The two most common EGFR somatic mutations are deletions in exon 19 (8 patients, 8.16%) and L858R point mutation on exon 21 (2 patients, 2.0%). These two mutations define NSCLC as sensitive to treatment with the EGFR tyrosine kinase inhibitors (EGFR-TKI) gefitinib and erlotinib.
Conclusion: Our results are in accord with data for European populations. Patients with NSCLC and EGFR mutation, either exon 19 deletions or L858R, have a longer survival following treatment with gefitinib or erlotinib.

Allelic imbalance in non-small cell lung cancer.

A. Shikeeva[1], *T. Kekeeva*[1,2], *L. Zavalishina*[1], *Y. Andreeva*[1], *G. Frank*[1];
[1]*Moscow Herzen Oncological Research Institute, Moscow, Russian Federation,*
[2]*I.M.Sechenov First Moscow State Medical University, Moscow, Russian Federation.*

Lung cancer is the leading cause of cancer deaths worldwide. Non-small cell lung cancer (NSCLC) comprises 80% of all lung cancers and is characterized by multiple genetic alterations such as loss of heterozygosity (LOH) and microsatellite instability (MSI).
We performed analysis of molecular-genetic alterations in tumor and in surrounding tissue in different histological types.
The study group included 70 patients with NSCLC. From each patient 3 samples were analyzed: tumor, 2 samples from surrounding normal lung tissue at 2 cm and 5 cm from tumor. Microsatellite analysis was evaluated by PCR using 7 polymorphic markers of chromosomal regions: 12p23.3, 2q35, 3p14.2, 3p22.2, 3p26.3, 9p22.1 and 17p13.3.
Our results demonstrated allelic imbalance (AI) in NSCLC samples with the following frequencies: D2S405 32/65 (47%), D2S164 - 26/60 (43%), D3S1300 - 40/67 (60%), D3S1768 - 33/63 (52%), D3S1539 - 34/65 (52%), D9S925 - 30/64 (47%), D17S938 - 31/63 (49%). LOH and/or MSI in surrounding tissue were not detected. AI in D9S925 (p = 0.005), D17S938 (p = 0.002) was strongly associated with squamous cell lung cancer. LOH and/or MSI in D3S1768 (p = 0.004) and D17S938 (p = 0.03) were linked to smoking status. Frequent genetic alterations in D2S405 (p = 0.01) correlated with early stage cancer (I-II), whereas alterations in D3S1300 (p = 0.0197) were associated with advanced stages of disease (III-IV).
Observed genetic alterations can be used as molecular markers of squamous cell lung cancer in difficult diagnostic cases and can be considered as prognostic markers.

P11.169
The analysis of genetic alterations in the NSCLC patients using hybridization with diagnostic biochips

M. A. Emelyanova[1], *I. S. Abramov*[1], *K. A. Arkhipova*[2], *I. B. Zborovskaya*[2], *L. N. Lyubchenko*[2], *N. N. Mazurenko*[2], *T. V. Nasedkina*[1];
[1]*Engelhardt Institute of Molecular Biology Russian Academy of Sciences, Moscow, Russian Federation,* [2]*N. N. Blokhin Russian Cancer Research Center of Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Specific epidermal growth factor receptor (EGFR) inhibitors (gefitinib and erlotinib) and anaplastic lymphoma kinase (ALK) inhibitor (crizotinib) are used for the treatment of non-small-cell lung cancer (NSCLC). Somatic mutations in EGFR gene and key effectors along EGFR signaling pathway (KRAS, BRAF, PIK3CA), as well as ALK rearrangements are associated with sensitivity to these drugs.
A biochip has been developed which allows detecting 13 mutations in 12, 13 and 61 codons of KRAS; 5 mutations in 858, 719, 790 codons and 13 deletions in exon 19 of EGFR; V600E of BRAF; 5 mutations in 542, 545, 546 and 1047 codons of PIK3CA gene. The technique of LNA (locked nucleic acid)-clamp PCR was used to increase the sensitivity of the assay followed by allele-specific hybridization of fluorescently labeled target on biochip. To determine the ALK rearrangements a biochip analyzing 11 breakpoint variants of EML4-ALK translocations has been designed. The reverse transcription PCR with chimeric EML4-ALK mRNA was used prior to hybridization.
To prove the feasibility of the method clinical samples from 84 unselected patients with NSCLC were analyzed. We identified EGFR mutations in 13 (15%), KRAS mutations in 14 (17%), PIK3CA mutations in 8 (10%) and EML4-ALK translocations in 2 (2%) of patients. The data on mutation analysis were verified by direct sequencing. We consider the biochip-based approach to be simple and useful diagnostic tool for identification of NSCLC patients which will respond to target therapy.
The work was supported by the Russian Foundation for Basic Research (grant #11-04-01950).

Analysis of Mannose Binding Lectin and Macrophage Inhibitory Factor Gene Variants in Lung Cancer Patients

M. Nacak[1], *I. Nacak*[2], *S. Pehlivan*[3], *S. Oguzkan Balci*[3], *M. Sanli*[4];
[1]*University of Gaziantep, Faculty of Medicine, Department of Pharmacology, Gaziantep, Turkey,* [2]*Sani Konukoglu Hospital, Department of Thoracic Surgery, Gaziantep, Turkey,* [3]*University of Gaziantep, Faculty of Medicine, Department of Medical Biology and Genetics, Gaziantep, Turkey,* [4]*University of Gaziantep, Faculty of Medicine, Department of Thoracic Surgery, Gaziantep, Turkey.*

Objectives: Lung cancer is caused by genetic and epigenetic changes leading to uncontrolled cell growth and metastasis. Macrophage migration inhibitory factor (MIF) and mannose-binding lectin2 (MBL2) implicated in the pathogenesis of several pathological disorders including cancer. The aim of this study was to examine the relationship between the MBL2 and MIF gene variants and lung cancer risk.
Methods: Eighty six lung cancer patients and 100 healthy controls were recruited in the study. Codon 54 A/B variant in MBL2 gene and -173 G/C variant in MIF gene were analysed by PCR-RFLP method.
Results: In the MBL2 variant, BB genotype was found significantly more frequent in lung cancer than controls (p<0.0010). Conversely, AB genotype was found significantly more frequent in controls than lung cancer (p<0.0098). The allele frequency of A and B was 0.779, 0.221 in cases compared with 0.815, 0.185 in controls. On the other hand, the distribution of G/G, G/C and C/C genotypes for MIF variant was 55.8%, 43% and 1.2% for cases and 55%, 41% and 4% for the controls. The allele frequency of G and C was 0.773, 0.227 in cases compared with 0.755, 0.244 in controls. No significant differences in allele/genotype distribution of the MIF variant were found between patients and controls.
Conclusion: Our data show that homozygous variant B allele of the MBL2 codon 54 polymorphism may be a risk factor for susceptibility to lung cancer. Further studies are required to confirm the exact role of MBL2 and MIF variants on lung cancer.

Maffucci syndrome (MS) is a rare congenital disorder characterized by multiple central cartilaginous tumors (enchondromas) that are accompanied by cutaneous spindle-cell hemangiomas. These patients have a high incidence of malignant transformation. No familial case is known and the ethiopathogenic cause remains to be unraveled. In enchondromatosis (Ollier's disease, OD), which is comprised of enchondromas only, four mutations in the PTHR1 gene have been identified in four patients; three were somatic and one was germline. No PTHR1 mutation has been detected in MS. On the other hand, in 77% of patients with MS and 81% of patients with OD, somatic IDH1, and more rarely IDH2, mutations have been observed. These changes are shared with other tumors, including glioblastomas, leukemias and thyroid cancers, and may thus be markers of cellular transformation.
To search for underlying somatic genomic causes, we screened MS tissues using Affymetrix SNP-chips. We looked for copy number variations (CNV), loss of heterozygosity (LOH) and uniparental (iso)disomy (UPD) by performing pairwise analyses between allele intensities in tumoral DNA versus the corresponding blood-extracted DNA. While common chromosomal anomalies were absent in constitutional DNA, several shared CNVs were identified in tumors. The most frequently observed is a large somatic alterations not present in CNV databases was a gain of 14q11.2. In the single chondrosarcoma, large chromosomal amplifications /deletions were observed in chromosomes 3, 6, 9, 10, 12 and 13. No loss of heterozygosity was observed in any Maffucci tissue. In conclusion, this study suggests new candidate gene for Maffucci syndrome located.

Over-Expression of FAT10 causes Malignant Transformation

C. G. Lee[1,2,3], *Y. Gao*[1], *S. S. Theng*[2], *W. B. Teo*[2], *J. Zhuo*[1];
[1]*National Cancer Centre, Singapore, Singapore,* [2]*National University of Singapore, Singapore, Singapore,* [3]*DUKE-NUS Graduate Medical School, Singapore, Singapore.*

The FAT10 gene is overexpressed in hepatocellular carcinoma (HCC) and other cancers. High levels of FAT10 protein lead to increased mitotic nondisjunction and chromosome instability (CIN). Here, we demonstrate that when NehepLxHT, an immortalized non-tumorigenic liver cell line, is stably transfected with high levels of *FAT10*, these cells not only demonstrate higher cell proliferation rate and increased resistance against camptothecin-induced apoptosis, it also exhibits transformation potential by its ability to grow on soft agar. Its role in malignant transformation is evident from anchorage independent growth, increased adhesion to collagen IV, increased cell migration and invasion in cells over-expressing *FAT10*. Through genome-wide expression analyses, genes involved in proliferation, transformation, migration as well as invasion were found to be significantly differentially expressed in cells expressing *FAT10*. The most significant network associated with *FAT10* over-expression was found to be "Cell Death, Inflammatory Response and Cancer" where the deregulated genes converge on the NFκB complex as the key nodal hub. Overexpression of *FAT10* leads to downregulation of IκB protein and activation of NFκB activity with consequent upregulation of *CXCR4* and *CXCR7* expression which was found play a role in facilitating the invasive property of *FAT10*-expressing cells.

Melanomas spontaneously occur in dogs, as in humans, due to genetic and environmental factors.
To characterize the homologies and differences between dog and human melanomas, we analyzed epidemiological data from 2350 melanocytic tumours and we analyzed in depth epidemiological, clinical and histopathological data from 150 canine melanocytic tumours. We found that melanomas occur in the same anatomical locations than humans and interestingly, specific dog breeds present higher risk to develop oral or cutaneous melanoma, strongly reflecting genetic predispositions.
To tentatively propose a histogenetic classification, the analysis of genes presenting frequent somatic alterations in human melanoma, was performed in dogs.
To decipher the genetic causes of melanoma in dogs, we set up, through the Cani-DNA dedicated canine biobank, a collection of cases and controls in high risk breeds. We collected over 500 blood samples and 200 melanoma tumour samples in different breeds. We first performed a genome wide association study, using DNA samples from 80 affected and 100 healthy poodles, a breed nearly exclusively affected by oral melanomas. Finally, an RNAseq analysis of matched healthy/tumour samples had been undertook on 20 melanoma cases.
Canine melanomas thus appear good naturally occurring models for studying human mucosal melanoma, and for melanoma of dermal origin and constitute specific models to investigate the non-UV pathways, otherwise poorly studied. In conclusion, predisposed dog breeds are invaluable models to identify novel genes and pathways in order to develop new therapies that will be beneficial both for dogs and humans.

Genetic variation in immuno-modulatory genes as markers of melanoma recurrence-free and overall survival.

J. Rendleman, S. Shang, J. Shields, C. Adaniel, N. Fleming, R. Shapiro, R. Berman, A. Pavlick, D. Polsky, Y. Shao, I. Osman, ***T. Kirchhoff****;*
New York University School of Medicine, New York, NY, United States.

The involvement of immune-related genes in melanoma progression has been demonstrated, suggesting the potential of these pathways in the prediction of disease susceptibility and prognosis. In this study, we performed an analysis of germline variants in immuno-modulatory genes for their association with melanoma survival in a well-characterized cohort of 817 melanoma patients. Germline DNA was genotyped for 94 SNPs tagging 55 immuno-modulatory genes using Sequenom iPLEX. Cox models were used to test associations between each SNP and recurrence-free and overall survival (RFS, OS), with adjustments for age, gender, subtype, thickness, ulceration, and anatomic site. ROC curves were constructed combining SNPs with clinical covariates and the area under the curve (AUC) was used to assess their utility in the classification of 3-year melanoma recurrence. The SNP rs2796817 in TGFB2 had strong associations with both RFS (HR=3.8, CI 95%: 1.3-11, p=0.02) and OS (HR=5.5, CI 95%: 1.6-19, p=0.029). Other interesting associations with OS came from IRF8 (rs4843861, HR=0.62, CI 95%: 0.39-0.99, p=0.017) and CD8A (rs3810831, HR=2.4, CI 95%: 0.91-6.2, p=0.048). A multivariate model including stage, subtype and rs3810831 from CD8A was shown to improve the AUC when compared to a model including only stage and subtype in classifying 3-year recurrence (0.77 vs. 0.79). The findings in this study provide evidence that the genetic variants in immuno-modulatory genes may represent novel biomarkers of melanoma prognosis. The validation analysis is currently underway with an expanded set of immune target genes as well as an additional independent cohort of melanoma patients.

Prevalence of the MITF p.Glu318Lys germline mutation in the EPIC and E3N prospective cohorts

M. Pertesi[1], *M. Kvaskoff*[2], *N. Forey*[1], *A. Chabrier*[1], *A. Bijon*[2], *L. Barjhoux*[3], *F. Le Calvez-Kelm*[1], *F. Clavel-Chapelon*[2], *D. Palli*[4], *,. EPIC*[5], *J. McKay*[1], *F. Lesueur*[1,6];
[1]*Genetic Cancer Susceptibility Group, International Agency for Research on Cancer, Lyon, France,* [2]*Inserm U1018, Centre for Research in Epidemiology and Population Health,*

Institut Gustave Roussy, Villejuif, France, [3]Inserm U1052, Cancer Research Centre of Lyon, Centre Léon Bérard, Lyon, France, [4]ISPO Cancer Prevention and Research Institute, Florence, Italy, [5]International Agency for Research on Cancer, Lyon, France, [6]Inserm U900, Mines ParisTech, Biostatistics, Institut Curie, Paris, France.

A recently identified recurrent germline mutation in the MITF gene, p.E318K (rs149617956), was shown to increase the risk of melanoma in highly-predisposed patients ascertained through the clinics. MITF encodes for the micropthalmia-associated transcription factor that plays a key role in the pigmentation pathway and acts as a melanoma oncogene. Codon 318 is located in a small-ubiquitin-like modifier (SUMO) consensus site and this missense substitution severely impairs the SUMOylation of MITF and leads to differential regulation of downstream targets. In the studied populations (France, England, Australia), the frequency of the mutation was less than 1% and 2-5 times more frequent in patients with a family history of melanoma and/or multiple malignant melanomas.
To further investigate the importance of the p.E318K mutation in European populations, we determined its frequency in 1,177 melanoma cases and 1,584 controls from two population-based prospective cohorts, EPIC (European Prospective Investigation into Cancer and Nutrition) and the French E3N (Etude Epidémiologique auprès de femmes de la Mutuelle Générale de l'Education Nationale).
The frequency of p.E318K was significantly higher among cases (0.5% vs. 0.2% in controls; Fisher Exact test p-value 0.04; OR 2.98; 95% confidence interval (CI), 0.95-10.96). These findings from two large population-based cohorts confirm an increased risk of melanoma in carriers of the MITF p.E318K mutation in European populations. We are now carrying out a full mutation screening of the coding sequence of MITF to investigate the possibility of other rare, likely deleterious mutations within this melanoma susceptibility gene.

Detection of EGFR, 1p36, 14q32 genomic copy alterations in Meningiomas

*I. G. Bedir[1], **M. Ozdemir**[1], S. Işıksoy[2], E. Çiftçi[2], B. Durak Aras[1], O. Çilingir[1], S. Artan[1], A. Arslantaş[3];*
[1]Osmangazi University, Medical Faculty, Department of Medical Genetics, Eskisehir, Turkey, [2]Osmangazi University, Medical Faculty, Department of Pathology, Eskisehir, Turkey, [3]Osmangazi University, Medical Faculty, Department of Neurosurgery, Eskisehir, Turkey.

Meningiomas are mostly benign, slow-growing tumors of the CNS that originate from arachnoidal cap cells and account for about 30% of all primary brain tumours. Chromosome 22q12.2 deletion, a region encoding the tumor suppressor gene *merlin*, represent the most common genetic alterations in early meningioma formation. Malignant meningioma progression, however, is associated with increased genetic instability and complex genetic alterations, including numerous genomic losses, gains, and amplifications. For the detection of genomic copy number aberrations of EGFR gene, 1p36/1q25 and IGH (14q32.3) loci, we conducted fluorescence in situ hybridization (FISH) analysis on histopathologically analysed fresh meningioma tissues from 30 cases (23 females and 7 males). Of all analysed tumors, 26 were benign whereas the remainings were atypical meningiomas. EGFR/CEP7 polysomy was detected in 26,9% of benign tumors while polysomy and EGFR gene amplification were seen in all atypical meningiomas. Chromosome 1p36 locus deletions were detected in 84.4% and 50% of benign and atypical meningiomas, respectively. The IGH locus deletions were seen in both benign (92,3%) and atypical (50%) tumors. Our data also confirmed the involvement of chromosomes 1p36 and 14q32 deletions in malignant meningioma progression

P11.177
Copy number changes and hypermethylation of tumor suppressor genes in meningiomas

***T. San-Miguel**[1], L. Navarro[1], L. Muñoz-Hidalgo[2], J. González-Darder[3], C. López-Ginés[1], M. Cerdá-Nicolás[1], R. Gil-Benso[1];*
[1]Department of Pathology, University of Valencia, Valencia, Spain, [2]Fundation for Research HCU-INCLIVA, Valencia, Spain, [3]Department of Neurosurgery. Clinic University Hospital, Valencia, Spain.

Meningiomas are the second most common intracranial tumors. They arise from the leptomeningeal brain and spinal-cord covering. In meningiomas, clinical malignancy is mainly predicted by histological grading based on World Health Organization (WHO) criteria, being grades II-III biologically more aggressive than grade I. However, an important problem in these tumors is that as grade I meningiomas are the most frequent, in absolute numbers they are also the most recurrent. In this work we study copy-number changes and methylation status of a set of tumor suppressor genes (TSG) in order to establish a relationship between genetic status and biological behavior.
Samples studied were 40 tumors, surgically removed and diagnosed in the Clinic University Hospital of Valencia. Formalin fixed, paraffin-embedded tissue tumor samples were available and representative areas of each were selected and punched for DNA extraction. Methylation-Specific Multiplex-ligation Probe Amplification (MS-MLPA) with ME001-C1 kit was performed according to manufacturer instructions, PCR products were separated by capillary electrophoresis and data was analyzed with Excel-based software. All cases showed deletions in at least one TSG. Most frequently deleted genes were ERS1 and TP73. Promoter hypermethylation was detected in TP73, PTEN, RASSF1 and HIC1 genes. Grade I tumors showed more frequently deletions, while in higher grade tumors hypermethylation was more patent. These results suggest that both mechanisms are implicated in meningioma biology and that a relationship may exist between an increased hypermethylation pattern and a more aggressive behavior in human meningiomas.
Supported by PROMETEO 2011-11/83. Generalitat Valenciana and TS by V Segles-UVEG grant.

P11.178
O6-methylguanine-DNA-methyltransferase (MGMT) is a surgery-activated gene

***E. A. Alekseeva**[1,2], A. S. Tanas[1,2], E. V. Prozorenko[3], D. V. Zaletaev[1,2], V. V. Strelnikov[1,2];*
[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation, [3]N.N. Blockin Russian Research Center for Oncology, Moscow, Russian Federation.

Genetic status of the MGMT gene encoding the DNA repair protein O6-methylguanine-DNA-methyltransferase is among the most important prognostic factors for glioblastoma patients and predicts response to treatment with alkylating agent temozolomide. It is shown that using temozolomide improves both overall and progression-free survival. Currently in clinical practice assessment of genetic status of MGMT is most commonly performed either as a study of the MGMT promoter methylation, or the determination of its mRNA expression level. It is known that surgical manipulations can lead to an increased expression of a number of so-called 'surgery-activated' genes. Since the current standard of treatment for glioblastoma patients includes maximal feasible surgical resection followed by radiotherapy and chemotherapy, the objective of this study was to investigate the effect of surgical procedures on the MGMT expression level in the blood of patients operated for glioblastoma. Peripheral blood samples taken 1 hour before surgery, during or within 1 hour after surgery and 8 days after surgery, were obtained from 10 glioblastoma patients. The assessment of the MGMT expression, performed by real-time PCR, has shown that all patients had in average a 2 times increased MGMT expression level in the first hours after the operation and a more than 5 times increase in 8 days after surgery. Thus, we can assume that MGMT is a surgery-activated gene. Obtained results may raise the question about adequacy of using of investigation the MGMT expression level for determining genetic status of this gene in clinical practice.

First experience with array-CGH in 19 monoclonal gammopathy of undetermined significance (MGUS) patients

***A. Mikulasova**[1,2,3], V. Vallova[1,4], J. Smetana[1,2], H. Greslikova[2], R. Kupska[2], L. Rihova[2,3], A. Potacova[2], V. Sandecka[5], L. Pour[5], R. Hajek[2,3,6], P. Kuglik[1,2,4];*
[1]Laboratory of Molecular Cytogenetics, Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic, [2]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Department of Clinical Hematology, University Hospital, Brno, Czech Republic, [4]Department of Medical Genetics, University Hospital, Brno, Czech Republic, [5]Department of Internal Medicine – Hematooncology, University Hospital, Brno, Czech Republic, [6]Institute of Clinical Haematology, University Hospital, Ostrava, Czech Republic.

The incidence of clonal chromosomal aberrations in plasma cells (PCs) is

considered as one of the most important and independent prognostic factors in patients with myeloma. Also in the premalignancy MGUS, there are chromosomal changes in PCs f.e. del(13)(q14), IGH translocation, 1q21 gain and hyperdiploidy, but it is not known much about them and their significance in relation to malignant transformation. Unfortunately, MGUS research is complicated by small amount of malignant cells that can be obtained from patients.

We analysed 19 MGUS (13M/6F; median age 64) using array-CGH, Agilent platforms "Human Genome CGH, 4×44K" (N=12) and "SurePrint G3 CGH+SNP, 4×180K" (N=7). DNA was isolated from separated PCs (using CD138, CD19 and CD56 markers) and amplified by MDA whole genome amplification.

We found chromosomal abnormalities in 58% (11/19) MGUS. In 26% (5/19) cases we found hyperdiploidy, thus gains of minimally two of following chromosomes: 3, 5, 6, 7, 9, 10, 11, 15, 17, 18, 19, 21. The most frequent were gains of chromosomes 9 (32%; 6/19) and 11 (26%; 5/19). Moreover, gains were found at 1q, 3q22.3-q29, 6p, 11q13.3-q25, 16p, Xq23-q28 and losses were found at 6q, 6q23.3, 8q24.21-q24.22, 13q13.3-q34, 16p11.2-p11.1, 16q11.2-q13, 16q21-q24.3, 16q23.1-q23.2.

In our study we optimized protocol of array-CGH from amplify DNA and we use it in first MGUS patients. We found there are various chromosomal changes in more then half of patients, mainly gains of whole odd chromosomes, what is also typical for myeloma, in which MGUS often develops.

TaqMan-based miRNA profiles classify expression in breast cancer and leukemia

L. Wong, *N. Mulakken, D. Ridzon, P. Brzoska;*
Life Technologies, Foster City, CA, United States.

MicroRNAs are small endogenous RNA molecules that play an important role in the regulation of developmental and physiological processes. Studies indicate that microRNAs are involved in the multilevel regulation of gene expression targeting a battery of mRNA genes. Researchers have discovered that microRNAs are efficacious biomarkers for the classification of tumors and prediction of outcome for many diseases because of their evolutionary conservation, unique expression signatures, relative stability, and abundance. To identify potential candidates involved in tumor progression in humans, we examined the expression of 750 microRNAs using Applied Biosystems TaqMan® MicroRNA Assays in five human breast cancer cell lines, and two human leukemia cell lines. Data from leukemia cell lines were compared to two cell lines of normal peripheral blood mononuclear cells, and breast cancer cell lines were compared to normal breast tissue. In addition, the two groups of cancer samples were examined relative to the expression levels of 38 different normal tissues. We confirmed several microRNAs that were previously identified to be associated with cancer. We also determined a group of microRNAs that were consistently differentially expressed relative to the normal samples in all cancer cell lines. In addition, we identified microRNAs that are uniquely expressed in breast cancer but not in Leukemia cell lines. Further, microRNA families that are represented frequently in the list of significant microRNAs in both types of cancers were determined. These findings provide insight into possible common and distinct pathways between breast cancer and leukemia and the role of microRNAs in human cancer.

MicroRNAs (miRNAs) are post-transcriptional gene regulators involved in a wide range of biological processes including tumorigenesis. Although deregulation of miRNA pathways has been associated with cancer, their genetic contribution to this complex disorder is still unravelled. We used logistic regression and gene-based permutation tests to analyse the genetic association of gastric cancer (GC) and its anatomical localization (cardia/noncardia) and histological subtypes (intestinal/diffuse), with 133 SNPs tagging 11 individual miRNAs and 26 miRNA clusters potentially involved in cancer, in 365 incident GC cases and 1284 matched controls (European Prospective Investigation into Cancer and Nutrition (EPIC) cohort). Various SNPs significantly associated with different subtypes of GC under the log-additive model, being the most significant ones those in two miRNA clusters on chromosome 7: three tagSNPs of the miR-29a/miR-29b-1 cluster associated with the diffuse phenotype (minimum p-value=1.7x10-4; OR(95% cl):1.72(1.3-2.3)) and one tagSNP of the miR-25/miR-93/miR-106b cluster associated with the cardia localization (OR(95% cl):0.56(0.37-0.86), p-value=5.378x10-3). We predicted several target genes for these miRNAs, some of which have been functionally validated and are implicated in cancer-related processes such as methylation (DNMT3A, DNMT3B), cell cycle (E2F1, CDKN1A, CDKN1C) and apoptosis (BCL2L11, VEGFA). Furthermore, we identified significant interactions between variants in some of these genes and in the chromosome 7 miRNA clusters. Deregulation of the expression of these miRNAs in gastric tumours also supports our findings, altogether suggesting that genetic variation in MIR29, MIR25, MIR93 and MIR106b genes may have a critical role in the genetic susceptibility to GC, probably through modification of their expression.

MicroRNAs (miRNA) are single strand, non-coding RNA molecules with the length of 18-25 nucleotides and play major roles in the regulation of gene expression. Mature miRNA molecules are partially complementary to one or more messenger RNAs and cause tumor suppressor or oncogenic mRNA degradation or inhibition of the protein translation.

In this study it is aimed to investigate the expression profiles of miRNAs in 50 cases diagnosed with brain tumor (32 glioblastoma cases (GBM)-grade-IV, 10 diffuse astrocytoma cases (DA)-grade-II, 8 anaplastic oligodendroglioma cases (AO)-grade-III) and in brain tumor cell lines as control group (U-87MG, U-118MG and LN18). Expression profiles of miRNAs were studied by microarray method. Putative target genes of miRNAs that showed significant changes were identified by using 7 databases.

In GBM cases, miR-495 and miR-432 expression showed significant 2-fold increase and miR-708-3p, mir-339-5p and miR-4286 expressions 4-fold, mir-331-3p, miR-625-3p, and miR-20a-3p showed 5-fold reduction compared to control group. mir-204 expression was significantly decreased 6 times in AO cases compared to control group. There was a significant increase in 18 miRNAs and decrease in 7 miRNAs in DA cases compared to control group. When miRNA expressions of DA, AO and GBM cases compared with each other, significant differences were found in 29 miRNA. In all cases miR-21 expression level was high and no mir-124 expression was detected.

Ultimately, novel genes could be effective in tumor development supposed to be regulated by miRNAs. Regulation of miRNA expression may affect specific gene targets in brain tumors.

CLRCC François Baclesse, Caen, France, [6]Inserm UMR 1079, Caen, France.

The new generation of sequencing strategies technologies is changing genetic diagnosis because of its huge sequencing capacity and decreasing cost. Using this new approach, challenge for physicians will be to apprehend clinical uses of the genetic data generated, even in gene panels. So far genetic testing in inherited diseases is targeted, relying on recognition of a well-known clinical presentation evocative of a targeted predisposition. As an ethical issue, patients will have to be counselled about potentials of the technology to reveal other genetic alterations than those initially searched, that may be relevant for their risk of future disease. We report the case of a woman suspected to have a *BRCA* mutation because of the occurrence of an ovarian seropapillar adenocarcinoma at age 62 and breast cancer in her sister at age 62. Next-generation sequencing (NGS) analysis reveal no mutation for the *BRCA* genes but an unexpected nonsense mutation in the *MSH2* gene further confirmed by direct Sanger sequencing method. Although Amsterdam II criteria were not fulfilled, pedigree data had noted two cases of colon cancer respectively in a paternal aunt (age 69) and cousin (age 54), but among a large family. Intriguingly, neither microsatellite instability nor loss of MMR protein expression were observed in the ovarian tumour. Given the paucity of data on ovarian tumour in Lynch syndrome, classically described as non serous and at a younger age, we discuss such unplanned results. This report highlights importance of anticipation of such unexpected results with NGS introduction in clinical daily practice.

Knowledge of tumor biology and especially cancer genetics is growing fast. Novel therapeutic strategies are continuously being developed (notably monoclonal antibodies and small molecules). This process was highly accelerated with the advent of Next-Generation-Sequencing. So-called panel analyses allow parallel examination of multiple genes on DNA-level within days including detection of low level mutation mosaicism by deep sequencing. The results were proven to be of prognostic value and may predict drug response. We used a commercially available hotspot panel (48 genes, Illumina) to analyze a total of 43 different tumor samples. The analysis encompassed both FFPE material and native tissue. Sequencing quality and results were comparable for both tissue types with an average number of reads above 1000000 and a depth at 100x of above 97 %. Each mutation was validated by a second method and proven to be somatic by comparison to a reference sample (e.g. blood, normal tissue). A total of 24 somatic mutations were identified in 19 different samples (19/43 = 0.44). We found well-known mutations in important cancer genes like KRAS, TP53, CTNNB1, PIK3CA and ERBB2, some of them of therapeutic relevance. An interdisciplinary oncogenetic tumor board discussed the results. In addition two germline variants were found and classified as variants of unknown significance (APC, MET). These two findings may be relevant for the families and genetic counseling was offered to both patients. On the basis of our current results we are extending our gene panel to a set of ~ 180 genes.

BACKGROUND: Neurofibromatosis type 1 (NF1) is a common dominant tumor predisposition syndrome affecting 1 in 3,500 individuals. The hallmarks of NF1 are the development of peripheral nerve sheath tumors either benign (dermal and plexiform neurofibromas) or malignant (MPNSTs).
METHODS: To comprehensively characterize the role of microRNAs in NF1 tumorigenesis, we analyzed 377 miRNAs expression using the 384-wells microfluidic TaqMan human microRNA Low Density Array in a large panel of 9 dermal and 41 plexiform neurofibromas, and 15 MPNSTs.
RESULTS: The most significantly upregulated miRNA in plexiform neurofibromas was miR-486-3p that targets the major tumor suppressor gene, *PTEN*. We confirmed *PTEN* downregulation at mRNA level. In plexiform neurofibromas, we also report aberrant expression of four miRNAs involved in the RAS-MAPK pathway (miR-370, miR-143, miR-181a, and miR-145). In MPNSTs, significant deregulated miRNAs were involved in *PTEN* repression (miR-301a, miR-19a, and miR-106b), RAS-MAPK pathway regulation (Let-7b, miR-195, and miR-10b), mesenchymal transition (miR-200c, let-7b, miR-135a, miR-135b, and miR-9), *HOX* genes expression (miR-210, miR-196b, miR-10a, miR-10b, and miR-9), and cell cycle progression (miR-195, let-7b, miR-20a, miR-210, miR-129-3p, miR-449a, and miR-106b).
CONCLUSION: We confirmed the implication of *PTEN* in genesis of plexiform neurofibromas and MPNSTs in NF1. Markedly deregulated miRNAs may serve for the basis of potential diagnostic and predictive biomarkers and could represent novel strategies for effective pharmacological therapies of NF1 tumors.

Mother-to-offspring inheritance of MLH1 promoter hypermethylation

A. T. Hoejland[1], *H. Okkels*[2], *P. H. Madsen*[2], *T. D. Jensen*[1], *M. B. Petersen*[1];
[1]*Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark,* [2]*Department of Biochemistry, Aalborg University Hospital, Aalborg, Denmark.*

MLH1 promoter methylation analysis is a relatively inexpensive test used to help distinguish between sporadic and non-sporadic colon cancers with loss of expression of the proteins **MLH1** and PMS2 by immunohistochemistry. However, in a subset of Lynch Syndrome (LS) cases a constitutional MLH1 epimutation has been identified. Until recently, constitutional MLH1 epimutations were thought not to be passed on to the next generations, but cases of mother-to- offspring inheritance of constitutional MLH1 epimutations have been reported a few times in the literature.
We present a case that regards a deceased female suspected constitutional MLH1 epimutation carrier with three LS- associated cancers (endometrial cancer age 60, colon cancer age 61 and rectal cancer age 75). There are no other LS-associated cancers in the pedigree. All cancers and a dermal lipofibroma from the deceased female were found to be hypermethylated in the C-region of the MLH1 promoter. Screening of the MLH1, MSH2, MSH6 and PMS2 genes in the three children of the proband revealed no pathogenic mutations. Preliminary studies suggest the presence of hypermethylation of the C-region of the MLH1 promoter in blood lymphocytes of all three children. Further investigation is ongoing and includes searching for a second hit in the proband's three LS-associated tumors and testing of the offspring and proband for epigenetic changes in other parts of the genome.
Hypermethylation is the most plausible cause of LS in the proband.
The above indicates that an epimutation can be transferred to the offspring.

Haematologie,Onkologie und Tumorimmunologie,Charite CBF, Berlin, Germany.

While the *MLL* "recombinome" is relatively well characterized in B-cell precursor acute lymphoblastic leukemia (BCP ALL), available data for adult acute T-lymphoblastic leukemia (T-ALL) are scarce. We performed fluorescence in situ hybridization (FISH) for an *MLL* split signal on 223 adult T-ALL samples obtained within the framework of the German Multicenter ALL 07/2003 therapy trial. Three biphenotypic leukemias (T-ALL/AML) were also included in the analysis. Samples showing any alteration by FISH were further investigated to characterize the *MLL* aberration. In addition, they were investigated for common genetic lesions known in T-ALL. Twenty-two cases (9.5%) showed an abnormal *MLL* signal by FISH analysis. Most of these appeared to be deletions or gains but in five cases (2.1%) a chromosomal translocation involving the *MLL* gene was identified. The translocation partners and chromosomal breakpoints were molecularly characterized. Three T-ALLs had an *MLL-AF6*/t(6;11) and two biphenotypic leukemias had an *MLL-ELL*/t(11;19). The chromosomal breakpoints in two of the *MLL-AF6*-positive cases were located outside the classical *MLL* major breakpoint cluster known from BCP ALL. In conclusion, the spectrum of *MLL* translocation partners in adult T-ALL much more resembles that of AML than that of BCP ALL and thus the mechanisms by which *MLL* contributes to leukemogenesis in adult T-ALL appear to differ from those in BCP ALL. Proposals are made for the diagnostic assessment of *MLL* fusion genes in adult T-ALL

P11.189

The partial tandem duplication of *MLL* gene in patients with AML and cytogenetic abnormality of chromosome 11

I. Sarova[1,2], *J. Brezinova*[1], *O. Fuchs*[1], *A. Kostecka*[1], *M. Vostry*[1], *J. Filkukova*[1], *S. Ransdorfova*[1], *S. Izakova*[2], *J. Cermak*[1], *Z. Zemanova*[2], *K. Michalova*[1,2];

[1]*Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic,* [2]*Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General Faculty Hospital and 1 st Faculty of Medicine of Charles University, Prague, Czech Republic.*

The partial tandem duplication of the *MLL* gene (PTD) has been described in bone marrow cells of 6 - 10% of adult patients with acute myeloid leukemia (AML) with normal karyotype and in most cases with trisomy 11 as a sole cytogenetic abnormality. We investigated 210 patients with AML at diagnosis by RT-PCR and the *MLL* PTD was proved and confirmed by DNA sequencing in 50 of them (23%). All 210 patients were examined by conventional cytogenetics and FISH with a locus-specific probe for the *MLL* gene (11q23.3). *MLL* PTD were detected with: normal karyotype (n=21), 0 mitosis (n=3), t(8;21)(q22;q22)/inv(16)(p13q22) (n=4), complex karyotype (n=5), and with other chromosome changes (n=17). Duplication of the exones 2 to 6 was the most frequent ones. Chromosome 11 abnormality was identified in 12 patients: trisomy 11 (n=2), partial trisomy 11q (n=1), alteration of 11p (n=1), balanced rearrangement of 11p/11q (n=1), and *MLL* gene rearrangement (n=7; mostly t(9;11)(p22;q23)).

In conclusion, patients with *MLL* rearrangements or *MLL* PTD constitute the groups of AML patients with specific clinical and biological features. We proved that these two different disrupting mechanisms can co-exist together. It is not clear, if one *MLL* gene allele is carrier of both mutations or two *MLL* alleles are affected or if they originated simultaneously or consequently. Therefore, further analyses on the larger cohort of patients focused on molecular, biological and clinical relationship of these rearrangements in malignant processes are needed.

P11.190

Multiplex Ligation-Dependent Probe Amplification (MLPA) assay as a diagnostic tool to detect genomic rearrangements in myelodysplastic syndromes (MDS).

R. A. Cifarelli[1], *O. Scarciolla*[2], *C. Dininno*[1], *L. Russo*[3], *A. Dell'Acqua*[3], *G. Lauria*[1], *E. Vitullo*[4], *A. Ciancio*[3], *C. Mannarella*[3], *A. Fragasso*[3];

[1]*X-life, Centro Ricerche e Diagnosi, ASM-ARPAB, Matera, Italy,* [2]*Medical Genetics – Hematology Unit, Matera Hospital, Matera, Italy,* [3]*Hematology Unit, Matera Hospital, Italy, Matera, Italy,* [4]*Clinical Pathology Unit, Matera Hospital, Italy, Matera, Italy.*

Approximately 50% of MDS patients present bone marrow cytogenetic abnormalities at diagnosis, with an important role on prognosis and tailored therapy. Conventional cytogenetics (CC) with fluorescence in situ hybridization (FISH) are performed to detect chromosome abnormalities. MLPA assay simultaneously detect 40 different chromosomal rearrangements(deletions/duplications) in a single reaction. The study aim was to validate the MLPA assay in MDS samples comparing the results with the CC approach. Cell cultures and total DNA were obtained by bone marrow samples from 62 MDS patients (M:40, F:22, median age 73 years, range: 44-88 years). For each sample at least 20 metaphases were examined according G-banding protocol and two MLPA reactions were performed according to the manufacturer's recommendations (MRC-Holland). Our study revealed a good correlation between CC and MLPA, since 46 cases (74.2%) showed identical results with both techniques. For the other 16 cases (25.8%), we found different results.

In 5/16 samples (8%) CC analysis failed while the MLPA assay showed in one sample three chromosome deletions and no anomalies in the other samples. In the remaining 11/16 samples (17.8%) we found discrepancies. First group included three samples (4.9%) in which MLPA detected separately two different deletions and one trisomy, while CC did not show any alteration. The second group included 8 samples (12.9%) in which MLPA did not identify any rearrangement. Our data suggest that MLPA, used in conjunction with CC, can improve diagnostic and prognostic assessment, particularly in MDS cases with karyotype failure or with small rearrangements.

Malignant pleural mesothelioma (MPM) is a rare and aggressive tumor strongly associated with asbestos exposure. Only 5-17% of individuals exposed to asbestos develop MPM, suggesting the involvement of other environmental, genetic or epigenetic risk factors.

DNA methylation is an important mechanism of gene silencing in human malignancies. The relationship between aberrant DNA methylation and inflammation has been documented in many types of cancers, including MPM. Asbestos exposure may contribute to MPM onset through this relationship.

We conducted an epigenome-wide scan searching for differentially methylated regions (DMR) in 40 MPM cases and 40 controls and high-exposed versus low-exposed. Methylation status was measured for ~470k CpG sites in DNAs from lymphocytes, using the HumanMethylation450 BeadChip (Illumina, S. Diego, CA).

Logistic regression analysis after adjustment for age, gender, center of recruitment showed no significant methylation change of single CpG site associated with MPM. However, a regional analysis showed multiple significant signals in several genomic regions. In particular, a significant decreased methylation ($P<10^{-7}$) has been identified for *BLCAP* (tumor suppressor gene) and *NNAT* (expressed in non-small cell lung carcinoma) genes in exposed subjects compared with non exposed, whereas no significant difference has been found between in the overall cases and controls at the regional analysis. These results suggest that different DNA methylation profiles can related to asbestos exposure induced tumorigenesis of MPM and that epigenetic changes are detectable also in blood DNA.

First case of Muir-Torre syndrome caused by a germline mutation in PMS2

A. Bier[1], *M. Jatzwauk*[1], *J. Plaschke*[1], *S. Reif*[1], *F. R. Kreuz*[1], *M. Kinzel*[2], *S. Krüger*[1];
[1]*Gemeinschaftspraxis für Humangenetik, Dresden, Germany,* [2]*Praxis für Medizinische Genetik, Berlin, Germany.*

The autosomal dominant inherited Muir-Torre syndrome (MRTES, OMIM #158320) is defined by the co-occurrence of internal malignancies with sebaceous gland tumours or keratoacanthomas. The most common internal malignancies are gastrointestinal and genitourinary cancers. MRTES is a clinical variant of the Lynch syndrome (HNPCC, hereditary nonpolyposis colorectal cancer) which is caused by mutations in one of the mismatch repair genes *MLH1*, *MSH2*, *MSH6* or *PMS2*.
To date, germline mutations in *MSH2*, *MLH1,* and *MSH6* have been reported for MRTES. Contradictory studies exist about the predominance of *MSH2* mutations in comparison to the frequency of *MLH1* mutations. Only a few cases of *MSH6* mutations have been published so far, whereas no *PMS2* mutation in MRTES has been described.
The patient presented here was diagnosed with right-sided colon cancer and nasal sebaceous gland adenoma at the age of 34. Her sister was also diagnosed with a nasal sebaceous gland adenoma at the age of 37, however she had no pathological findings in colonoscopy. The parents of the siblings were apparently healthy. The brother refused any examination. The maternal grandmother suffered from breast cancer.
No mutation in *MLH1*, *MSH2* and *MSH6* was identified. Analysis of *PMS2* revealed the heterozygous missense mutation c.53T>C, p.Ile18Thr in exon 2, which has not been described yet. All four *in silico* prediction programs applied (SIFT, PolyPhen-2, AGVGD, MutationTaster) classified the mutation as pathogenic with highest scores.
As this is the first description of a *PMS2* mutation in a MRTES patient, *PMS2* mutations should also be considered in this condition.

Changes of multidrug resistance genes expression in human leukemic and myeloma cells after exposure to resveratrol derivatives

A. Bogucka-Kocka[1], *M. Cioch*[2], *J. Kocki*[3];
[1]*Dept. Pharmaceutical Botany, Lublin, Poland,* [2]*Dept. Haematology, Medical University, Lublin, Poland,* [3]*Dept. Clinical Genetics, Medical University, Lublin, Poland.*

Multidrug resistance is a mechanism in which many of cancers develop the chemotherapy resistance. The phenomenon of multidrug resistance (MDR) is the ability to actively pump in chemotherapeutics through the membrane transport proteins in the cellular and nuclear membranes.
The aim of this study was to determine some genes expression levels changes regulating the process of multidrug resistance that occured in the leukemic cells under the influence of resveratrol and six derivatives (stilbenes).
Quantitative RT-PCR analysis demonstrated some significant differences in the gene expression levels regulation. All the stilbenes caused a very high MDR1 gene expression level reduction in the H9 lymphocytes.
The MRP1 gene expression was the lowest one in 1301 and J45.01 cell lines after the exposure to some stilbenes. The MDR1 gene expression was the lowest one in the EOL1 cell lines after exposure to one stilbene. Two stilbenes decreased MVP gene expression level in J45.01 cell line.
Our results have provided some preliminary data suggesting that the resveratrol and derivatives play an important part in the leukemia chemotherapy.

Introduction
Multiple myeloma (MM) is a clonal bone marrow disease characterized by the neoplastic transformation of differentiated B cells. In many newly diagnosed patients, the abnormal clones have a low proliferative activity and, therefore, most of the analyzable metaphase cells are derived from normal hematopoiesis. As a result, only 30-40% of the new patients have an abnormal karyotype by conventional cytogenetics. Fluorescence *in situ* hybridization (FISH) increases detection rate to 90%. Both numerical and structural abnormalities are found and complex karyotypes are common.
Material and methods
The authors reviewed the cytogenetic results of 128 samples, referred to the Cytogenetic Laboratory of Centro Hospitalar de Trás-os-Montes and Alto Douro, with a presumptive diagnosis of MM, between January 2008 and February 2013.
Cytogenetic and G-banding analysis were performed according to standard techniques. In some cases, FISH technique was applied, with probe panel for del(13)(q14), del(17)(p13), t(4;14) and t(11;14) (Vysis).
Results and discussion
Metaphases were obtained in 95% cases. Of these, 44 cases had chromosomal abnormalities, mostly associated with MM [aneuploidies, del (13q), del (17p)]. FISH technique allowed confirming the results obtained by conventional cytogenetics and enhancing detection rate in 3% of cases.
Despite the small number of cases, the results obtained are consistent with those described in the literature and revealed the importance of conventional cytogenetics in the study of MM.

Whole genomic methods represents effective tool for studying genomic changes in cancer cells. Aim of this study was to find and describe genes whose expression is dependent on the DNA copy number (gene dosage) in patients with multiple myeloma. Total of 57 patients with MM were simultaneously examined by arrayCGH for DNA copy number variations (gain/losses) utilizing Agilent Human Genome CGH Microarray 4x44K Arrays and for gene expression utilizing Affymetrix GeneChip Human Gene 1.0 ST. Gene dosage-dependent genes were defined by Spearman correlation [R>0.5, p(FDR)<0.05] of CNV status and expression level and analysed using DAVID Bioinformatics software.
Total of 852 from all 27391 transcripts were strongly and significantly dependent on gene dosage. Cytogeneticaly, majority (25%) of all 852 genes were located on chromosome 1 (with 19 genes mapped to 1q21 locus). Other involved genes were mostly located on chromosomes 15 (8.7%), 19 (8.7%), and chromosome 13 (8.6%). Pathway analysis showed most genes to be involved in PDGF pathway, ubiquitin proteasome pathway, Ras pathway and TNFR1 signaling pathway.
Although almost all chromosomes have been at least once affected by either gain or loss of genetic material, number of genes with affected exrrpession is relatively low. We anticipate two mechanism for expression level compensations: i) increase of related supressors activity in case of gains ii) impact of second allele in case of losses.
This work was supported by IGA grants NT 11154 and NT 13190.

Multiple myeloma (MM) is the second most common hematological malig-

nancy. It is characterized by malignant transformation of clonal proliferation of B-lymphocytes and their accumulation in bone marrow. Our previous results showed large genetic heterogeneity among MM patients when genome-wide analyses were done. In order to obtain more detailed description of genetic lesions in MM we utilized novel high-density CGH+SNP microarrays for detection of LOH/UPD regions and copy number abnormalities (CNAs) and in cohort of 48 MM patients. Overall, we found 16 regions affected with LOH/UPD in 23% (11/48) of cases. The most frequently was affected chromosome 6p in 8.3% (4/48); other regions in single cases were found in chromosome 4, 7, 9, 11, 14, 16, 17, 18, 20 and 22.
The most common observed genetic lesions were trisomies of odd-numberded chrmosomes (3, 5, 7, 9, 11, 15, 19 and 21), gain 1q, and monosomy 13. We observed loss of genetic material in loci for genes associated with adverse prognosis for MM patients in 1p32.3 (FAF1, CDKN2C), 11q22 (BIRC2, BIRC3), 14q32.32 (TRAF3, AMN) and 16q12.1 (CYLD), which are associated with deregulations of important signaling pathways such as NF-κB (TRAF3, CYLD, BIRC2, BIRC3), or essential for cell cycle (CDKN2C, RB1) and apoptosis (WWOX, FAF1).

Multiple primary malignant tumours: Clinical comparison of patients with and without detected germline mutations in cancer susceptibility genes.

J. Whitworth, *E. Maher;*
Birmingham Women's Hospital, Birmingham, United Kingdom.

Multiple primary malignancies (MPM) represent a significant proportion of overall cancer diagnoses. Individuals diagnosed with a primary cancer are more likely to develop a (second) malignancy than the general population, which can be explained in part by inherited genetic predisposition. In addition to MPM in itself, predisposition can be suggested by clinical factors such as positive family history and early age of diagnosis.
Individuals diagnosed with two or more malignancies at a relatively young age (≤60) may be more likely to harbour germline mutations in cancer susceptibility genes. 210 such patients were identified among referrals to a UK cancer genetics service, 157 of whom had no demonstrated mutation despite undergoing germline genetic testing in 71 cases.
Clinical parameters including tumour diagnosis age, Manchester score and revised Bethesda criteria (cases involving breast and colorectal cancers respectively) were compared between groups with and without detected mutations. A multiple tumour score based on Manchester score but incorporating all malignancies in a single lineage was also applied.
Results are shown in the table. Of note was the similarity in tumour diagnosis age and the fact that around a fifth of patients without mutations had a multiple tumour or Manchester score higher than the mutation group median. These data suggest that any MPM might be a useful clinical indicator of germline mutations in established or novel cancer susceptibility genes.

Comparison of clinical measures between groups with and without detected mutation

All cases	**Mutation group N = 53**	**No mutation group N = 157**
Mean age of tumour diagnosis	44	46
Mean multiple tumour score	20.7	13.2
Median multiple tumour score	17	12
% cases with multiple tumour score higher than mutation group median	N/A	21
Cases involving breast cancers	**N = 25**	**N = 107**
Mean Manchester score	25.3	13.9
Median Manchester score	20	14
% cases with Manchester score ≥ 15	80	38.3
% cases with Manchester score higher than mutation group median	N/A	20.5
Cases involving colorectal cancers	**N = 25**	**N = 41**
% cases with ≥ 1 Revised Bethesda criteria for MSI testing	84	58.5

P11.198
Identification of a patient with atypical MUTYH-associated polyposis through detection of the *KRAS* c.34G>T mutation in liver metastasis

M. P. Buisine[1,2,3], *S. Cattan*[1], *J. Leclerc*[1,2,3], *V. Nicolas*[1], *A. Wacrenier*[1], *S. Lejeune*[1];
[1]*University Hospital, Lille, France,* [2]*UMR Inserm 837, Lille, France,* [3]*Lille North of France University, Lille, France.*

MUTYH-associated polyposis (MAP) is an autosomal recessive colorectal adenomatous polyposis syndrome due to bi-allelic germ line mutations in the *MUTYH* gene that encodes a DNA glycosylase involved in base excision repair. A deficiency of MUTYH function results in somatic G:C>T:A transversions that can be observed in *APC* and *KRAS* genes.
We report the case of a 33-year-old woman with atypical MAP, diagnosed via detection of the somatic *KRAS* c.34G>T mutation. The patient was admitted to our institution with stercoral peritonitis and liver nodules diagnosed initially as abscesses upon imagery. Further investigation revealed hepatic metastasis of an occult colonic cancer. Given her young age, she was sent to the Oncogenetics Unit even if family history was negative. The hypothesis of Lynch syndrome was excluded by the tumor phenotype (microsatellite stable phenotype and maintenance of expression of MMR proteins). Rather, the diagnosis of MAP was suspected on the basis of the presence of the somatic *KRAS* c.34G>T mutation in liver metastasis. *MUTYH* gene sequence analysis identified two germ line mutations: c.[494A>G];[1395_1397delGGA] (p.[Tyr165Cys];[Glu466del]) (refseq NM_001048171.1) confirming the diagnosis of MAP. Twelve months later, total colectomy was finally performed, which showed the presence of an adenocarcinoma of the sigmoid colon and more than 30 adenomatous polyps.
This case was interesting in view of the unusual presentation of MAP, with stercoral peritonitis revealing metastatic colon cancer in a 33-year-old woman. Moreover, it highlights the potential value of the somatic *KRAS* c.34G>T mutation for identifying patients with atypical MAP.

P11.199
The t(2;11)(p21;q23) without MLL rearrangement - a possible marker of good prognosis in MDS patients

P. Dvorak[1], *D. Lysak*[2], *S. Vokurka*[2], *K. Michalova*[3], *I. Sarova*[3], *A. Jonasova*[4], *M. Hruba*[1], *A. Rykovska*[1], *I. Subrt*[5];
[1]*Institute of Medical Genetics, University Hospital Pilsen, Pilsen, Czech Republic,* [2]*Department of Haematology and Oncology, University Hospital Pilsen, Pilsen, Czech Republic,* [3]*Cytogenetic Department, Institute of Haematology and Blood Transfusion; Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General Faculty Hospital and 1st Faculty of Medicine, Charles Univ., Prague, Czech Republic,* [4]*1st Department of Internal Medicine, General Faculty Hospital and 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [5]*Institute of Medical Genetics, University Hospital Pilsen;Faculty of Medicine in Pilsen, Charles University in Prague, Pilsen, Czech Republic.*

Chromosomal abnormalities are detected in approximately 50% of patients with *de novo* myelodysplastic syndromes (MDS) and are of great value for the diagnosis, classification and prognostic stratification. However, some non-random chromosomal changes, which can be found in approximately 10% of *de novo* MDS patients, still don't have clearly defined prognostic value. The t(2;11)(p21;q23) translocation has an overall frequency of approximately 1% and belongs to the group of abnormalities that are characteristic for *de novo* MDS. Patients with the t(2;11)(p21;q23) have been shown to share some common clinicopathological features like lower age compared to the median age of MDS patients at diagnosis (mostly under 60) and strong male predominance (3M:1F). Cytological or histological assessment of bone marrow usually reveals only mildly presented MDS with marked dysplasia in megakaryopoiesis. Recently, it was proved that t(2;11)(p21;q23) without *MLL* gene rearrangement results not in direct oncogene activation but in up-regulation of miR-125b-1. The over-expression of miR-125b has been shown to target several important genes for hematopoietic development such as *JUN*, *STAT3*, and *BAK1*. However, most of the clinical data dealing with the t(2;11)(p21;q23) has been collected without known status of *MLL*. Contrary to other studies, this is the first report with evaluation of the clinical outcome of patients with the translocation without *MLL* being affected. Despite the low number of cases in our study (7 patients), our results indicate that the t(2;11)(p21;q23) could be associated with a good prognosis for MDS patients.

PHOX2B gene encodes for a homeobox transcription factor involved in autonomic neuron development, and regulates the transcription of key enzymes of the catecholamine synthesis, including the Tyrosine hydroxylase (TH). Germline mutations in PHOX2B predispose to peripheral neuroblastic tumors (PNT), frequently in association with other neurocristopathies such as Hirschsprung disease (HSCR) or congenital central hypoventilation syndrome (CCHS). These syndromic presentations are commonly thought to have a good prognosis. Although some in vitro data suggest PHOX2B mutations impair neuronal differentiation, their physiopathological role in PNT remains speculative.
We have analysed eight patients from six different families presenting with peripheral neuroblastic tumors associated with non-polyalanine expansion mutations in PHOX2B. We describe clinical features, somatic arrayCGH profiles, and histological pattern including INPC (International Neuroblastoma Pathology Classification) and immunohistochemistry with PHOX2B and TH antibodies.
Four patients had hypoventilation syndrome and/or HSCR, four had no neurocristopathy. We found three ganglioneuromas and two ganglioneuroblastomas, hence illustrating that PHOX2B mutations are found in predominantly differentiated tumors. All tumours showed a retained nuclear expression of PHOX2B protein, while TH was variably expressed. Among the syndromic forms, we report two patients with stage 4 disease and one patient with stage 3 disease. Segmental chromosomal rearrangements, associated with aggressive disease, were found in four tumours by arrayCGH profiling. One patient died of the tumour, one died of hypoventilation and six patients were alive, with a median 14 months follow-up.
Our series finally suggests that PHOX2B mutations preclude neither tumour differentiation nor TH expression, but may be associated with aggressive genomic patterns.

P11.201
PHOX2B over-expression as a pathogenic mechanism in neuroblastoma

E. Di Zanni[1], *R. Ravazzolo*[1,2], *I. Ceccherini*[1], *T. Bachetti*[1];
[1]*Laboratorio di Genetica Molecolare/U.O.C. Genetica Medica Istituto G.Gaslini, Genova, Italy,* [2]*DINOGMI, Università di Genova e CEBR, Genova, Italy.*

Neuroblastoma (NB) is an embryonic tumor derived from impaired neural crest cells differentiation. The heterogeneous genetic etiology is suggested by the identification of gain of function mutations of genes encoding for the receptor tyrosine kinase Anaplastic Lymphoma Kinase (ALK) and the transcription factor Paired-like Homeobox 2B (PHOX2B) in a limited proportion of NB patients.
A role for *PHOX2B* in NB is strengthened also by the following observations:
1. *PHOX2B* and ALK genes over-expression in NB cell lines and samples;
2. PHOX2B-mediated *ALK* transcriptional regulation.
For all these reasons, and in particular for the early role of PHOX2B in development, we are investigating mechanisms that may underlie *PHOX2B* expression.
We have planned to perform a drug repositioning approach to identify pathways responsible for driving such over-expression.
We have produced IMR32 NB cell line (characterized by high *PHOX2B* expression) stably transfected with the *PHOX2B* promoter upstream the *Luciferase* gene and have performed the following studies:
1. By a cell-based approach, a little set of molecules, selected on the basis of their effects in other diseases models, has been tested for their role on *PHOX2B* promoter activity, gene expression and protein amount;
2. By a high throughput approach, a library of 43 molecules specifically acting on epigenetics mechanisms has been added to the NB cell line and analyzed for their effects of *PHOX2B* transcription.
Luciferase activity has revealed several molecules effective in down-regulating *PHOX2B* gene expression, actually under investigation to identify regulatory pathways through which they act on the PHOX2B promoter.

P11.202
Transduction of Neurofibromin corrects the mechanosensoric blindness in cultured NF1 haploinsufficient fibroblasts

K. Mellert[1], *S. Lechner*[2], *M. Lamla*[3], *K. Scheffzek*[2], *D. Kaufmann*[1];
[1]*University of Ulm, Institute of Human Genetics, Ulm, Germany,* [2]*Division of Biological Chemistry, Biocenter Innsbruck Medical University, Innsbruck, Austria,* [3]*Institute of Organic Chemistry III, University of Ulm, Ulm, Germany.*

Recently, we found a new function of neurofibromin in the sensoric mechanism to submicron topographies. In cultured NF1 (Neurofibromatosis type 1) haploinsufficient fibroblasts a partial mechanosensoric blindness was characterized. Here, we investigated whether transduction of neurofibromin corrects the mechanosensoric blindness in NF1 haploinsufficient fibroblasts. The partial mechanosensoric blindness was measured as reduced orientation of the cells on defined submicron topographies. To overcome the common problem of endosomal entrapment of transduced proteins, combination treatments of transduction and endosomolytic treatments were performed. In these experiments, the orientation of NF1 haploinsufficient fibroblasts increased by inducing an uptake of functional recombinant neurofibromin. The partial mechanosensoric blindness is reduced by these treatments. These data suggest that dysregulations in cultured NF1 cells can be corrected by a cellular replacement of the lacking protein.

New markers of susceptibility to osteosarcoma: microRNAs

N. Bilbao-Aldaiturriaga[1], *E. López-López*[1], *I. Martin-Guerrero*[1], *A. Gutierrez-Camino*[1], *A. Patiño-García*[1], *M. Zalacain-Diez*[2], ***A. Garcia-Orad***[1];
[1]*Basque Country University, Leioa, Spain,* [2]*University Clinic of Navarra, Pamplona, Spain.*

Purpose
Osteosarcoma is the most common primary bone cancer in children and young adults. Susceptibility to osteosarcoma is due, at least in part, to complex and multiple genetic factors.
MicroRNAs (miRNAs) are non-coding RNAs that act as negative regulators of the expression of other genes. Deregulated miRNAs have been reported in osteosarcoma, showing their importance in the disease. Recent studies have provided evidence that single nucleotide polymorphisms (SNPs) in miRNA-related genes can affect miRNA levels and function. These SNPs have been associated to risk in different cancers, but such studies are lacking in osteosarcoma.
The aim of this study was to evaluate the role of miRNA-related SNPs in susceptibility to osteosarcoma.
Materials and Methods
We analyzed 99 blood samples from osteosarcoma patients and 387 healthy controls. We studied 118 SNPs in pre-miRNAs and in miRNA biogenesis pathway genes.
Results
For the first time, six polymorphisms in miRNA related genes were significantly associated ($p<0.05$) with osteosarcoma risk. Of them, 3 were located in genes involved in miRNAs biogenesis (CNOT1, CNOT4 and SND1) and 3 in miRNA genes (mir-585, mir-612 and mir-499).
Conclusion
Our results suggest that SNPs in miRNAs and miRNA biogenesis pathway may affect osteosarcoma susceptibility.

Could triaging family history of cancer during palliative care enable earlier genetic counselling intervention?

N. S. Lakhani[1,2], *J. Weir*[3], *A. Allford*[4], *J. Kai*[5], *J. G. Barwell*[1,6,7];
[1]*Leicester Royal Infirmary - UHL NHS trust, Department of Clinical Genetics, Leicester, United Kingdom,* [2]*University of Leicester, Leicester, United Kingdom,* [3]*Leicester Royal Infirmary - UHL NHS trust, Leicester, United Kingdom,* [4]*Genetic Alliance - UK, London, United Kingdom,* [5]*University of Nottingham, Faculty of Medicine & Health Sciences, Nottingham, United Kingdom,* [6]*LNR-CLAHRC, Leicester, United Kingdom,* [7]*GENIE, Leicester, United Kingdom.*

Background. Patients are commonly referred to cancer genetics services when all affected family members are deceased. This makes genetic testing and risk assessment more difficult, reducing the benefit from screening and prophylactic treatment.
Methods. Observational, retrospective, cohort study of 508 randomly selected patients referred to a regional cancer genetics unit, using review of case notes to explore whether a simple clinical '3, 2, 1' family history rule could have been used to improve timely and appropriate referrals for genetic assessment. The '3, 2, 1' criteria are: *three* affected relatives with the same/associated cancers, across *two* generations, with at least *one* person affected aged under the age of 50 years.
Results. Most (71% [362]) genetic risk assessment referrals were in unaffected individuals and 22% (80) of these were referred after all affected family members had died, including 24% (19) who lost their last remaining affected relative in the previous year. Most (59% [301]) referrals met all '3, 2, 1' criteria, and 67% of these could have been made earlier in clinical practice. A further 23% (115) met two of the three criteria.
Conclusion. Using a simple clinical '3, 2, 13, 2, 1' family history rule in cancer care and particularly in palliative care could enable earlier cancer genetic risk assessment for unaffected relatives, improving the potential to benefit from targeted screening and intervention.

P11.206

Altered interphase FISH profiles of chromosomes 4, 8q24 and 9q34 in pancreatic ductal adenocarcinoma are associated with a poorer patient outcome.

M. L. Gutiérrez[1], *D. G. Hernández-Mejía*[1], *O. Bengoechea*[2], *M. González-González*[1], *M. E. Sarasquete*[1,2], *M. M. Abad*[2], *L. Corchete*[1,2], *E. Fonseca*[2], *M. Gonzalez-Diaz*[2], *L. Muñoz-Bellvis*[2], *A. Orfao*[1], *J. M. Sayagués*[1];
[1]*Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Hospital Universitario de Salamanca, Salamanca, Spain.*

Introduction. Pancreatic ductal adenocarcinoma (PDAC) is a fatal disease with an overall survival (OS) of almost 5-years. Currently, no consistent tumor markers exist which contribute to predict patient prognosis and/or survival. Here we analyze the cytogenetic profile of PDAC tumors and its act on patient survival.
Patients and Methods: The frequency and prognostic impact of the copy number alterations of chromosomes 1, 4, 7, 8, 9, 17, 18, 20 and Y, were analyzed by iFISH (n=21probes) in 55 PDAC patients. The prognostic value of chromosomal alterations showing an impact on OS were validated in a external cohort of PDAC patients analyzed by comparative-genomic arrays from public databases (n=44 cases).
Results: Overall, for all alterations identified only alterations of chromosomes 4 and 9q34 as well gains of chromosome 8q24 (p=.04; p=.01and p=.01, respectively) were associated with a shorter patient OS. The prognostic impact of 8q24 chromosome gains and changes at chromosome 9q34 were confirmed in the external dataset (p=.05 and p=.03, respectively). Based on these cytogenetic variables a scoring system was built and patients were classified into 3 different risk groups: low-(no adverse cytogenetic features), intermediate-(one adverse feature) and high-risk (>1 adverse features) with OS rates at 4-years of: 80%, 16% and 0%, respectively (p<.001).
Conclusion: Here we show that alterations of chromosomes 4, 8q24 and 9q34 in PDAC tumors are associated with a poorer patient outcome. Additional prospective studies in larger series of patients are necessary to confirm the clinical utility of the new prognostic markers here identified.

HIF2A germline mutations cause polycythemia but recently *HIF2A* somatic mutations were described in several patients with polycythemia and paraganglioma (PGL) or pheochromocytoma (PH). Herein, we report *HIF2A* mutations in three different patients with PH or PGL. Patient 1 was a woman suffering from congenital polycythemia diagnosed at 16 years, operated on for a PH at 45 years and for abdominal PGL at 64 years. She was also diagnosed for a somatostatinoma. Patient 2 was operated on PH at 24 years and was then lost to follow-up. Patient 3 was a child suffering from polycythemia from infancy and operated on for non-functional adrenal PGL at 11 years. No germline mutations on the main PGL susceptibility genes nor in *PHD2* gene were identified. We then sequenced *HIF2A* gene in the DNA extracted from paraffin-embedded tumors of the three patients. We identified a somatic *HIF2A* heterozygous mutation in PH, PGL and somatostatinoma of patient 1 (c.1586T>C; p.Leu529Pro) and in the PH of patient 2 (c.1591C>T; p.Pro531Ser) but both mutations were absent in the corresponding germline DNA. In patient 3, we found a *HIF2A* heterozygous mutation (c.1625T>C; p.Leu542Pro) at somatic level while the mutation was also present at mosaic stage at germline level. All mutations disrupt the hydroxylation domain of HIF-2α protein. Altogether, these reports demonstrate that *HIF2A*-related syndrome is due to a postzygotic genetic event occurring at an early developmental stage that can affect males or females. A germline mosaicism should always be considered during the genetic counseling of a newly identified patient.

P11.208

Next generation sequencing (NGS) for pheochromocytoma/paraganglioma genetic testing

E. KHALIFA[1,2], *C. Leschi*[1], *C. Simian*[1], *L. Mansour-Hendili*[1,2], *N. Abermil*[1,2], *A. Venisse*[1], *V. Nau*[1], *F. Le Quellec*[1], *X. Jeunemaitre*[1,2], *A. Gimenez-Roqueplo*[1,2];
[1]*Assistance Publique-Hôpitaux de Paris, Hôpital européen Georges Pompidou, Service de Génétique, PARIS, France,* [2]*Université Paris Descartes, Faculté de Médecine, Paris Cité Sorbonne, Paris, France.*

BACKGROUND: Pheochromocytomas and paragangliomas (PPGL) are rare sporadic or familial endocrine tumors. Currently, germline mutations at different genes have been identified in around 35% of the cases. The major susceptibility genes are *SDHB*, *SDHD*, *VHL*, *RET*, *SDHC* whereas *NF1*, *TMEM127*, *MAX*, *SDHA*, *SDHAF2* and *HIF2A* are mutated in <10% of the cases. Germline mutations in *SDHB*, *SDHD*, *SDHC* and *VHL* explain more than 80% of inherited PPGL.
OBJECTIVE: To develop and implement a NGS-based workflow for a one-step assay PPGL genetic screening.
METHODS: Together with Multiplicom, we designed and optimized the SDH MASTR™ assay, enabling the amplification of the coding regions of *SDHB*, *SDHD*, *SDHC* and *VHL* (step 1) and then to incorporate molecular barcodes (Multiplex Identifiers - MIDs) in each amplified product (step 2). NGS was performed on a Roche GS Junior system. Twenty-eight DNA samples containing various variants and mutations, previously identified by Sanger method or MLPA, were used. The sequencing data were analysed with AVA (Amplicon Variant Analyzer, Roche) and SeqNext software (JSI Medical Systems).
RESULTS: All the variants previously identified by Sanger sequencing of the 28 patients were found with the new NGS PPGL workflow. The validation is yet ongoing on a set of new patients blindly analysed in comparison with our routine direct Sanger sequencing strategy.
CONCLUSION: Our first results suggest that this strategy is a cost-effective option for PPGL genetic testing. *RET*, *MAX* and *TMEM127* will be further added in the assay in order to test seven PPGL susceptibility genes in a single run.

P11.209

Preliminary data on AIP and AHR genotyping in apparently sporadic acromegalic patients.

P. D. Romeo[1,2], *M. Ragonese*[1], *S. Puglisi*[1], *M. L. Torre*[1], *F. Ferraù*[1], *A. Albani*[1], *O. R. Cotta*[1], *C. Salpietro*[2], *C. Rigoli*[2], *F. Trimarchi*[1], *S. Cannavò*[1];
[1]*Department of Clinical and Experimental Medicine – Endocrinology; University of Messina, Messina, Italy,* [2]*Department of Pediatric, Gynecological, Microbiological and Biomedical Sciences – Genetics and Immunology Pediatrics; University of Messina, Messina, Italy.*

Context: Germline mutations of the *AIP* (aryl-hydrocarbon receptor interacting protein) gene are associated with a predisposition to pituitary adenomas. Such mutations are found in about half of patients with familial acromegaly, but penetrance is incomplete.
Objective: This is a preliminary study concerning genotyping of AIP and AHR genes in a small group of acromegalic patients with sporadic pituitary adenoma.
Patients and Methods: The entire coding sequence of the *AIP* and *AHR* genes were screened for germline mutations in 18 patients (M= 8, age 57.5±12.8 yrs±SD) with diagnosis of acromegaly in adult age. Genotyping was performed by direct automated sequencing.
Results: A missense AIP mutation, R304Q, whose pathogenic role has already been confirmed, was found in 1 (5.5%) of 18 patients. Furthermore, in all patients we found 2 polymorphic AIP variants, rs641081 (c.682C>A) and rs4930199 (c.920A>G) in homozygosity, with uncertain pathological role. Concerning AHR gene, 15 (83%) out of the 18 patients showed a major polymorphic variant rs2066853 in heterozygous state, 1 (5.5%) showed the rs2066853 (c.1661G>A) and the rs4986826 (c.1708G>A) variants in compound heterozygosity and in 1 patient (5.5%) showed both variants in homozygosity and heterozygosity state, respectively. The pathogenic role of AHR gene variants is still unconfirmed.
Conclusion: On the basis of this preliminary data, we can conclude that AIP mutations with potential pathogenetic role are present in 5.5% of subjects with adult onset acromegaly due to apparently sporadic GH-secreting pituitary adenoma. On the contrary, no AHR gene mutations have been detected in this small group of acromegalic patients.

New Gene Tests for Familial Colorectal Cancer Patients; *POLE, POLD1* and *GREM1* Analysis.

T. Bedenham[1], *T. Cranston*[1], *I. Tomlinson*[2,3], *A. Seller*[1];
[1]*Molecular Genetics Laboratory, Churchill Hospital, Oxford, United Kingdom,* [2]*Wellcome Trust Centre for Human Genetics and Oxford NIHR Biomedical Research Centre, Oxford, United Kingdom,* [3]*Oxford Regional Genetics Service, Churchill Hospital, Oxford, United Kingdom.*

Many colorectal cancer patients who undergo genetic testing for mutations in known colorectal cancer susceptibility genes do not have a pathogenic variant identified. Recently Jaeger *et al* and Palles *et al* reported variants in three genes associated with an inherited polyposis / adenoma phenotype in colorectal cancer patients.
Jaeger *et al* identified a 40kb duplication at 15q13.3 encompassing the region 3' of the *secretogranin-5* (*SCG5)* gene to upstream of *Gremlin1* (*GREM1).* The duplication is located on a specific haplotype and has only been found in Ashkenazi Jewish patients to date. The phenotype associated with this variant is hereditary mixed polyposis syndrome type 1, characterised by multiple polyps of different types including; serrated, juvenile, Peutz-Jegher, adenomas and carcinomas.
Palles *et al* identified variants in the proof reading domains of the *polymerase D1* (*POLD1)* and *polymerase E* (*POLE)* genes. The variants are associated with a phenotype similar to MutYH associated polyposis (multiple adenomas) or Lynch syndrome (large adenoma / early onset carcinoma). Patients with *POLD1* mutations are also at risk of developing endometrial tumours and brain tumours.
We have screened a cohort of patients who have previously had no variants identified in appropriate colorectal cancer susceptibility genes, for variants in *POLD1* and *POLE* or the *SCG5-GREM1* duplication, as dictated by their phenotype.
We present our results and discuss whether these molecular analyses should be considered as a routine reflex test for patients who have no mutation identified in the polyp predisposing or mismatch repair genes.

Ministry of Health / State Scientific Center of Coloproctology, Moscow, Russian Federation.

Familial Adenomatous Polyposis (FAP) - is an important inherited CRC syndrome. It is caused by a germline mutation in the adenomatous polyposis coli
(*APC*) gene and it is most often
inherited in an autosomal dominant manner. Inherited mutations in *MYH* gene can also provide these diseases. Biallelic *MYH* mutations are the genetic reason of an autosomal
recessive mode of inheritance but we also observed risk of developing FAP in monoallelic *MYH* gene mutation carriers of some populations. The object of our
research is to investigate
germline mutation in specific gene-supressor *APC*
and *MYH* genes as well. We study DNA
of 17 patients with classic form of FAP and 5 patients with attenuated FAP. We found
11 mutations (5 nonsense, 4 deletions and 2 splice acceptor) in *APC* and 1 heterozygous missense mutation
in *MYH* genes in 17
patients with classic form of FAP (70,5%). Also 2 heterozygous *MYH* missense
mutations has been found at attenuated form in 5 patients (40%). 5 of all 14 mutations (35,7%) have been found for the first
time.

Prostate cancer (PCa) is a complex trait and several susceptibility genes have been implicated by genome-wide linkage or association studies. The genomic region 13q14 is frequently deleted in sporadic and familial PCa. It is widely recognized as a possible locus of tumor suppressor gene(s) as it has been found to be deleted also in other cancers. We have previously shown that homozygous carriers for *ARLTS1* (ADP-ribosylation factor-like tumor suppressor protein 1 or *ARL11*, located at 13q14) T442C variant are associated with an increased risk for unselected and familial PCa. The role of the variant was further strengthened with the observation of greater frequency among malignant tissue samples, PCa cell lines and xenografts. In this study we performed *ARLTS1* interaction studies, as the functional network of *ARLTS1* is poorly known. First differences of *ARLTS1* expression status between PCa cases (n=84) and controls (n=15) was studied. Statistically significant (p=0.0037) difference in *ARLTS1* expression between the groups encouraged to eQTL analysis to detect regulatory variants. Altogether fourteen significant *cis*-eQTLs affecting *ARLTS1* expression levels were found. Interestingly, two of the most significant eSNPs located in *PHF11* and *SPRYD7* genes, which are functioning in immune system processes. This is in concordance with our previous results in which *ARLTS1* co-expression was highly connected to expression of genes functioning in immune system processes. Two additional eQTLs located in histone methyltransferase *SETDB2* gene which modulates the expression of its target genes epigenetically. In conclusion, this study identifies novel regulators for *ARLTS1* gene expression and PCa risk.

S. Siltanen: None. **T. Rantapero:** None. **D. Fischer:** None. **V. Laitinen:** None. **J. MPindi:** None. **O. Kallioniemi:** None. **T. Wahlfors:** None. **J. Schleutker:** None.

P11.214

Fine-mapping of chromosomal region 11q13.5 in Finnish prostate cancer

R. Nurminen[1,2], *R. Lehtonen*[3], *T. L. Tammela*[1,4], *T. Wahlfors*[1,2], *J. Schleutker*[1,2,5];
[1]*University of Tampere, Tampere, Finland,* [2]*Fimlab Laboratories, Tampere, Finland,* [3]*University of Helsinki, Helsinki, Finland,* [4]*Tampere University Hospital, Tampere, Finland,* [5]*University of Turku, Turku, Finland.*

The identified prostate cancer (PrCa) associated single-nucleotide polymorphisms (SNPs) explain only a part of PrCa heritability. Chromosomal region 11q13-14 is associated with PrCa. Previously we screened *EMSY* at 11q13.5 for mutations in Finnish PrCa patients and identified a rare intronic mutation IVS6-43A>G that increases risk of aggressive PrCa and associates with familial PrCa. No causal factor(s) predisposing to PrCa has been identified from 11q13-14.

The aim of the study was to characterize the genetic structure of 11q13.5 and to asses if there are additional PrCa risk variants. The study included a total of 4034 PrCa patients and 908 controls of Finnish origin. We imputed SNPs and structural variants on 0.9 Mb at 11q13.5 and validated the associations by genotyping. Imputation was performed with IMPUTE2 using 1000 Genomes reference population. Haplotype analysis was conducted to study haplotype blocks, linkage disequilibrium and haplotype associations.

Two correlated SNPs at *EMSY* were associated with PrCa. SNPs were located in consecutive introns in close approximation to IVS6-43A>G. *EMSY* variants formed a common predisposing haplotype and a rare protective haplotype. In addition, five correlated intergenic SNPs and a one-nucleotide insertion associated with PrCa. Both a predisposing and protective haplotype was identified. The findings indicate that two regions at 11q13.5 contribute to PrCa predisposition with complex genetic structure. Further studies are needed to determine the genetic mechanism of susceptibility and functionality of the regions.

Determination of GADD45γ methylation level in prostate cancer with high resolution melting analysis and evaluation of the possible correlation with apoptosis

O. Can[1], *V. Caner*[1], *N. Sen Turk*[2], *L. Tuncay*[3], *S. Eskicorapci*[3], *E. Tepeli*[4], ***O. Cetin***[4], *C. Baris*[1], *G. Bagci*[1];
[1]*Pamukkale University, School of Medicine, Department of Medical Biology, Denizli, Turkey,* [2]*Pamukkale University, School of Medicine, Department of Medical Pathology, Denizli, Turkey,* [3]*Pamukkale University, School of Medicine, Department of Urology, Denizli, Turkey,* [4]*Pamukkale University, School of Medicine, Department of Medical Genetics, Denizli, Turkey.*

Prostate cancer (PCa) is the second most common cancer type worldwide in men. It is believed that deregulation of important cellular mechanisms is involved in the pathogenesis of PCa although the exact mechanism of its pathogenesis has not been clearly elucidated. "Growth Arrest DNA Damage-Inducible 45" (GADD45) is one of the most important gene family in these mechanisms and consists of 3 members: GADD45α, GADD45β, GADD45γ.

The aims of this study are to detect the protein expression and methylation profile of GADD45γ in benign prostate hyperplasia (BPH) (60 patients) and PCa (56 patients), to examine the correlation between protein expression and methylation profile, and to evaluate whether apoptosis is related to these two parameters.

We found that the methylation frequency for GADD45γ was quite low in PCa compared with BPH (p=0.000). This was consistent with the literature with the reported frequency of the gene in solid tumors was lower than in hematological malignencies. In both groups, there was no correlation between GADD45γ methylation and protein expression, but there was a significant difference between Bcl-2 and Bcl-xL expressions in both groups (p=0.000 and p=0.003, respectively). A statistically significant relation between GADD45γ expression and apoptosis was not found although GADD45γ expression was higher in PCa than that in BPH.

In summary, we found that the methylation of GADD45γ was not common in PCa, the regulation of apoptotic pathways is more complex than we expected and GADD45γ is not the only key factor for the cells to direct into the apoptotic process.

Association analysis of polymorphisms in candidate genes on 11p15 locus with prostate cancer in Bulgarian patients

D. L. Kachakova[1], *E. Popov*[2], *A. Mitkova*[1], *A. Vlahova*[3], *T. Dikov*[3], *S. Christova*[3], *C. Slavov*[2], *V. Mitev*[1], *R. Kaneva*[1];
[1]*Molecular medicine centre, MU- Sofia, Sofia, Bulgaria,* [2]*Department of Urology, MU –Sofia, Clinic of Urology, Alexandrovska University Hospital, Sofia, Bulgaria,* [3]*Department of General and Clinical Pathology, MU–Sofia, General and Clinical Pathology Clinic , Alexandrovska University Hospital, Sofia, Bulgaria.*

Introduction More than 70 susceptibility loci associated with prostate cancer (PC) have been identified. PRACTICAL consortium has recently found association of 11p15 locus with PC. To investigate in detail the region associated with PC in the Bulgarian sub-sample we analyzed polymorphisms in several of the plausible candidate genes *IGF2, INS-IGF2, TH* and *ASCL2,* located in the vicinity of the most strongly associated marker rs7127900.

Materials and Methods Using TaqMan® method 176 PC samples and 169 controls were genotyped for polymorphic variants rs11603378, rs2239681, rs10770125 in *IGF2*, rs3842756 in *INS-IGF2*, rs2070762 in *TH*, rs11564710, rs7127900 and rs55930300 in *ASCL2* located on locus 11p15. We have preformed allele, genotype and haplotype analysis.

Results Allele and genotype frequencies of the variants rs11603378, rs10770125, rs3842756 and rs55930300 did not show significant differences between PC patients and controls. In contrast, the following genotypes and alleles were more common in patients than in controls: GG (OR=1.69, p=0.041) for rs2070762, CA (OR=2.12, p=0.0007) and A allele for rs11564710, GA (OR=1.7, p=0.018) and A allele for rs7127900. Association with aggressive disease showed the genotype CA (OR=3.76, p=0.003) of rs11564710. The haplotype T-G-G-C-G-C-G-A (rs11603378-rs2239681-rs10770125-rs3842756-rs2070762-rs11564710-rs7127900-rs55930300) was more common in patients with high Gleason score (p=0.026).

Conclusions In Bulgarian patients markers rs11564710 and rs2070762 showed stronger association with PC than the initial finding with rs7127900. One of the variants (rs11564710) showed correlation with aggressive PC. Additional study in larger cohort and different approach is needed to elucidate the association and the potential causal variants on 11p15 related to prostate carcinogenesis.

P11.217

Epistatic interactions between prostate cancer susceptibility loci: evidence from Serbian population

Z. Nikolic[1], *G. Brajuskovic*[1], *V. Vukotic*[2], *N. Filipovic*[2], *S. Cerovic*[3], *D. Savic Pavicevic*[1], *S. Romac*[1];
[1]*Faculty of Biology, University of Belgrade, Belgrade, Serbia,* [2]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia,* [3]*Military Medical Academy, Belgrade, Serbia.*

Prostate cancer (PCa) is the most common non-skin cancer among males in western populations and the sixth leading cause of cancer death worldwide. Still, molecular factors involved in PCa etiology remain largely unknown. Studies of genetic association of PCa have identified over 30 PCa susceptibility loci. To date, no conclusive evidence of epistasis between these loci in PCa has been obtained. The aim of this study was to test for epistasis between genes at 8q24, 17q12, 7q36 and 19p13. The study population included 175 PCa patients, 161 patients with benign prostatic hyperplasia (BPH) and 115 healthy controls derived from general population. Genotyping of ten selected single nucleotide polymorphisms (SNPs) was performed by PCR-RFLP method and by Taqman® SNP genotyping assay, while PLINK software was used for statistical analysis of obtained data. Case-only analysis of epistasis in PCa showed interaction between rs3918226 (7q36) and rs7501939 (17q12) (P=0.023). Case-control analysis of epistasis, in which BPH patients were considered as a control group, also showed interaction between these two loci (P=0.038; OR=2.875). This analysis yielded evidence of epistatic interaction between rs1799983 (7q36) and rs3787016 (19p13) (P=0.042), as well as between rs6983287 (8q24) and rs3760511 (17q12) (P=0.021). Case-control analysis of epistasis in the dataset that included 10 SNPs in PCa patients and controls derived from general population showed epistatic interaction between rs2070744 (7q36) and rs7837688 (8q24) (P=0.045), as well as between rs7501939 (17q12) and rs6983287 (8q24) (P=0.032). These results suggest possible epistatic interactions between genes located at 8q24, 17q12, 7q36 and 19p13 in PCa.

P11.218

Simultaneous interpretation of combinative molecular analysis with histological and clinical data in prostate cancer patients

A. Tsvetkova[1,2], *A. Todorova*[1,2], *G. Georgiev*[3], *V. Mitev*[1];
[1]*Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*Military Medical Academy Sofia, Sofia, Bulgaria.*

Early detection of prostate cancer (PCa) can increase the chances of patients for a favorable outcome in the fight with this social significant disease. The aim of the study was to interpret simultaneously the results of DD3 marker, the TMPRSS2-ERG gene fusions, hypermethylation of GSTP1 gene promoter and to use this data for early diagnosis of PCa patients. An attempt to correlate the molecular data with histology (Gleason score and Tumor Node Metastasis, TNM) is made. Altogether, 16 individuals with PCa, 14 benign prostate hyperplasia (BPH) and 6 suspected for a prostate malignancy are studied. The following specific biological samples are used: 20 "tru-cut" prostate biopsies; 8 prostate tissues from radical prostatectomy; 17 blood samples, 6 urinary sediments, obtained after DRE (digital rectal examination). Patients with aggressive PCa were found to be positive for DD3 marker, for GSTP1 gene promoter hypermethylation and for TMPRSS2-ERG fusion, which correlates with Gleason score (5-7 moderate-differentiated tumors) and Gleason score (8-10 low-differentiated tumors). The molecular testing might help to clarify invasive, fast progressive, androgen-independent subtype cancer with high potential to form metastases. Our results suggest that positive molecular status in patients with borderline histological result might help for better estimation of high risk for development of PCa and strict monitoring. A combinative study of DD3, TMPRRS2-ERG fusions and the GSTP1 promoter hypermethylation provides a useful molecular arsenal in monitoring of PCa by the achievement of greater sensitivity and accuracy.

Acknowledgements: the study was supported by the grants №4-D/2011 and 26-D/2012, Medical University Sofia, Bulgaria.

Increased fitness in PTEN mutation carriers due to increased cancer survival is rationale for childhood PTEN testing.

L. H. Sunde[1], *G. Evans*[2], *I. Blanco*[3], *R. Susman*[4], *C. Herlofson*[1], *N. Clarke*[1], *G. Capella*[3], *L. Mæhle*[1], *P. Møller*[1];
[1]*Oslo University Hospital, Oslo, Norway,* [2]*St Marys Hospital, Manchester, United Kingdom,* [3]*Catalan Institute Of Oncology, Barcelona, Spain,* [4]*Royal Brisbane and Women's Hospital, Brisbane, Australia.*

PTEN mutation carriers may develop cancer from early childhood onwards. Mutation carriers are rare, mutation carrying families are small, and *de-novo* mutations have been demonstrated. All these observations fit the model of an early-onset autosomally dominantly inherited disorder being infrequent due to reduced fitness, and prevalence maintained by *de-novo* mutations (Lynch et al. Am J Hum Gen 1997, 1254).

We have examined the filed data from PTEN mutation carriers in four clinical genetic centres. Fifty-nine mutation carriers were identified, of whom 27 (46%) had developed cancer, 14 (52%) of whom had had two or more cancers. Total survival years after cancer was 403 years (mean 14.9). After inclusion, patients with cancer were followed for 199 observation years. One died 64 years old from breast cancer (annual death rate cancer patients after inclusion = 0.5%). Four had had thyroid cancer before 20 years. Youngest age at diagnosis of breast cancer was 24 years. She was alive and 54 years at end of study. No patient less than 20 years had been subjected to genetic testing due to cancer. Mutation carriers had an average number of children.

The results were that all early onset cancers associated with PTEN mutations had been cured in the last generation, and through that the cause of previous reduced fitness probably removed. Young patients with thyroid or breast cancer should be offered PTEN mutation testing. Children in PTEN mutation carrying families are at risk for curable childhood cancer and should be offered predictive genetic testing.

Differential expression of glycolysis pathway genes in renal and lung cancer

A. Kudryavtseva, *&. DMITRIEV, A. SNEZHKINA, G. KRASNOV, A. SADRITDINOVA, N. MELNIKOVA, L. UROSHLEV, M. DARII, N. OPARINA;*
EIMB RAS, Moscow, Russian Federation.

Glycolysis is the major pathway of glucose catabolism accompanied by a synthesis of ATP. There are more than 30 genes in the glycolysis pathway that can be considered as housekeeping genes because of the high conservatism and the evolutionary antiquity of the process. Using bioinformatic analysis of transcriptomic databases and methods of quantitative real time PCR, we investigated the expression of these genes in papillary renal cell carcinoma and squamous cell lung cancer. Quantitative analysis of mRNA levels showed that only some of the glycolytic pathway genes remained relatively stable; in papillary renal cell carcinoma, these genes included *HK1, ADPGK, GPI, PGK1, PKM2,* and in squamous cell lung cancer these genes included *ADPGK, ALDOA, GAPDH, PGK1, BPGM, ENO1, PKM2*. For the first time we found frequent increases of mRNA expression of genes *PFKP, ALDOA* and *GAPDH* in renal cancer, as well as *GPI* gene in lung cancer using qPCR. For the remaining genes, differential expression was shown - we found both gains and losses of mRNA levels. Thus, we identified several genes that can be used as reference for qPCR transcriptome analysis in renal and lung cancer, and a number of differentially expressed genes that could be potential oncomarkers.

The development of clear cell renal cancer prognostic markers based on gene co-expression.

N. V. Apanovich[1], *S. V. Poyrkov*[1], *A. A. Korotaeva*[1], *A. S. Markova*[2], *A. S. Bavykin*[1], *V. P. Shubin*[1], *N. I. Pospekhova*[1], *B. S. Kamolov*[2], *V. B. Matveev*[2], *A. V. Karpukhin*[1];
[1]*Research Centre For Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*Cancer Research Centre, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Despite of a number of microchip expression data, there are no recognized prognostic gene expression profile for clear cell renal cancer (CCRC) at the present time. We used an approach consisting in bioinformatics analysis of accumulated data followed by quantitative investigation of gene expression. Several databases (Oncomine: www.oncomine.org, GEO: www.ncbi.nlm.nih.gov/geo, CGED: http://lifesciencedb.jp/cged/) and 4000 publications, selected by keywords in PubMed, were screened. There were 200 genes selected with expression two times more than in normal renal tissue observed in more than 50% of CCRC samples. Expression profiles of these genes were determined in CCRC in comparison with normal renal tissue by quantitative RT-PCR. Near 130 genes were expressed two times above normal in 40% of samples. The cluster of 22 co-expressed genes was found. Analysis of transcriptional regulation showed that most of the genes in the cluster are regulated by a single gene - HIF1A. This may explain their co-expression. The grade score of anaplasia was correlated with a number of highly expressed genes of the cluster. The relationship of a number of co-expressed genes with the TNM classification was identified.

In summary, the identified genes, on their function and role in the development of cancer, can be markers of prognosis, reflecting the propensity for aggressive behavior of the tumor.

Gene-gene interactions of GSTM1, CYP1A1, IL4, IL16, VDR, PON1, VEGF genes contribute to renal cell carcinoma susceptibility in populations of Bashkortostan Republic of Russia

L. R. Kutlyeva[1], *I. Gilyazova*[1], *A. Zagidullin*[2], *V. Pavlov*[2], *A. Khaliullin*[2], *E. Klimentova*[3], *A. Shafigina*[3], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Science Centre, RAS, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation,* [3]*Bashkir State University, Ufa, Russian Federation.*

Unraveling the nature of genetic interactions is crucial to obtaining a complete picture of complex diseases. Renal cell carcinoma (RCC) is the most common neoplasm affecting the adult kidney. It's known that a predisposition to RCC due to a number of polymorphisms of genes involved in the metabolism of xenobiotics, anti-tumor immunity, angiogenesis and transcription.

The goal was to investigate the association of SNPs in seven genes with RCC and to evaluate gene-gene interactions in the development of RCC. A case-control association study of twelve SNPs in the genes GSTM1,CYP1A1,IL4,IL16,VDR,PON1,VEGF included 200 RCC patients from Bashkortostan Republic of Russia and 250 controls. Statistical analysis was held using logistic regression model and GMDR method.
The analysis showed genotype rs662*T/T and allele rs662*T of rs662 in PON1 gene (OR=3,23(95%CI 1,40-7,65);OR=1,49(95%CI 1,07-2,08), respectively) and genotype rs731236*G/G of the VDR gene(OR=2,42(95%CI 1,07-5,77)) to be markers of the increased risk for RCC development. The genotype rs2228570*T/T of rs2228570 in VDR was the marker of low risk for RCC (OR=0,61(95%CI 0,39-0,93)). We identified the most informative model of gene-gene interactions for RCC development in population of Russians (rs2243259(IL-4))-rs4778889(IL-16)). The combination of genotypes rs4778889*C/C(IL16)-rs2243250*T/C(IL4) was the marker of the decreased risk for RCC in Russians (OR=0,47(95%CI 0,22-1,01)), whereas the combination of genotypes rs4778889*T/C(IL16)-rs2243250*T/C(IL4) was the marker of the increased risk for RCC(OR=4,50(95%CI 1,33-16,78)). The analysis gene-gene interactions in Tatar ethnic origin found the statistically significant model (rs2243259(IL-4))-rs22432250(VDR)-rs731236(VDR)) predisposing to RCC development. Detecting interactions among disease associated SNPs may reveal basic biological mechanisms critical for the disease development.

Clinical evaluation of Myelodysplasia using a SNP microarray

S. Schwartz, *P. Papenhausen, S. Anderson;*
Laboratory Corporation of America, Raleigh, NC, United States.

Over the past 1½ years we have evaluated over 1000 patients, to delineate the utility of a SNP microarray (Affymetrix Cytoscan HD) approach for the study of myelodysplasia. Results have shown that: (1) Over 23% of chromosomally normal patients with myelodysplasia were found to have an abnormality detectable by the SNP array; (2) Approximately 120 different cases of segmental aUPD were observed, representing approximately 15% of the patients; (3) This technology has been especially useful in cases equivocal for MDS, where in approximately 25% of cases the SNP array was informative when flow cytometry and pathology studies could not provide a definitive diagnosis; (4) Even when cytogenetics and/or FISH demonstrated an abnormality, the array provided additional results in 59% of patients; (5) In addition to the abnormalities routinely detected by cytogenetics and FISH, the array detected numerous abnormalities including: deletions and aUPD of 4q (TET2); 21q (RUX1); 11q (Cbl); 17p (TP53), 9p (JAK2), 17q (NF1), 1p (likely MPL or NRAS) and aUPD of 7q (EZH2); (6) Of these alterations, involvement of TET2 and RUNX1 are the most commonly detected; (7) The precision and breakpoint analysis suggest two different genes on 7q may be important, not only EZH2 (distal), but also SERPINE1 which has been implicated in several submicroscopic 7q22.1 deletions and also when ASXL1 was included in the 20q deletion; (8) Overall this work clearly illustrates the additional important diagnostic and prognostic information detected by a SNP array analysis and the involvement of significant genes not detectable by routine analysis.

Novel mutations in spliceosomal gene *PRPF8* show ring sideroblast, proliferative, and missplicing phenotype in patients with myeloid neoplasms

A. Kurtovic-Kozaric[1], *H. Makishima*[1], *B. Przychodzen*[1], *J. Singh*[2], *M. Konarska*[3], *R. A. Padgett*[2], *J. P. Maciejewski*[1];
[1]*Department of Translational Hematology and Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, United States,* [2]*Department of Molecular Genetics, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, United States,* [3]*Rockefeller University, New York, NY, United States.*

The pathogenesis of myelodysplastic syndromes is complex and associated with vast heterogeneity in histomorphology and molecular somatic lesions. To understand the molecular somatic lesions in MDS, we applied whole exome sequencing in 352 patients. Commonly mutated gene was *PRPF8*, found on 17p13.3, coding for an essential protein in the spliceosomal core. Germline mutations in *PRPF8* have been shown to cause the autosomal dominant retinitis pigmentosa type 13. More than 80% of mutated *PRPF8* cases showed presence of ring sideroblasts in their pathologies. Furthermore, when we analyzed additional 23 cases using SNP arrays that had 17p deletion, 65% of cases contained ring sideroblasts. The knockdown of *PRPF8* showed increased colony formation. Since PRPF8 is extremely well conserved between humans and yeast, we created homologous mutants in yeast. All mutants showed the same phenotype--defect in the second step of splicing. These results suggest that the mutant PRPF8 might activate incorrect splice sites leading to frame shifted mRNAs. To understand the global effects of PRPF8 splicing defects, we analyzed RNA-seq data for 2 mutant cases of *PRPF8* and 17 cases of del17p or low PRPF8 expression. Misspliced genes included genes involved in progression, metabolism, and retinitis pigmentosa. Novel somatic mutations of PRPF8 are associated with myeloid malignancies with increased ring sideroblasts, followed by the evidence of similar pathogenesis by haploinsufficiency. Somatic events constitute loss of function, resulting in the change of splice site recognition function which is associated with proliferating potential and could be a considered as a new therapeutic target.

Peutz-Jeghers syndrome (PJS) is a rare, hereditary predisposition characterized by the occurrence of hamartomatous polyps in the gastrointestinal tract, mucocutaneous pigmentation and increased risk of cancer in multiple internal organs. The incidence of the syndrome, depending on the studied population, has been estimated to range from 1:300 000 even up to 1:25 000 births. PJS is an autosomal dominant disease and, in most of the cases, it is caused by mutations in the STK11 gene.
The majority of causative DNA changes identified in patients with PJS are small mutations and, therefore, developing a method of their detection is a key aspect in the advancement of genetic diagnostics of patients suffering from PJS. In our study, we designed 13 pairs of primers which amplify in the same temperature and enable the examination of all coding exons of the STK11 gene by the HRM analysis.
In our group of 41 families with PJS, small mutations of the STK11 gene were detected in 22 families (54%). In the remaining cases all of the coding exons were sequenced. However, this did not allow detection of any additional mutations. Therefore, the developed methodology is a rapid and cost-effective tool of searching for small mutations in PJS patients and made it possible to detect all the STK11 gene sequence changes occurring in our group.
The study was financed by the Ministry of Education and Science, Poland, grant number N402 481537

Comprehensive genetic characterisation of pediatric T-cell acute lymphoblastic leukaemia

K. Karrman[1], *A. Castor*[2], *M. Behrendtz*[3], *L. Olsson*[1], *M. Ehinger*[4], *A. Biloglav*[1], *K. Paulsson*[1], *B. Johansson*[1];
[1]*Department of Clinical Genetics, Lund, Sweden,* [2]*Department of Pediatrics, Lund, Sweden,* [3]*Department of Pediatrics, Linköping, Sweden,* [4]*Department of Pathology, Lund, Sweden.*

Several genetic events need to accumulate in a single cell in order for clo-

nal expansion of a malignant T-lymphoblast to occur. To elucidate further the genetic aberrations resulting in T-cell acute lymphoblastic leukaemia (T-ALL) conventional chromosome banding, fluorescence *in situ* hybridization (FISH), single nucleotide polymorphism (SNP) array, expression, and large scale sequencing analyses were preformed in a consecutive series of 47 pediatric T-ALL patients. Cytogenetic analyses were informative in 41 cases, displaying a normal karyotype in 54% of cases. Recurrent cytogenetic aberrations comprised T-cell receptor (TCR) rearrangements (*TRA@/TRD@* at 14q11 and *TRB@* at 7q34) and deletions of 6q and 9p. FISH for TCR rearrangements resulted in aberrant hybridization patterns in 26% of investigated cases of which 25% were cytogenetically cryptic. The median copy number alteration displayed by SNP array was 3 (range 0-10), with the majority being less than 10 Mb. Six genes were recurrently targeted by deletions: *CDKN2A/CDKN2B*, *STIL*, *PTEN*, *LEF1*, and *RBI*. Eight paired diagnostic-relapse samples were analysed with SNP array; two samples displayed the same aberrations at diagnosis and relapse, three cases harboured additional changes in the relapse, two cases shared some aberrations but also harboured unique aberrations, and one sample had completely different aberrations between diagnosis and relapse. The expression and sequencing data are currently being analysed. Taken together, the presented data illustrate the multistep genetic process required for T-ALL to occur.

P11.227

Effect of siTRF2 knockdown, a shelterin protein, on the radiosensitivity of telomerase-immortalised human mesenchymal stem cells

O. Orun[1], *P. Mega Tiber*[1], *T. Cankaya*[2], *N. Serakinci*[3];
[1]*marmara univ, istanbul, Turkey,* [2]*dokuz eylul university, izmir, Turkey,* [3]*Near East University, Lefkosa, Cyprus.*

Imperfect capping of telomeres can lead to tumor formation. The cap structure is preserved by shelterin complex where TRF2 is an important member of it. Telomerase-induced bone-marrow derived human mesenchymal stem cells (hMSC-telo1) were used to assess the role of TRF2 knockdown in radiosensitivity. Radiation response and transformation efficiencies of these cells were previously well documented (Serakinci et al. 2008).
siTRF2 knockdown efficiency was found to be 78.53% vs 81.8% for non-radiated (NR) and radiated (R) groups (vectors was kindly provided by Drs Zaffaroni & Marco) respectively, in time point of 48 hours after application of radiation, whereas they were 72% vs 62% after 72 hours (2.5 Gray).
The siTRF2 knockdown cells at 48th time point showed a significant increase in the levels of SA-β-gal (senescence) after exposure to IR, but that difference diminished in 72 hours. Previously we have shown that SA-β-gal ratio was 30% and 76% before and ten days after irradiation, for hMSC-telo1(Serakinci 2007). In this study siTRF2 was found to be highly toxic after 96 hours and senescence difference was much less pronounced in NR and R groups (22% vs 33%).
Colony forming efficiency was found to be decreased in siTRF2 knockdowns following 48 hour incubation, but this difference also did not extend to 72 hours.
Conclusion: We found that knockdown of TRF2 increase the short time cellular effect of irradiation, thus, our data suggest that knockdown of TRF2 might a tool for increasing radiation induced senescence and radiosensitivity of cells for therapeutic purposes.

P11.228

Telomere length in histologically free margins of oral squamous cell carcinoma

B. Popovic[1], *J. Carkic*[1], *D. Jelovac*[2], *N. Nikolic*[1], *J. Milasin*[1];
[1]*Institute of Human genetics, School of Dentistry, Belgrade, Serbia,* [2]*Clinic for Maxillofacial Surgery, School of Dentistry, Belgrade, Serbia.*

Telomere shortening over a critical length leads to chromosomal instability, which might be a key event in the initiation of carcinogenesis. Telomere length as well as different genetic alterations that could be found in tumor free margins of oral carcinoma may be of great importance for estimation of oral pathogenesis.
The aim of this study, was to measure relative telomere length (RTL) in histologically free tumor margins of patients with oral squamous cell carcinoma (OSCC), using real-time PCR. RTL was evaluated by comparing telomere/single copy gene (T/S) ratio in 36 samples of tumor margins and T/S value in reference cell line (293T). The estimated RTL values in margins according to tumor stages were: 1.63 in stage I (25%), 1.37 in stage II (28%), 2.45 in stage III (28%), and 1.67 in stage IV (19%). Also, mean telomere length values of adjacent mucosa in correlation to lymph node status were as follows: 1.67 and 2.12, in cases with negative (68%) and positive (32%) local invasion, respectively.
Overall, a statistically significant increasing of telomere length in free margins of patients with advanced stages was observed (p=0.032). The same trend toward longer telomeres in cases with lymph node metastasis was found, but there was no a significant association. However, our data indicate that telomere length in tumor adjacent, histopathologically confirmed as free of neoplastic cells, might be a valuable tool in prognosis of oral carcinoma.

P11.229

A novel case of TEL/AML1-positive acute lymphoblastic leukemia with t(2;12;21): Is translocation involving 2p13 the secondary genetic change for leukemogenesis in TEL/AML1-positive acute leukemia?

J. Yun, *S. Lee, S. Kim;*
Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of.

TEL-AML1 (ETV6-RUNX1) fusion is the most common in childhood B-cell progenitor acute lymphoblastic leukemia (BCP-ALL) and is related with favorable prognosis. Complex chromosomal translocations, involving three or more different chromosomes, have been rarely observed in leukemia with t(12;21)(p13;q22), and to our knowledge, only three cases involving chromosome 2 were reported with different breakpoints. This is the first TEL/AML1 positive BCP-ALL case with novel three-way molecular variant involving 2p13. The patient was 3-year-old female with lethargy and severe leukocytosis at the time of onset. The leukemic cells were CD34 negative immature B cells. Cytogenetic analysis showed that 45,X,-X,t(2;12;21)(p13;p13;q22) on chromosome study and one TEL-AML1 fusion signal with a single TEL signal on FISH analysis. The patient is alive with complete remission for 14 months although she had histories of invasive fungal and bacterial infections after induction chemotherapy. TEL-AML1 fusion interferes with normal function of the transcription factor RUNX1 and has been considered as necessary but not sufficient for the developmenet of leukemia. Many researchers suggest that secondary genetic event in addition to TEL-AML1 fusion is necessary for leukemogenesis. Regarding 2p13, several cases of acute or chronic B cell leukemia with t(2;14)(p13;q32) were reported as sole chromosomal abnormality. Furthermore some authors suggested that t(2;14)(p13;q32) could be recurrent genetic abnomality with mention of BCL11A gene on 2p13 as a strong candidate for leukemogenesis. This case contributes to further delineate the role of 2p13 rearrangement in leukemogenesis and the clnical course of BCP-ALL with this rare chromosomal aberrancy.

New germline JAK2 mutations resistant to current JAK2 and HSP90 inhibitors are responsible of a hereditary thrombocytosis in two pedigrees

C. MARTY[1], *C. SAINT MARTIN*[2], *S. GROSJEAN*[2], *J. SALIBA*[1], *C. PECQUET*[3], *E. LEROY*[3], *A. HARUTYUNYAN*[4], *J. ABGRALL*[5], *C. LEGRAND*[1], *E. SOLARY*[3], *R. KRALOVICS*[6], *S. CONSTANTINESCU*[3], *A. NAJMAN*[7], *W. VAINCHENKER*[1], *I. PLO*[1], *C. BELLANNE-CHANTELOT*[2];
[1]*Institut Gustave Roussy, INSERM U1009, Villejuif, France,* [2]*Hôpital Pitié-Salpêtrière, Department of Genetics, Paris, France,* [3]*Ludwig Institute for Cancer Research, de Duve Institute, Brussels, Belgium,* [4]*CeMM Research Center for Molecular Medicine, Vienna, Austria,* [5]*CHU de Brest, Service d'Hématologie, Brest, France,* [6]*CeMM Research Center for Molecular Medicine, Department of Internal Medicine I, Vienna, Austria,* [7]*Hôpital Saint-Antoine, Service des Maladies du Sang et de Thérapie Cellulaire, Paris, France.*

Thrombocytosis are rare entities characterized by an abnormal proliferation of the megakaryocytic lineage resulting in overproduction of platelets. The majority of thrombocytosis are sporadic essential thrombocythemia classified as myeloproliferative neoplasms (MPNs) due in half cases to mutations in JAK2 (*JAK2 V617F*) or in molecules affecting the thrombopoietin receptor (MPL)/JAK2 axis. Familial cases of thrombocytosis exist and are usually transmitted by autosomal dominant inheritance. They are subdivided as MPN-like disorders with incomplete penetrance or as pure thrombocytosis with a complete penetrance of hematological abnormalities.
We identified two families with hereditary thrombocytosis presenting three novel heterozygous germline mutations of *JAK2*. One family carries the *JAK2*

R867Q mutation located in the kinase domain, while the second family revealed double mutations in cis, one in the pseudokinase and the other in the kinase domains (*JAK2 S755R/R938Q*). These substitutions are gain-of-function mutations exhibiting spontaneous cell growth and constitutive signaling in Ba/F3-MPL cell models. Moreover, these mutations required MPL to be in active dimeric orientations to signal. In contrast to JAK2 V617F, both JAK2 R867Q and S755R/R938Q half-lives were significantly increased which correlated with an increased cell surface expression of MPL. Consequently, these mutations conferred a resistance to classical JAK2 inhibitors and HSP90 inhibitors compared with *JAK2 V617F*.
These results suggest that mutations in the kinase domain of JAK2 might confer only a weak activation of oncogenic signaling specifically dependent on MPL, indicating that their identification in familial cases of thrombocytosis might be underestimated.

Thyroid carcinomas are the most often carcinomas of endocrine system. Most often occurs papillary and follicular thyroid cancer: tumors with well prognosis, low benignity and slow progress but often giving recurrences and regional or remote metastasis and as well progression from well differentiated thyroid cancer to malignant anaplastic carcinoma.
The aim of this study was to analyze the prevalence of polymorphic variants I157T (c.470T> C, rs17879961) and R145W (c.433C> T, rs137853007) CHEK2 gene and its putative correlation with the risk of causing differentiated thyroid cancer (DTC).
Group of 623 patients 574 females and 49 males) with differentiated thyroid cancer and 500 individuals (297 females and 203 males) from population group were examined. The analysis of gene variants, using the method of pyrosequencing, showed no variation in response to changes in R145W, and confirmed diversity of the I157T in both group of patients with DTC in 4,36% and 2,6% in population. Performed statistical analysis allowed to demonstrate the relationship between the presence of the I157T variant and the occurrence of thyroid cancer. Odds ratio for the rare allele C against the wild one T, amounted 0,5855 at P = 0,0310. Obtained data proved as well correlation between the C allele and higher risk of DTC morbidity for women in Polish population. There has been also observed the increasing impact of age on disease morbidity in Polish population. Project supported by Polish Ministry of Science and Higher Education grant N N402 287436.

P11.232

Variant c.723A in cyclin D1 gene (CCND1) as a risk allele in differentiated thyroid cancer occurring.

M. Kaczmarek-Ryś[1], *K. Ziemnicka*[2], *J. Hoppe-Gołębiewska*[1], *S. T. Hryhorowicz*[3], *A. Pławski*[1], *A. Woźniak*[3], *A. Barańska*[4], *M. Gołąb*[2], *M. Szkudlarek*[2], *M. Ruchała*[2], *R. Słomski*[1,5];
[1]*Institut of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [2]*The Department of Endocrinology and Internal Diseases, University School of Medical Sciences, Poznań, Poland,* [3]*The Nanobiomedical Center, Adam Mickiewicz University, Poznań, Poland,* [4]*The Department of Toxicology, University of Maastricht, Maastricht, Netherlands,* [5]*The Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.*

Polymorphisms in the genes critical to cell cycle control are strong candidates for association with elevated risk of cancer. The CCND1 gene (11q13) encodes the cyclin D1, playing an important role in the transition from G1 to S phase of cell cycle during cell division. Mutations, amplification and over expression of this gene, which alters cell cycle progression, are observed frequently in a variety of tumors and may contribute to tumorigenesis.
We examined common CCND1 gene polymorphisms in cohort of Polish patients with differentiated thyroid cancer (DTC) and Polish population. Analysis concerned the CCND1 c.723G>A polymorphism (rs9344; p.Pro241=), which is located in exon 4, and increases the frequency of alternate splicing and c.669C>T (rs3862792; p.Phe223=).
DNA was extracted from whole blood lymphocytes of 652 patients diagnosed with differentiated thyroid cancer. The population group included 824 subjects. To perform genotyping we used the pyrosequencing technique (PSQ96).
We observed statistically higher frequency of allele A in rs9344 locus in thyroid cancer patients (p=0,0173). We observed also statistically significant differences between genotypes in subjected group. Genotypes AA and GA occurs more frequently in patients with DTC (p=0,0467) than in population group.
We did not observed any statistically important differences in frequencies of genotypes or alleles in rs3862792 locus in subjected groups.
Our findings indicates that A allele in locus rs9344 in homozygotes and heterozygotes as well, may be a risk allele in the development of differentiated thyroid cancer in Polish population. Research funded by grant no. N N402287436.

P11.233

TNF siRNA as modulators of apoptosis and angiogenesis, in cell migration and invasion in triple negative breast cancer cells (TNBC)

I. Berindan-Neagoe[1,2,3], *V. Pileczki*[3,4], *R. Cojocneanu Petric*[3,5], *L. Pop*[6], *C. Braicu*[1,3];
[1]*Department of Functional Genomics and Experimental Pathology, Oncological Institute Ion Chiricuta, Cluj-Napoca, Romania,* [2]*Department of Immunology, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania,* [3]*Research Center for Functional Genomics, Biomedicine and translational Medicine Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [4]*of Pharmacy, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [5]*Faculty of Biology and Geology, Babeş-Bolyai University, Cluj-Napoca, Romania,* [6]*Research Center for Functional Genomics, Biomedicine and Translational Medicine, University of Medicine and Pharmacy Iuliu Hatieganu,, Cluj-Napoca, Romania.*

Tumor necrosis factor-alpha (TNF-α) is a proinflammatory cytokine that has been linked to breast cancer development. Estrogen metabolic pathway is also involved in breast carcino-genesis and DNA adducts formation. A particular case is the TNF- α modulation in TNBC (triple negative breast cancer). Currently there are several TNF-α antagonists applied in clinical use and these agents have provided significant benefits for a variety of cancers. In the last years a special interest have received triple negative breast cancer which is a highly aggressive subtype that observed particularly in young patients with a poor overall survival rate and no target therapy.
In our experiments, we used as an *in vitro* model for triple negative breast cancer - the cell line Hs578T - for evaluation of gene expression profiling of signaling networks involved in apoptosis using PCR-array genes. Treatment with special designed siRNA molecules to target TNF-α mRNA has been done for angiogenesis modulation and most relevant genes were evaluated by qRT-PCR
Knockdown of *TNF-α* gene was connected with activation of apoptosis processes and inhibition of cell migration and invasion, as monitored using the xCELLigence RTCA System and by *in vitro* matrigel angiogenesis assay. There are down-regulated genes involved in cell survival and angiogenesis, whereas the up-regulated ones with pro-apoptotic role.
TFN-α represents a central molecule in the modulation of processes, apoptosis and angiogenesis. TFN-α gene silencing offers an alternative therapeutic strategy in triple negative breast cancer.

P11.234

The association of apoptotic protein expressions SAG, p73 and p53 with prognosis in cervical carcinoma

P. Mega Tiber[1], *L. Baloglu*[2], *S. Ozden*[3], *O. Orun*[1];
[1]*Marmara univ, Istanbul, Turkey,* [2]*Stockholm University, Stockholm, Sweden,* [3]*Dr.Lutfi Kirdar Kartal Education and Research Hospital, Istanbul, Turkey.*

Radiotherapy, applied on advanced stage cervical carcinoma, can only be effective in low resistance cells. Thereby the tumor response and survival rates are highly variable among individuals with different tumor radiosensitivity.
Tumor growth is intimately associated with apoptosis in tissues and apoptosis seems as a likely candidate to estimate prognosis of a treatment.
To further elucidate the roles of apoptotic factors, we determined mRNA expression levels of proteins which are important in apoptotic pathways, especially focusing on a recently identified sensitive-to-apoptosis protein (SAG). In this study, pairwise comparison of expression levels for SAG / Bcl-X_L, Bcl-X_L / Bak and p73 / p53 showed significant correlation with each other. Bak expressions were far from significance in all analyses, probably as a result of joint action of Bax and Bak.
Patients with high levels of SAG expression had a low spontaneous apoptotic index, as expected. Besides, these two factors were clear indicative of better survival rates. Local free, disease free and overall survival have all indicated a higher profile in patients who had lower levels of expressions for both SAG and Bcl-X_L proteins. Overall survival rates after five-years follow-up period have indicated to a better survival in group with low SAG and low Bcl-X_L expressions (P =0.014 and 0.002 respectively).
Conclusion: Our findings approves that SAG is a strong candidate to estimate survival in cervical cancers and shows signifcant correlation with apoptosis and better survival. However we have not observed such a correlation neither with p53 nor p73 expressions.

P11.235
The TP53 gene Arg72Pro polymorphism is associated with the increased risk of cervical cancer in Russians

***N. A. Nigmatullina**, A. A. Arkhipova, B. G. Begiev, I. I. Ahmetov;*
Kazan State Medical University, Kazan, Russian Federation.

The P53 tumour-suppressor protein (encoded by the TP53 gene) has been called the guardian of human cells against cancer. Recent studies have shown that the heterozygosity for TP53 gene Arg72Pro polymorphism is protective against different types of cancers. The current consensus is that TP53 Arg72 allele is more effective at inducing apoptosis and protecting stressed cells from neoplastic development while 72Pro allele is more effective at inducing cell cycle arrest and senescence. The aim of the study was to examine the association of the TP53 genotypes with the odds ratio (OR) for cervical cancer among women. TP53 gene variants were determined in 123 women with cervical cancer (all Caucasians and citizens of Russia). Cases were then compared with ethnically matched healthy controls (n=467). The TP53 Arg72 allele frequency was not different between cases and controls (67.5% vs. 69.8%). However, those women with homozygous genotypes (Arg/Arg, Pro/Pro) were at 2.6 times the risk for cervical cancer [OR, 2.587; 95% CI, 1.595-4.195] compared to women with the heterozygous (Arg/Pro) genotype (frequency of Arg/Pro genotype: 19.5% vs. 38.5%; P<0.0001). In conclusion, the heterozygosity for TP53 gene Arg72Pro polymorphism is protective against cervical cancer in Russian women.

P11.236
Magnetic resonance imaging screening in Li Fraumeni Syndrome: An exploratory whole body MRI study (the SIGNIFY study)

***E. Killick**[1], E. Bancroft[2], M. Leach[1,2], R. Eeles[1,2];*
[1]Institute of Cancer Research, Sutton, United Kingdom, [2]Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom.

Li Fraumeni Syndrome predisposes individuals to a range of malignancies with a lifetime cancer risk of up to 90% in women and 70% in men. Current UK national screening recommendations are for breast screening with mammography and MRI in women. Some centres employ family specific screening tailored to malignancies found within a family, most centres have an "open-door" policy. Recent evidence suggests there may be a survival benefit for more intensive screening, including whole body MRI, but there are no published data on the psychological impact of such screening programmes. The primary end-point of this study is to assess incidence of malignancies diagnosed in asymptomatic *TP53* mutation carriers using whole body MRI without contrast, against general population controls. The secondary end-points are to evaluate any incidental findings and assess the psychological impact of whole body MRI screening. Recruits must be aged between 18 and 60. Cases must carry a germline *TP53* mutation and must not have been diagnosed with a malignancy in the last 5 years; controls must be non-related individuals with no personal history of malignancy. *TP53* mutation carriers and population controls will undergo conventional and diffusion weighted MRI, reported independently by two radiologists blinded to their mutation status. An intersite virtual MDT will be held at regular intervals to discuss the diagnosis and management of incidental findings. A series of questionnaires will be used from time of recruitment up to a year after the MRI scan to assess the psychological impact of screening. Initial results will be shown.

BACKGROUND: Adrenocortical carcinomas (ACCs) are among the most common cancers in children affected with the Li-Fraumeni/Li-Fraumeni-like (LFS/LFL) syndromes, caused by germline mutations in the TP53 gene. In Brazil, a particular common mutation, TP53 p.R337H, is due to a founder effect and is strongly associated with ACC. We describe for the first time, the molecular and clinical follow-up of a patient diagnosed with ACC and homozygous for p.R337H. CASE PRESENTATION: At age 11 months, the female child was diagnosed with a virilising anaplastic ACC, which was completely excised without disturbing the adrenal capsule. Family history was consistent with LFL. Genotyping identified the p.R337H mutation in homozygosity in genomic DNA from lymphocytes and fibroblasts. Haplotype analysis confirmed the occurrence of the mutation in the Brazilian founder haplotype previously described. No other TP53 germline or somatic or rearrangements were identified. At age 9 years, the child was asymptomatic and had no evidence of endocrine derangements. Full body and brain magnetic resonance imaging failed to detect any suspicious lesions, and cardiopulmonary exercise testing results were within the normal reference for the child's age, ruling out a major exercise capacity deficiency. CONCLUSION: Our results support the hypothesis that p.R337H, the most common TP53 mutation ever described in any population, is a conditional mutant. Observations over a long period of clinical follow-up suggest that p.R337H homozygotes don't have a more severe disease phenotype than heterozygotes. Homozygotes for p.R337H will require careful surveillance for lifetime cancer risk and for effects on metabolic capacity later in life.

P11.238
Impact of polymorphisms in genes of p53 pathway on clinical manifestations of the Li-Fraumeni-like syndrome

***G. Macedo**[1,2], I. Araujo Vieira[1], J. Giacomazzi[1], D. Paskulin[1,2], A. Brandalize[1], P. Ashton-Prolla[1,2,3];*
[1]Laboratório de Medicina Genômica, CPE, Hospital de Clínicas de Porto Alegre (HCPA), Porto Alegre, Brazil, Porto Alegre, Brazil, [2]Programa de Pós-Graduação em Genética e Biologia Molecular, Universidade Federal do Rio Grande do Sul (UFRGS), Porto Alegre, Brazil, [3]Serviço de Genética Médica, HCPA, Porto Alegre, Brazil.

Li-Fraumeni Syndrome (LFS) and its variant, Li-Fraumeni-like Syndrome (LFL), are autosomal dominant disorders characterized by increased predisposition to multiple early-onset cancers, caused by a germline mutation in the *TP53* tumor suppressor. The core tumors of the syndrome are soft tissue and bone sarcomas, brain tumors, breast cancer, and adrenocortical carcinoma (ACC). In Southern Brazil, a germline mutation (*TP53* p.R337H) with incomplete penetrance is present in 0.3% of the general population and has been associated with a broader cancer spectrum than that observed in LFS. The environmental and genetic factors underlying cancer risk and tumor patterns in LFS/LFL patients are not completely understood. In this study, the single-nucleotide polymorphisms (SNPs) *MDM2* SNP309T>G (rs2279744), *MDM4* C>T variation (rs1563828) and *HAUSP*

G>A (rs1529916) were genotyped using TaqMan assays in 59 p.R337H *TP53* mutation carriers with different tumors and 100 *TP53* wild-type healthy controls. The *HAUSP* SNP showed a borderline effect (*P*=0.051) as genetic modifier of tumor type in cancer affected mutation carriers. The genotype in heterozygosity was observed in 7/9 (77.8%) mutation carriers with ACC as compared to 6/21 (28.6%) of those diagnosed with breast cancer. In contrast, we did not observe any statistically significant association between *MDM2* and *MDM4* SNPs and clinical manifestations. Our results suggest that there may be an effect of the *HAUSP* polymorphism rs1529916 on the type of tumor developed by *TP53* p.R337H carriers. Further studies with a larger sample size and possibly, other SNPs in the *HAUSP* gene should be undertaken to confirm this observation.

P11.239

20 years of Li-Fraumeni syndrome in France

G. Bougeard[1], *S. Baert-Desurmont*[2], *R. Sesboüé*[1], *M. Renaux-Petel*[2], *V. Bonadona*[3], *C. Bonaïti-Pellié*[4], *T. Frebourg*[2], *&. The French LFS working group*[5];
[1]*Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France,* [2]*Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine and Rouen University Hospital, Rouen, France,* [3]*UMR UCBL/CNRS 5558, centre Léon Bérard, Lyon, France,* [4]*Inserm and Paul Brousse Hospital, Villejuif, France,* [5]*-, -, France.*

The Li-Fraumeni syndrome (LFS) represents a remarkable genetic predisposition to cancer characterized by a wide tumour spectrum including sarcomas, premenopausal breast cancers, brain tumours and adrenocortical carcinomas. Twenty-three years after the demonstration that LFS results from TP53 germline mutations, we have identified 188 unrelated French LFS families harbouring TP53 alterations, thanks to the Chompret criteria elaborated by the French LFS working group to facilitate the clinical recognition of the syndrome. The update of clinical data performed in 280 affected mutation carriers who had developed 478 tumours revealed that the median age of first tumour onset was 27 years (17y in males versus 28y in females), that 44% of patients developed 2 to 6 multiple primary tumours, and that at least 20 of secondary tumours developed within the radiotherapy field of a previous tumour. The most frequent tumours observed were breast carcinoma (110), soft-tissue sarcoma (85+7 breast sarcoma), osteo/chondrosarcoma (52), brain tumours (40) and adrenocortical carcinomas (35). Among 102 patients with adrenocortical carcinoma referred for TP53 testing, 51% of children and 22% of adults carried a TP53 mutation. Germline TP53 alterations were in 61% missense mutations and in 5% genomic rearrangements. Patients harbouring dominant negative missense mutations developed first tumour 16 years earlier than patients with null mutations (22y versus 38y). We found that TP53 mutation carriers harbouring the MDM2 285-309 G-G haplotype developed tumours 5 years earlier than patients harbouring other haplotypes (p=0.043), indicating that the MDM2 285-309 G-G is a higher risk haplotype in patients with germline TP53 mutations.

P11.240

Germline copy number variation of genes involved in chromatin remodelling in families suggestive of Li-Fraumeni syndrome with brain tumours

J. M. Flaman[1], *J. Aury-Landas*[1], *G. Bougeard*[1], *H. Castel*[2], *H. Hernandez-Vargas*[3], *A. Drouet*[1], *J. Latouche*[1], *C. Férec*[4], *D. Leroux*[5], *C. Lasset*[6], *I. Coupier*[7], *Z. Herceg*[3], *T. Frebourg*[1];
[1]*Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France,* [2]*Inserm U982, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France,* [3]*Epigenetics Group, International Agency for Research on Cancer, Lyon, France,* [4]*Inserm, U1078, Brest, France,* [5]*University Hospital, Department of Genetics, Grenoble, France,* [6]*Cancer Genetics, CRLCC Léon Bérard, Lyon, France,* [7]*Department of Genetics, CRLCC Val d'Aurelle Paul Lamarque, Montpellier, France.*

Germline alterations of the tumour suppressor *TP53* gene are detected approximately in 25% of the families suggestive of Li-Fraumeni syndrome (LFS) characterised by a genetic predisposition to a wide tumour spectrum, including soft-tissue sarcomas, osteosarcomas, premenopausal breast cancers, brain tumours, adrenocortical tumours, plexus choroid tumours, leukaemia, and lung cancer. The aim of this study was to determine the contribution of germline copy number variations (CNVs) to LFS in families without detectable TP53 mutation. Using a custom-designed high-resolution array CGH, we evaluated the presence of rare germline CNVs in 64 patients fulfilling the Chompret criteria for LFS, but without any detectable *TP53* alteration. In 15 unrelated patients, we detected 20 new CNVs absent in 600 controls. Remarkably, in 4 patients who had developed each brain tumour, the detected CNV overlap the *KDM1A, MTA3, TRRAP* or *SIRT3* genes encoding p53 partners involved in histone methylation or acetylation. Focused analysis of *SIRT3* showed that the CNV encompassing *SIRT3* leads to SIRT3 overexpression and that in vitro SIRT3 overexpression prevents apoptosis, increases G2/M and results in a hypermethylation of a subset of genes involved in cancer. This study supports the causal role of germline alterations of genes involved in chromatin remodelling in genetic predisposition to cancer and, in particular, to brain tumours.

Over the past 30 years, the genetics of inherited cancer syndromes associated with germline mutations in tumor suppressor genes (TSGs) has been dominated by Knudson's two-hit model. This model implied that onset of malignant transformation resulted from full inactivation of the TSG. Recently, a new "continuum model" has been proposed, which introduces more versatile concepts such as gene dosage-sensitivity, specific phenotype of heterozygote cells and tissue specificity. Mutations in the von Hippel-Lindau (VHL) tumor suppressor gene are associated with a complex spectrum of conditions from no symptoms or polycythemia to predisposition to several types of tumor. We report here an atypical family bearing two VHL gene mutations in cis (R200W and R161Q), together with structural modeling, functional and transcriptomic studies of these mutants. We demonstrate that the complex pattern of clinical manifestations related to distinct VHL mutations is perfectly correlated with a gradient of VHL dysfunction in hypoxia signalling pathways, which supports the new quantitative "continuum model" of tumor suppression.

The index-case was a 12-years old girl, operated on for a pheochromocytoma (PH). Her father and grandfather were also affected by PH or paragangliomas (PGL) several years ago. Genetic counselling was organized in a specialized oncogenetic multidisciplinary consultation, including systematic psychological approach. In this family, the diagnosis of PH was delayed for the child, although her father and grandfather were aware of their medical history, illustrating the denial as a defensive mechanism against guilt

of disease transmission. In this context, testing three generations required reflexion about the temporality of the test.
VHL, *RET*, *SDHB*, *SDHD*, *SDHC*, *MAX* and *TMEM127* were first investigated in the index-case. A single neutral variation of unknown significance (UV) was identified on *VHL* gene (c.414A>G; p.Pro138Pro). That UV was inherited from the paternal branch and was present on tumor DNA associated with loss of heterozygosity. The *VHL* gene is composed of 3 exons encoding a 4.7 kb mRNA and a minor *VHL* transcript deleted from exon 2 (*VHLΔ2* isoform). The UV was absent in Exome Variant Server but ESEfinder analysis suggested the creation of a new cryptic splicing site. Further investigations on RNA extracted from leucocytes of each patient and from the tumor, compared with RNA from similar samples of controls showed a high expression of *VHLΔ2* isoform in patients' leucocytes and the absence of main *VHL* transcript in the PH. The diagnosis of von Hippel Lindau disease was made on those biological data and this family now benefits from a specific follow-up of the disease.

Mutational analysis of the Wilms' tumor gene (WT1) in Greek patients presenting with nephroblastoma

*I. Fylaktou[1], S. Megremis[1], A. Mitsioni[2], F. Komianou[3], **S. Kitsiou-Tzeli**[1], C. J. Stefanidis[2], E. Kanavakis[1], J. Traeger Synodinos[1];*
[1]Medical Genetics, Athens University, "Aghia Sofia" Children's Hospital, Athens, Greece, [2]Departement of Pediatric Nephrology, "P. A. Kyriakou" Children's Hospital, Athens, Greece, [3]Department of Pediatric Nephrology, "Aghia Sofia" Children's Hospital, Athens, Greece.

Wilms' tumor (WT) or nephroblastoma is a childhood tumor of the kidney. It affects children below the age of 5 and has an incidence of 1 in 10000 children. Most cases are sporadic, unilateral and not associated with other symptoms of systemic disease. The average age of diagnosis is 42-47 months for children with unilateral tumors and 30-33 months for children with bilateral tumors. WT displays a high heterogeneity. Mutations in genes such as *WT1, β-catenin, WTX, TP53* and *CTNNB1* as well as deletions in the chromosomal region of *WT1* (chr11p.13) are implicated in the pathogenesis or progression of the WT. Heterozygous *WT1* mutations account for 20% of WT. In this study, we examined 8 sporadic cases and 1 familial case with nephroblastoma. Mutation analysis of the *WT1* gene (exons 2-9) in patients (and their parents) revealed alterations in 5/8 sporadic cases. De novo mutations were found in exon 8 (the novel p.Q374P and p.R362X), exon 9 (p.R390X and p.R394W/N) and intron 9 c.1432+4C>T. Polyphen-2 (http://genetics.bwh.harvard.edu/pph2/) indicated that the p.Q374P (legacy name) is probably damaging with a score of 0.992. Thus, 5/8 cases presented with mutations in *WT1* indicating that molecular investigation of this gene is useful to support the definitive diagnosis. Concerning the non-characterised patients' mutational analysis will be continued in the other exons of *WT1* as well as in the other genes implicated to be involved in the presentation of WT.

P11.244
Targeted resequencing of BRCA1 and BRCA2 in familial breast cancer

***M. W. Wong-Brown**[1], S. Li[2], M. Wilkins[2], K. A. Avery-Kiejda[1], N. A. Bowden[1], R. J. Scott[1];*
[1]University of Newcastle, Hunter Medical Research Institute, New Lambton Heights, Australia, [2]University of New South Wales, Sydney, Australia.

Breast cancer affects about 13,000 women every year in Australia. Inherited loss-of-function mutations in *BRCA1* and *BRCA2* predispose to high risk of breast and/or ovarian cancer. Since the discovery of breast cancer susceptibility genes *BRCA1* and *BRCA2*, there have not been any other genes identified that play a significant role in predisposition to inherited breast cancer. A large proportion of individuals with inherited breast cancer are negative for *BRCA* mutations and despite numerous research efforts, further breast cancer susceptibility genes still remain elusive.
We hypothesize that genetic anomalies are present in the *BRCA1* and *BRCA2* genes in a subset of individuals with familial breast cancer where no genetic anomalies where identified using Sanger sequencing. This study aims were to identify genetic anomalies in *BRCA1* and *BRCA2* by completely re-sequencing 200kb surrounding *BRCA1* and *BRCA2* using next-generation sequencing.
This pilot study involves 10 individuals with familial breast cancer, had previously been screened and found to be negative for *BRCA1* and *BRCA2* coding region mutations. Targeted next-generation paired-end sequencing of regions containing *BRCA1* and *BRCA2* was performed using Illumina GAIIx. Genetic differences in the form of single nucleotide variants and insertions/deletions were identified in most individuals tested in regions that had previously remained unexplored, such as the non-coding regions of BRCA1 and BRCA2, the 5'UTR, 3'UTR and promoter sites. Variants in these sites are being further analysed for effect on expression of transcript.
This study has comprehensively investigated *BRCA1* and *BRCA2* and surrounding genomic regions in a mutation-negative inherited breast cancer population.

P12.01
Discrepancies between prenatal aCGH on cell cultures and postnatal aCGH on blood DNA: two case reports.

***a. guichet**, E. Colin, A. Ziegler, D. Bonneau;*
service de genetique, angers, France.

Chromosomal microarray (CGHa) is becoming the first-tier diagnosis test for prenatal diagnosis allowing detection of small chromosomal rearrangement. We report two cases of discrepancies between aCGH performed using DNA obtained either from chorionic villus culture or from amniotic fluid cell culture and aCGH performed using DNA obtained from blood after birth.
Case 1:
aCGH, performed on a chorionic villus culture performed because of nuchal translucency at ultrasound examination, evidenced two duplications (95Mb 6q11q25 duplication and 1,5Mb 15q21 duplication). Both of these abnormalities were absent on aCGH performed on DNA obtained after birth.
Case 2
aCGH, performed on amniotic fluid culture at 33weeks of gestation because of abnormalities of foetal corpus callosum at ultrasound, evidenced two duplications (54Mb 1q22q32 duplication and 4,8Mb 11q24q25 duplication) and associated with one deletion (38Mb 1q32q44 deletion). None of these abnormalities were present on aCGH performed on DNA obtained from blood after birth.
Discrepancies between aCGH performed using DNA obtained from culture cells and DNA directly extracted from tissue have been reported in few cases in the literature.
We discuss the reasons of such discrepancies and we recommend caution in the interpretation of copy number variation evidenced on prenatal cell cultures. Finally, we recommend when possible to perform aCGH using DNA directly extracted and not DNA obtained from cell cultures.

P12.02
A whole-genome reference panel enriched in Italian lower-frequency variants.

***M. Cocca**[1,2], M. Traglia[1,2], Y. Memari[3], K. Walter[3], C. Sala[2], L. Bomba[3], G. Girotto[1], C. Masciullo[2], C. Barbieri[2], P. D'Adamo[1], P. Gasparini[1], N. Soranzo[3], D. Toniolo[2];*
[1]Institute for Maternal and Child Health – IRCCS "Burlo Garofolo", Trieste, Italy, [2]Division of Genetics and Cell Biology, San Raffaele Research Institute, Milano, Italy, [3]Human Genetics Wellcome Trust Sanger Institute Genome Campus, Hinxton, CB10 1HH, United Kingdom.

Genetically isolated population cohorts have contributed to large-scale discovery efforts of genetic loci associated with complex traits shared between different European populations. Additional opportunities for novel discoveries of complex trait loci arise from exploiting the population specific enrichment in low frequency variants characteristic of these populations.
The Italian Network of Genetics Isolates (INGI) has collected up to 3000 individuals sampled for a large set of phenotypes from several isolated populations along Italy. We sequenced a subset of 110 individuals randomly selected from the Val Borbera cohort (VBI), and a second subset of 250 individuals from Friuli Venezia Giulia (FVGI) maximally representative of ancestral chromosomes, using low-coverage whole-genome sequencing.
After genotype calling and refinement, accurate quality controls steps were applied to obtain a reliable set of rare and common variants.Through comparison between INGI cohorts, with other Italian (e.g. the Tuscany population from 1000G[1]) and European populations (in 1000G or in the WTSI-led UK10K project[2]) we have produced a full catalog of genetic variation, common and rare, in each population.
With this approach we expect to produce an imputation reference panel specific for Italian/Southern European populations, containing a complete

set of genome-wide low frequency and rare variants that could be exploited to search for causative variants for a large set of phenotypes.

Array CGH and fetal pathology : pitfalls of cell culture.

C. Schluth-Bolard[1,2], *E. Alix*[1], *J. Michel*[1], *A. Labalme*[1], *M. Cordier*[1], *S. Collardeau-Frachon*[3], *I. Rouvet*[4], *A. Vasiljevic*[3], *M. Zabot*[4], *M. Till*[1], *D. Sanlaville*[1,2];
[1]*HCL, Service de Génétique, BRON Cedex, France,* [2]*CRNL, CNRS UMR 5292, INSERM U1028, Université Claude Bernard Lyon I, Lyon, France,* [3]*HCL, Service d'Anatomie Pathologie, BRON Cedex, France,* [4]*HCL, Service de Biotechnologie Cellulaire, BRON Cedex, France.*

aCGH has proven its usefulness to detect Copy Number Variation (CNV) in malformed fetuses. Currently, this technique is either performed on DNA extracted from fetal tissue or cell cultures. Here, we report two fetuses with discordant pathogenic CNV depending on the nature of the sample studied.
The first fetus presented a spina bifida and termination of pregnancy (TOP) was performed at 21 weeks of gestation (WG). aCGH, performed from DNA extracted from fibroblast culture after 3 passages highlighted three pathogenic CNV: 2q12.3 duplication, 22q11.2 deletion and a 14q12-q21.3 mosaic deletion (50%). Interstitial 14q deletion wasn't confirmed by FISH in the subculture. Given this discrepancy, a second aCGH was performed from DNA extracted from frozen liver of the fetus showing only the 2q duplication and 22q deletion.
For the second polymalformed fetus a TOP was performed at 25 WG. aCGH was performed on DNA extracted from amniocytes culture (9 passages), highlighted three CNV : 7p22.3-p22.1 duplication, 2q23.3q31.1 and 16q24.3 deletions. FISH studies on frozen thymus only confirm the interstitial 2q deletion, while the three anomalies were confirmed on amniocytes subculture. A second aCGH performed on the DNA extracted from the thymus only confirmed the 2q deletion.
These observations emphasize the possibility of occurrence of unbalanced chromosomal rearrangements in cultured cells possibly favoured by hyper stimulation and chromosome abnormality. These observations emphasize the importance to check identified CNV on fetal tissue. Also, we proposed to perform aCGH from DNA extracted from fetal tissue.

P12.04
Comparative study between single strand sequencing and double strand sequencing in breast cancer predisposition.

A. REMENIERAS*, V. BOURDON, T. NOGUCHI, H. SOBOL;*
INSTITUT PAOLI CALMETTES, MARSEILLE, France.

Currently, next generation sequencers are of the top of sequencing technologies. But Sanger sequencing is still keeping as reference method for genetic testing in clinical. However, there's no consensus on methodology as many publications validated this method without evaluating the analytical sensitivity between sequencing with double strand as matrix versus sequencing single strand.
The aim of this study was to compare sensitivity between sequencing single strand (Sss) and sequencing double strand (Sds) for evocative patients of breast cancer and ovary predisposition.
We took runs of 50 patients for whom *BRCA1/BRCA2* genes were tested using 3130/3500 (ABi) sequencers and Sds for diagnosis to have routine variation detection rate. Analysis was done by Seqscape V.2.7 (ABi). For our study reading was done by one biologist who analyzed once only one strand (forward or reverse) and several months later two strands together.
656 variations were identified for our 50 patients:
-34 were missed in Sss (27) even in Sds (7): respectively, detection rate was about 95% for Sss and 99% for Sds but after verification of differences between the 2 methods in Seqscape we realized that errors were only dues to operator reading and not technologies. Lacks appeared when quality sequences wasn't good enough.
-3 were identified in Sss whereas they were only artifacts not confirmed by resequencing.
Our results indicate that Sss and Sds sensitivities were similar with required conditions of quality. Improvement of our methods by quality standards and resequencing allows us to use Sss instead of Sds for diagnosis.

P12.05
Presence and potential of cell free DNA in forensic casework

M. Vandewoestyne*, D. Van Hoofstat, A. Franssen, F. Van Nieuwerburgh, D. Deforce;*
Laboratory of Pharmaceutical Biotechnology, Ghent University, Ghent, Belgium.

Cell free nucleic acids (CNAs) have been found to exist in many biological media, including blood, saliva, semen and urine, and have been subject of research in oncology and non-invasive prenatal diagnosis. The origin of CNAs remains obscure, although necrosis, apoptosis and active secretion have been suggested as potential mechanisms by which CNAs are released.
To date, several studies have been performed on the potential of extracellular mRNA profiling in forensic science to identify the biological origin of forensic stains. Less is known about the potential value of cell free DNA in forensic casework. Recent studies suggest that this cell free DNA is a contributing factor to DNA recovered from touched items and state that it is likely that a substantial proportion of cell free DNA is being discarded with the supernatant during standard extraction processes. This would imply that potentially valuable information would be discarded as well.
To investigate the presence and potential of cell free DNA in forensic casework, DNA profiles of cell pellet and concentrated supernatant from 30 artificial case like samples and from 100 real forensic samples were compared. Presence of cell free DNA was shown in all investigated sample types. Moreover, in some samples additional alleles, not detected during analysis of the cell pellet, were detected. In 16% of the samples, the cell free DNA had an added value.
The results presented here indicate that cell free DNA deserves further consideration since it has the potential to increase the DNA yield in forensic casework samples.

Metabochip-based copy number variants (CNVs) calling and association with body mass index (BMI) in adults: benchmarking and meta-analysis

A. Macé[1,2], *K. Männik*[3], *R. Mägi*[4], *S. Jacquemont*[5], *J. S. Beckmann*[2], *A. Metspalu*[4], *A. Reymond*[3], *Z. Kutalik*[1,2];
[1]*Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, University of Lausanne, Lausanne, Switzerland,* [3]*Center of Integrative Genomics, University of Lausanne, Lausanne, Switzerland,* [4]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [5]*Service de Génétique Médicale, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

Many single nucleotide polymorphisms influence common disease susceptibility but, to date even cumulatively, they explain only part of the heritability. As large and rare CNVs were also found to be associated with common diseases/traits, it was suggested that part of the missing heritability could be accounted for by rare variants with intermediate penetrance. The extent of this contribution remains however largely unknown. To address this question, we are collecting cohorts genotyped on Metabochip and other Illumina platforms to identify new rare or short CNVs associated with BMI and other complex traits.
We assessed CNV detection sensitivity, specificity and optimal filtering parameters of PennCNV calls on 300 unrelated adults genotyped on both Metabochip and OmniExpress. Assuming that CNVs called in high probe-density regions of the Metabochip are genuine, we examined the concordance with results of the OmniExpress platform. We assessed how different filtering parameters, such as length, number of probes, confidence score, influence true positive and false discovery rates (TPR, FDR). We then defined thresholds that gave an optimized CNV call reliability. TPR and FDR typically decreased as the minimum length threshold increased, revealing the difficulty in detecting CNVs smaller than 20kb (TPR=0.034, FDR=0.775) on OmniExpress chip.
We performed a preliminary genome-wide CNV association meta-analysis (N=8295) based on our filtering. As a proof-of-concept we confirmed the well-known *SH2B1*-BMI CNV association and found several promising hits to be replicated in additional Metabochip-genotyped cohorts. To the best of our knowledge, this is the first effort to discover small CNVs associated with adult BMI.

Key elements for implementation of NGS-based diagnostics - it is the people, not the machines

T. Vrijenhoek[1], *C. G. D. Centre for Genome Diagnostics*[2];
[1]*University Medical Centre Utrecht, Utrecht, Netherlands,* [2]*Centre for Genome Diagnostics, Utrecht, Netherlands.*

The scope of next-generation DNA sequencing (NGS) is transitioning from research to diagnostics (and beyond), but the conditions for routine clinical application have not been clearly defined. Well-defined technical standards and guidelines are obvious prerequisites, but the clinical genetics centres in the Netherlands went beyond performance criteria; they auto-assessed the performance of NGS as a diagnostic tool in their laboratories. All centres participated in a pilot project to analyse the internal organisation and process of NGS-based diagnostics, from sample intake to reporting. We sent a request to all laboratories to provide an NGS-based diagnosis for the same patients with cardiomyopathy. Instead of identifying a 'winner', we constructed a systematic overview of the key elements for transition of NGS from research to diagnostics. Despite the variety in approaches (targeted, exome; WES, whole genome; WGS) and performance criteria, the laboratories produced high-quality data and generally identified the same known clinically relevant variants. Subsequent steps – uniformly interpreting results, exchange of data, reporting the diagnosis – appeared more challenging. Although some of the bottlenecks are due to technological barriers – e.g. transfer speed for data exchange – the major limitations are inherent to the general organisation of diagnostic care. We present the practical outcomes of the pilot, along with proposals for dealing with the emerging role of research in a diagnostic context, for responsibly managing patient data, and for appropriately informing physicians and patients. We thereby provide a practical contribution to the debate about the role of NGS in future diagnostics.

T. Vrijenhoek: None. **C.G.D. Centre for Genome Diagnostics:** None.

P12.08

Sequencing of sodium bisulfite converted DNA as a method to discriminate different patterns of methylation in human genome

M. Lukova[1,2], *A. Todorova*[1,2], *T. Todorov*[2], *V. Mitev*[1];
[1]*Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria.*

Many regions in human genome are differentially methylated (DMRs) on maternal or paternal copy and this helps genes to work properly. Methylation changes along these DMRs are associated with different pathologies. Beckwith-Wiedemann syndrome (BWS) is an overgrowth disorder, mainly caused by epigenetic alterations in one of the two imprinting control regions (ICR1 and ICR2) on chromosome 11p15. The most common defect in ~50% of BWS cases is loss of methylation at KvDMR (ICR2). Here, we introduce sequencing of sodium bisulfite converted DNA as an alternative technique for determining the methylation status of KvDMR in BWS patients. In order to be able to compare the results with those, obtained by MS-MLPA (methylation specific-multiplex ligation probe amplification), PCR primers were designed over the region to cover two of the MS-MLPA specific probes. Altogether, 4 patients with KvDMR demethylation showed loss of methylation in the analyzed by sequencing CpG sites. The obtained sequencing results in patients and normal controls are totally in accordance with the MS-MLPA data.

The same technique was applied to analyze methylation status in the FMR1 gene promoter, hypermethylated in Fragile X syndrome. The results showed very good discrimination between the normal unmethylated promoter in healthy males and hypermethylated promoter in Fragile X full mutated boys.

In conclusion, sequencing of bisulfite converted DNA can be applied to study other DMRs, as for example H19DMR (ICR1) locus in Beckwith-Wiedemann/Silver-Russell syndromes.

Acknowledgements: the study was supported by the grant №7-D/2012, Medical University Sofia, Bulgaria.

P12.09

Evaluating laboratories' interpretation of genetic test results through a EuroGentest External Quality Assessment survey

E. Girodon[1,2], *S. Berwouts*[3], *M. Rodriguez de Alba Freiria*[4], *A. Roux*[5], *D. E. Barton*[6], *L. Hoefsloot*[7], *S. Gardner*[8], *O. Kamarainen*[8], *B. Fowler*[9], *M. A. Morris*[10], *E. Dequeker*[3], *R. J. Hastings*[11];
[1]*APHP, GH Henri Mondor, Genetics department, Creteil, France,* [2]*INSERM U955 equipe 11, Creteil, France,* [3]*University of Leuven, Biomedical Quality Assurance Research Unit, Leuven, Belgium,* [4]*Fundacion Jimenez Diaz, Genetics department, Madrid, Spain,* [5]*CHU de Montpellier et IURC, Molecular genetics, Montpellier, France,* [6]*National Centre for Medical Genetics, University College of Dublin, Dublin, Ireland,* [7]*Radboud University Nijmegen Medical Centre, Department of Human Genetics, Nijmegen, Netherlands,* [8]*St Mary's hospital, Genetic Medicine, Manchester, United Kingdom,* [9]*University Children's Hospital, Paediatrics, Basel, Switzerland,* [10]*HUG, Genetics department, Genève, Switzerland,* [11]*John Radcliffe Hospital, Oxford University Hospitals NHS Trust, Women's Centre, Oxford, United Kingdom.*

Interpretation of test results is a key component of a genetic laboratory report, with potential implications for the patient and the family. In order to evaluate laboratory performance in this area, a EuroGentest survey among External Quality Assessment (EQA) programmes, from four European providers (CEQA, CF Network, EMQN & ERNDIM) was undertaken, with the aim of determining the interpretation elements that were missing in reports, in regard to existing guidelines and recommendations.

EQA reports from 2011 representing 519 participations in six programmes: cystic fibrosis, Friedreich ataxia, hereditary deafness at the DFNB1 locus, postnatal microarray, prenatal diagnosis of chromosomal abnormalities on amniotic fluid and metabolic diseases, were evaluated using criteria derived from the OECD Guidelines.

Mean interpretation scores varied between cases, ranging from 1.61/2 to 1.98/2. Despite heterogeneity among schemes in the scoring systems and in assessment, the data analysis revealed the following: 1) although the answer to the clinical question was provided in most reports, the survey emphasized the need to clearly restate the indication of testing; 2) items related to follow-up testing were the most often omitted, e.g. recommendation to search for a second mutation or to test the parents. 26-36% of molecular genetics and 29% of cytogenetics reports did not mention the recurrence risk of disease and/or the possibility of prenatal diagnosis for future pregnancies.

This first and preliminary survey emphasizes the need to find effective training and communication processes, including harmonization of assessment between EQA programmes, so that laboratories can improve the interpretation content of their reports.

Background: the use of FISH probes with expired validity date is a recurrent dilemma in cytogenetic diagnostic laboratories and became more complex with accreditation process.

Some companies provide FISH probes with very short expiration date (6 months) but the procedure used for the determination of the expiration date of commercial probes is not clear. Many laboratories are impacted by this short "expiration date" as FISH probes are expensive and their use is not predictable since cytogenetic abnormalities are rare and various. When producing home-made probes the problem is similar: how to establish the expiration date after labelling, required for accreditation ISO 15189 ?

Method: We did a pilot studies in 10 cytogenetic laboratories. All Laboratories tested their oldest home-made and commercial FISH probes in order to obtain an overview of the possible longevity of probes. The commercial probes originated from various providers, with various dyes. Home-made probes had been labelled by different protocols mostly by nick translation. The hybridisation was considered satisfactory when observed in at least 20 metaphases and 50 nuclei.

Results: **Commercial probes**: 31 probes expiring between 1998 and 2012

were tested from october 2012 to 2013 and gave satisfactory signals in all cases except one.
Home-made probes: 45 probes labelled from 2002 to 2011 were tested recently, 44 showed visible satisfactory signal. The four oldest probes labelled 10 years ago gave perfect signal.
This pilot studies shows that the labelled probes have longer validity period than expected, over 10 years for some of them when tested.

Comparison between standard and novel PCR-based method for the detection of mutation in the FMR1 gene

N. Teran, *H. Jaklič, A. Šmerc, B. Peterlin;*
University Medical Centre Ljubljana, Dept. of Obstetrics and Gynecology, Institute of Medical Genetics, Ljubljana, Slovenia.

Fragile X syndrome is the most common inherited form of mental retardation. Fragile X carriers are known to be associated with premature ovarian failure in females and fragile X-associated tremor/ataxia syndrome in males. The pathogenic mutation is mostly caused by CGG repeat expansion in the FMR1 gene. Normal allels contains from 6-50 CGG repeats. Premutated alleles have expansions between 55 and 200 repeats, but CGG repeats over 200 are indentified as full mutations.
Rutine testing for FMR1 mutation rely on conventional PCR and Southern blotting (PCR/SB), however, analysis is costly and time-consuming, requires large amounts of DNA sample and may have poor sensitivity to detection of lower abundance mosaic alleles.
Aim of this study was to compare the novel FMR1 PCR-based method to the previously used PCR/SB method.
DNA samples were extracted from different specimen sources: whole blood, culture of amniotic fluid and chorionic villi. Additionaly, bucal swab, uncultured chorionic villi and amniotic fluid samples were tested using FMR1 PCR-based method. Cohort of 50 samples contained 12 full mutations, 1 premutation/full mutation, 23 premutations, and 14 normal samples (PCR/SB results).
Novel FMR1 PCR-based metod identified normal alleles within 0-3 repeats of previously reported allele sizes. Results have shown a mosaic premutation pattern in 8/23 samples previously recognized as non-mosaic premutation. In one sample previously reported as premutation, mosaic premutation/full mutation pattern was identified.
We concluded that the novel FMR1 PCR-based method is more sensitive, compatible with uncultured chorionic villi and amniotic fluid as well significantly reducing testing time.

P12.12
A novel assay for automated electrophoretic analysis of genomic DNA

A. Ruefer[1], *D. McDade-Walker*[2], *M. Gassmann*[1], *A. Padmanaban*[3];
[1]*Agilent Technologies, Waldbronn, Germany,* [2]*Agilent Technologies, Edinburgh, United Kingdom,* [3]*Agilent Technologies, Life Sciences Application Center, Bangalore, India.*

The success of any study in the field of genomics depends primarily on the quality of starting material available, like genomic DNA. The integrity and quantity of genomic DNA clearly affects experimental workflows such as aCGH microarrays or next generation sequencing library construction. With these experiments being expensive in time, effort and reagent consumption, an initial quality control (QC) check of genomic DNA is recommended.
The novel Agilent genomic DNA ScreenTape has been developed specifically for the electrophoretic separation, sizing and quantification of genomic DNA samples. This ready-to-use device, which runs on the Agilent 2200 TapeStation instrument, provides a reproducible QC method for analyzing the integrity and quantity of genomic DNA combined with the convenience of an automated system. The genomic DNA ScreenTape requires only one microliter of sample, minimizes sample preparation efforts, and suits variable throughput needs with individually contained separation channels. The TapeStation system provides automated, reproducible sample loading and returns digital electrophoretic data in less than 2 minutes per sample. Results are presented as gel image, data tables and in an electropherogram view. The ability to overlap and compare electropherograms enables a clear discrimination of sample quality across different degradation states, sample types and concentrations.
This study presents data on key performance characteristics of the novel genomic DNA ScreenTape, like molecular weight size range, accuracy and reproducibility of sizing and quantification results, as well as detection sensitivity. In addition the genomic DNA ScreenTape was used to characterize genomic DNA prepared with different extraction protocols.

P12.13
Recurrent chromosomal abnormalities in human pluripotent stem cells and their derivatives

C. Varela[1], *C. Fonseca-Bernardo*[2], *M. Peschanski*[2], *A. L. Perrier*[2], ***N. Lefort***[2];
[1]*CECS / ISTEM, evry, France,* [2]*INSERM U861 / ISTEM, evry, France.*

Due to their original properties, human pluripotent stem cells (hPSC) and their progenies are highly valuable not only for regenerative medicine but also as tools to study development and pathologies or as cellular substrates to screen and test new drugs. However, their unlimited self-renewal property bears the risk of tumor formation, which could potentially be exacerbated by the presence of genomic abnormalities. Quality control of hPSC is, therefore, essential for the reproducibility of research experiments and for the safety of clinical applications based on these cells. As hPSC are often propagated for extended period of time, these necessary controls include monitoring and controlling of the integrity of the genome of these cells.
Chromosomal abnormalities such as gain of chromosomes 12, 17 and X occur non-randomly and quite commonly in hPSC lines. Using high-resolution analysis we identified a region of the genome that is highly unstable in hPSC, located on chromosome 20 (20q11.21). We have also identified a systematic abnormality that affects neural derivatives of hPSCs namely jumping translocation of chromosome arm 1q. All these genomic aberrations may have negative consequences on all stem cell applications.
These chromosomal defects, observed in culture, reflect tumorigenic events that occur in vivo, particularly in testicular germ cell tumors (trisomies 12 and 17), in early stage of cervical cancer (20q11.21) and in pediatric brain tumors with poor clinical outcome (duplication 1q).
These results raise the importance of understanding structural variations of chromosomes in hPSC, as they will have a significant impact on future medical applications.

Quantitative real time reverse transcriptase-PCR (qRT-PCR) is used in the study of gene expression of cancer researches. Selection of reliable reference genes as an internal control has a critical importance. The objective of this study was to evaluate a set of housekeeping genes (HKGs) to be used in the normalization of gene expression in HNSCC. Malignant and non-malignant tissue samples were obtained from 12 patients with primary untreated larynx and tongue squamose cell carcinoma. Reference genes used were glyceraldehyde-3-phosphate dehydrogenase (GAPDH), actin beta (ACTB), tubulin alpha 1 (TUBA1), 18S rRNA (18S), and 28S rRNA (28S). Widely used softwares, geNorm and NormFinder, were utilized in the evaluation of the data. Results from geNorm showed that average expression stability values (M) of all candidate genes were smaller than 1.5 (accepted M value for geNorm) indicating that all the evaluated genes can be used as HKGs although 18S and 28S were found to be the most stable HKG (followed by ACTB, TUBA1, and GAPDH). Based on NormFinder, 28S was the most stable and GAPDH and 28S were considered to be the best combination in the studies evaluating the specific gene expression in tissues obtained from various HNSCC.

Comparison of different DNA binding fluorescent dyes for applications of high-resolution melting analysis

*M. Surovy[1], J. Radvanszky[2], G. Minarik[1,3], **L. Kadasi**[1,2];*
[1]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, [2]Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia, [3]Institute of Molecular Biomedicine, Faculty of Medicine, Comenius University, Bratislava, Slovakia.

High-resolution melting (HRM) analysis of PCR amplicons is a flexible tool adaptable for a wide range of applications, such as mutation screening, genotyping and methylation studies. As several commercial HRM chemistries have been released, together with chemistries used for other applications, we have decided to test twelve different green fluorescent DNA binding dyes for their suitability to use in HRM based mutation screening, genotyping of single nucleotide changes (through both unlabelled probes and small amplicons) and genotyping of a large in/del polymorphism. We also compared some basic properties of the dyes, such as fluorescence intensity enhancement in the presence of dsDNA, general applicability in melting curve analysis, effect on dsDNA melting temperature (Tm) and PCR inhibitory effect. The studied dyes were LCGreen Plus (LC), EvaGreen (EG), ResoLight (RL), SYBR Green I (SG) and eight different green fluorescent dyes from the SYTO family (S11, S12, S13, S14, S16, S21, S24 and S25). In general, the dyes designed for HRM applications (LC, EG and RL) performed very well in our study, as it was expected. SG, S12, S21, S24 and S25 had less suitable properties for HRM applications. S11, S13, S14 and S16 allowed us to obtain results of similar quality (especially S13 and S16) as the HRM dyes, with some properties even exceeding them. Our results suggest, that some, but not all of the SYTO family members, may represent suitable tools for a variety of different HRM applications.

Indian Hedgehog (IHH) and LRBA: New genes for Hirschsprung disease

***Y. Sribudiani**[1], R. K. Chauhan[1], M. M. Alves[1], C. Kockx[2], T. van Essen[2], R. Brouwer[2], M. van den Hout[2], W. van Ijcken[2], I. T. Shepherd3[3], A. Brooks[1], R. M. W. Hofstra[1];*
[1]Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands, [2]Center for Biomics, Erasmus Medical Center, Rotterdam, Netherlands, [3]Department of Biology, Emory University, Atlanta, GA, United States.

Hirschsprung is characterized by the absence of enteric ganglia in a variable length of intestinal tract. A large, multi-generational Dutch family with five affected family members with HSCR, revealed linkage to 4q31.3-q32.3. As the family shows an autosomal dominant mode of inheritance with incomplete penetrance, we assume that the mutation in the linkage region is necessary but not sufficient to cause disease development. To identify the mutation in the linkage region, but also mutations elsewhere in the genome, we exome sequenced two patients. One variant rs140666848 (T > C) in exon 20 of the *LRBA* gene was found in the linkage region. In addition, missense mutations in *RET* (P398L) and *IHH* (Q50K) were identified in each patient, respectively. Functional analysis of the RET and IHH variants showed that both mutations give rise to a non-functional protein. The *LRBA* variant is located downstream of *MAB21L2*, a gene which plays a role in the proliferation of enteric neural crest cells during enteric nervous system (ENS) development in Zebrafish. We hypothesize that this variant might regulate *MAB21L2* expression in ENS. Luciferase assays showed that the region containing the variant does show enhancer activity. Currently we are testing whether the variant, when compared to wild type sequence, show significant differences on gene expression level, using luciferase assays. Our data shows that combination of mutations, as expected, cause autosomal dominant disease with reduces penetrance. Furthermore, we show for the first time that *IHH* mutations can contribute to Hirschsprung disease.

P12.17

Production of CE-marked reference materials and WHO international standards for *in vitro* genetic diagnoses: quantitative controls for *JAK2* V617F and beyond

***J. Boyle**, C. Lockie, M. Hawkins, E. Gray, P. Metcalfe, J. Hawkins;*
NIBSC, South Mimms, United Kingdom.

NIBSC produces reference materials for human nucleic acid-based diagnostics where there is strong evidence of need, increasingly in the quantitative monitoring of cancer biomarkers. These control materials are produced as either CE-marked reference materials or World Health Organization international standards, suitable for *in vitro* diagnostic use in Europe or worldwide, respectively. In 2009, the 1st WHO International Genetic Reference Panel for *BCR-ABL* Translocation Quantitation for the monitoring of chronic myeloid leukaemia established NIBSC's role in improving the quality of cancer molecular monitoring.
In 2013, production began on the *JAK2* V617F Tumour Genotyping Reference Panel. The *JAK2* V617F mutation (c.1849G>T) is commonly present in chronic myeloproliferative disorder patients, making the JAK2 protein an obvious candidate for drug-targeting. It is therefore important to identify V617F-positive patients and to monitor treatment response by mutant clone quantitation. The panel of sensitivity controls will comprise a dilution series of *JAK2* V617F genomic DNA (UKE-1 cell line-derived) in a wildtype genomic DNA background (MRC-5 cell line-derived) at 10, 5, 1, 0.1 and 0%. The samples will be stored at ambient temperature in the highly stable matrix of GenTegra tubes. Dilutions will be confirmed by deep sequencing and material performance independently verified with commonly used techniques. The panel is intended as a CE-marked *in vitro* diagnostic device for *JAK2* V617F assay validation, including specificity and sensitivity determination. Tumour genotyping standards are also proposed for *BRAF*, *KRAS* and *PIK3CA*. NIBSC seeks input from clinicians and scientists worldwide to ensure the developing needs of cancer genetic diagnostics are met.

P12.18

Implementation of a Diagnostic Pipeline for Marfan und Long QT Syndrome with Next Generation Sequencing (NGS) using Illumina TruSeq Custom Amplicon Panels

***I. Vogl**, S. Eck, S. Eck, C. Heberle, S. Küçük, C. Marschall, K. Mayer, H. Klein;*
Center of Human Genetics and Laboratory Medicine, Martinsried, Germany.

Amplicon panels for Marfan syndrome (MFS, FBN1) and LongQT syndrome (LQTS, KCNE1, KCNH2, SCN5A, KCNQ1 and KCNE2) were designed using Illumina's TSCA design studio. To evaluate a diagnostic pipeline based on NGS, we analyzed a total of 53 patients whose Sanger sequencing data were already available. Using a single Illumina MiSeq run we sequenced 25 samples for MFS and 28 samples for LQTS. Bioinformatic data analysis was carried out using CLC Genomics Workbench 6.0. A first variant call was performed by using the following parameters in the CLC software: A probability of 70% that the variant is true and a coverage cut-off of 20 reads. Broken pairs and non-specific matches were ignored.
Results: All true positive variants were observed with an average per base quality of more than 20. Using these criteria, all point mutations from Sanger sequencing could also be detected in the MiSeq data. 8 of 11 deletions (3 exons were not covered in all samples), all indels and 3 of 5 insertions were detected.
Based on these results the filters were refined for causal mutation detection: Variants which were found in more than 20% of the samples were filtered out. Variants which showed an average quality lower than 20 and a frequency lower than 5% were sorted out. Variants were annotated with special created tracks for each subpanel (gene names, exon numbers, and amino acid changes), HGMD biobase annotation and dbSNP.

Microarray testing for urgent paediatric referrals: audit of six years clinical experience

***J. J. Waters**, L. Platts, R. Wang, D. Morrogh, N. Lench;*
Great Ormond St Hospital for Children, London, United Kingdom.

Rapid reporting of urgent results for babies up to three months of age forms a clinically important part of our service. Rapid FISH (for 13, 18 and 21 aneuploidy testing/confirmation of chromosomal sex) and karyotyping +/- targeted FISH is now complemented by microrray. In April 2010, chromosomal microarray (Roche-Nimbelegen, 12x135K) was introduced as a first line test for all appropriate referral categories at Great Ormond St Hospital for Children an in January 2011 for all users.We have audited the last six calendar years for this patient referral group (babies =< 3 months) (n=3163) and the results are tabulated below by test type selected.Target turnaround times/success rates/mean days to report/percentage reported within turnaround time for the above test categories are: **Rapid Aneuploidy (13,18 and 21)/Sexing**: 1 day; 100%; 1.1 days; 100%; **Urgent Karyotyping +/- FISH**: 7

days; 94.8%; 5.7 days; 94.9% and **Urgent Microarray**: 7 days; 100%; 7.6 days; 86.1%. (2011-12 financial year audit data).
Rates of clearly significant abnormalities (details will be presented) were comparable across the audited period, probably reflecting the fact that babies with overt dysmorphic features are more likely to be tested at this time. Ordering and selection of the appropriate test continues to involve education of clinicians, sample availability and clinical judgement on the part of laboratory staff.

Sample numbers by test category

	2007	2008	2009	2010	2011	2012
Rapid anaeuploidy/ sexing (interphase FISH)	149	153	148	116	111	131
Urgent Karyotyping +/- FISH	383	349	351	315	240	127
Urgent microarray	0	6	11	48	236	289

P12.20
Simplifying diagnostic mitochondrial genome analysis with HaploGrep and Mitomaster online algorithms

S. L. Hume, *B. Elyas, R. Kelln, L. Vicen, L. Podemski, S. Taylor, M. Somerville; University of Alberta, Edmonton, AB, Canada.*

Mitochondrial genome analysis is complicated by the abundance of polymorphisms as every individual carries, on average, 30 sequence variants when compared to the revised Cambridge Reference Sequence (rCRS). Additionally, haplogroup-specific variant frequencies are lacking, thus making the assignment of variant pathogenicity problematic. To simplify our lab analysis time we chose to implement two online algorithms: HaploGrep, and Mitomaster, following sequence analysis with both Seqscape™ (Life Technologies) and Seqpilot™ (JSI Medical Systems). Using our new process, those variants that do not fall into the patient's predicted haplogroup, are further examined by Mitomaster to obtain frequencies, species conservation and general variant information relevant to assigning pathogenicity. These algorithms were validated using 40 full mitochondrial genomes of various haplotypes and permitted successful identification of likely pathogenic variants. Therefore, this new mitochondrial variant analysis workflow has reduced our overall analysis time and improves specificity by permitting the categorization those variants that are more likely to be pathogenic.

P12.21
The MLPA-dHPLC procedure for NF1 gene analysis.

S. PINSON[1,2], *P. Combemale*[3], *S. Giraud*[1], *A. Calender*[1];
[1]*Hospices Civils de Lyon, Lyon, France,* [2]*NF rhone Alpes Auvergne, Lyon, France,* [3]*CLB, Lyon, France.*

The identification of mutations in the NF1 gene causing neurofibromatosis type 1 (NF1) is still presenting a considerable amount of work mainly because of the large size of the gene (350 kb - 60 exons) and the restricted number of recurent mutations. The high frequency of NF1 which is affecting 1 in 3500 individuals lead us to choose two complementary methods to perform NF1 gene analysis : the multiplex ligation-dependant probe amplification (MLPA) first and then the automated denaturing high performance liquid (dHPLC) screening method.
The sensitivity was evaluated in a MLPA-dHPLC analysis of a panel of unrelated french NF1 patients with at least two consensus diagnostic criterias (global mutation detection rate to 96%).
Our results and the high detection rate confirm that the association of the MLPA and dHPLC techniques provides an accurate, fast and automatizable method for the identification of NF1 mutations.

Massive targeted re-sequencing for the diagnosis of neurological diseases: a 200-gene panel

A. Romera López[1], *V. Volpini*[2], *A. Matilla*[3], *C. Collado*[1], *R. Rodríguez-De Pablos*[1], *V. Fernández-Pedrosa*[1], *D. Cantalapiedra*[1], *L. Pérez-Cabornero*[1], *J. M. Rosa-Rosa*[1], *J. C. Triviño*[1], *S. Zúñiga-Trejos*[1], *R. Miñambres*[1], *M. Gil*[1], *S. Santillán*[1];
[1]*Sistemas Genómicos, Paterna, Spain,* [2]*Instituto de Investigación Biomédica de Bellvitge, Barcelona, Spain,* [3]*Hospital Germans Trias i Pujol, Barcelona, Spain.*

Today, neurological diseases have become a major health concern worldwide, with more than 600 pathologies affecting the central- and peripheral-nervous system. The incidence of these pathologies among the population is not negligible and it is estimated that diseases such as Parkinson affects ~ 0.3% of the E.E.U.U. population. The Diagnosis of neurological diseases is not straightforward, mainly due to the presence of nonspecific overlapping clinical symptoms, and genetic testing becomes essential to confirm clinical diagnosis. Nevertheless, conventional techniques have been insufficient to provide a comprehensive molecular diagnosis, given the high number of genes implicated.
We designed a NGS targeted re-sequencing panel for 200 genes associated with neurological diseases, including: i) syndromic and non-syndromic ataxias (>80 genes) ii) Charcot-Marie-Tooth disease (34g) iii) syndromic and non-syndromic myasthenia (40g) iv) syndromic and non-syndromic paraplegia (28g). The panel includes a total of 1.3 Mb comprising coding exons, splice sites and 5' and 3' untranslated regions (UTR) of these 200 genes. To test this panel, all these regions were fully sequenced in 7 control patients with known mutations and in two HapMap cell lines (NA12144 and NA12813). Enrichment of the exonic regions and sequencing were carried out using *SureSelect Enrichment System* (Agilent) and *SOLiD 5500* (Life Technologies), respectively.
Here, we present the results obtained during the validation of our panel, showing its high level of efficiency. Our targeted re-sequencing system offers massive analysis of 200 genes involved in Neurological diseases, making the comprehensive molecular diagnosis of these disorders feasible.

P12.23
Personalised clopidogrel therapy by teststrip-based CYP2C19 genotyping

H. Puehringer, *B. Rauscher, C. Oberkanins; ViennaLab Diagnostics GmbH, Vienna, Austria.*

Introduction: Clopidogrel (Plavix™) is widely prescribed to reduce recurrent ischaemic complications in patients with acute coronary syndromes and/or post-percutaneous interventions. High interindividual variations in and non-responsiveness to clopidogrel-induced platelet inhibition often complicate the treatment. Genetic polymorphisms in the CYP2C19 gene, which encodes the principle enzyme responsible for the bioactivation of this prodrug, lead to reduced enzyme activity and reduced levels of clopidogrel's active metabolite. Patients carrying defective CYP2C19 variants have a higher risk for major adverse cardiovascular events than noncarriers, whereas individuals with increased enzyme activity are more at risk for developing bleeding.
Methods: A genetic test (StripAssay) was developed for the detection of the CYP2C19 loss-of-function alleles *2, *3, *4, *5, *6, *7 and *8, as well as for the gain-of function allele *17. The StripAssay is based on multiplex PCR, followed by reverse-hybridisation of biotin-labeled amplification products to a parallel array of allele-specific oligonucleotides immobilised on membrane teststrips.
Results: Genotyping for functionally enhanced (*17) or defective (*2 - *8) CYP2C19 variants allow the classification of patients into ultrarapid, extensive and poor metabolisers for clopidogrel. Favourable properties, such as the rapid DNA extraction protocol, ready-to-use reagents and teststrips, as well as the potential for automation of the hybridisation/detection step, make the StripAssay convenient and easy to perform within less than six hours.
Conclusion: A simple and reliable diagnostic tool was developed for predicting the response of patients to clopidogrel treatment. The CYP2C19 StripAssay will assist clinicians to achieve a more individualised antiplatelet therapy.

P12.24
Evaluation of GWAS chip-genotyping of fetal DNA extracted from umbilical cord tissue and WGA-DNA extracted from filter paper bloodspots

S. Chappell[1], *W. K. Lee*[2], *S. Shooter*[3], *R. McGinnis*[3], *L. Morgan*[1];
[1]*University of Nottingham, Nottingham, United Kingdom,* [2]*University of Glasgow, Glasgow, United Kingdom,* [3]*Wellcome Trust Sanger Institute, Cambridge, United Kingdom.*

The InterPregGen consortium is searching for maternal and fetal pre-

eclampsia susceptibility genes by genome-wide association screening (GWAS). We examined suitability for chip-genotyping of fetal DNA extracted from umbilical cord tissue and filter paper (Guthrie) blood spots.

Methods:

Cord-DNA was extracted from 50-100mg of umbilical cord. DNA extracted from Guthrie spots was whole genome amplified (WGA) using Illustra GenomePhi-V2.

DNA quality was assessed by agarose electrophoresis and Sequenom genotyping. 36 cord-DNA samples and 18 WGA-DNA samples were genotyped using Illumina HumanOmniExpress BeadChips. Genotyping quality was assessed by subject call rate (CR) and heterozygosity (HET) and by comparing fetal GWAS P-value distributions with distributions for case-control association (ASSOC) and Hardy-Weinberg Equilibrium (HWE) in 2000 pre-eclamptic mothers and 5000 controls already rigorously QCed.

Results:

ASSOC and HWE distributions for cord- and WGA-DNAs with CR>95% were similar to corresponding maternal-case distributions implying absence of frequent, widespread errors in genotypes of cord or WGA subjects. However, CR<95% occurred in 22% of WGA- versus 11% of cord-DNAs and lower CRs were associated with lower HET which was significantly lower in WGA-DNA (0.277; SD0.010) than cord-DNA (0.289; SD0.007) (P<0.0001). Lower CR was also associated with higher genotyping error (lower genotype concordance) in 6 DNA replicates genotyped twice. Cord-DNAs with CR <0.95 had passed initial QC checks; only 1/18 degraded samples had CR <0.99.

Conclusions:

Cord- and WGA-DNA are suitable for GWAS when CR>95%. However, WGA-DNA yields more samples with CR<95%, lower HETs and likely higher genotyping error. Checks of cord-DNA quality are poor predictors of chip-genotyping success.

P12.25

Higher quality standards should be aimed for: feedback from EQA for *KRAS* mutation testing in colorectal cancer

*L. Tembuyser[1], M. Ligtenberg[2], N. Normanno[3], S. Delen[4], H. van Krieken[2], **E. Dequeker**[1];*
[1]University of Leuven, Biomedical Quality Assurance Research Unit, Leuven, Belgium, [2]Radboud University Nijmegen Medical Centre, Department of Pathology, Nijmegen, Netherlands, [3]Istituto Nazionale Tumori – Fondazione Pascale, Naples, Italy, [4]University of Leuven, Leuven, Belgium.

KRAS mutational status has become an essential biomarker in personalized medicine. Since 2009 the ESP *KRAS* EQA Scheme evaluates the reliability and accurateness of *KRAS* testing on a yearly basis.

In the ESP *KRAS* EQA Scheme 2012, 105 laboratories from 26 different countries participated. Participants were asked to test samples from eight invasive colorectal carcinomas and two external quality controls, using routine testing procedures and submitting results within 14 days after sample receipt. Performance was evaluated on both genotype results and written reports.

Only seventy-five out of 105 participants made no genotyping errors (71%). Nineteen laboratories genotyped one out of 10 samples wrong (18%), 11 laboratories made two or more errors (10%). Both false positives and negatives occurred, as well as incorrectly genotyped mutations and technical failures. One sample, mimicking a tumor cell content of 10%, resulted in a high number of false negative results, which uncovers weakness in test performance for samples with less optimal characteristics. The errors and genotyping scores will be studied over the years. Written reports were evaluated for the presence and correctness of 29 elements, of which nine were marked to determine a reporting score. Results indicate that several essential elements are frequently missing, including clinical interpretation, method sensitivity, and use of a reference sequence. Correct nomenclature according to HGVS guidelines is not sufficiently integrated.

The ESP *KRAS* EQA Scheme is an important tool in assessing quality in *KRAS* testing. Results indicate that performance can be improved, both in mutation analysis and result reporting.

Using Lean Six Sigma tools to improve the clinical genetic laboratory

***T. L. Stockley**[1,2];*
[1]The Hospital for Sick Children, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada.

Clinical genetic laboratories are under increasing pressure to provide rapid results on increasingly complex tests, while maintaining low test costs and high levels of quality. In 2012 the Division of Molecular Genetics at the Hospital for Sick Children in Toronto, Canada began a multi-part project to apply Lean Six Sigma methodology to improve efficiency of the hospital's divisional clinical Cytogenetic and Molecular Genetic laboratory operations. Lean Six Sigma methods are continuous improvement tools based on the scientific method to solve chronic process and quality problems. Molecular Genetic and Cytogenetic laboratory operations were analyzed to define highest needs for initial Lean Six Sigma projects, which included 1) Lean facility design for merger of separate Molecular and Cytogenetic laboratory services into a combined Genome Diagnostic laboratory, 2) Process improvement methods to increase throughput of genomic sequence variant reporting and 3) Definition of metrics to manage laboratory workflow and turnaround time. Methods used include Value Stream Mapping to define current and future states, defining wastes and use of 5S to standardize work areas, defining key performance measures for current state and impact of changes, and use of DMAIC (define, measure, analyze, improve, control) cycles as a data drive strategy to solving operational problems. To date the project has achieved improved turnaround time for variant reporting (Molecular Genetics, 20% improvement), and better utilization of space and personnel matched to sample flow in the new Genomic Laboratory.

Ten year experience with the use of real-time PCR in the detection of ΔF508

***B. Nagy**, R. G. Nagy, J. Rigo Jr., L. Lazar;*
1st Dept. of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary.

Objective: Cystic fibrosis is the most common autosomal recessive genetic disorder in the Caucasian population. About 1400 different genetic mutation, deletion, etc. were detected until now in the cystic fibrosis transmembrane regulator gene (CFTR). This makes the molecular diagnosis difficult, while about 60 % of the cases is caused by ΔF508 in Hungary. We started to use the real-time PCR in the clinical genetic practice 10 years ago.

Materials and Methods: We isolated the DNA from 188 samples (High Pure PCR Template Preparation kit; Roche, Germany) from different tissues (97 blood, 14 amnioticfliud cells and 77 CVS). Quantitative real-time PCR with melting curve analysis was performed to detect ΔF508 by using hybridization probe system (TIB MolBiol, Germany).

Results: We detected 112 normal healthy, 65 heterozygous and 9 ΔF508 homozygote samples. We observed recognizable difference in the melting point in the normal (56ºC) and ΔF508 (49ºC) PCR products.

Conclusion: Based on our ten years experience it seems that real-time PCR and melting curve analysis is a reliable and sensitve method for the detection of ΔF508. The source of the sample does not have effect on the results. The applied primer and probe set design gives additional information for the presence of other mutations in the ΔF508 region.

Flexible Throughput RNA Sample QC using the Agilent 2200 TapeStation system

***M. T. Connelly**[1], A. Inche[1], D. Boland[1], A. Padmanaban[2], E. Graf[3], C. Tissott[3];*
[1]Agilent Technologies UK Ltd., Edinburgh, United Kingdom, [2]Agilent Technologies UK Ltd., Bangalore, India, [3]Agilent Technologies UK Ltd., Waldbronn, Germany.

The Agilent TapeStation system provides a flexible solution for automated analysis of up to 96 samples using pre-packaged reagents and minimal manual handling. Here we present a new assay - the RNA ScreenTape assay - to enable robust quantification and quality analysis of Total RNA samples from both eukaryotic and prokaryotic sources from 100 pg/µl to 500 ng/µl. The new assay additionally benefits from the ability to provide separation of contaminant genomic DNA allowing more accurate purity assessment of sample material.

This study compares the performance of the RNA ScreenTape and High Sensitivity RNA ScreenTape assays against the "gold standard" Agilent 2100 Bioanalyzer and NanoDrop for RNA quality and quantity determination. We conclude that the new RNA ScreenTape and High Sensitivity assays provide

correlated data to these existing technologies, as well as exceeding these technologies in terms of flexibility or quality of data generated.

Transcriptome Analysis on the Ion Proton™ System

K. Bramlett[1], *Y. Sun*[2], *J. Schageman*[1], *L. Qu*[1], *C. Hinahon*[1], *B. Setterquist*[1];
[1]*Life Technologies, Austin, TX, United States,* [2]*Life Technologies, San Francisco, CA, United States.*

RNA-Seq technology has become widely utilized as a tool to understand the transcriptome of a given experimental system. This method utilizes next generation sequencing platforms to sequence a cDNA library in order to gain information about the RNA content and transcriptional status of a sample of interest. Profiling the transcriptome of a system in this way has become an invaluable tool in many genomic studies.
The newly launched Proton™ system utilizes the same simplified chemistry first introduced with the Personal Genome Machine (PGM™). The increased sequencing depth of the Proton™ instrument and the Ion PI™ chip now lends this simplified sequencing technology to true whole transcriptome evaluation including sequencing analysis of polyadenylated RNAs, long non-coding RNAs, and non-adenylated transcripts.
Here we report transcriptome sequencing of ribosomal RNA (rRNA) depleted control RNAs analyzed on the Proton™ instrument with the Ion PI™ chip. The transcriptome profiles of two well-studied RNAs utilized in the historic Microarray Quality Consortium (MAQC) were analyzed by Proton™ sequencing. External RNA Control Consortium transcripts (ERCCs) were spiked into the control RNAs to provide a known set of RNA sequences useful in monitoring sample preparation, sequencing and data analysis. Differential expression profiles between two control RNAs generated from transcriptome sequencing on the Proton™ compare well to profiles generated during the MAQC study. This study demonstrating over 50M mapped reads from each Proton™ transcriptome sequencing run and good sensititivity and dynamic range, solidifies the Proton™ sequencing system as a viable platform for complex transcriptome analysis.

RNA-sequencing is an increasingly popular technology for genome-wide analysis of transcript structure and abundance. However, the sources of technical and inter-laboratory variation have not been assessed in a systematic manner. To address this, seven centers of the GEUVADIS consortium sequenced mRNAs and small RNAs of 465 HapMap lymphoblastoid cell lines (incl. large numbers of replicates). The variation between laboratories appeared to be considerably smaller than the already limited biological variation. Laboratory differences mainly manifested in differences in insert size and GC content. The randomized study design allowed nearly full correction of these laboratory effects. In small RNA sequencing, the miRNA content differed widely between samples due to competitive sequencing of rRNA fragments. This did not affect relative quantification of the miRNAs. We conclude distributed RNA-sequencing is well feasible when proper standardization and randomization procedures are used. The combined sequencing data from this project significantly extended our understanding of the genetic basis of transcriptome variation and generated an unprecedented resource of novel transcripts and eQTLs.

High-throughput sample identification and tracking for exome and custom targeted sequencing projects

E. Souche[1], *J. K. J. Van Houdt*[1,2], *K. Herten*[2], *S. Jackmaert*[2], *G. Matthijs*[1], *J. R. Vermeesch*[1,2];
[1]*Center for Human Genetics, KULeuven, Leuven, Belgium,* [2]*Genomics Core, UZ Leuven, Leuven, Belgium.*

New sequencing technologies combined with capture-enrichments methods enable large-scale re-sequencing of whole exomes or targeted gene panels. To ensure quality and traceability in these sequencing efforts we developed a custom SNP panel. It includes 32 highly informative SNPs across European, Asian, and African populations. Most SNPs have a minimum allele frequency of at least 0.3, and are distributed across the genome with one or two SNPs per chromosome. In the latter case we selected one SNP on the P arm and one on the Q arm. The SNPs were selected from regions that are well covered by the different exome capture chemistries and can be reliably genotyped from exome sequencing data. The Sequenom® MassArray® iPlex® Gold - SNP genotyping platform was used for genotyping around 200 samples that have been exome sequenced. Our custom panel allowed the identification of samples swaps and the retrieval of the right samples. Parents-siblings could be easily discriminated, sharing only 50% of genotypes. Our panel provides a highly accurate and robust method for sample tracking and identification. By including the SNP loci in new designs of gene panels, this iPLEX assay can be used for all targeted re-sequencing samples.

P12.32
About sequence quality: impact on clinical applications

T. Noguchi, *V. Bourdon, H. SOBOL;*
Laboratoire d'oncogénétique moléculaire, Marseille, France.

Advance of sequencing technologies is accelerating with a surprisingly fast rhythm, and several new sequencing platforms aimed at small laboratories and the clinical diagnostic market are released. Some of laboratories are already started to test these machines in clinical situations.
Nevertheless, it doesn't necessary mean the end of Sanger sequencing: comparative studies show that performance of next-generation sequencing (NGS) platforms varies considerably and they produce different types of errors. Most annoyingly these machines are based on very dissimilar technologies (a semiconductor technology for the Ion Torrent PGM, a sequencing-by-synthesis technology for Illumina MiSeq) and it makes practically impossible to conceive a standardized clinical platform.
Therefore Sanger sequencing remains the sequencing "gold-standard" for the accreditation of clinical laboratories according to the major international standard ISO 15189.
However, even in Sanger sequencing the sequence quality definition remains fuzzy and too empirical for clinical applications. Available guidelines describing all important parameters to insure the sequence quality didn't give clear advices on how to use them.
We realized a heuristic analysis of more than 31 000 sequence traces generated in the clinical diagnosis and demonstrated that the sequence traces qualities are inherently variable in routine practices and the most commonly used criterion "average quality value" alone is too inaccurate and not sufficient for clinical uses.
We demonstrated that with a combination of three parameters (average quality value, relative sequence intensity and electropherogram profile) and applying our decision making diagram, it is possible to determine accurately the quality of any sequence.

Rapid genotyping for the prevalent mutation of XPC gene: a useful tool for genetic counseling

C. M. Ged[1,2], *S. Bensenouci*[3], *H. Rezvani*[1], *H. de Verneuil*[1], *A. Taieb*[2], *K. Ezzedine*[2];
[1]*INSERM U1035-Université Bordeaux Segalen, Bordeaux, France,* [2]*CHU de Bordeaux Centre des maladies rares de la peau, Bordeaux, France,* [3]*CHU d'Oran, Oran, Algeria.*

Xeroderma Pigmentosum (XP) has a higher prevalence in countries where consanguinity is frequent such as North Africa, where the disease represents a major health concern. Among the 8 defective NER subtypes XP-A to XP-G, type C is the most frequent, with a common frame shift mutation of XPC gene present in more than 90% of the patients. We set up a simple assay based on fragment size analysis which permitted accurate determination of the 3 possible genotypes on an automatic sequencer. Compared to classical sequencing, the method allows substantial lower cost, higher throughput, improved resolution and time saving. We tested 50 DNA samples from 20 unrelated families from Algeria and quickly confirmed the presence of the common frame shift at the homozygous or heterozygous state in affected children and obligate carriers, respectively: 17 unrelated patients (85 %) were accurately diagnosed as XP type C; 3 patients did not harbor the common mutation of XPC gene, 2 had the common nonsense mutation described in XPA gene, and the last one was investigated for XPV gene. Sequencing needs were drastically reduced by using the new assay as a screening test. This work describes a genetic test readily available for screening and diagnostic purposes in XP which may greatly facilitate genetic counseling in exposed families from low-income countries, and help promoting early management of this severely cancer prone and devastating photosensitive disease.

Diagnostic Whole Exome Sequencing in patients with clinically suspected, genetically heterogeneous syndromes

P. Joset*, D. Niedrist, C. Otte, I. Sudholt, K. Steindl, A. Baumer, A. Rauch;*
Institute of Medical Genetics, University of Zurich, Schwerzenbach-Zurich, Switzerland.

Identification of disease causing mutations in genetically heterogeneous conditions by Sanger sequencing is time-consuming, costly and often unsuccessful. Targeted next generation sequencing (NGS) techniques of limited disease specific gene panels enable very deep sequencing likely ensuring low false negative results for the genes investigated, but is not useful if the clinically suspicion was not correct or the affected gene was not in the panel. We therefore investigated the diagnostic power of whole exome sequencing as a mutational screening tool in patients with clinically suspected, genetically heterogeneous syndromes. In order to establish an optimized work-flow for diagnostic whole exome sequencing using the SOLiD 5500XL platform we used DNA of 7 patients with a variety of known disease causing mutations. In the initial approach with pooling of 8 samples on one flowchip 3 mutations out of 5 were not detected due to low coverage. We therefore changed the procedure to pool only 4 samples resulting in an average 100x coverage and optimized the analysis setting by permutation of the various alignment and filter parameters. We then used an optimized protocol with 16% aberrant allele calling in at least 3 reads and 6x coverage to analyze five patients with suspected genetically heterogeneous syndromic diagnosis and unknown mutation. Using these settings disease causing mutations were identified in all 7 subsequently tested patients for Joubert syndrome, Fraser syndrome, Noonan syndrome, primary microcephaly and others. Our results thus demonstrate that whole exome sequencing is a powerful diagnostic tool in patients with suspected genetically heterogeneous syndromes.

ABCB4 gene encodes a canalicular phospholipid translocator MDR3 involved in biliary phosphatidylcholine excretion. Several phenotypes have been described in association with ABCB4 mutations mostly 1) Progressive Familial Intrahepatic Cholestasis 3, a severe liver disease of childhood; 2) Intrahepatic Cholestasis of Pregnancy; 3) "Low Phospholipid Associated Cholelithiasis" syndrome. So far, the genotyping of ABCB4 gene was performed by Sanger technology in all French laboratories involved in this genotyping. Due to a considerable increase of patients to test, Sanger sequencing technology is no longer adapted. Therefore, the aim of the study was to genotype at least 32 patients at the same time using Next Generation Sequencing technology and to compare the most accurate data with those of Sanger technology. Patients were diagnosed with these ABCB4 - related diseases. DNA was extracted from blood using the Puregene kit (Qiagen). Specific PCR of 27 exons and junction introns were performed. Pooling of all PCR was done for each patient and a second PCR was run using multiplexing tag primers (one by patient). After purification of the tag mixture amplification of 32 patients, a pool of the 32 template DNAs was prepared. The library was then submitted to emulsion PCR and pyrosequencing in a picotiter-plate in the 454 Instrument GS Junior (Roche). Several softwares were used to analyze the data. We ran 290 DNAs. The vast majority of sequence variations were confirmed by Sanger technology indicating that this new technology is reliable and time-efficient for the screening of ABCB4 variants on large scale.

Alport syndrome (ATS) is a clinically heterogeneous progressive nephropathy caused by mutations in three large genes: the X-linked COL4A5 gene, thought to be responsible for the majority of cases (85%), and the autosomal COL4A3-COL4A4 genes accounting for a minority of cases (15%). We developed a protocol for the simultaneous analysis of COL4A3-COL4A4-COL4A5 genes using a benchtop Next Generation Sequencer (Artuso et al, 2012 Eur J Hum Genet). Here, this approach is employed to screen a cohort of 100 ATS patients. Overall, 57 mutations are identified in 54 patients, including 41 novel mutations. Unexpectedly, nearly 40% of cases were autosomal, mostly dominant, indicating that autosomal forms are underestimated. The method has proved particularly useful in that fraction of cases (28) that lakked a diagnostic orientation according to traditional criteria and/or formal genetics. In such cases the traditional diagnostic workflow would have led to the analysis of COL4A5 as first, based on mutation frequency prioritization. NGS directly identified a consistent number of autosomal cases (13) with a significant reduction of turnaround time. The most important finding of this study is that a fraction of families (5) that would not have been classified as X-linked, based on traditional criteria relying on the greater severity in males, eventually turned to be X-linked. This last observation shows for the first time X-linked "forme fruste" and highlights the necessity of revaluating the ATS natural history. This in turn might lead to a reassessment of the prognosis that usually is discussed with patients during genetic counseling.

P13.04

Mutation analysis in patients with Alport syndrome using multiplex PCR and next generation sequencing

L. Heidet[1], *V. Morinière*[2], *K. Dahan*[3], *S. Lebbah*[1], *P. Nitschké*[4], *C. Bole*[5], *M. Gubler*[6], *C. Antignac*[2,6,7];
[1]*APHP, Pediatric Nephrology Unit, Necker Hospital, Paris, France,* [2]*APHP, Genetics Department, Necker Hospital, Paris, France,* [3]*IPG, Human Genetics Center, Gosselies, Belgium,* [4]*Paris Descartes University, Bioinformatics department, Paris, France,* [5]*Imagine Fundation, Necker Hospital, Genomics platform, Paris, France,* [6]*Inserm U983, Paris, France,* [7]*Imagine Fundation, Necker Hospital, Paris, France.*

Alport syndrome (AS) is an inherited nephropathy associated with mutations in *COL4A5* (X-linked AS) or in *COL4A3* and *COL4A4* (autosomal recessive and dominant AS). Mutation screening of these 3 large genes is time consuming and expensive. Here we carried out next generation sequencing (NGS) mutation analysis in 70 unrelated patients using a PCR-multiplexing approach allowing amplification of 149 amplicons covering all but 3 exons of the 3 genes. Amplicon-PCR-derived fragments were checked by capillary electrophoresis and then processed for sequence analysis on Ion PGM using the 170-200 bp chemistry, on an Ion 316 chips (Life Tech). Bioinformatic analysis was performed using an in-house web interface. All targeted positions but one were covered at least 15X. We identified 71 mutations (19 in *COL4A5*, 32 in *COL4A3*, 20 in *COL4A4*) thought to be pathogenic in 59 patients. All were confirmed by Sanger sequencing. Genescan analysis of multiplex PCR products allowed the discovery of 5 large rearrangements (3 deletions, 2 duplications) that would not have been detected by conventional sequencing. Sequencing the 3 genes at once was particularly helpful as in 7 cases considered to be likely X-linked (based on genealogy analysis and including one case with weak α5(IV) labelling of skin basement membrane) we found mutations in *COL4A3* or *COL4A4*, and in one case considered to be probably autosomal we identified a *COL4A5* mutation. We conclude that the combined approach of multiplex PCR amplification and NGS is highly efficient, reduces time and cost and strongly facilitates diagnostic mutation analysis in AS.

P13.05

Challenges and solutions for preparing NGS libraries from clinical samples

J. Langmore, *E. Kamberov;*
Rubicon Genomics, Ann Arbor, MI, United States.

Clinical samples are difficult to prepare for NGS. Plasma, serum, urine, single cancer and fetal cells, formalin-fixed tissue, and even fresh tissue are collected as small samples of variable quantity and quality. To obtain high-quality, reproducible results, the enzymology and chemistry of NGS library preparation need to be highly efficient and robust over wide ranges of DNA and RNA size, quantity, and quality. In addition, the libraries must be prepared with minimal number of steps, sample transfers, and elapsed time.
We will show that careful design and quality control of library preparation can yield high-quality libraries by objective criteria, including a) library diversity, b) sensitivity, c) uniformity of coverage, d) balance and breadth of GC coverage, e) reproducibility over a 100X range of sample input and insensitivity to the number of PCR amplification cycles used, and f) high concordance with NGS results from microgram amounts of undamaged DNA using PCR-free methods. These criteria can be routinely achieved for non-invasive prenatal screening, PGS/PGD, and for mutation detection in formalin-fixed tissue and small numbers of circulating tumor cells.

Exome Sequencing Identifies a Novel *RP1* Mutation in a Belgian Family with Autosomal Dominant Retinitis Pigmentosa

C. Van Cauwenbergh[1], *F. Coppieters*[1], *J. De Zaeytijd*[2], *S. De Jaegere*[1], *C. Claes*[3], *E. Fransen*[3], *G. Van Camp*[3], *B. P. Leroy*[2,1], *E. De Baere*[1];
[1]*Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium,* [2]*Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium,* [3]*Center for Medical Genetics, Antwerp University, Antwerp, Belgium.*

Purpose: Identifying the genetic cause in a Belgian family with autosomal dominant retinitis pigmentosa (adRP) using genomewide linkage analysis and exome sequencing.
Methods: Five affected and eight unaffected individuals from a Belgian adRP family underwent genomewide linkage analysis using BeadChips (Illumina) and multipoint linkage analysis (Merlin). Exome sequencing was performed in two affected individuals (TruSeq Exome Enrichment Kit, HiSeq, Illumina). The CLC Genomics Workbench was employed for read mapping and variant calling. Linkage regions and RetNet genes were used for filtering.
Results: Genomewide linkage analysis revealed two regions with a maximum LOD score of 1.7. As to the exome data, 11.3/12.7 and 12.9/14.5 million reads could be mapped against the human genome. Integrated linkage- and RetNet gene-based filtering of exome data revealed a heterozygous *RP1* change in both patients: p.Leu749fs and p.Leu750fs respectively. Of note, variant calling failed to correctly call this change. Sanger sequencing confirmed following mutation: c.2245_2248delinsTGAG (p.Leu749X). This mutation co-segregates with disease, one unaffected individual excepted, suggesting incomplete penetrance. It creates a premature stop codon that may lead to a truncated protein. The mutation belongs to the 'Class II' mutations, frequently reported nonsense mediated decay-insensitive truncations, with a net dominant negative effect.
Conclusions: Combined linkage-based filtering of exome data revealed a novel *RP1* mutation in a Belgian pedigree with adRP. Our study expands the spectrum of *RP1* Class II mutations leading to adRP with incomplete penetrance. Interestingly, the findings of this study can be used as a starting point for further research on modifiers influencing *RP1* expression.

We have established a National Registry of Balanced Translocations and Inversions in Finland by ascertaining all known Finnish carriers (n=2575). Our registry contains medical records of all available carriers in each family including relatives carrying the same rearrangement identical-by-descent. As a pilot study, we have focused on families identified from this resource, which appear to have a phenotype correlating to the balanced translocation. In our first gene mapping pilot we identified a potential positional candidate gene for intracranial and aortic aneurysm. Here, we present a family where all carriers (n=6) of t(1;12) manifest first with learning problems and later with unexplained neurological symptoms, which seem to lead to cerebral infarctions without identified predisposing factor.
Conventional methods for breakpoint mapping are laborious and with insufficient resolution to identify the disrupted loci. The next-generation sequencing paired end approach serves this aim exceptionally well, as it allows focusing on the precise break region from the vast DNA information overload. Here, we employ genome-wide mate pair sequencing using Illumina platform to fine-map and subsequently identify the specific breakpoints in this family.
Disease-associated balanced rearrangements are a unique resource for bridging genotype to phenotype in patients with both early-onset Mendelian disorders as well as complex and late-onset diseases. Our registry facilitates diagnostic purposes, genetic counseling, and subsequent follow-up and, moreover, the identification of asymptomatic carriers in at-risk families. It also provides us momentum towards characterizing more generally the molecular basis of all translocations in Finland and their associated phenotypic effects.

Targeted high-throughput sequencing for mutation detection in Bardet-Biedl Italian patients

S. Palchetti, *C. Pescucci, I. Passerini, G. Marseglia, M. Benelli, A. Sodi, L. Berti, U. Menchini, F. Torricelli;*
AOU Careggi, Florence, Italy.

Bardet-Biedl syndrome (BBS) is characterized by truncal obesity, polydactyly, hypogonadism, developmental delay, learning disabilities, progressive retinopathy, renal disease and susceptibility to diabetes mellitus. Although BBS is mainly transmitted in an autosomal recessive manner, few families exhibit a tri-allelic mode of inheritance. To date, 16 different BBS genes (BBS1-BBS16) are known and BBS1 and BBS10 show the highest mutation frequency in BBS patients.
Six unrelated patients evaluated by standard ophthalmologic examination and with a clinical diagnosis of BBS were analysed by targeted re-sequencing of 130 retinopathies-related genes on HiScanSQ Illumina platform (mean coverage 500X). Bioinformatic analysis identified a mean of 1100 sequence variants per sample. Filtering pipeline (exonic function, frequency, prediction and inheritance model) leads to distil a mean of 10 candidate variants per sample. The candidate variants were independently validated by Sanger sequencing and segregation analysis was performed.
We identified two known causative deletions in BBS9 (c.1877_1880del) and BBS7 (c.712_715del) genes and a novel frameshift deletion in BBS10 (c.804_805del). Morever, a patient is compound heterozygote for two novel variants in BBS10 (c.1677_1678insA and c.1220T>C); one patient present a homozygous variant in BBS2 gene (c.209A>G) and one novel heterozygous variant (c.538C>T) in BBS3 gene. The last patient has two variants in BBS12 gene both in homozygous status [c.1044del (novel) and c.61T>C (described)].
NGS approach has enabled us to detect variants in BBS genes. Although for described variants and ins/del frameshif variants the genotype-phenotype correlation is clear, in order to clarify tri-allelic variants' role in BBS-onset, further association studies are required.

Next-generation sequencing (NGS) methods are advancing in genome diagnostics laboratories worldwide. However, the implementation of NGS based tests according to diagnostic standards is challenging for individual diagnostic laboratories. In order to facilitate the implementation of NGS in the Dutch laboratories the Dutch Society for Clinical Genetic Laboratory Diagnostics (VKGL) initiated a workgroup. The result of this workgroup will be presented. We provide best practice guidelines and criteria for validation and implementation of NGS applications in a clinical setting. We introduce the concept of 'diagnostic yield' as the main performance characteristic to evaluate diagnostic testing for a given genetic disease. We recommend that the laboratory procedures including the tested genes are recorded in a publicly available document describing the complete 'diagnostic routing'. In addition, we propose the use of a 'core disease gene list' for specified genetic diseases. This core disease gene list encloses the significant genes for a defined genetic disorder and these should all be included in a diagnostic test in order to establish a molecular diagnosis. This will ensure a clear and standardized quality of care throughout the genetic diagnostic laboratories. The best practice guidelines and criteria that will be presented are accepted by Dutch Society for Clinical Genetic Laboratory Diagnostics.

P13.10

Targeted next generation sequencing approach of Brugada syndrome and sudden cardiac death

D. Proost[1], *G. Vandeweyer*[1], *G. Mortier*[1], *C. Vrints*[2], *B. Loeys*[1], *J. Saenen*[2], *L. Van Laer*[1];
[1]*Center of medical genetics, University of Antwerp, Antwerp, Belgium,* [2]*Department of Cardiology, Antwerp University Hospital, Antwerp, Belgium.*

Brugada syndrome (BrS) is a heritable primary electrical disorder with typical ECG alterations accounting for up to 20% of sudden cardiac death (SCD) in young patients (<45 yrs) without apparent structural cardiac abnormalities. BrS is genetically heterogeneous and so far a dozen causative genes have been identified. A clinical diagnosis is not always straightforward as expressivity is variable and penetrance is low. Therefore molecular confirmation of the diagnosis is important for further patient management and therapy. The consecutive molecular screening of all BrS genes using conventional methods is expensive and labor-intensive. To shorten the turn-around-timeand to reduce the overall cost of molecular testing, we have developed a BrS gene panel for next generation sequencing of eight BrS genes (*CACNA1C, CACNA2D1,CACNB2,GPD1L,KCNE3,SCN1B,SCN3B* and *SCN5A).*
After optimalisation of multiplex PCR, designed by Multiplicom, sequencing was initially performed on a GS junior (Roche), and later adapted for Miseq (Illumina). To date we have screened 58 patients: 8 patients with unexplained SCD, 14 patients with atypical BrS ECGs and 36 patients with type 1 BrS ECGs. We identified 15 genetic variants, all in the latter group. Twelve variants (10 mutations and 2 variants of unknown significance) were discovered in the *SCN5A* gene, whereas one and two mutations were identified in *CACNA1C* and *CACNB2*, respectively. Our results demonstrate that a next generation panel approach can increase the genetic yield from 33% (if only SCN5A analysed) to 42% in probands with typical BrS ECGs, whereas no mutations werd found in atypical BrS or unexplained cardiac deaths.

Brugada syndrome (BS) is a cardiac arrhythmic disorder characterized by typical electrocardiographic pattern that can lead to sudden cardiac death at young age.
BS is inherited as an autosomal dominant trait with incomplete penetrance and variable phenotype expressivity; however, genetic bases have been only partially understood. Most mutations are located in the SCN5A gene, encoding the α-subunit of the Na+ cardiac channel, but more than 70% of BS patients remain genetically undiagnosed.
Our study aims to increase the proportion of genetically diagnosed BS patients, identifying new syndrome-related genes and causative variants by target resequencing.
We analysed 100 BS patients for a panel of 158 candidate genes, mainly encoding cardiac ion channels, structural proteins, modulators of ionic flow and regulatory proteins. We used the Agilent SureSelect target enrichment protocol and we performed the deep sequencing on Illumina GAIIx. We also developed an automated bioinformatics pipeline based on BWA aligner to map reads versus the hg19 reference with great accuracy. For each sample, at least 2 million paired-end reads was successfully mapped. More than 98% of the target sequences were covered with more than 230X mean depth by gene and the 90% of the bases are sequenced above a 50X depth.
We detected 87 novel missense mutations, 2 nonsense and 2 splice-site variants, 16 indels in 64 different genes. Almost all of these mutations are privates. In 25 candidate genes we identified also 48 clinical variants that can contribute to phenotype modulation.

Kingdom, [4]Department of Cardiac Surgery, Children's Hospital Boston, Harvard Medical School, Boston, MA, United States, [5]USSD Cardiochirurgia Pediatrica, Bergamo, Italy, [6]Dipartimento Cardiovascolare, Bergamo, Italy, [7]German Center for Cardiovascular Research (DZHK), Charité, Berlin, Germany.

BACKGROUND: The hypoplastic left heart syndrome (HLHS), mainly characterized by an underdeveloped left ventricle, accounts for significant mortality and morbidity in infancy. Despite strong evidence of an underlying genetic aetiology, only a minority of cases can be explained on genetic bases. Our aim was to discover novel causative genes using whole-exome sequencing (WES) in combination with functional studies in zebrafish and cellular models.

METHODS AND RESULTS: We have analyzed by WES 15 unrelated parents-child trios. Our analyses lead to the identification of several *de novo* mutations in different genes involved in cardiac development and tissue remodeling in heart. Missense mutations have been detected in genes belonging to HDAC pathway, which regulates mesoderm differentiation into cardiac muscle cells. Other genes are associated to NOTCH signaling pathway, which is involved in impaired endothelial to mesenchymal transition (EndMT). Using morpholino antisense oligonucleotides in a novel candidate gene, we were able to show severely impaired chamber formation. Moreover, our newly established animal model of endocardial fibroelastosis strengthened the role of aberrant EndMT in the development of HLHS.

CONCLUSIONS: Our results confirm an extreme genetic heterogeneity in HLHS pathogenesis, as previously reported by our group. Moreover, our data suggest that different molecular defects interfering with EndMT, development of the atrioventricular valves and ventricular chamber formation are at basis of HLHS. The elucidation of genetic defects of HLHS may lead to a more appropriate classification of patients potentially useful for therapeutic management.

Comprehensive molecular genetic analysis for Arrhythmogenic Cardiomyopathy: conventional and Next Generation Sequencing

E. Lazzarini[1], *A. Albiero*[2], *I. Rigato*[1], *B. Simionati*[2], *E. Carturan*[1], *D. Corrado*[1], *G. Thiene*[1], *C. Basso*[1], *K. Pilichou*[1];
[1]Department of Cardiac Thoracic and Vascular Sciences, University of Padua, Padua, Italy, [2]BMR Genomics, Padua, Italy.

Background: Arrhythmogenic cardiomyopathy (AC) is an autosomal dominant disease characterized by progressive fibrofatty replacement of the working myocardium and an increased risk of sudden death. Mutations in desmosomal encoding genes are accounting for
approximately 50% of AC patients and 10% of AC patients are multiple mutation carriers.

Aim: The aim of the present study was to develop a NGS whole-exome strategy in order to assess its potential diagnostic value in comparison with conventional screening approaches.

Methods: Twenty-eight patients identified by classical clinical screening at the Referential Clinical-Genetic Centre of Arrhythmic Cardiomyopathies underwent genetic evaluation. Nucleotide sequencing was performed both on an Applied Biosystems 3730XL DNA Analyzer and an Illumina Hiseq2100 platform. Novel variations absent in NHLBI GO Exome Sequencing Project (ESP) and dbSNP databases, were considered potentially pathogenetic.

Results: Sanger sequencing identified causative mutations in 82% of the probands, of which 11 were multiple mutation carriers. Novel putative causative nucleotide variations were identified in desmocolin-2 (S868F, T524A, H604L, N629L), plakoglobin (A458T, E654L), desmoglein-2 (N330T, N330H, R292H, I386F), desmoplakin (L2487fsX189, C2259X, E2090K, E1833V) and plakophilin-2 (H179N, K37X, N670fsX683, S70N) genes. Whole-exome sequencing confirmed 68 out of 90 variations, including causative mutations and polymorphisms, with a sensitivity of 80% and a specificity of 100%.

Conclusions: Whole-Exome Sequencing represents a fast, cost-effective and comprehensive approach for mutation screening, however further data are needed to optimize variant detection parameters and therefore to define it as a diagnostic tool for AC.

P13.14

Adiponectin G276T gene polymorphism is associated with myocardial infarction in south Indian patients with type 2 diabetes: A hospital based study

S. Dayakar[1,2,3], *T. Parvathi Kumara Reddy*[4], *B. Shyamala Sesikeran*[3], *M. Sadhnani*[5];
[1]Post Box No:1096, Flat No:48, Area 9, Pacific Village, Lilongwe, Malawi, [2]Department of Clinical Biochemistry, Institute of Genetics and Hospital for Genetic Diseases,Osmania University, Hyderabad, India, [3]Apollo Hospitals Educational And Research Foundation, Hyderabad, India, [4]Instituto de Genetica,Dpto.de Biología Molecular Y Genomica, Centro Universitario de, Guadalajara, Jalisco, Mexico, [5]Department of Clinical Biochemistry, Institute of Genetics and Hospital for Genetic Diseases,Osmania University, Hyderabad-500016, India.

Adiponectin has anti-atherogenic properties and reduced serum adiponectin levels are associated with Myocardial infarction (MI). In this study, we examined the relationship between MI and *adiponectin* (*ADIPOQ*) gene G276T polymorphism that is associated with serum adiponectin levels in type 2 diabetic patients. We enrolled 425 subjects with type 2 diabetic (males, 61.1%; age, 54.9 ± 7.9 years old) to determine their genotypes regarding *ADIPOQ* G276T polymorphisms, and evaluated the association between this polymorphism and the prevalence of MI. The prevalence of MI tended to be higher as the number of G alleles increased [GG (9.5%), GT (6.8%), TT (5.6%), p value for trend = 0.0059] and was significantly higher in the subjects with GG genotype compared to those with GT or TT genotype (9.5% vs. 6.6%, p = 0.0060). Multiple logistic regression analyses revealed that the number of G alleles (Odds ratio (OR) = 1.49 with 95%) CI 1.09-2.05, p = 0.0125) and GG genotype (OR = 1.66 with 95%CI 1.13-2.43, p = 0.0098) were significantly associated with MI even after adjustment for conventional risk factors. Interestingly, further the presence of obesity significantly increased the risk of MI in the subjects with GG genotype (OR = 1.67 with 95%CI 1.14-2.44, p = 0.0090) but not in the subjects with TT or GT genotype (OR = 1.17 with 95%CI 0.73-1.89, NS). It is likely that the G allele of the *ADIPOQ* G276T polymorphism is a susceptibility allele for MI in type 2 diabetic patients, especially when they accompany with obesity.

Introduction of NGS in diagnostics for cardiomyopathies results in increased diagnostic yield

M. van Slegtenhorst[1], *M. van Tienhoven*[1], *M. Wessels*[1], *C. Kockx*[2], *J. Verhagen*[1], *M. Michels*[3], *W. van Ijcken*[2], *H. Brüggenwirth*[1], *D. Halley*[1];
[1]Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands, [2]Center for Biomics, Erasmus Medical Center, Rotterdam, Netherlands, [3]Department of Cardiology, Erasmus Medical Center, Rotterdam, Netherlands.

Cardiomyopathies are a group of disorders characterised by extreme genetic and clinical heterogeneity, with >40 causative genes known to date. In the past 10 years, diagnostic testing of affected individuals using serial Sanger sequencing of a limited number of genes has been expensive and time-consuming. The aim of this study was to develop an NGS-based workflow for routine diagnostics to improve genetic testing for a group of cardiomyopathy patients (HCM/DCM/NCCM).

An NGS-based targeted workflow was designed by developing an enrichment array (Agilent Sure Select) for 46 genes, running12 pooled barcoded samples on the Miseq system (Illumina), followed by mapping and variant calling using the SeqNext software package (JSI). Fifteen frequently mutated genes, previously tested by Sanger sequencing, were selected to validate the process. Testing the workflow also showed that it is possible to detect deletions of up to 65 bp and duplications of up to 28 bp.

At present, samples of the first 55 patients have been tested and analysed. Fifteen patients showed a pathogenic mutation and in five of them, the causative mutation would not have been found using the conventional approach. Furthermore, in a young severely affected patient at least two pathogenic mutations were identified. Variants of unknown significance (VUS) were found in 27 patients and 13 patients did not show any pathogenic mutation or VUS.

In conclusion, targeted NGS is an effective approach for cardiomyopathy diagnostics, resulting in increased diagnostic yield. One of the major challenges remaining is to solve the increased number of VUS identified.

[1]*Murdoch Childrens Research Institute, Melbourne, Australia,* [2]*Centenary Institute, Sydney, Australia,* [3]*Baker IDI Research Institute, Melbourne, Australia,* [4]*Royal Melbourne Hospital, Melbourne, Australia.*

Inherited cardiac diseases, such as cardiomyopathy or inherited arrhythmia, are clinically important genetic disorders, as well as significant causes of sudden death. Genetic testing for these conditions remains limited due to complex genetic pathology. They are often heterogeneous disorders with overlapping clinical symptoms, which may not always be penetrant. This adds to the complexity of determining whether variants identified are pathogenic, influence clinical severity or just normal variation within the genes. In addition some of the associated genes are amongst the largest genes described, which further reduces the practicality of detailed genetic testing and the availability of published information.
We have developed a 100-gene cardiac next generation sequencing [NGS] panel to screen for the arrhythmias, cardiomyopathies, aortopathies and unexplained sudden death conditions. To date we have tested greater than 150 samples. By analyzing the entire gene panel in all samples, we have been able to determine the value of the clinical phenotype to variant analyses, normal variation within these genes, and identified possible new gene associations for these conditions. In addition, we have been able to further determine the strengths and limitations of different forms of NGS technology and the validations required for use of this technology in clinical testing.

Analyses of 96 samples

Panel	Disorder	Pathogenic	Unclassified	Negative
Arrhythmia [28 genes]	LQT	13	3	2
	Brugada	3	-	1
	CPVT	3	1	1
	ARVC	2	-	-
Cardiomyopathy [65genes]	DCM	3	3	-
	HCM	17	4	15
72 gene panel	Sudden Death	15	7	3

P13.17

Genetic causes of cardiomyopathies identified by Whole Exome Sequencing

F. Girolami[1], *S. Bardi*[1], *M. Benelli*[1], *E. Contini*[1], *G. Marseglia*[1], *C. Pescucci*[1], *B. Tomberli*[2], *F. Cecchi*[2], *I. Olivotto*[3], *F. Torricelli*[1];
[1]*Genetic Diagnostic Unit, Careggi University Hospital, Florence, Italy,* [2]*University of Florence, Department of Clinical and Experimental Medicine, Florence, Italy,* [3]*Referral Center for Myocardial Diseases, Florence, Italy.*

Genetic basis of hereditary cardiomyopathies (CMs) are not yet entirely understood. We studied 12 patients with different form of hereditary CMs, by Whole Exome Sequencing (WES).
Twelve families with early onset CMs were selected: 8 families with hypertrophic cardiomyopathy (HCM), 1 with dilated cardiomyopathy, 1 with arrhythmogenic cardiomyopathy, 1 with unexplained juvenile sudden cardiac death and 1 unclassified form. WES was performed on IlluminaHiScan SQ platform. After bioinformatics analysis, data were filtered and the cosegregation was tested in the family.
We obtained 98% mapped reads against genome with mean coverage on target of 60X. More than 61000 variants were found within each family. Variant calling selected about 18700 of them, both exonic and splice-site. By filtering and prioritization about 20 previously unreported variants were selected for each sample. However, only 4 of them turned out to be potential mutations. Cosegregation analysis, performed in 7 families, identified two potentially disease-causing mutations: the c. 1357C>T (p.Arg453Cys)myosin heavy chain 7 gene variant in a large Italian family with HCM, and thec.878A>T, (p.Glu293Val) desmoplakin gene variant in a family with ARVC.
Whole exome sequencing enable the identification of causative variant in two-third of families with hereditary CMs. These preliminary results underline the promising role of NGS technologies. However, due to the huge amount of data arising from NGS analysis, bioinformatics management becomes crucial and traditional genetic rules are still needed to understand and interpret the real significance of new variants.

A novel strategy for identification of Performance Enhancing Polymorphisms in athletes: new determinants that can modify Hypertrophic cardiomyopathy (HCM) risk

S. I. R. Santos[1,2,3], *V. Marques*[2,4], *P. Justiniano*[2], *J. Quintas*[2], *P. V. Baptista*[5], *A. R. Fernandes*[1,2,3];
[1]*Instituto Superior Técnico, Lisboa, Portugal,* [2]*Escola de Engenharia, Universidade Lusófona de Humanidades e Tecnologias, Lisboa, Portugal,* [3]*Departamento Ciências da Vida, FCT, New University of Lisbon, Caparica, Portugal,* [4]*Faculdade de Farmácia, Universidade de Lisboa, Lisboa, Portugal,* [5]*CIGMH, Departamento de Ciências da Vida, Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Caparica, Portugal.*

In the last years, performance enhancing polymorphisms (PEPs) have been described as genetic variants that relevantly influence phenotypic traits related to athletic performance. Hypertrophic cardiomyopathy (HCM), an autossomal dominant genetic disease, is the primary cause of sudden cardiac death in the young and athletes. PEPs have been identified in over 230 genes, both in nuclear and mitochondrial DNA, coding for proteins involved in metabolic pathways, oxygen transport, muscle biogenesis and blood flow. Therefore, it is important to tackle the most relevant genetic features related to physical performance that can influence training adaptation and/or HCM risk being in this regard, considered molecular biomarkers related to athletic performance.
Our aim was to identify PEPs in 20 normal athletes and 20 HCM pacients (athletes) of a Portuguese cohort in 19 genes previously described: ACE, ACTN2, ACTN3, ADRA2A, AGTR1, BDKRB2, CALM3, CKM, EPAS1, FHL1, GLA, MTDN5, NEXN, NOS3, PPARα, PPARGC1A, RAF1, TTR and VCL. Athletes´ DNA was extracted from peripheral blood and genotyped using high throughputt technologies such as High Resolution Melting (HRM) (LightCycler 480®, Roche) and Next Generation Sequencing (NGS) (Ion Torrent PGM platform, Life Technologies®) for which a genomic library was specifically constructed. Using HRM several polymorphisms were identified in ACTN2, AGTR1, GLA, RAF1 and TTR genes. Moreover, several new genetic variations were identified by NGS, nevertheless, due to the high complexity of NGS data analysis, these results are still under validation. Genetic data provided from these studies will allow contributing to establish an association between PEPs, athletic performance and HCM risk.

Massive parallel Sequencing in non-syndromic familial CHD

Y. Jia[1], *J. Louw*[1], *J. Breckpot*[1], *M. Gewillig*[2], *K. Devriendt*[1], *A. Corveleyn*[3];
[1]*Department of Human Genetics, University Hospitals Leuven, Leuven, Belgium,* [2]*Cardiovascular Developmental Biology, University Hospitals Leuven, Leuven, Belgium,* [3]*Laboratory for Molecular Diagnosis, University Hospitals Leuven, Leuven, Belgium.*

The majority (~74%) of Congenital Heart Defects (CHD) occurs as an isolated defect (non-syndromic CHD). Non-syndromic CHD with familial recurrence represent ~4% of all CHD cases. Identification of disease genes involved in non-sydromic CHD is difficult, not only different genes can be involved, also different inheritance patterns exist. Resequencing all genes using massive parallel sequencing technology offers the unique opportunity to identify causative mutations. In order to determine the proportion of non-syndromic familial CHD cases that can be explained by the currently known cardiac genes, we performed targeted sequencing in selected non-syndromic CHD families. For target genes capturing, we used NimbleGen Sequence Capture 385K Arrays and NimbleGen SeqCap EZ Choice library. We included 43 genes and 13 miRNAs in the probe design for the arrays, and 14 additional genes in the in-solution library. The target genes were selected via CHD Wiki (http://homes.esat.kuleuven.be/~bioiuser/chdwiki). The sequencing was initially performed on the 454 FLX platform and subsequently on the Illumina HiSeq 2000 platform. In total we performed targeted sequencing in 39 patients from 15 non-syndromic CHD families. The sequencing coverage is highly reproducible and uniform between multiple samples. The data analysis is ongoing and results will be presented at the meeting. For the families in which no shared mutation in the affected members were found in the target genes, we will perform exome sequencing to search for novel CHD associated genes.

Exome sequencing in research and diagnosis of Congenital Disorders of Glycosylation

*C. Medrano[1], A. I. Vega[1], J. Wesselink[2,3], P. Gómez-Puertas[2,3], L. R. Desviat[1], M. Ugarte[1], C. Pérez-Cerdá[1], **B. Pérez**[1];*
[1]CEDEM, CBMSO (CSIC-UAM), CIBERER-Madrid, IDIPAZ, Madrid, Spain, [2]BioMol-Informatics, S.L., Universidad Autóma de Madrid, Madrid, Spain, [3]Centro de Biología Molecular Severo Ochoa (CSIC-UAM), Universidad Autónoma de Madrid, Madrid, Spain.

Congenital disorders of glycosylation (CDG) are a heterogeneous group of disorders caused by genetic defects in the protein glycosylation pathway. Most of them have a wide clinical spectrum and biochemical approaches cannot point out to a solely genetic defect, making diagnosis complicated and high-time consuming. Up to now, we have detected over 40 CDG patients but there is still remaining a group of unsolved cases. Here we present the preliminary results obtained by whole exome sequencing in a group of 7 patients clinically and biochemically selected as potential CDGs. The analysis was performed by combination of in solution capture kit SureSelect (Agilent) and subsequent next-generation sequencing with HiSeq (Illumina). On average, coverage was 50 fold and we detected over 270.000 SNVs per patient. We performed an *in silico* capture of 150 candidate genes involved not only in the glycosylation pathway but also in galactosemia, glycogen storage diseases and nucleotide-sugars and dolichol synthesis pathway. We also filtered them out so that their frequency in Exome Sequencing Project (ESP) were lower than 0.5% and focused on pathogenic changes predicted by SIFT and mutations already described in HGMD®professional. The initial results have allowed the detection of pathogenic mutations in DPAGT1, DPM1 and GALT genes. Based on the clinical and biochemical features of the GALT patient, we analyzed and identified two more GALT-deficient patients by Sanger sequencing. In summary, whole exome sequencing is a potential technique that provides an efficient analysis for heterogeneous disorders comprising a large cohort of genes such as CDG.

P13.21

Profiling circulating miRNAs in plasma samples of Celiac Disease patients

***R. Almeida**[1,2], V. Kumar[1], R. Moderman[1], C. Wijmenga[1], M. Laass[3], S. Withoff[1];*
[1]Department of Genetics, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [2]University of Brasilia, Brasília, Brazil, [3]3Department of Pediatric Gastroenterology and Hepatology, Technical University Dresden, Dresden, Germany.

Celiac disease (CeD) is an autoimmune disorder triggered by gluten in genetically predisposed individuals. Its affects around 1% of the world population and thus far the only treatment available is a gluten-free diet (GFD). Diagnosis of CeD is currently based on symptoms and serology, but vague symptoms can mean that possibly 7 out of 8 patients with CeD are not diagnosed or misdiagnosed. We aim to identify novel biomarkers that can lead to better identification and monitoring of this disease.
MicroRNAs (miRNA) are small non-coding RNAs that are involved in many cellular processes by fine-tuning gene expression. Recently, it was found that circulating miRNAs in plasma can be excellent biomarkers for disease or even the disease-stage, partly because of their unexpected stability in plasma.
We aim to profile circulating miRNAs in plasma samples from CeD patients before and after GFD. To date, we have isolated miRNAs from 10 plasma samples from 5 individuals (5 samples before and 5 after GFD). Next generation sequencing libraries were sequenced on the Illumina HiSeq2000 and the results were analyzed using previously described methods. In a pilot experiment, we found miR-155 to be significantly more highly expressed before GFD than afterwards (*P*-value=0.04). MiR-155 is known to be involved in inflammation and immunity, and it activates the innate immune system and Th1 and Th17 cells. We are now expanding this cohort to 50 patients to validate the results and improve the power to discover novel biomarkers.

Hedgehog acetyltransferase (HHAT) mutation in autosomal recessive chondrodysplasia-pseudohermaphrodism syndrome identified by exome sequencing.

***P. Callier**[1], P. Calvel[2], M. Resh[3], P. Makrythanasis[2], C. Thauvin[1], F. Santoni[2], M. Guiponni[2], A. Vannier[2], S. Lambert[1], F. Huet[1], F. Mugneret[1], L. Faivre[1], S. Antonarakis[2], S. Nef[2];*
[1]Département de Génétique, Dijon, France, [2]Department of Genetic Medicine and Development, Geneve, Switzerland, [3]Cell Biology program, Memorial Sloan-Kettering Cancer Center, New York, NY, United States.

Chondrodysplasia-pseudohermaphrodism syndrome (MIM 600092) following autosomal recessive inheritance has only been reported in 2 siblings in literature [Nivelon et al., 1992]. The clinical phenotype comprised severe dwarfism with generalized chondrodysplasia, severe microcephaly with cerebellar vermis hypoplasia, facial anomalies, hypoplastic irides, coloboma of both optic discs, myotonia and 46,XY disorder of sexual development with complete gonadal dysgenesis. Until now, the pathogenesis of this striking association was unknown. Here, we report for the first time the involvement of HHAT (*H*edge*h*og *a*cetyl*t*ransferase) in this congenital human disorder using exome sequencing. Within 13 genes with mutations compatible with an autosomal recessive inheritance, we identified a homozygous missense mutation (p.G287V) of HHAT, confirmed by Sanger sequencing. HHAT is a protein catalysing the attachment of a palmitate moiety to hedgehog proteins, thus enabling their long-range action as morphogens during embryonic development. Functional studies showed that the palmitol transferase activity of the G287V mutant HHAT protein is abolished in vitro. Interestingly, previous analysis of *hhat*-deficient mice [Dennis JF et al ., 2012 (PMID:23055936) and Chen MH et al., 2004 (PMID:15075292)] showed early lethality associated to reduced growth, chondrodysplasia and holoprosencephaly. These data suggest that mutation in the HHAT gene is responsible for the Chondrodysplasia-pseudohermaphrodism syndrome by modification of Hedgehog proteins action due to defective palmitoylation.

P13.23

Gene panels for the rapid diagnosis of connective tissue disorders and familial arterial diseases

***P. J. Coucke**, M. Baetens, K. Wettinck, I. Vereecke, E. Debals, W. Steyaert, F. Malfait, O. Vanakker, B. Callewaert, J. De Backer, S. Lefever, J. Vandesompele, S. Symoens, A. De Paepe; Center for Medical Genetics, Gent, Belgium.*

Genetically heterogeneous connective tissue disorders, such as the Ehlers-Danlos syndrome (EDS), Cutis Laxa (CL) or Familial Thoracic Aortic Aneurysms (FTAA) are cumbersome to diagnose at the molecular level due to overlapping clinical features that hamper the selection of the right gene for testing. Next Generation Sequencing (NGS) technology has enabled the development of gene panels which provide a clinically relevant and cost effective solution for the molecular diagnosis of those heterogeneous disorders. Here, we present a highly efficient approach for the diagnosis of a range of genetically heterogeneous connective tissue disorders. We developed 9 panels (*FTAA-panel1-2; EDS-panel1-2; OI panel1-2 (Osteogenesis Imperfecta); CL panel; PXE panel (Pseudoxanthoma Elasticum); ST panel (Stickler))* for a total of 51 causative genes. Using a high-throughput PCR enrichment platform, all coding exons are amplified by a uniform PCR approach followed with paired-end sequencing on a 454 NGS sequencer (Roche), hereby significantly enhancing the efficiency of this approach. With the application of our new FTAA panel 1 containing 7 FTAA genes (*FBN1, TGFBR1/2, ACTA2, TGFB2, SMAD3 and COL3A1*), we identified causative mutations in 10 of 35 patients with a syndromal or non-syndromal form of FTAA. Interestingly, in several of them the nature of the causative gene revealed to be different from the initially suspected gene. Moreover, in some, the mutation had remained undetected with conventional sequencing, illustrating the power of this efficient strategy. Concurrent work is exploring this NGS approach on the MiSeq instrument (Illumina).

P13.24

Cystic fibrosis and molecular analysis of CFTR locus: comparison of three technical approaches by targeted Next Generation Sequencing (NGS)

***P. Gueguen**[1,2,3], M. Audrezet[1,2], A. Despres[1], C. Le Marechal[1,2,3], C. Ferec[1,2,3];*
[1]Laboratoire de génétique moléculaire - CHRU, Brest, France, [2]INSERM U1078, Brest, France, [3]Faculté de Médecine, UBO, Brest, France.

23 years after the discovery of the *CFTR* gene, more than 1900 anomalies are described in the world, the majority of them being single base-pair substitutions or micro-insertions/deletions. Identification of mutations has important implications for genetic counselling, prenatal diagnosis, cascade screening in families, as well as for understanding the genotype-phenotype relationship.
Since a few years, NGS technologies enable us to overcome the classical approaches of whole coding sequence sequencing at single nucleotide resolution.
The aim of our study is to compare 3 different strategies with the Ion Torrent

technology (Life Technologies, LT): Ampliseq (LT), Haloplex (Agilent) and home-made Long Range PCR (LR).
Preliminary results showed that the coverage of the *CFTR* locus by Ampliseq is limited to 51% and includes 86% of exons with a depth generally consistent between amplicons. Haloplex approach gives more heterogeneous depth and coverage. Finally, LR-PCR showed coverage consistent with the design but differences at depth between each LR amplification.
The development of libraries by the two first approaches is rapid (less than 24h) and technically easy. For LR-PCR, It takes about two days to build a library with long and time- consuming manual steps.
Sequencing result for the *CFTR* gene were validated with wild-type samples and DNA carrying known variants (mutations and polymorphisms) previously identified by DHPLC, HRM and sequencing.
In conclusion, the sequencing of the entire *CFTR* locus by NGS is a tool that can quickly respond to issues such as prenatal diagnostic and the most promising approach seems to be the LR strategy.

P13.25
Development of a comprehensive gene screen for dilated cardiomyopathy using next-generation sequencing.

S. L. Reid[1], *K. Thomson*[1], *J. Woodley*[1], *M. Shanks*[1], *J. Taylor*[1], *J. Hayesmoore*[1], *E. Blair*[2], *H. Watkins*[3], *A. Seller*[1];
[1]*Oxford Molecular Genetics Laboratory, Oxford, United Kingdom,* [2]*Department of Clinical Genetics, Oxford, United Kingdom,* [3]*Oxford University Department of Cardiovascular Medicine, Oxford, United Kingdom.*

Dilated cardiomyopathy (DCM) is a heart muscle disease with an estimated prevalence of 1:2500; it is clinically heterogeneous and appears to be familial in ~30% of cases. The genetic basis of DCM is complex with over 30 genes reported to be involved, few are associated with any differentiating phenotype and the majority of genes account for less than 1% of cases. This clinical and genetic heterogeneity means that traditional analysis strategies, undertaking testing on a gene by gene basis, have had limited utility in a clinical setting. Next Generation Sequencing (NGS) technology means that it is now feasible to develop comprehensive and sensitive genetic tests for DCM, incorporating analysis of the most commonly involved genes in a single test. A diagnostic NGS workflow for the analysis of 28 DCM genes has developed and validated using Haloplex enrichment technology (Agilent Technologies) followed by sequencing on the MiSeq (Illumina). Initial results demonstrate that this is a sensitive and robust assay with an average of 97.5 % of target regions consistently covered to x30 depth. The results of this study will be presented to demonstrate the analytical and clinical sensitivity in our validation cohort; the potential utility of this test strategy in a clinical setting will be discussed.

P13.26
NADf chip, a two-color microarray mutation detection tool for the diagnosis of deafness in North Africa

S. Masmoudi, *I. Chakchouk, M. Ben Said, F. Jbeli, S. Loukil, H. Hadj Kacem;*
Centre of Biotechnology Of Sfax, Sfax, Tunisia.

Hearing impairment (HI) is the most prevalent sensorineural disorder. Genetic causes are responsible in two-thirds of prelingual cases. About 70% of hereditary HI cases are non-syndromic (NS); the other 30% are associated to other symptoms. NSHI is exclusively autosomal recessive and highly heterogeneous. Among the most common syndromic forms, Usher and Pendred syndromes are inherited in an autosomal recessive pattern. Autosomal recessive HI is particularly frequent in countries with high rate of consanguinity such as Northern Africans. This population shares several common features, such as history and social behaviors that promote the spread of founder mutations. The most current strategy used for molecular genetic testing in North African countries relies on PCR-RFLP and Sanger sequencing techniques. The extreme genetic heterogeneity of HI renders its molecular diagnosis using these methods time-consuming and very expensive. We designed and optimized a NADf (North African Deafness) chip using multiplex PCR coupled with two-color arrayed primer extension (APEX) for the simultaneous analysis of 60 mutations that are commonly found in Northern African deaf patients. These mutations are distributed over 40 different exons and introns. We used the fluorescent dyes Cy3 and Cy5 that are compatible with the most common scanners. Our array showed 100% sensitivity and specificity in the detection of 40 HI mutants, and ensures robust genotyping. The whole procedure can be performed to completion in a single day. Our miniaturized assay format allows simultaneous genotyping of eight different test samples at minimized reagent costs and is therefore amenable to large scale screening.

Type 1 diabetes (T1D) is a complex autoimmune disease with high heritability. Genetic association studies identified more than 56 susceptibility loci outside the major HLA locus, but a remarkable portion of heritability (up to 40%) remains unexplained. We thought part of the missing heritability could be attributable to variants segregating in families with closely related affected individuals. With the aim to assess this hypothesis, we sequenced the whole-exome of 32 Sardinian individuals representing 16 parent+offspring affected pairs. Being Sardinia an isolated population, we can not exclude that a founder, highly penetrant variant, shared among those families, is present on the island. Samples were sequenced with the TruSeq Exome Enrichment Kit (Illumina), that provides coverage across 62 Mb of exomic sequence, including 5' UTR, 3' UTR, microRNA, and other non-coding regions. Reads were aligned using Burrows-Wheeler Algorithm (BWA) to the reference human genome (build 37). Alignments for each sample were converted to BAM format, sorted, indexed and processed with MarkDuplicates from the package Picard-tools 1.81 for removing PCR duplicates. The local indel realignment and recalibration was performed according to the GATK (v. 2.2-15) pipeline. On average, mean depth is 52.5x and a total of 98.9% of Q20 bases were observed. We are now performing multisample variant calling of both SNPs and indels using the HaplotypeCaller algorithm in GATK. Our results will elucidate whether an highly penetrant variant shared between families or private variants in genes on the same pathway can explain disease segregation in those trios.

Objectives: Whole exome sequencing (WES) and Sanger sequencing can be used for the molecular characterization of monogenic diseases but these techniques are still expensive and labor-intensive. Here, we aimed to develop a cost-effective high-throughput approach for molecular diagnosis of genetic diseases. We assessed a new technology in 45 patients presenting with monogenic forms of diabetes or obesity, of which causal mutations were already known.
Methods: We designed a PCR-based sequence enrichment panel targeting exons of 43 known susceptibility genes for monogenic forms of diabetes and obesity. Each of the 45 DNA samples was processed on the RDT1000 (RainDance). Fragmented DNA mixed with PCR reagents was processed into microdroplets that were fused with microdroplets containing the primer library. The resulting microdroplets were subsequently amplified by PCR. Finally, all 45 amplicon enriched samples were sequenced on the HiSeq2000 (Illumina) at mean coverage depth of 100×.
Results: The mean depth was ≥8× for 99% of targeted regions resulting in a good uniformity of coverage in each sample. The known mutations of 43 patients were confirmed. These included missense, nonsense and splice site muta-

tions as well as deletions. Two proven variants were not retrieved due to issues in Indel detection algorithm and homopolymer sequencing errors. Surprisingly, we found that three patients carry other potentially causal mutations than the expected one.
Discussion: Microdroplet based PCR enrichment combined with next generation sequencing is a promising technique for molecular diagnosis of genetic diseases. It may replace Sanger sequencing as it is far more cost effective and quicker.

P13.29
Targeted next generation sequencing for identification of genotypes and associated phenotypes in epileptic encephalopathy

E. H. Brilstra[1], *M. J. A. van Kempen*[1], *Y. K. Lam*[1], *R. van t Slot*[1], *F. E. Jansen*[2], *B. P. C. Koeleman*[1], *C. de Kovel*[1];
[1]*Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Department of Child Neurology, University Medical Center Utrecht, Utrecht, Netherlands.*

Known monogenic causes for epileptic encephalopathy (EE) explain only a fraction of all patients. To explain more cases, the phenotypic spectrum associated with mutations in known genes needs to be further explored, and new genes for EE need to be identified. In order to do so, we selected 342 genes with a known or possible relationship to EE and performed targeted next generation sequencing of these genes in 64 EE patients. To investigate how common deleterious mutations in these genes are in healthy people, we also performed this sequencing in 64 healthy persons.
After filtering, in the EE patients 144 variants that were novel and unique for the patient group, were found, 0-6 per sample. Of those 34 were in known epilepsy or encephalopathy genes, of which six have been confirmed by Sanger sequencing (at this time), but two were not. In controls 94 unique and novel variants were found, of which 9 in genes previously found to be associated with epilepsy or encephalopathy. Therefore, patients seem to be enriched for mutations in known epilepsy-related genes.
One interesting variant was a non-synonymous mutation in CACNA1A in a patient with moderate intellectual disability, refractory epilepsy and ataxia. CACNA1A is commonly found to be mutated in patients with familial hemiplegic migraine and/or (episodic) ataxia. Another interesting variant was in KCNMA1, which has previously been found mutated in a family with generalized epilepsy and paroxysmal dyskinesia. Follow-up is underway.

P13.30
Exome sequencing as a diagnostic tool identifies a novel mutation associated with congenital generalized lipodystrophy.

J. Klar[1], *J. Schuster*[1], *T. Khan*[2], *M. Tariq*[2], *P. Arzoo*[2], *N. A. Malik*[3], *K. Mäbert*[1], *S. M. Baig*[2], *N. Dahl*[1];
[1]*Department of Immunology, Genetics and Pathology, Uppsala, Sweden,* [2]*Human Molecular Genetics Laboratory, National Institute for Biotechnology and Genetic Engineering (NIBGE), Faisalabad, Pakistan,* [3]*Human Molecular Genetics Laboratory, National Institute for Biotechnology and Genetic Engineering (NIBGE), Faialabad, Pakistan.*

Exome sequencing has emerged as a diagnostic tool in cases of genetic heterogeneity or when clinical and/or laboratory data from patients is unattainable. We identified a consanguineous Pakistani pedigree with three members, two females and one male, with short and muscular stature, mild mental retardation and acromegalic appearance. The diagnosis remained unclear in the absence of further clinical information and laboratory data. We then performed exome sequencing on affected members and we identified a homozygous novel variant on chromosome 11 in intron 5 of the *BSCL2* gene encoding Seipin. Mutations in the *BSCL2* gene cause congenital generalized lipodystrophy type 2 (CGL2). The transition (c.574-2A>G) identified in this family is predicted to alter the intron 5 acceptor splice site and expression analysis of the mutated allele confirmed skipping of exon 6.
Patients with CGL2 are born without body fat and later develop insulin resistance, hypertriglyceridemia, hepatic steatosis and early onset of diabetes. Clinical re-evaluation of affected family members showed lipodystrophy and axillary acanthosis nigricans. Thus, congenital generalized lipodystrophy was confirmed despite cholesterol and triglycerid levels within normal ranges.
The cost of exome sequencing has become more and more affordable and could represent a universal diagnostic tool for genetic disorders at early stages of investigations or, as illustrated here, when access to clinical information is limited.

P13.31
Diagnostic application of exome sequencing in Limb Girdle Muscular Dystrophies and Distal Myopathies.

M. Krahn[1,2,3], *J. Desvignes*[1,3], *M. Lathrop*[4], *N. Lévy*[1,2,3], *M. Bartoli*[1,2,3];
[1]*Aix Marseille Université, Faculté de Médecine, Marseille, France,* [2]*APHM, Département de Génétique Médicale, Hôpital Timone Enfants, Marseille, France,* [3]*INSERM UMRS 910, Marseille, France,* [4]*Centre National de Génotypage, Evry, France.*

Exome sequencing offers promising perspectives for molecular diagnosis of genetically heterogeneous diseases, either as a first-tier-approach, or following an initial negative result of targeted single-gene-analysis. In autosomal recessive muscular dystrophies, the latter situation may account of approximately 10-20% of samples screened for a selected gene after clinical orientation.
This includes dysferlinopathies which present mainly as Limb-Girdle Muscular Dystrophy or distal myopathy (Miyoshi myopathy).
Among our cohort constituted during the past 12 years for mutational analysis of the dysferlin gene (DYSF), we included 37 samples initially addressed for diagnostic suspicion of dysferlinopathy, without identified disease-causing mutation (DCM). Exome sequencing (Agilent Sureselect V3 and Illumina sequencing) yielded a mean depth of 68X and an overall coverage of >10% for 98.4% of the targeted exons. Variants were filtered through the "Gene Table of Neuromuscular Disorders" list of genes, disease-group "muscular dystrophy" (http://www.musclegenetable.fr ; 34genes). In six samples, molecular diagnosis could be concluded by identifying compound heterozygous or homozygous DCM in previously known LGMD or distal myopathy genes (including CAPN3, ANO5 and GNE). In three additional samples, respectively one DCM was identified, warranting further targeted exploration (including MLPA/CGH) for the identification of a possible second DCM. For the remaining 28 samples, no DCM were identified among the disease-group "muscular dystrophies", which points to further genetic heterogeneity with regard to the currently known list of genes implicated in muscular dystrophy. Widening of the informatics filter to the entire "Gene Table of Neuromuscular Disorders" list (297genes) identified several mutated candidates which are under further investigation.

Here we describe the combined approach of whole exome sequencing (WES) and subsequent functional studies in the identification and characterization of a novel activating *NPR2* gene mutation in a healthy male with extreme tall stature (221 cm). GH hormone overproduction, known syndromes, and a deletion in chromosome 15q25.2q25.3 containing 8 protein-coding genes had been excluded as the cause of tall stature. WES was performed and analysis of the data with a home-made analysis pipeline elucidated a heterozygous missense mutation in the *NPR2* gene (c.1963C>T p.Arg655Cys) within the NPR2 kinase homology domain as the most likely pathogenic event. This variant was not present as a known variant in any of the available databases. The *NPR2* mutation was not found in the patient's sister or son, who are tall but within the normal range. His parents were not available for analysis. Transfection studies of the mutant NPR2 protein in HEK293 cells resulted in increased basal and CNP stimulated NPR2 activity. Co-expression of wild-type and mutant NPR2 resulted in increased activity, close to the value of mutant NPR2 alone, suggesting a dominant positive effect. Co-immunoprecipitation studies confirmed heterodimer formation of wild-type and mutant NPR2. Studies using skin fibroblasts of the patient showed increased NPR2 activity after stimulation with CNP, confirming that the mutant NPR2 enhances CNP-NPR2-cGMP signalling. This pathway is critically involved in bone development by stimulating growth plate chondrocyte differentiation and proliferation. We conclude that the identified *NPR2* mutation in our patient is responsible for the extremely tall stature.

Targeted next-generation sequencing (NGS) is a powerful technology that is transforming the understanding of human disease. The Haloplex PCR method combines target enrichment and sequencing library preparation in a simple one day protocol without the requirement for dedicated instrumentation. While the Haloplex method is highly specific and results in deep coverage across targets of interest for variant identification, specimens such as formalin-fixed paraffin-embedded (FFPE) tissues present challenges due to age, presence of interfering substances, limited material, and DNA template degradation and damage. To make the Haloplex protocol even more robust when using difficult samples, we examined the effect of probe design parameters on enrichment metrics and variant calling performance using several disease-specific panels with various sample types. We focused on targeting shorter fragment sizes, capturing both strands of the target DNA, building redundancy into design, and adjusting stringency settings for targets with high homology to other regions of the genome. We demonstrate how these advanced design considerations improved the performance of the disease panels in terms of coverage, uniformity, and specificity. We also discuss the effect of probe design on coverage of hotspot regions, false positive rates due to formalin-induced damage, and allelic balance in the case of low frequency mutations. Our results demonstrate the utility of Haloplex for targeted next-generation sequencing using challenging samples often encountered during disease research and assay development.

Genetic etiology for the majority of families with breast/ovarian cancer (BC/OC) is unknown. This could be due to a genetic heterogeneity with multiple loci of unequal frequency and penetrance. Next generation sequencing can be used to search predisposition genes by sequencing the entire protein-coding sequence (exome). In a still ongoing analysis (ISCIII Miguel Servet funded) we applied whole-exome sequencing to multiple affected relatives from eight BC/OC families. Genomic library was prepared from 1 µg of DNA. Exome enrichment was performed using the SureSelect XT HumanAllExon 50Mb (Agilent). Sequencing, paired-end 2x100, was performed on a HiSeq2000 instrument (Illumina). Reads were aligned to the human genome (hg19) using the Burrows-Wheeler Aligner algorithm. Single nucleotide variants (SNVs) and indels were identified using the GATK software and annotated with Annovar. Variants were filtered for confident calls using a ≥30 quality threshold, ≥15 read depth, and ≥ 0.15 allele frequencies. The average read depth for capture target regions was 98.84. Prior to further filtering, variants were assessed for overtly deleterious mutation in known BC/OC genes. Then, variants in the 1000 Genomes Project, NHLBI Exome Sequencing Project, and dbSNP database with minor allele frequency of ≥1% were removed. Next, variants functionally deleterious in heterocigosis (frameshift and nonsense SNVs) were identified. After filtering, an average of 37 deleterious mutations was identified per individual. Only those genes with deleterious mutations shared by the affected relatives were considered. Priority was given to genes implicated in well-established pathways associated to cancer. The variant validation will be done by Sanger sequencing.

Prediction and prioritization of non-coding variants of uncertain significance in heritable breast cancer

P. K. Rogan, *E. J. Mucaki, E. Dovigi, C. Viner, B. C. Shirley, S. Dorman, A. Stuart, J. Knoll, P. Ainsworth;*

University of Western Ontario, London, ON, Canada.

We present an approach to prioritize pathogenic non-coding, variants of uncertain significance (VUS) based on information analysis of changes in DNA and RNA sequences bound by regulatory factors. Complete gene sequences were captured by solution hybridization, enriching for variants in genes that harbor breast cancer risk mutations. Oligo baits for ATM, BRCA1, BRCA2, CDH1, CHEK2, PALB2 and TP53 spanned complete coding and adjacent intergenic regions. A novel probe design captured both repeat-free and effectively single-copy, divergent repeat sequences. After sequencing 21 patient samples, information theory-based sequence analysis prioritized non-coding variants predicted to occur within sequences recognized by proteins or protein complexes. VUS were screened for mutations affecting binding sites in mRNA splicing, by transcription factors (TFBS), and proteins interacting with untranslated regions (UTR). Information theory based models of exon recognition predict the relative abundance of natural, cryptic, and mutant splice isoforms resulting from predicted mutations (Mucaki et al 2013). We introduce a similar approach to detect mutations altering TFBS and UTR binding sites. Information weight matrices were computed by entropy minimization of ENCODE ChIP-seq data for 47 transcription factors expressed in breast cancer. Novel variants in patients were then evaluated for alteration of TFBS affinity. We predict 9 splicing, 10 TFBS, and 6 UTR variants affect gene expression of 6 protein coding genes in the patient samples (from 7,909 variants in 7 genes). This strategy more comprehensively covers non-coding regions in breast cancer genes than repeat masking, and introduces a unified framework for systematic interpretation of VUS that affect expression.

In order to optimize the molecular diagnosis of hereditary breast and ovarian cancer (HBOC), we developed a NGS-based routine screening based on the capture of 21 genes (exons and introns) involved in HBOC, pooling of 12 indexed DNA, 2x76bp paired-end sequencing on a GAIIx and confirmation by Sanger sequencing or MLPA/QMPSF. The bioinformatic pipeline includes CASAVA, NextGENe, CNVseq and Alamut-HT. The procedure allows the analysis of 80 patients per run with a 60x coverage. We validated this procedure first by analysis of 60 DNA with deleterious SNV, indels or genomic rearrangements of BRCA1 or BRCA2, then by performing in parallel the NGS and Sanger se-

quencing/MLPA analyses of BRCA1 and BRCA2 in 160 patients. All mutations detected by conventional procedures were detected by NGS. We then analysed 707 new patients for SNV and Indels. We detected 91 variations inducing a premature codon stop or a splice defect, in BRCA1(n=28), BRCA2(n=24) and 39 in the other genes: ATM(n=5), CHEK2(n=5), PALB2(n=5), MRE11A(n=4), RAD51C(n=3), NBN(n=3), RAD50(n=2), BARD1(n=1), CDH1(n=1), MSH2(n=4), PMS2(n=2), PMS1(n=1), MLH3(n=1), RAD51D(n=1) and RAD51B(n=1). Interpretation of these potentially deleterious variants is being performed by segregation studies within the families. We also detected potentially deleterious 21 missense mutations, including 11 within BRCA1 and BRCA2 (Align GVGD score > C65 MAF in ESP sample <0.01). These results demonstrate the efficiency of this NGS procedure to perform molecular diagnosis of HBOC and shows that the fraction of potentially deleterious mutations detected within the other genes than BRCA1 and BRCA2 justifies their analysis.

P13.37

Ultra-Fast BRCA1/2 Analysis for Clinical Diagnostics of DNA from Blood Samples

A. H. Petersen, *A. Bojesen;*
Department of Clinical Genetics Vejle Hospital, Vejle, Denmark.

Several studies have indicated that, hereditary breast and ovarian cancer patients who harbor mutations in BRCA1/2 can benefit from new therapeutics, known as poly-ADP-ribose polymerase (PARP) inhibitors. Patients suitable for entry in protocols using PARP inhibitors are typically at a late stage of their cancer disease. If patients without prior knowledge of mutations in BRCA 1/2 should benefit from treatment, very fast screening for mutations in BRCA 1/2 is needed. Therefore, we developed a novel in-house ultra-fast BRCA1/2 mutation analysis, making it possible to screen the coding regions, the intronic regions (33-1881 bp) flanking the exons and the 5' and 3' UTRs of the BRCA1 and BRCA2 genes within two weeks. This allows BRCA1/2 positive patients to be enrolled in clinical trials at an earlier stage, since traditional Sanger sequence based screening of BRCA1/2 may take up to, as long as 3 months, in Denmark.
Method: Genomic DNA was subjected to 13 individual LongRange PCR amplifications (In House primer design and Qiagen LongRange PCR kit). 1 ng of pooled amplicon DNA was used as input DNA for the library preparation (Nextera XT, Illumina). Sample libraries were multiplexed and sequenced on a MiSeq (PE 2x 150 bp, dual indexing). Data analysis was performed using CLC Genomic Workbench. Patient DNA was tested for larger InDels using MLPA P002-C2 and P045-B3.
Results: A total of 60 patient samples have been analyzed since August 2012. The average analysis time is 13.3 days (8 to 25 days), and 6 disease causing mutations have been detected.

P13.38

Screening FFPE archival tissue for mutations in BRCA1 and BRCA2 - A new paradigm in genetic counselling/investigation

A. Bojesen[1], *K. D. Steffensen*[2], *M. M. Aagaard*[1], *A. H. Petersen*[1];
[1]*Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark,* [2]*Department of Oncology, Vejle Hospital, Vejle, Denmark.*

By revealing the BRCA status of deceased relatives using archival Formalin-Fixed Paraffin-Embedded (FFPE) samples, genetic counsellors get an extra tool to make more qualified risk assessment on living family members. The elucidation of a family's BRCA status may also release family members from psychological worries, if the test result is BRCA negative. Importantly, if the test result is positive for a disease causing BRCA mutation, the genetic counsellors can guide the family members about the benefits of genetic testing and screening programs.
The department of Clinical Genetics at SLB-Vejle Hospital, Denmark, is implementing a targeted sequencing strategy of 29 cancer genes including BRCA1/2 for routine analysis of mutations in DNA extracted from FFPE samples < 10 years old. The first study included 7 FFPE samples and 1 blood sample, all with a known germline BRCA mutation, and focused on examining the quality of the chosen method for targeting the cancer genes, and setting up a data analysis pipeline. A second study involves FFPE samples from 20 cancer specimens with a known germline BRCA1/2 mutation and focus on examining the relationship between the age of FFPE sample, quality and amount of DNA required to get a successful result.
Results: All BRCA mutations were identified except from a large deletion. The mean coverage was between 628-1079x, and 74.9-98.5% of the target region had a coverage of at least 30x. Through these studies, expertise will be gained providing the genetic counsellors with an important tool in the battle against inherited cancer disposition.

Over 200 genes have a well-documented implication in monogenic forms of intellectual disability (ID), including 100 located on the X-chromosome. While there is a good coverage for diagnostic demands in patients with evocative syndromic forms, in lesser syndromic patients the diagnostic offer is limited to Fragile-X and CGH-array analyses and most cases hence remain undiagnosed.
We tested a targeted exon-capture strategy of 220 ID genes (100 XLID genes and 120 autosomal genes mostly associated to dominant forms) coupled with multiplexing and NGS. We successfully analyzed 50 patients (mostly males and sporadic cases) with undiagnosed moderate to severe ID.
We identified eight certainly-causative mutations: five maternally-inherited in X-linked genes (DMD/DP71, KDM5C, MAOA, MECP2, SLC9A6) and three truncating de novo in autosomal genes (DYRK1A, RAI1, TCF4). We also reported four likely-causative X-linked mutations in HUWE1, IQSEC2, SRPX2 and FLNA requiring additional validation analyses.
Interestingly, the DMD/DP71 mutation is a very distal frameshift in a patient with no muscular phenotype. The MECP2 mutation is an exceptionally complex rearrangement detected in an 11 years-old boy with severe ID and his unaffected mother. Patients with RAI1 and TCF4 mutations did not present with clear phenotypic traits evocative of Smith-Magenis or Pitt-Hopkins syndromes.
The identification of certainly/likely causative mutations in 16%/24% of the patients proves the relevance of our strategy for the diagnosis of ID, being more cost-effective than trio-exome sequencing while leading to a comparable proportion of diagnostic results (16%/41% in 100 trios, de Ligt et al.; 31%/43% in 51 trios, Rauch et al., 2012).

P13.41

Using Ion AmpliSeq™ RNA to Detect Fusion Transcripts in Human Oncology Samples

S. Magdaleno, *J. Schageman, L. Chapman, B. Setterquist;*
Ambion, Inc, a part of Life Technologies, Austin, TX, United States.

We have developed a new method of targeted RNA sequencing application for low input and degraded FFPE total RNA samples using the Ion AmpliSeq™ RNA technology. This technology has been shown to be technically reproducible, quantitative and to maintain excellent correlation with qPCR using TaqMan gene expression assays. We have applied this novel targeted RNA sequencing approach to the detection of fusion transcripts in human disease tissues.
Panels of amplicons were designed to all the known fusion transcripts associated with mesenchymal neoplasms (soft tissue tumors). The Ion AmpliSeq™ RNA technology was used to quickly scan through all known chimeric

transcription factors in the COSMIC database that have been observed in soft tissue tumors. This was accomplished by generating a fusion transcript AmpliSeq™ RNA panel that contained oligo primers specific for highly observed fusion transcripts as well as, rare fusion transcripts in a single tube. Thus, if the fusion transcript is expressed in the sample, that amplicon will be present and contribute to the mapped reads on the Ion PGM. If the fusion transcript is not present in the sample, the unused oligonucleotides are destroyed and no reads are produced. With this approach hundreds of fusion transcripts can be screened in a simultaneously in a single tube on the Ion PGM with resolution down to the single nucleotide level. Data from positive and negative control tissues will be demonstrated as a proof of principle for the use of Ion AmpliSeq™ RNA for the detection of fusion transcripts in oncology samples.

To meet challenges in terms of throughput and turnaround time, many diagnostic laboratories are shifting from Sanger sequencing to higher throughput second-generation sequencing (SGS) platforms. Bearing in mind that the performance and quality criteria expected from SGS in diagnostic or research settings are strikingly different, we have developed an Ion Torrent PGM-based routine diagnostic procedure for *BRCA1/2* sequencing. The procedure was first tested on a training set of 62 control samples, and then blindly validated on 77 samples in parallel with our routine technique. The training set was composed of difficult cases, e.g. insertions and/or deletions of various sizes, large-scale rearrangements and, obviously, mutations occurring in homopolymer regions. We also compared two bioinformatics solutions in this diagnostic context, an in-house academic pipeline and the commercially available NextGene software (Softgenetics). NextGene analysis provided higher sensitivity, as 4 previously undetected nucleotide variations were found. Regarding specificity, an average of 1.5 confirmatory Sanger sequencings per patient was needed for complete *BRCA1/2* screening. Large-scale rearrangements were identified by two distinct analyses, i.e. bioinformatics and fragment analysis with electrophoresis profile comparison. Turnaround time was enhanced, as series of 30 patients were sequenced by one technician, making the results available for the clinician in 10 working days following blood sampling.
BRCA1/2 genes are a good model, representative of the difficulties commonly encountered in diagnostic settings, which is why we believe our findings are of interest for the whole community and the pipeline described can be adapted by any user of PGM for diagnostic purposes.

BACKGROUND: Colorectal cancer predisposition can occur either in the Lynch Syndrome (4 genes) and also with Familial Adenomatous Polyposis (2 genes). We developed an Ion Torrent PGM-based routine diagnostic process for sequencing those genes based on the Multiplicom HNPCC and FAP MASTR kit. The goal was to estimate the performance of this system and to extend to the routine diagnostic process.
METHODS: The procedure was first tested on a training set of 16 samples from patients with a suspicion of Lynch syndrome and 16 samples from patients with an attenuated polyposis syndrome. For those 32 patients, a screening with qPCR-HRM method was performed for *MLH1* , *MSH6* , *MSH2* (85 variants) and *MUTYH* (42 variants). The variants were 4 deleterious in *MSH2* , 2 in *MLH1* , 4 in *MSH6* . The variants were 4 deleterious in *APC* and 1 monoallelic and 1 biallelic in *MUTYH* gene. All data were analyzed with NextGene module.
RESULTS: All deleterious variants were detected. The difficulties were observed mainly with homozygous variants, *PMS2*pseudogene and indel variants in homopolymer region. In addition to mutants already identified, two deleterious mutations were identified in *PMS2* and *APC* gene, whereas the screening was pending. The assets and limitation of the approach will be discussed.
CONCLUSIONS: This new approach offers the possibility to propose a widest panel of screened genes, reducing the time lag in the diagnostic process due to unspecific tumor information (attenuated polyposis or no molecular data available).

P13.44

IonTorrent: 2nd generation sequencing in a diagnostic laboratory

B. Dworniczak, *S. Fleige-Menzen, N. Bogdanova, P. Pennekamp;*
University Hospital Muenster, Muenster, Germany.

Molecular diagnosis of complex human genetic diseases is still challenging because in most cases multiple genes harboring putative deleterious mutations have to be investigated. So far in most diagnostic laboratories Sanger sequencing is used but capillary sequencing is excessive time-consuming and expensive at least for the screening of multiple genes. Recently next-generation sequencing (NGS) technologies have started to be applied, but because these technologies are made especially for large sequencing projects it is not easy to scale it down for screening a set of disease causing genes in a diagnostic laboratory. To fill this gap table top NGS systems have been introduced by Life Sciences (Ion Torrent PGM) from Illumina (MiSeq) and from Roche (GS Junior). While Illumina and roche launched sequencer adapted to established technology IonTorrent introduced a sequencing device using a sequencing technology based on the detection of hydrogen ions that are released during the polymerization of DNA.
To validate this technology in respect to usability, software requirements and accuracy we tested several gene panels comprising between 3 and 420 genes covering between 200 and 16000 exons. Regions of interest were enriched in different ways: single PCR, multiplex PCR (AmpliSeq, IonTorrent; GeneRead NGS System, Qiagen) or HaloPlex custom specific kits (Agilent). Our validation showed that for enrichment multiplex PCR is the superior technology and that with the exception of one all tested software packages are either excessive time consuming or did not find the mutations at all and still need urgent improvements.

Kallmann syndrome (KS) is a rare disorder characterized by absent/defective sense of smell and absent/incomplete puberty resulting from defects in the development of the hypothalamic GnRH neuron population. X-linked recessive, autosomal dominant (AD) and autosomal recessive (AR) inheritance patterns have all been described in KS patients, and di-or oligogenic inheritance of the disorder has also been suggested. Mutations in the many genes already connected with the disorder explain only about 30-40 % of the cases, implying new disease genes are yet to be found. Whole-genome sequencing data of a male KS patient and his healthy parents and brother was analyzed to search for candidate causal variants in the coding regions of the patient's genome. Different filtering criteria were used for different modes of inheritance: 1) AD de novo mutation; 2) homozygous AR mutation; 3)

compound heterozygous AR mutation; 4) AD mutation with sex-dependent penetrance. We only considered novel variants. Scenarios 1 and 2 were ruled out as no candidate variants were left after filtering. No obvious causal variants were found for scenarios 3 and 4. Comparison of the patient's genome against that of his healthy brother revealed variants in several interesting genes involved in cell migration and axon guidance, including ITGB1 and NDNF. Additional analysis of de novo copy number variations and detection of SNPs and indels in genes encoding miRNAs revealed no further candidate variations. These results highlight the many challenges still present in the study of genetically heterogeneous disorders.

A combined NGS and CGH arrays approach identifies novel TRIM32 mutations in an unclassified case of limb-girdle muscular dystrophy

*J. Nectoux[1,2,3], F. Leturcq[1,4], J. Urtizberea[5], R. Ben Yaou[4], I. Nelson[4], A. Cobo[5], M. Arné-Bes[6], E. Uro-Coste[6], I. Richard[7], S. Baulande[8], P. Nitschke[9], M. Claustres[10], G. Bonne[4], J. Chelly[1,2,3], N. Levy[11], **M. Cossée**[10];*

The EU-funded NMD-Chip project was established to design, develop and validate new sensitive high throughput DNA arrays to efficiently diagnose patients affected with neuromuscular disorders (NMDs). In this context, both CGH arrays to detect copy number variations as well as Sequence Capture (SC) arrays for massive re-sequencing and point mutation detection, have been set up, allowing the simultaneous screening of more than 50 genes known to be involved in NMDs, in addition to hundreds of candidate genes selected from experimental and published data. Thanks to these combined NGS and CGH arrays approaches, we report here the molecular diagnosis of TRIM32 compound heterozygous mutations in a 50 year-old male patient suffering from slowly progressive muscle weakness, characterized by a late age of onset (30y), unspecific limb-girdle muscular dystrophy with scapular winging and moderately elevated CPK (400U/l). For this patient, sequencing of TRIM32 using the custom in-solution DNA SC library revealed first a distal frameshift mutation, c.1603delC (p.Leu535Serfs*21) which appeared at homozygous state. Because there was no history of consanguinity, a possible deletion of the other allele of TRIM32 has been investigated by CGH array, which allowed the identification of a large deletion of chromosome 9 encompassing the whole TRIM32 gene. Defects in TRIM32 have already been reported in limb-girdle muscular dystrophy type 2H (LGMD2H), also known as muscular dystrophy Hutterite type, a rather mild and progressive myopathy characterized by a wide phenotypic heterogeneity. These novel mutations confirm that integrity of the C-terminal domain of TRIM32 is necessary for muscle maintenance.

P13.47

Identifying the incidence of rare genetic disorders in infants with liver disease using targeted next generation sequencing.

***K. E. McKay**[1], Z. Gray[2], A. Yeung[1], H. Bair[1], C. Lloyd[2], J. L. Hartley[2], C. Hendriksz[3], F. Macdonald[1], D. A. Kelly[2], P. Gissen[4];*

[1]West Midlands Regional Genetics Service, Birmingham, United Kingdom, [2]Birmingham Children's Hospital, Birmingham, United Kingdom, [3]Salford Royal Hospital, Birmingham, United Kingdom, [4]UCL Institute for Child Health, Birmingham, United Kingdom.

Background: The incidence of infantile liver disease due to rare genetic disorders, including Niemann Pick type C (NPC), progressive familial intrahepatic cholestasis (PFIC) and citrin deficiency (CD) is unknown. Early genetic diagnosis allows targeted therapy avoiding inappropriate liver transplantation. Traditional testing by sequential sequencing of the genes involved using Sanger sequencing is costly and time consuming. Next generation sequencing (NGS) permits simultaneous analysis of multiple genes whilst reducing time to diagnosis and cost.

Aim: To develop a targeted NGS screen to diagnose genetic disorders in infants with liver disease.

Methods: 14 centres worldwide recruited 230 infants less than 2 years old presenting with cholestasis, acute liver failure or splenomegaly. The 6 genes involved in NPC, PFIC and CD were sequenced using 48.48 Access Array (Fluidigm) and GS Junior (Roche). Variants were classified into likely pathogenic, unknown significance (VUS), and likely non-pathogenic groups.

Results: Testing was complete in 181 cases. A genetic diagnosis was possible in 18 patients (10%, see Table). A further 7 patients (5%) had only one likely pathogenic mutation, and approximately 20% had VUS only with no pathogenic mutations.

	Number of patients	
Gene	Diagnosis	Carrier
NPC1	1	2
NPC2	0	0
ATP8B1	3	1
ABCB11	9	1
ABCB4	5	5
SLC25A13	0	0

Conclusions: The combined incidence of these genetic diseases in infantile liver disease is 10% with PFIC type 2 being the most common. NGS has shown to be an efficient method of analysing multiple genes for these disorders; pros and cons will be discussed.

Massive parallel sequencing in molecular diagnostics: universal tailed amplicon sequencing of lynch syndrome genes

***M. F. Hansen**[1], L. Lavik[2], B. Gilde[2], T. Vold[2], U. Neckmann[1], W. Sjursen[2,1];*

[1]Department of Laboratory Medicine, Children's and Women's Health, The Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, Norway, [2]Department of Pathology and Medical Genetics, St. Olavs Hospital, Trondheim, Norway.

Lynch syndrome accounts for 3-5% of all colorectal cancers (CRC), making it the most common hereditary CRC syndrome. The disease is inherited in an autosomal dominant manner, and is attributed to mutations in either of the DNA mismatch repair (MMR) genes *MSH2*, *MSH6*, *MLH1* and *PMS2*.

We have one year experience in the use of massive parallel sequencing (MPS) (GS Junior, 454 technology, Roche) for diagnostic detection of germline mutations in Lynch syndrome genes. A time- and cost effective workflow suitable for routine molecular diagnostics has been developed. The GS Junior system is based on emulsion PCR (emPCR) to clonally amplify single stranded DNA molecules to be sequenced. Before emPCR a DNA amplicon library is prepared by two-step PCR based amplification of the regions of interest. With the use of molecular barcodes (multiplex identifier sequences, MIDs), many amplicons from several patients can be pooled and sequenced together. All amplicons are sequenced in parallel by pyrosequencing chemistry. Data analysis is done with the AVA-software supplied by Roche. A well-known problem with Pyrosequencing is incorrect basecalling in homopolymeric regions. Our workflow circumvents this issue by Sanger sequencing amplicons that contain homopolymers.

Implementation of diagnostic MPS at our laboratory has led to decrease in sample turnaround time and costs. We find the technology to be good in terms of sensitivity and well suited for use in molecular diagnostic laboratories.

Effect of a novel intronic FBN1 mutation on splicing revealed by splicing minigene assay.

***L. Grodecká**[1,2], P. Cibulková[3], M. Dvoráková[3], R. Krenková[3], R. Richterová[3], A. Baxová[4], A. Sípek[4], T. Honzík[4], T. Freiberger[1,5];*

[1]Molecular Genetics Laboratory, CKTCH, Brno, Czech Republic, [2]Central European Institute of Technology, Masaryk University, Brno, Czech Republic, [3]Laboratory of medical genetics, AGEL Laboratories, Novy Jicin, Czech Republic, [4]General University Hospital in Prague, Prague, Czech Republic, [5]Central European Institute of Technology, Masaryk university, Brno, Czech Republic.

A girl presenting severe neonatal form of Marfan syndrome (MFS) was born

to healthy parents. Mutational screening of patient's DNA revealed an intronic change, 20 bp deletion in intron 34 (c.4211-32_-13del) in the *fibrillin-1* gene (*FBN1*). *In silico* predictions of the effect of the deletion on pre-mRNA splicing showed marked drop in both the 3' splice site score and the polypyrimidine tract score. As we were not able to perform RT-PCR directly from patient's RNA, we took advantage of splicing minigene assay. We cloned exon 35 together with neighbouring intronic regions into the vector pET. After transfection of HeLa cell line with the wild type and mutant constructs, we isolated total RNA and performed RT-PCR. Its results clearly showed that the mutation led to exon 35 skipping in the majority of RNA. In patient, this splicing aberration presumably caused the in frame deletion of 126 nucleotides from *FBN1* mRNA.
The splicing minigene analysis is not a standard diagnostic procedure and the results driven from this highly artificial system could differ from the real situation in the patient. We can not be sure about precise RNA aberration that the examined mutation induced. On the other hand, since we have detected that the mutation affects splicing under certain conditions, there is high probability that the mutation disrupts normal splicing to some extent. Furthermore, we have not detected any other mutation neither in the *FBN1* gene nor in other MFS-related genes. Hence, we regard the mutation as causal one in this case.

P13.50

Comparison of screening for Marfan syndrome using SSCP and NGS

M. Dvorakova, *R. Krenkova, P. Cibulkova;*
Laboratory of Molecular Biology, Laboratore AGEL a.s., Novy Jicin, Czech Republic.

Background: Marfan syndrome (MFS) and Marfan-like diseases are inherited autosomal dominant disorders that affect connective tissue, the tissue that strengthens the body's structures, mainly involving the cardiovascular, skeletal and ocular systems. The estimated incidence is of about 1:5 000 - 1:10 000 and approximately 30% of cases are associated with *de novo* mutations. MFS is caused by mutations in fibrillin-1 gene (*FBN1*, 15q15-q21.1.) resulting in defective glycoprotein fibrillin-1. Recently, two other genes TGFBR2 (3p22) and TGFBR1 (9q22) have shown to effect MFS.
Aims: In this study we performed analysis of all exons of FBN1 gene, except exon 1, in order to identify pathogenic mutations in unrelated patients with clinical diagnosis of MFS. 758 patients were analyzed by SSCP (single-strand conformation polymorphism) and 56 by NGS (next generation sequencing).
Materials and Methods: DNA was isolated from whole blood, the molecular analysis included SSCP and NGS (GS Junior454, Roche). Exons with abnormal migration patterns and changes in nucleotide sequence were confirmed by direct sequencing. Newly detected sequence variants were subjected to *in silico* predictions.
Results: We identified 129 *FBN1* mutations by SSCP and 16 *FBN1* mutations by NGS.
Conclusions: We have confirmed 129 cases of Marfan syndrome caused by *FBN1* mutation by SSCP analysis, which constitutes detection about 17%, and 16 cases by NGS, which constitutes detection about 29%. We have found that NGS is a more sensitive method for screening MFS than SSCP.

Preventive genetic testing using microarray technology is perspective prophylactic approach in medical practice

M. M. Litvinova[1,2], *K. G. Shevchenko*[2], *A. V. Polyakov*[3], *A. A. Isaev*[2];
[1]*I Moscow State I.M. Sechenov Medical University, Moscow, Russian Federation,* [2]*Human Stem Cells Institute, Moscow, Russian Federation,* [3]*Research Centre for Medical Genetics of Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Currently personalized medicine is developing very rapidly. The main focus of such approach is usually concentrated on detection of genetic predisposition to common complex disorders whereas less attention is devoted to preventive genetic testing for monogenic diseases. Our previous work proved that DNA-analysis for monogenic defects can be useful among newborns. Testing program "Gemascreen" includes 6 conditions: cystic fibrosis, phenylketonuria, spinal muscular atrophy, autosomal recessive deafness, Gilbert syndrome, lactase deficiency. From 211 cases the genotyping results of 115 analyses were found to be essential for health maintenance of the examined persons. In 19 cases the results were beneficial to the planning of individuals' future reproductive behavior (table 1).
To improve diagnosticum the microarray "Ethnogene-400" was developed based on APEX technology. The microarray allows to diagnose 80 monogenic disorders, 12 multifactor diseases and includes several pharmacogenetic tests (table 2). During design of the microarray several points were taken into account: Frequencies of diseases in Russian population; Known genetic cause of the disorder together with existence of common mutations in particular genes; Technical capability. Thus using of the microarray "Ethnogene-400" will facilitate the prophylactics of genetic disorders in the families of asymptomatic carriers and increase life quality and longevity in general population.

Genotyping results of 211 newborns for the most common monogenic disorders and conditions

Total amount of analyses: 211	Cases			
	Hetero-zygous	Homo-zygous		Homo-zygous
Disorders			Conditions	
Cystic fibrosis (CFTR)	3		Gilbert syndrome (UGT1A1)	25
Phenylketonuria (PAH)	2		Lactase deficiency (LCT)	89
Spinal muscular atrophy (SMN)	5			
Autosomal recessive deafness (GJB2)	8	1		
Total	18	1		114

Monogenic diseases from Federal list of Russian newborn screening program included into microarray

Disorder	Gene	Disease frequency	Amount of testing mutations	Testing informativity
Cystic fibrosis	CFTR	1/8 500	24	82%
Phenylketonuria (type 1)	PAH	1/10 000	16	87%
Phenylketonuria (type 2)	PTS	1/200 000	3	18%
Galactosemia	GALT	1/20 000	6	70%
Deafness (isolated neurosensory, autosomal recessive)	GJB2	1/5 000	6	91%
Deafness (Pendred syndrome)	SLC26A4	1/10 000	6	50%

P13.52

Targeted PCR-based enrichment and next generation sequencing for diagnostic testing of Primary Microcephalies (MCPH and Seckel Syndrome).

S. Drunat[1,2], *J. Masliah-Planchon*[1,2], *C. Vignal*[1], *H. Cave*[1], *S. Passemard*[3,2], *A. Verloes*[3,2];
[1]*Génétique Moléculaire, APHP, Hôpital Robert Debré, Paris, France,* [2]*U676-INSERM, Hôpital Robert Debré, Paris, France,* [3]*Génétique Clinique, APHP, Hôpital Robert Debré, Paris, France.*

Primary Microcephalies (PM) are a group of recessive disorders characterized by reduced head circumference without additional severe brain malformations, normal motor development and mental retardation. PM encompass two phenotypes, primary microcephalic dwarfism (PMDW or Seckel syndrome), with growth retardation and Autosomal recessive primary microcephaly (MCPH), with normal stature. MCPH and PMDW share the same pathogenesis and may result from mutations in at least 15 genes. Due to genetic heterogeneity, exhaustive conventional Sanger sequencing for PM diagnosis is expensive and time consuming and then, 50 to 75% of PM patients from the Caucasian population have no identified gene defect. In order to develop an efficient mutation-screening strategy for diagnosis, we evaluated a multiplex PCR-based approach in combination with next generation sequencing on 96 patients. The coding exons of 24 genes known to cause PM were targeted. 48 samples were screened with a first primer panel design. 95.2% of initially targeted regions were effectively covered. Sequencing resulted in a mean coverage of 301X with 88% of targeted regions being covered more than 25X. In targeted regions, we detected, on average, 163 variants per patient. Filtering and ranking finally yielded to 27 potentially pathogenic mutations still under investigations. The following 48 patients were screened with a second panel of primers designed to improve the coverage of the targeted regions and are still being analyzed. Our study shows the effectiveness of this strategy available to routine laboratories and its optimization will achieve the reliability required before its implementation in the context of the diagnosis.

Maturity-onset diabetes of the young (MODY) is a monogenic form of diabetes mellitus characterised by autosomal dominant inheritance, a young age of onset and pancreatic β-cell dysfunction. It is both clinically and genetically heterogeneous with mutations at the moment in at least thirteen genes. Genetic testing for MODY has become a routine procedure allowing to set up proper treatment and discriminate from type 2 diabetes (T2D) whose symptoms are often overlapping. Although more than 40 loci associated with T2D or glycemic traits have been reported and reproduced, only a minor part of the genetic component of the disease has been explained, and the causative variants and affected genes are unknown for many of the loci.
To determine the role of low-frequency coding variants in traits reflecting pancreatic β-cell function, insulin sensitivity and glycemia, we performed targeted resequencing technology by high-throughput sequencing in 27 patients with suspected MODY/T2D. They were Sanger sequencing-negative for mutations in the GCK, HNF1A, HNF4A, HNF1B genes. We excluded common, non-coding and synonymous gene variants, and performed in-depth analysis on filtered sequence variants in a pre-defined set of 103 genes implicated in glucose metabolism. We found, in association with known heterozygous SNPs already described in diabetes, rare and pathogenetic variants, demonstrating that this approach led to a genetic diagnosis in most of patients.
Interestingly two novel possible causative variations in MAFA gene, implicated in diabetes in animal models, in two different families could identify this gene as the fourteenth MODY gene.

P13.54

Validation of a novel high-throughput gene variation identification assay for diagnosis of monogenic diabetes

M. Hollensted[1], *R. Gao*[2], *X. Wan*[2], *Y. Liu*[2], *A. P. Gjesing*[1], *O. B. Pedersen*[1], *X. Yi*[2], *T. Hansen*[1,3,4];
[1]*The Novo Nordisk Foundation Center for Basic Metabolic Research, Section of Metabolic Genetics, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [2]*BGI Shenzhen, Shenzhen, China,* [3]*Steno Diabetes Center, Gentofte, Denmark,* [4]*Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark.*

Introduction: Maturity-Onset Diabetes of the Young (MODY) is a monogenic form of diabetes. It is a heterogeneous disorder and to date, 13 genes in which mutations may cause MODY have been reported. These distinct molecular etiologies explain the clinical heterogeneity and also differential responsiveness to treatment observed among MODY patients. MODY patients are often misdiagnosed as either type 1 or type 2 diabetes patients, resulting in suboptimal treatment, and the importance of correct MODY diagnosis through genetic testing is thus evident. So far, however, genetic screening has been performed using expensive and time-consuming Sanger sequencing.
Aim: To validate a novel high-throughput, cost-effective gene variation identification assay for diagnosis of monogenic diabetes.
Methods: We generated a novel targeted DNA capture and Illumina next-generation sequencing assay which is applicable to whole genome regions (including exons, introns, and untranslated regions of selected genes). A study sample of 70 Danish patients carrying previously identified causative variants in six of the known monogenic diabetes genes (*HNF4A, GCK, HNF1A, HNF1B, INS* and *KCNJ11*) were screened applying the novel assay.
Results: Among the 70 analyzed disease samples, we identified 63 small size single nucleotide polymorphisms and indels as well as seven larger deletions and duplications as the pathogenic variants. Our results are consistent with previously identified pathogenic mutations based on Sanger sequencing and the use of a Multiplex Ligation-dependent Probe Amplification assay.
Conclusion: The established platform is a cost-effective and high-throughput gene testing method which may be applied in clinical diagnosis of monogenic diabetes.

Hereditary myofibrillar myopathies (MFMs) are a group of rare neuromuscular disorders with a great genetic heterogeneity. Currently, the molecular genetics diagnosis is based on a gene-by gene approach (six causative genes identified until now) which is time consuming and expensive. Furthermore, to date, up to 50 % of MFM patients remain devoid of genetic confirmation of their disease. In a selected group of seven MFM patients we adopted high throughput techniques as WES (Whole-Exome-Sequencing) and CGH (Comparative Genomic Hybridization) to identify causative mutations, also supported by gene prioritization based on an algorithm providing candidate genes to interrogate the exome. Except for one with an autosomal dominant inheritance, all cases were sporadic. In all muscular biopsies, focal areas strongly immunoreactive with antibodies against desmin, αB-crystallin and myotilin were present within muscle fibers. Among these MFM patients, we identified two pathogenic mutations in FLNC gene, two variations in the titin (TTN) gene and a genomic duplication in LAMA2 gene. We also identified a variation located within the CAMK2D gene (not known to be involved in muscular diseases) as a novel variation with a possible role in MFM phenotype, to be confirmed in larger patients series and by functional evidence. We are currently studying a further cohort of 12 MFMs cases by WES analysis and pathway-driven candidate genes interrogation. We propose that these approaches may be the ideal tools for gene identification in MFM and other similarly clinically/genetically
heterogeneous muscle diseases.

Targeted "ciliome" sequencing for gene identification in nephronophthisis and associated ciliopathies

P. Krug[1,2,3], *E. Filhol*[1,2,3], *C. Masson*[3,2], *M. Parisot*[2], *C. Bole-Feysot*[2], *P. Nitschké*[3,2], *I. Perrault*[4,2,3], *R. Salomon*[1,2,5], *T. Attié-Bitach*[6,2,3], *K. Tory*[7,1,2], *C. Antignac*[1,2,8], *C. Jeanpierre*[1,2,3], *S. Saunier*[1,2,3];
[1]*Inserm U983, Paris, France,* [2]*Imagine Institute, Paris, France,* [3]*Université Paris Descartes, Sorbonne Paris Cité, Paris, France,* [4]*Inserm 781, Paris, France,* [5]*Department of Paediatric Nephrology, AP-HP, Necker Hospital, Paris, France,* [6]*Inserm U781, Paris, France,* [7]*Ist Department of Pediatrics, Semmelweis University, Budapest, Hungary,* [8]*Department of Genetics, AP-HP, Necker Hospital, Paris, France.*

Nephronophthisis (NPH) is an autosomal recessive, clinically and genetically heterogenous renal ciliopathy and a major cause of end stage renal failure in childhood. NPH is frequently associated with extra renal defects, retinal degeneration, cerebellar hypoplasia, polydactyly, cystic liver, situs inversus and skeletal anomalies.
To identify new genes underlying NPH and characterize the genetic bases of the phenotypic variability, we have recently developed a targeted high throughput approach allowing exome sequencing of 1200 ciliary genes (SureSelect Agilent technologies and SOLiD5500 XL Platform). We screened 113 patients presenting with isolated (28 cases) or syndromic (85 cases) NPH, in whom NPHP1 deletion, the most frequent mutational event, had been excluded.
Two pathogenic mutations in known ciliopathy genes were identified in 54 patients (48%). A major result is that all the genes encoding components of the intraflagellar retrograde transport (6 IFT-A genes and DYNC2H1) are frequently mutated (20 patients, i.e. 18%). Moreover, we identified 20 new

candidate genes, based on the presence of homozygous or compound mutations predicted to be damaging (frameshift, stop, missense) in 25 patients (22%). Among the 36 patients without any causative mutation identified, 14 presented with isolated NPH.
In conclusion, this method proved successful for both identifying mutations in already known ciliopathy genes as well as in novel candidate genes and to highlight the phenotypic variability associated with mutations of the same gene. Further analysis of the ciliome data will allow us to characterize the epistatic effect of mutations that could explain the phenotypic variability.

P13.58
Identification and characterization of a new candidate gene for steroid resistant nephrotic syndrome

A. Provenzano[1], *B. Mazzinghi*[2], *L. Giunti*[2], *F. Becherucci*[3], *L. Murer*[4], *M. Materassi*[3], *P. Romagnani*[5,3], *S. Giglio*[6,2];
[1]*Medical Genetics Unit, Department of Biomedical, Experimental and Clincal Sciences, University of Florence, Firenze, Italy,* [2]*Medical Genetics Unit-Meyer Children's University Hospital, Firenze, Italy,* [3]*Pediatric Nephrology Unit Meyer Children's University Hospital, Firenze, Italy,* [4]*Pediatric Unit Salus Pueri University of Padova, Padova, Italy,* [5]*Department of Biomedical, Experimental and Clincal Sciences, University of Florence, Firenze, Italy,* [6]*Medical Genetic Unit, Department of Biomendical, Experimental and Clinical Sciences, University of Florence, Firenze, Italy.*

Nephrotic syndrome (NS) is characterized by consistent proteinuria, oedema, hypoalbuminemia, and it can be classified as steroid-sensitive (about 90%) or steroid-resistant (SRNS-about 10%). To date, mutations in at least 15 genes have been found to cause SRNS and although mutations in *NPHS1* or *NPHS2* are frequent causes of children SNSR, mutations in other genes are very rare. In addition, multiple allelism and heterogeneity together with a phenotypic clinical overlap require an extensive mutational analysis effort to identify the molecular aetiology. To identify SRNS by molecular diagnosis has important clinical implication, as this would prevent unnecessary administration of corticosteroids and immunosuppressants.
We performed targeting and whole-exome (re)sequencing in 25 probands with a diagnosis of a paediatric SNSR (including 25 subjects steroid-sensitive). Because mutations in several genes have been demonstrated to lead to familial or sporadic SNSR, we focused our attention on these genes and on those candidates potentially implicated in the pathogenesis of the disorder. We identified a putative new candidate gene that may allow to define a novel clinical entity in the field of genetic disorders (hyperactivation of this gene was described to cause NS in podocyte-specific transgenic mice). Definition of the causative role of these mutations would represent the first case of an defect leading to a disorder where SRNS is part of a more complex clinical syndrome including also immunologic alterations. The results of our work may lead to the identification of a new causative gene for SRNS and provide definition of a previously unidentified clinical syndrome

Next generation sequencing for neurofibromatosis type 1 molecular diagnosis

E. Pasmant[1,2], *A. Luscan*[1,2], *P. Goussard*[2], *M. Vidaud*[1,2], *B. Parfait*[1,2], *D. Vidaud*[1,2];
[1]*UMR745 INSERM, PRES Sorbonne Paris Cité, Université Paris Descartes, Faculté des Sciences Pharmaceutiques et Biologiques, Paris, France,* [2]*Service de Biochimie et de Génétique Moléculaire, Hôpital Cochin, AP-HP, Paris, France.*

Neurofibromatosis type 1 (NF1) is a tumor predisposition syndrome with a worldwide birth incidence of 1 in 2500. NF1 is caused by dominant loss-of-function mutations of the NF1 gene (Neurofibromin 1). NF1 is a large gene containing 60 translated exons over ~280 kb. Most NF1 patients have private loss-of-function mutations scattered along the NF1 gene. Here, we present a NF1 targeted next generation sequencing (NGS) strategy developed at the Cochin Hospital (AP-HP, Paris, France). The custom primers panel targeting the entire NF1 coding exons and the 5' and 3' UTRs were designed using the AmpliSeq Designer. The targeted region (~12 kb) was amplified by 149 Amplicons of 200 bp using 20 ng of genomic DNA. NGS libraries preparation was performed using the Ion AmpliSeq Library Kit 2.0. Template-positive bar-coded samples were loaded on Ion 314 chips and sequenced with an Ion PGM Sequencer (Lifetechnologies). The 314 chip capacity allowed mixing 22 bar-coded samples, providing a 150X average coverage. Data were reanalyzed using the Torrent Suite 3.4. Sequence alignment and extraction of SNPs and indels were performed using the Variant Caller plugin on the Ion Torrent Browser. DNA sequences were visualized using the Integrated Genomics Viewer (IGV) from Broad Institute. Identified mutations were confirmed using Sanger sequencing. We validated this approach by testing 50 NF1 mutated DNA samples previously characterized by means of Sanger sequencing at DNA and cDNA levels. A prospective NGS study of 200 NF1 patients will confirm this method as a reference for routine molecular diagnosis.

Whole exomic next-generation DNA sequencing from dried blood spot DNA

D. Gavrilov, *R. Majumdar, A. McDonald, D. Oglesbee;*
Mayo Clinic, Rochester, MN, United States.

Efficient DNA sequencing approaches, such as next-generation sequencing (NGS), allows for simultaneous re-sequencing of many genes of interest (up to all genes in the genome) with greater speed and lower cost than by other methods. However, studies of applying this technology to dried blood spots (DBS) have not been completed. Here, we describe a comparative whole exome sequence (WES) analysis of DNA isolated from DBS and peripheral blood from the same individual. DBS DNA was sequenced on MiSeq (Illumina Inc.) platform using the Nextera Enrichment DNA Sample Prep Kit (Illumina Inc.). DNA from whole blood was sequenced on HiSeq 2000 (Illumina Inc.) with SureSelect V4 capture kit (Agilent). Although data obtained from the HiSeq had much higher read output, both sample types generated good quality data with high alignment percentages and the DBS enrichment was possible as seen by the high percentage of mapped reads (in capture region) numbers (97.7%). When assessing regions that were common to both capture kits (~31 Mb), over 95% of a total of 5,000-6,000 identified variants were identical between the studied sample types. Our preliminary data suggests that DNA isolated from DBS can be processed through our NGS system and results in accurate and specific reads. Moreover, the data imply that DBS are potentially a viable option for performing WES experiments with possible application for newborn screening. For our future studies, we propose to use the HiSeq2000 as sequencing platform as it results in a greater depth of coverage greater reliability.

P13.61
Adult patients with normal intellectual ability experience high satisfaction and low distress after diagnostic whole-exome sequencing: Preliminary results.

A. S. Sie, *J. B. Prins, W. A. G. van Zelst-Stams, M. R. Nelen, H. G. Yntema, L. Spruijt, S. Vermeer, J. A. Veltman, I. Feenstra, N. Hoogerbrugge;*
Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Background: Our Human Genetics department is one of the first offering diagnostic two-step whole-exome sequencing (WES). This study aimed to evaluate acceptance, risk perception and distress of WES in adults.
Patients/Methods: Between August 15th 2011 and June 20th 2012, 213 patients were offered diagnostic WES for colorectal/kidney cancer <40 years (n=51), deafness (n=60), blindness (n=41) or movement disorders (n=61), 177 (83%) accepted. Baseline questionnaires including risk perception and heredity-specific distress (IES) were sent to 141 adults with normal intellectual ability, 111 (79%) were returned. Follow-up after initial WES-results from disease-related gene sets, including satisfaction, is ongoing (currently n=73).
Results: Baseline responders were diagnosed with: 26% cancer, 27% deafness, 12% blindness, 35% movement disorders. Median age was 49 [22-79], 50% women, 83% with a positive family history. At follow-up, diagnostic suggestive mutations were found in 26%. Nearly all responders (94%) were satisfied with WES. Heredity risk perceptions were similar in baseline and follow-up: believing heredity caused their disease (77% and 69%) and expecting WES to find a genetic cause (51% and 46%). However, significantly more patients believed chance likely caused their disease (44% versus 58%, p=0.04) and fewer expected incidental findings (27% versus 19%, p=0.08). Heredity-specific distress was reported in only 17% versus 13%.
Conclusion: Acceptance was high in the group offered diagnostic WES after genetic counseling. Adults with normal intellectual disability reported low distress. After initial WES-results, they were highly satisfied. At follow-up heredity risk perceptions were unchanged, while perceptions of random

causality increased.

Next generation sequencing (NGS) is changing genetic diagnosis due to its huge sequencing capacity. The aim of this study was to develop an NGS based workflow for routine diagnostics for congenital long QT syndrome. Long QT syndrome is a genetic disease associated to delayed cardiac repolarization that is reflected by electrocardiographic feature of QT prolongation and T wave abnormalities, its predisposition for syncope, seizure, and sudden cardiac death in young individuals with structurally normal hearts. Mutations in 13 genes have been reported causing this pathology but current diagnostic testing is restricted to a small number of genes and 25% remained unresolved. A NGS-based workflow was designed using Haloplex Agilent libraries followed by MiSeq Illumina sequencing. We will describe our approach to the validation of the entire workflow (assay design, sample preparation, bioinformatic analysis and scientific analysis) of a NGS targetted enrichment of the 13 genes known to cause long QT syndrome. The validation process will include: defining minimum coverage criteria, assigning quality and coverage thresholds for SNP calling, defining criteria for filtering of benign polymorphisms and assessing SNP concordance between next generation sequencing and Sanger sequencing. Preliminary data showed that on a training set of 16 DNA samples of patients containing 16 unique pathogenic mutations, all mutations were detected and all samples were enriched with >70 % specificity, resulting in an average depth of coverage exceeding 100 fold after two runs of Illumina MiSeq sequencing. The results for 30 DNA patients negative for the major genes will be presented.

P13.63
Molecular diagnosis of monogenic diabetes applied to Next-Generation Sequencing

S. Clauin[1], *L. Heyrman*[2], *S. Beaufils-Langlois*[1], *A. Rotthier*[2], *C. Saint-Martin*[3], *J. Del-Favero*[2], ***C. Bellanné-Chantelot***[3,4];
[1]*Hôpital Pitié-Salpétrière, Département de Génétique, Paris, France,* [2]*Multiplicom N.V, Niel, Belgium,* [3]*Hôpital Pitié-Salpétrière, Département de Génétique, PARIS, France,* [4]*Institut de Cardiométabolisme et Nutrition, Paris, France.*

Monogenic diabetes (MODY) is characterised by autosomal dominant inheritance of young-onset diabetes due to defective insulin secretion. It is both clinically and genetically heterogeneous. The identification of a mutation has important implications for clinical management in diabetes. We co-developed with Multiplicom, a MASTR assay as front-end amplification for NGS based mutation and CNV detection in 7 MODY genes.
The MASTR assay comprises 99 amplicons enabling the amplification of all coding exons of 7 MODY genes (*GCK, HNF1A, HNF4A, HNF1B, ABCC8, KCNJ11* and *INS*) and 21 control amplicons for CNV analysis, all amplified in 5 multiplex reactions.
To verify the MASTR assay workflow, sixteen patients with know mutations were analysed using the standard MASTR protocol followed by sequencing on the 454 GS Junior instrument. The resulting sequencing data were analysed by AVA2 and SeqNext software tools.
We obtained an average of 100.000 reads per run (8 samples) corresponding to on average of 94X coverage per amplicon. All 17 known mutations (10 substitutions, 7 indels), 1 complete gene-deletion and 196 SNP at homozygous or heterozygous state were identified except one subtitution in a low-coverage amplicon and two indels located in homopolymer stretches. However, both indels were identified by GeneScan analysis of the MASTR assay. Based on the current analysis further optimisation of 10 amplicons is required to reach sufficient (40X) individual amplicon coverage for all amplicons with an average coverage of 100X.
In conclusion, the MASTR assay based NGS workflow seems well suited for the routine diagnosis of monogenic diabetes genes.

P13.64
Next Generation Targeted Amplicon Resequencing with Long Sanger-Like Read Lengths on the GS FLX+ System

D. Gratalo, *M. Mohiuddin, R. Winer, M. Driscoll, B. Simen, J. Nealis;*
454 Life Sciences Corporation, A Roche Company, Branford, CT, United States.

The Roche 454 GS FLX+ System features the unique combination of long reads, exceptional accuracy and high-throughput, making the system well suited for genomic projects that require large quantities of long reads such as *de novo* whole genome sequencing and assembly of large, complex organisms. With the launch of v2.9 system software, the long read and high accuracy sequencing capabilities will be available for amplicon applications. Here we describe our current development program leveraging an acyclic nucleotide flow pattern, Flow Pattern B, for highly accurate targeted sequencing of amplicons 700-800 base pair and longer. The longer reads allow more direct transition of existing Sanger amplicon designs to massively parallel sequencing with minimal re-design, direct haplotype phasing across longer spans, and improved identification of complex genetic variations including large insertions, deletions and block substitutions. The technique is also promising for metagenomic studies targeting 16S and 18S rRNA subunits by allowing full coverage of 6-7 variable regions in a single uni-directional amplicon read which enables the investigator to generate accurate diversity and abundance profiles. The advancements in long read sequencing will be applied to the GS Junior System as well.

P13.65
Targeted Next Generation Sequencing (NGS) for the molecular diagnosis of Autosomal dominant polycystic kidney disease (ADPKD)

M. P. AUDREZET, *P. GUEGUEN, A. DESPRES, C. FEREC;*
CHRU BREST, BREST, France.

Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic disorder, with an estimated prevalence ranging from 1/500 to 1/1000.
Mutation-based diagnosis in ADPKD is complicated by genetic and allelic heterogeneity, with 2 genes involved, *PKD1* and *PKD2*. Moreover, *PKD1* is duplicated over 2/3 of its length and is extremely rich in pyrimidic nucleotides.
Since a few years, NGS technologies enable us to overcome the classical approaches of whole coding sequence sequencing at single nucleotide resolution.
The aim of this study was to develop and validate a strategy to analyse both genes by Next generation sequencing (NGS) with the IonTorrent technology (Life Technologies).
As the complexity of the two genes renders impossible the use of target enrichment, we develop a home-made long range (LR) PCR strategy, followed by fragmentation and multiplexing to build our libraries. Thanks to PCR optimization, accurate quantification of our amplicons, we obtained a good coverage of the two loci and a depth generally consistent between each LR amplification for a multiplexing of 16 samples per run.
We used this approach to characterize the molecular defects in a series of DNA from patients with typical ADPKD carrying known variants (mutations and polymorphisms) previously identified by Sanger sequencing.
We identified an average of respectively 14 and 2 variations in *PKD1* and *PKD2* genes and all the molecular abnormalities, with the exception of one mutation affecting an homopolymer repeat were found.
In conclusion, NGS is a promising strategy for ADPKD molecular diagnosis as targeted therapies are under development.

A diagnostic strategy based on Next Generation Sequencing

C. Ruiz-Lafora, J. Valero, M. Bermejo, M. Molero, L. Rausell, M. Garcia-Hoyos, M. Perez-Alonso, ***J. Garcia-Planells****;*
Instituto de Medicina Genomica (IMEGEN), Paterna (Valencia), Spain.

Next Generation Sequencing (NGS) technologies are revolutionizing Genetics and Medicine reducing cost and timeline. Nevertheless their clinical utility still remains somewhat limited. Reduced sensibility compared with Sanger sequencing (gold standard), high volume of data and elevated number of incidental findings are some of the main obstacles. Our main objective is to develop a NGS based strategy that fulfills the following requirements: a) high sensibility comparable with Sanger, b) 100% representation of the regions of interest (ROI) and c) reduction of the information without clinical utility.
We have developed a protocol based on the specific amplification by PCR of coding regions of genes with clinical association and sequencing in a MiSeq Personal Sequencer. This protocol has been validated by comparison with the current gold standard sequencing technology, Sanger sequencing, in more than 900 nucleotide variations: substitutions and small indels, in homozygosis, heterozygosis or hemizygosis.
This strategy NGS based shows a specificity and robustness comparable with Sanger sequencing and a higher sensitivity detecting mosaicisms. The specific design, high coverage and sensitivity and the complete representation of the ROIs provide to this strategy a high clinical utility making possible its application at diagnostic level.

CORIMAGEN: Advanced diagnostics of cardiovascular risk and sudden death prevention in paraffin tissue.

R. Miñambres*[1], J. Lucena[2], A. Rico[2], M. Santos[2], E. Zorio[3], P. Molina[3], J. Giner[3], C. Buades[1], D. Cantalapiedra[1], P. Fernández[1], J. Rosa[1], S. Zúñiga[1], Á. Ballester[1], M. Gil[1], C. Collado[1], V. Fernández[1], S. Santillan[1];*
[1]Sistemas Genómicos, Paterna, Spain, [2]Forensic Pathology Service, Institute of Legal Medicine, Sevilla, Spain, [3]Sudden Death Unit, la Fe Hospital, Valencia, Spain.

Objectives: To analyze the accuracy of NGS in paraffin tissue for the study of genetics diseases in specific cases. We have developed a conceptual model for a complete genetic test in Sudden Death (SD) prevention.
Methods: NGS analysis was performed sequencing 72 genes related to cardiomyopathy and SD. FFPE spleen tissue and blood samples were collected at the postmortem examination. Autopsy reports indicated Arrhythmogenic Cardiomyopathy (AC) as a tentative cause of death. NGS was performed in SOLiD v4. Bioinformatic analysis was carried out according to our pipeline and pathogenic variants were then confirmed by Sanger.
Results: Firstly studied the correlation between fresh and FFPE tissue and we found a 76% of correlation. In first patient, we found a variant in *TMEM43* in both FFPE tissue and blood DNA. This has been previously described as a pathogenic mutation associated with AC. It was only found in the index case, suggesting its involvement in this cardiomyopathy. Second case we found two uncertain variants in *TTN* and *CACNB2*, which were detected also in both samples. Several healthy members also carried these variants suggesting a) these variants are no pathogenic b) One of them is pathogenic although with incomplete penetrance.
Conclusions:
-NGS in FFPE shows a high concordance with fresh tissue 76%
-We have detected the same variants in fresh and FFPE tissue.
-Additional studies are necessary.
-NGS is suitable for the study of FFPE tissue samples in specific families and circumstances.

Comprehensive massive parallel DNA sequencing strategy for the genetic diagnosis of the RAS/MAPK related syndromes

A. Justino*[1], P. Dias[2], M. J. Pina[1], C. Ribeiro[1], S. Sousa[1], L. Cirnes[1], A. B. Sousa[2], J. L. Costa[1], J. C. Machado[1];*
[1]IPATIMUP, Porto, Portugal, [2]Department of Genetics, Hospital de Santa Maria de Lisboa, Lisbon, Portugal.

The Noonan, Cardio-facio-cutaneous, Costello and LEOPARD syndromes are members of the RASopathies. Mutations in 11 genes have been causally linked to these disorders. Recently, an exome sequencing study also associated the gene *A2ML1*. Due to the genetic and clinical heterogeneity of these disorders it is challenging to define straightforward strategies of gene selection for their molecular diagnosis. Therefore, the aim of this study was to develop and validate a massive parallel sequencing (MPS) based strategy for the molecular diagnosis of RASopathies.
Genomic DNA of 50 clinically defined cases of RASopathies, including 3 suspected cases of prenatal diagnosis were used to optimize, validate and evaluate the new MPS methodology. A multiplex PCR-based strategy for the enrichment of the 12 genes and a dedicated variant prioritization pipeline was established. All samples were studied using both Sanger sequencing and Ion Torrent PGM.
All variants identified by Sanger sequencing were detected with our MPS approach. The most frequent mutated gene was *PTPN11* (n=15). Mutations in less frequent genes, like *CBL* (n=3), *SHOC2* (n=1) and the novel *A2ML1* (n=2) were found. The methodology resulted in an experimental approach with a specificity of 99.7% and a maximum analytical sensitivity ≥97.7% with a confidence of 95%.
In conclusion, here we present a workflow that provides a comprehensive genetic screening tool in patients with RASopathies in a fast and cost-efficient manner. This approach demonstrates the potential of a combined MPS-Sanger sequencing based strategy as an effective diagnostic tool for heterogeneous diseases and for prenatal genetic testing.

A novel nonsense mutation in *EDA* associated with nonsyndromic tooth agenesis

T. Nikopensius*[1,2], T. Annilo[1], T. Jagomägi[3], C. Gilissen[4], M. Kals[2], K. Krjutškov[1], M. Eelmets[1], U. Gerst-Talas[1], M. Remm[1], M. Saag[3], A. Hoischen[4], A. Metspalu[1,2];*
[1]Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, [2]Estonian Genome Center, University of Tartu, Tartu, Estonia, [3]Department of Stomatology, Faculty of Medicine, University of Tartu, Tartu, Estonia, [4]Department of Human Genetics, Nijmegen Center for Molecular Life Sciences, Institute for Genetic and Metabolic Disease, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Mutations in the ectodysplasin-A (*EDA*) gene have been generally associated with X-linked hypohidrotic ectodermal dysplasia (XLHED), which is characterized by skin lesions, sweat gland dysfunctions, and defective morphogenesis of teeth, hair, and nails. Recently, missense mutations in *EDA* have been reported to cause familial nonsyndromic tooth agenesis. In this study, we report a novel *EDA* mutation in an Estonian family segregating nonsyndromic tooth agenesis with variable expressivity. Affected individuals had no associated defects in other ectodermal organs. Using exome sequencing capture, we identified a heterozygous nonsense mutation c.874G>T (p.Glu292X) in the TNF homology domain of *EDA* in all affected females. This protein-altering variant has arisen *de novo* and the potentially causative allele was transmitted to affected offspring from affected mother. Glu292 is a highly conserved residue located on the outer surface of the EDA protein. We suggest that dental phenotype variability described in heterozygous female carriers of *EDA* mutation may occur because of the differential pattern of X-chromosome inactivation, which retains certain level of EDA-receptor signaling in tissues involved in tooth morphogenesis, resulting in tooth agenesis rather than XLHED.
The present study broadens the mutation spectrum for this locus and demonstrates that *EDA* mutations may result in nonsyndromic tooth agenesis in heterozygous females.

P13.70

Use of next-generation sequencing for diagnostics of connective tissue disorders

M. M. Weiss[1], *A. Maugeri*[1], *R. Straver*[1], *D. Van Beek*[1], *S. Dentro*[1], *G. Pals*[1,2], *E. Sistermans*[1], *Q. Waisfisz*[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Center for Connective Tissue Disorders, Amsterdam, Netherlands.*

Connective tissue disorders (CTDs) are a candidate for application of next-generation sequencing (NGS) in the DNA diagnostics setting because of the large size and large number of genes involved. The complex spectrum of, often overlapping, phenotypes, makes differential diagnosis difficult. For familial thoracic aortic aneurysms (FTAA), Marfan syndrome (MFS), Ehlers-Danlos syndrome (EDS) and Osteogenesis imperfecta (OI), more than 40 genes have been described. We currently perform approximately 2000 genetic analyses per year for patients suspected of a CTD. To improve diagnostics, we designed a platform for the parallel analysis of a set of CTDs, including all known genes for FTAA, MFS, EDS and OI.
A solution-based target enrichment kit was designed to capture all exons and flanking splice sites of 42 genes involved in CTDs. Sixty CTD patients, previously tested by Sanger sequencing and/or MLPA, were sequenced in multiplex on two separate lanes of a HiSeq2000 run. Subsequently, all samples were analyzed using a home-made pipeline, which specifically analyses six gene panels depending on the phenotype.
In the CTD patients, if coverage met our quality criteria (~97%), all mutations previously identified with Sanger sequencing were detected. Low coverage fragments (~3%) will be analyzed by Sanger sequencing analysis.
We offer the NGS CTD kit as a diagnostic service since January 2013. The NGS methodology offers advantages in terms of time-efficiency, especially in CTD with a complex spectrum of phenotypes and difficult differential diagnosis. Furthermore, this approach offers the possibility to associate mutations in known genes with novel, CTD related phenotypes.

Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary renal disorder caused by mutations of *PKD1* and *PKD2* genes and affecting approximately 1 in 500-1,000 births. ADPKD is a systematic disorder causing decline in renal function which often results in renal failure in adulthood.
The autosomal recessive form of polycystic kidney disease caused by mutations in the *PKHD1* gene is less common than ADPKD but it usually presents in early childhood when up to 50% of affected neonates die of pulmonary hypoplasia.
The aim of this work is the optimization of the molecular methods to provide reliable and fast presymptomatic, prenatal and preimplantation diagnostics of polycystic kidney disease. Presymptomatic DNA analysis has been performed in our laboratory for over 20 years by the linkage analysis. Nowadays the analysis performed within research projects also includes detection methods as heteroduplex analysis, Multiplex Ligation-dependent Probe Amplification and high resolution melting analysis. Recently we have added the next generation sequencing as well as a new mutational detection method in the *PKHD1* gene which is too complex for conventional detection methods.
So far, mutations of the PKD genes have been detected in more than 50% of 150 Czech families with ADPKD. Most mutations were unique for Czech population. Determination of localization and type of mutations within the *PKD* and *PKHD1* genes and their genotype-phenotype correlation improves DNA diagnostics together with the assessment of the clinical prognosis of patients.
Supported by the grant project IGA MZCR NT 13090-4 and PRVOUK- P25/LF1/2.

PhenoVar: a phenotype-driven analysis of exome sequencing data - proof of principle.

Y. Trakadis[1], *C. Buote*[2], *J. Therriault*[2], *H. Larochelle*[2], ***S. Levesque***[2];
[1]*McGill University Health Center, Montreal, QC, Canada,* [2]*University of Sherbrooke, Sherbrooke, QC, Canada.*

BACKGROUND: Widespread clinical utilization of Exome Sequencing (ES) requires an approach addressing issues such as incidental findings and accurate prediction of causal mutations among massive amount of variations. We propose a phenotype-driven analysis of exome data to predict diagnosis in the clinical setting.
METHODS: Control exome-files, modified to include a previously published pathogenic mutation, were combined to the corresponding published phenotypic data of ten test patients with varied polymalformative syndromes and were used to test the efficiency of our software, PhenoVar, in predicting their diagnoses. For each test patient, a geneticist blinded to the diagnoses reviewed the phenotype and selected 3 traits using terms in Human Phenotype Ontology. Modified exome variants file was input along with selected phenotypic traits in PhenoVar. PhenoVar calculated phenotypic similarity between the test patient and a database consisting of simulated patients for each OMIM phenotype with known molecular basis. Final diagnostic score assigned to a given OMIM entry took into consideration both the patient's phenotype and mutations. Resulting OMIM entries list was sorted according to diagnostic score and filtered using a minimal phenotypic weight threshold to prevent undesired discovery of incidental findings.
RESULTS: PhenoVar predicted the correct diagnosis in 5 / 10 patients, while in 8 / 10 patients the diagnosis ranked within top 5 predicted most likely diagnoses and within top 20 in all. No incidental findings were found using our minimal phenotypic threshold.
CONCLUSION : Results suggest that this "phenotype-driven" approach could render widespread use of ES more practical, ethical and clinically useful.

Homozygous frameshift deletion of *KIAA1279*, encoding for KIF1B-binding protein, results in autosomal recessive polymicrogyria

S. VALENCE[1,2], *K. Poirier*[1,2], *N. LEBRUN*[1,2], *F. ENCHA-RAZAVI*[3,4], *T. ATTIE-BITACH*[3,4], *J. CHELLY*[1,2], *N. BAHI BUISSON*[1,2,5];
[1]*Institut Cochin - INSERM U1016, Paris, France,* [2]*Institut Cochin, Université Paris-Descartes, CNRS (UMR 8104), Paris, France,* [3]*Département de Génétique, AP-HP, hôpital Necker, Paris, France,* [4]*INSERM U781, Hôpital Necker-Enfants Malades, Paris, France,* [5]*Neurologie pédiatrique AP-HP, hôpital Necker, Paris, France.*

Polymicrogyria (PMG) is a clinically heterogenous malformation of cortical development, characterized by a loss of the normal gyral pattern which is replaced by many small and infolded gyri separated by shallow sulci that are partly fused in their depths. Causes of PMG are heterogeneous and include acquired and genetic causes. There are more than 100 syndromes possibly associated with PMG but mutations in specific genes such as *SRPX2*, *GPR56*, *TUBB2B*, *TUBB3, NHEJ1*, *TUBA1A, TUBA8* and *WDR62* have been reported only in a minority of patients.
Nonsense mutations in the *KIAA1279* gene known to encode the KIF1B-binding protein, were initially described in patients with Goldberg-Shprintzen syndrome (GOSHS, MIM 609460).
By combining whole genome genotyping using single-nucleotide polymorphism (SNP)-array and whole exome sequencing, we identified a new pathogenic mutation in *KIAA1279* in two fetuses with severe PMG born from a healthy, consanguineous Pakistani parents. It consists of a frameshift deletion of 2 exons leading to premature termination of the translation. By detailed phenotypic analysis of both fetuses, we found that this homozygous mutation in *KIAA1279* gene causes PMG with microcephaly, but no additional sign suggestive of GOSHS.
This study expands the spectrum of KIF1B-binding protein related disorders and supports its critical role in neuronal migration and organization. Furthermore, the accurate molecular diagnosis of this family exemplifies the power of the combined strategy -SNP-array and exome sequencing- in the diagnosis of Mendelian disorders and allows us to broaden and refine our understanding of *KIAA1279*-related disorders.

Involvement of HYDIN in primary ciliary dyskinesia unveiled by a series of exome pitfalls

E. Kott[1], *P. Duquesnoy*[1], *B. Copin*[2], *R. Chiron*[3], *F. Dastot-Le Moal*[2], *G. Montantin*[2], *N. Collot*[2], *L. Jeanson*[1], *E. Escudier*[1,2], *M. Legendre*[1,2], *S. Amselem*[1,2];

Primary ciliary dyskinesia (PCD) are rare autosomal recessive disorders resulting from structural/functional defects of motile cilia, leading to recurrent respiratory infections. To identify new molecular defects involved in PCD, we combined homozygosity mapping and whole exome sequencing (WES). 3,953 sequence variations were identified in the homozygous regions of a consanguineous patient with a typical clinical PCD phenotype and subtle ultrastructural defects (i.e. abnormal central complex sheath). These include a frameshift (c.11709delT) in exon 69 of HYDIN, a gene that has just recently been involved in PCD. Although already described as SNP, we paid particular attention to this variation, given its presence in the homozygous state in the patient and apparently in the heterozygous state in all controls tested. The existence of a 99%-identical pseudogene of HYDIN (HYDIN2) led us to look for HYDIN variations with a 0.5 frequency and to note that at least one third of the so-called "SNPs" (including c.11709delT) are not true polymorphisms but represent sequence differences between HYDIN and HYDIN2. The apparent homozygosity of those fake "SNPs" in the patient revealed a homozygous intragenic deletion involving exons 68 to 71 of HYDIN (c.11469-750_12126+181del4046bp). As subsequently shown by the analysis of HYDIN transcripts obtained from nasal brushing, this deletion, which results in shorter transcripts, leads to a frameshift and a premature stop codon (p.Phe3824SerfsX20). This study, which underlines the role of HYDIN in the pathogenesis of PCD, illustrates the importance of cautious analysis of sequence variations identified by WES, in order to thwart multiple possible exome pitfalls.

Identity-by-Descent Mapping and Exome Sequencing Reveals a New Candidate Gene for the Primary Congenital Glaucoma locus GLC3E

H. Verdin[1], *B. P. Leroy*[1,2], *B. D'haene*[1], *E. Vantroys*[1], *S. Lefever*[1], *F. Coppieters*[1], *P. G. Kestelyn*[2], *E. De Baere*[1];
[1]*Center for Medical Genetics, Ghent University, Ghent, Belgium,* [2]*Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium.*

Primary congenital glaucoma (PCG) is caused by developmental anomalies of the trabecular meshwork and the anterior chamber angle, resulting in increased ocular pressure and optic nerve damage from early life. PCG mostly displays an autosomal recessive inheritance. To date, four PCG loci are known (GLC3A-D), with two genes identified, *CYP1B1* and *LTBP2*. Here, we aimed to map the disease gene in a four-generation consanguineous family with PCG from Jordan.
Mutations in known PCG genes were excluded. Identity-by-descent (IBD) mapping was performed in six affected members using genomewide SNP genotyping (250K, Affymetrix). Two affected individuals underwent exome sequencing (TruSeq Exome Enrichment; HiSeq, Illumina; CLC Bio).
IBD mapping revealed a common region of 11.5 Mb on 19p13.2-p13.11, being a new candidate PCG locus named GLC3E. Using IBD filtering of exome data and Ingenuity Variant analysis, we found a homozygous missense variant c.304C>T (p.R102C) in a novel candidate gene for GLC3E. This variant is predicted to be deleterious. It was absent in 718 Caucasian control chromosomes and was found in one out of 156 Jordan control chromosomes, being consistent with its reported minor allele frequency. The potential GLC3E might play a role in Toll- and BMP-signalling pathways. In addition, its mutations might dysregulate mitochondrial complex I. Its expression domain in the eye anterior segment is currently being investigated in zebrafish and mouse.
We identified a new candidate gene for the GLC3E locus, confirming the genetic heterogeneity of PCG, and possibly representing the third PCG gene.

P13.76

Next Generation Sequencing (NGS) for rare hemochromatosis forms: Ampliseq versus Long-Range PCR

G. Le Gac[1,2,3], *P. Gueguen*[1,2,3], *M. Audrezet*[1,2], *A. Despres*[1], *C. Le Marechal*[1,2,3], *C. Ferec*[1,2,3];
[1]*Laboratoire de génétique moléculaire - CHRU, Brest, France,* [2]*INSERM U1078, Brest, France,* [3]*Faculté de Médecine, UBO, Brest, France.*

Rare forms of hemochromatosis are associated with private missense mutations in five iron metabolism genes (*HFE*, *HJV*, *HAMP*, *TFR2* and *SLC40A1*). The Sanger sequencing method is commonly used to track these mutations. However, depending of the strategy used by laboratories, this method can be time consuming and quite expensive. Here, we aimed to explore whether next generation sequencing could improve the molecular diagnosis of hemochromatosis. We also considered the *FTL* gene that has been associated with different forms of inherited hyperferritinemia.
We have compared two strategies with using the Ion Torrent platform (Life Technologies, LT): Ampliseq(LT), which was designed to explore the whole coding sequences, the intron/exon junctions and the 5' and 3'untranslated regions (12.6 kb), and a home-made Long Range PCR(LR) method, which allowed us to explore the six entire loci (74 kb). Variants (mutations and polymorphisms) previously identified by Sanger sequencing were used for validation.
The coverage by Ampliseq is limited to 90.3% and only includes 94.9% of CDS, with a depth consistent between amplicons. The LR-PCR method allows analysing of regions not covered by Ampliseq but differences at depth are observed between LR amplicons. Libraries constructs from the LR-PCR method are two-times longer and require more manual steps.
NGS with using the Ampliseq technology could be used as a first screening method to diagnose rare forms of hemochromatosis and inherited hyperferritinemia without iron overload. Advances in technology should rapidly permit to improve coverage of the coding regions and to get an exhaustive and fully accurate reading.

Gene panel for screening of RASopathies using HaloPlex target enrichment and next-generation sequencing

S. Ekvall, *B. Baskin, B. Jonsson, E. Falk-Sörqvist, G. Annerén, M. Bondeson;*
Department of Immunology, Genetics and Pathology, Uppsala, Sweden.

RASopathies are a group of clinically and genetically related disorders, including Noonan, LEOPARD, cardio-facio-cutaneous (CFC), Costello, Legius and neurofibromatosis-Noonan syndrome and neurofibromatosis type 1 (NF1). These disorders result from mutations affecting the RAS-MAPK signaling pathway, which explains the clinical overlap within this group of syndromes. In the clinical setting, RASopathy-associated genes are traditionally tested sequentially using Sanger sequencing until a likely causative mutation is identified, which is laborious, time consuming and expensive.
We have utilized the advent of next-generation sequencing technology to develop a cost-effective multi-gene sequencing panel for RASopathies by using HaloPlex target enrichment, sample barcoding and sequencing with MiSeq. Our multi-gene panel targets the coding sequences of *NF1, PTPN11, SOS1, RAF1, BRAF, HRAS, KRAS, NRAS, SHOC2, SPRED1, MEK1, MEK2* and *CBL* (about 40 kb).
To validate the gene panel, 10 patients with known disease-causing mutations associated with NF1, Noonan, CFC and Costello syndrome were investigated. Five samples were pooled and run on a single lane of the MiSeq. Obtained sequences were analyzed using commercial data programs. The gene panel was highly specific; ~93% of sequencing reads aligned to targeted regions. Average read depth in the region of interest (ROI) was >2000 and ~98% of targeted bases in ROI had at least 30x coverage. All known mutations were identified, including a 4 bp deletion and a splice site mutation in *NF1*. Screening of additional RASopathy patients is presently underway.
Conclusively, the validated RASopathy-multi-gene sequencing panel presented here enables rapid and cost-effective high throughput screening of individuals with RASopathies.

Massively parallel sequencing identifies the large majority of mutations causing red blood cell membrane disorders.

*B. van der Zwaag[1], R. van Wijk[2], M. G. Elferink[1], M. J. Vogel[1], I. J. Nijman[1], E. Cuppen[1], W. W. van Solinge[2], **H. K. Ploos van Amstel**[1];*
[1]Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands, [2]Laboratory for Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands.

Hereditary disorders of the red blood cell (RBC) membrane constitute a major cause of hereditary hemolytic anemia, and are caused by mutations affecting structural proteins of the RBC cytoskeleton and their anchoring to the RBC membrane. Hereditary spherocytosis (HS) and elliptocytosis (HE) are common abnormalities, hereditary pyropoikilocytosis (HPP) and stomatocytosis (HST) are rare. In most cases the mode of inheritance is autosomal dominant. Traditionally, RBC membrane disorders are classified according to morphological appearance on blood smear. Molecular analysis has long been hampered due to the size of the genes involved, but has become feasible with the advent of Next Generation Sequencing (NGS). We set up and implemented an NGS based test to sequence seven genes associated with RBC membrane disorders: *SPTA1, SPTB, ANK1*, *SLC4A1*, *EPB41*, *EPB42* and *RHAG*. After enrichment of gDNA using a custom Agilent SureSelectXT kit (targeted at 650 clinically relevant genes) exons and flanking intronic sequences were determined using a SOLID™-5500XL system (~92% of bases covered with >99% sensitivity). Causative mutations, most of which were novel, were identified in 16/20 patients with defined membranopathies, predominantly in the *SPTA1* and *ANK1* gene. Surprisingly, no mutations were detected in the *SLC4A1* gene, a major cause of HS. NGS based DNA diagnostics has thus been shown to be a highly reliable and effective method to detect mutations in patients with hereditary RBC membrane disorders. The efficacy on these RBC membrane disorders might well be indicative for other disorders like epilepsy, heart and kidney diseases using the same custom enrichment kit.

Next generation sequencing in renal disorders: molecular and clinical aspects of renal tubular acidosis

V. Palazzo[1], *A. Provenzano[1], R. Artuso[2], E. Andreucci[2], M. Materassi[3], F. Emma[4], E. Benetti[5], M. Caruso[6], G. Ghiggeri[7], M. Genuardi[1], P. Romagnani[8,3], I. Pela[9], S. Giglio[1,2];*
[1]Medical Gentic Unit, Department Of Biomedical Experimental And Clinical Sciences, University Of Florence, Firenze, Italy, [2]Medical Genetic Unit Meyer Children's University Hospital, Firenze, Italy, [3]Pediatric Nephrology Unit Meyer Children's University Hospital, Firenze, Italy, [4]Pediatric Nephrology Unit Bambin Gesù Children's Hospital, Roma, Italy, [5]Pediatric Unit Salus Pueri University Of Padova, Padova, Italy, [6]Nephrology Unit Bergamo, Bergamo, Italy, [7]Pediatric Nephrology Unit Gaslini Children's Hospital, Genova, Italy, [8]Department Of Biomedical Experimental And Clinical Sciences University Of Florence, Firenze, Italy, [9]Department of Sciences for Woman and Child's Health, University of Florence, Firenze, Italy.

Molecular genetics has allowed the identification of the structure and function of the several main transporters and ion channels involved in renal disorders. Between that, distal renal tubular acidosis (dRTA) received increased attention because of advances in the understanding of the molecular mechanism. We studied 90 subjects with dRTA (where possible also their families) analyzing the *SLC4A1/ATP6V1B1/ATP6V0A4* genes and we focused on the clinical features and their correlation with the different types of mutations. Furthermore, in some of our cases we reported the association with medullary sponge kidney (MSK), a rare congenital renal disorder, characterized by diffuse ectasia of the tubules precaliceali collecting duct. In some subjects we have found variants in *ATP6V0A4* and *ATP6V1B1* genes, providing evidence of a possible role of the subunits B1 and a4 apical pump H^+ATPase in the pathogenesis of the MSK. Of all the individuals tested, 35 were negative after molecular analysis of the genes above cited and then we polarized our efforts to characterize from a clinical-molecular point of view families affected by RTA applying next generation sequencing strategy. We decided also to analyze genes encoding for SLC4A4/NBCe1, for ENaC subunits, those responsible for PHA2 and for the other the V-ATPase subunits and other pathway's genes that for us may be responsible of this genetic disorders (SLC26A11 and SLC4A9 subunits, SLC4A7 and SLC4A8 transporters, isoforms of the carbonic anhydrase, various G-protein-coupled receptors activated by protons or divalent cations). We will show the results of this new pilot study.

Next generation sequencing analysis of Inherited Retinal Dystrophies (IRD) using Agilent Haloplex technology.

M. E. Shanks[1,2], *P. Clouston[1], E. Packham[1], S. Reid[1], K. Thomson[1], J. Taylor[3], A. H. Nemeth[4,5], S. Downes[5], A. Seller[1];*
[1]Oxford Molecular Genetics laboratory, Oxford, United Kingdom, [2]Oxford Biomedical Research Centre, Univeristy of Oxford, Oxford, United Kingdom, [3]Biomedical Research Centre, University of Oxford, Oxford, United Kingdom, [4]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, [5]Oxford Eye Hospital, John Radcliffe Hospital, Oxford, United Kingdom.

Introduction: IRD is a common cause of vision loss (population prevalence ~ 1/3500) with significant genotype and phenotype heterogeneity. Genetic testing in clinical diagnostics has been limited because a similar clinical phenotype may be caused by mutations in numerous genes, all of which could require testing. Targeted gene capture and Next generation sequencing has provided the opportunity to investigate multiple genes per patient. We have designed a targeted retinal panel for 45 common causative genes and one deep intronic splice site associated with retinal degeneration.
Method: Our retinal panel workflow uses Agilent's Haloplex enrichment technology with Illumina's MiSeq platform. A bioinformatics pipeline has been designed to annotate and filter our results; using SoftGenetic's Next GENe as a variant caller and WAnnovar for annotation. Variants identified at a frequency of <5% in EVS and 1000 genomes are taken forward for literature investigation.
Results: Each MiSeq run produces > 4Gb of data and our validation experiments indicate that 96-98% of bases are covered at a minimum of 30 reads. Within the first panel of 10 patients, a pathogenic homozygous frameshift in AIPL1 was found in a Lebers congenital amaurosis (LCA) patient, whilst a second patient, with Usher II, had a pathogenic premature stop in the USH2A gene.
Conclusions: The Haloplex protocol is a fast, simple and efficient workflow that is suitable for use in a diagnostic setting for large gene screens in heterogeneous conditions.

P13.81

Application of Whole Exome Sequencing (WES) for the genetic characterization of families with an unusual phenotype of autosomal dominant Retinal Dystrophy (adRD)

P. Fernández San José[1], *B. Almoguera[1,2], F. Blanco-Kelly[1], M. Cortón[1], H. Hakonarson[2], C. Ayuso[1];*
[1]Department of Genetics, IIS-Fundación Jiménez Díaz, Madrid, Spain, [2]Center for Applied Genomics, Chidren's Hospital of Philadelphia. 3615 Civic Center Blvd. Philadelphia, PA 19104, Philadelphia, PA, United States.

Autosomal dominant retinal dystrophies (adDR) are a group of inherited diseases clinically and genetically heterogeneous. Late Onset Retinal Degeneration (LORD, MIM# 605670) is a rare subtype of adDR, which can be caused by the mutation p.Ser163Arg in C1QTNF5 gene. Patients with this mutation present a phenotype characterized by late onset with nictalopia and drusenoid deposits at the beginning, followed by midperipheral deposits, chorioretinal atrophy and electroretinographic reduced b wave.
Three members of family with and initial diagnosis of Retinitis Pigmentosa (RP) and/or Macular Degeneration (MD) and six healthy relatives were studied using Whole Exome Sequecing (WES). adDR common mutations were previously screened and discarded by adDR microarray (Asper Biotech) and Sanger sequencing for the most frequent genes responsible for adDR.
WES analysis identified the mutation p.Ser163Arg in C1QTNF5 gene in heterozygosity in all the affected members of the family.
The further screening of this mutation by Sanger sequencing in a cohort of 200 non-characterized adDR patients enabled the characterization of an additional family with a similar phenotype.
The follow up of patients is important for a precise diagnose on adDR families. The evaluation of new strategies for analysing infrequent adDR genes should be considered on patients with complex or unusual diagnose in order to exclude adDR known genes before performing WES.

Inherited retinal diseases (IRDs) are probably the most genetically heterogeneous disorders in man. To date, more than 190 genes have been identified and the number of loci that influence phenotype variability is expanding. In consequence, the diagnosis is not always easily performed due to phenotypic and genetic overlap. Current diagnostic approaches have been focused on the systematic evaluation of a set of known genes for each phenotype but this approach may fail in patients with inaccurate diagnosis. To overcome these limitations, we conducted an exome sequencing approach for the diagnosis of 7 unsolved families clinically diagnosed of autosomal recessive Retinitis Pigmentosa (arRP). In total, 28 samples were sequenced on SOLID 5500xl platform and stringent bioinformatic filters were applied. The most likely disease-causing variants were validated by Sanger sequencing and potential pathogenicity was assessed by functional predictions and frequency in controls. As a result, 10 likely pathogenic variants (6 novel) were detected in 6 out of 7 families. In two presumed arRP families, syndromic retinal disease genes were implicated. Clinical revaluation showed extraocular features that were overlooked at the time of first diagnosis. In other case (a sporadic RP patient) the inheritance pattern assigned was arRP (the most frequent one for sporadic RP cases), explaining why the disease-causing mutations were not found before. Our results reinforce the role of exome sequencing in the diagnosis of retinal diseases as a global approach even when clinical diagnosis or presumed inheritance pattern were not accurate. Supported by ISCIII (PI11-02923), FRA (CIVP16A1856) and CEICE (CTS-03687).

AmpliSeq™ RNA: Targeted sequencing of genes on the PGM ™

L. Chapman*, J. Schageman, B. Sanderson, A. Cheng, K. Bramlett;*
Life Technologies, Austin, TX, United States.

As Next Generation Sequencing matures, it is quickly moving into translational research applications where it has promise to be a useful tool for evaluation of human samples. RNA profiling using NGS (RNA-seq) is one of the applications where this potential is currently being realized. RNA-seq experiments have traditionally started with a whole-transcriptome library preparation that produces a sequencing template from all RNA species in a sample. However, in many cases, only a handful of the genes present are necessary to make a clinically relevant diagnosis.
We have demonstrated new technology that allows for RNA-seq from a panel of directed amplicons using an AmpliSeqTM approach with Ion Torrent semiconductor sequencing. This approach offers many advantages over microarray or qPCR such as faster turnaround and data analysis, sample multiplexing, lower RNA inputs, and ability to use degraded or FFPE-derived samples. In addition, the technique simultaneously provides quantitative gene expression information and gene sequence at the single nucleotide level.
For this targeted RNA-Seq method, cDNA is generated from total RNA, followed by amplification using primers designed for targeted genes. Resulting amplicons are prepared for sequencing using the AmpliSeqTM technology and sequenced on the Ion Torrent sequencing platforms. We demonstrate that the technique produces results that are technically reproducible, quantitative, and have excellent correlation with qPCR using TaqMan® gene expression assays. Employing barcodes, we have also tested multiple samples on a single chip thereby increasing the cost-effectiveness of the tool for higher throughput laboratory settings.

Sudden cardiac death (SCD) in the youth is a quite heterogeneous, mostly genetic disorder. In a large family with six victims of SCD (5 males/1 female, age of death 20 +6 years) WES was performed (Agilent SureSelect capture, Illumina sequencing) in an individual with stress induced ventricular tachycardia. A mean reading depth of the targeted sequences of 130x was reached (coverage: 92% >10x). Overall, 2008 variants were rare (MAF<1% in 1000 Genomes Project) and filtered for presence in 392 selected genes associated with inherited heart disorders. Hereafter, 8 (0.3%) coding variants remained (6x ns, 1x splice-site, 1x del). After analysis for evolutionary conservation, pathogenicity prediction (PP) and presence in the ESP database, 3 out of 8 (RYR2, RYR3, PLEC1) were checked for familial co-segregation. The RYR2 variant c.1082G>A (p.Cys361Tyr) is novel and likely to be causative, since sequence alignment showed high conservation, absence in databases and PP mostly (6:1) as 'deleterious'. Mutations in cardiac ryanodine receptor gene cause catecholaminergic polymorphic ventricular tachycardia (CPVT1). This RYR2 variant was also present in 5 additional family members (one SCD victim). The variants in PLEC1 c.12741C>G, p.Asp4247Glu) and RYR3 (c.7604T>C, p.Leu2535Pro) also affected highly conserved amino acids; PP was not conclusive (PLEC1: 2:3; RYR3: 4:1) and no clear clinical cosegregation for the RYR3 variant (SCD victim negative). The observation that in this large SCD family some relatives also were at cardiac risk may indicate presence of other gene variants causing a confounding overlay. This would have been undetected in a smaller family set.

Spinal Muscolar Atrophy - NGS targeted resequencing of the entire SMN2 gene

S. Radovic[1], *G. Dubsky de Wittenau*[2], *F. Cesca*[2], *F. Cattonaro*[1], *M. Morgante*[2,3], *F. Curcio*[4], *R. I. Lonigro*[2,4];
[1]*IGA Technology Services, Udine, Italy,* [2]*University of Udine, Udine, Italy,* [3]*Institute of Applied Genomics, Udine, Italy,* [4]*Azienda Ospedaliera di Udine, Udine, Italy.*

Genetic heterogeneity of individuals highlights the need to enhance personalized medicine to achieve effective treatments of human diseases. Spinal muscular atrophy (SMA) is an autosomal recessive neuromuscular disease characterized by degeneration of α-motorneurons in the spinal cord. The primary SMA-determining gene is SMN1, absent in about 95% of patients. The neighbouring nearly identical SMN2 gene fails to generate adequate levels of full-length SMN protein (FL-SMN). Still, SMN2 copy numbers can vary between 1 and 6, potentially modifying the severity of the disease. However, all SMN2 alleles are not functionally equivalent since they produce FL-transcripts with different efficiencies, most probably due to variations in their sequence.
We established a new method to identify genetic polymorphisms in the complete genomic region of SMN2. We resequenced 40 SMN2 gene copies from 12 SMA subjects with varying SMN2 copy numbers using the Illumina platform and a pooled indexing strategy. We identified a total of 69 SNPs and 40 INDELs out of which 21 and 37, respectively, had not been reported previously. So far, we confirmed by genotyping assays the first fifteen SNPs that were chosen for validation. The estimated variant frequencies are usually indicative of the number of variant gene copies per subject when related to the individual's SMN2 copy numbers.
The method we described is ready to be used to identify variants/haplotypes associated with a particular SMA phenotype.

Proximal monosomy of 13q due to 6;13 translocation

H. Mkrtchyan[1], *A. Hovhannisyan*[1], *A. Gasparyan*[1], *L. Nazaryan*[2], *S. Midyan*[1], *N. Tommerup*[3];
[1]*Center of Medical Genetics and Primary Health Care, Yerevan, Armenia,* [2 1]*; Wilhelm Johannsen Centre for Functional Genome Research, Institute of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark,* [3]*Wilhelm Johannsen Centre for Functional Genome Research, Institute of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark.*

Chromosome 13q deletion is associated with varying phenotypes, which seem to depend on the location of the deleted segment. Although various attempts have been made to link the 13q deletion intervals to distinct phenotypes, there is still no acknowledged consensus correlation between the monosomy of distinct 13q regions and specific clinical features. Here we describe a case of proximal monosomy 13q in a 8 month-old boy. He was referred for cytogenetic study due to different dysmorphic features involving a brachydactily, beaked nose, high frontal hairline, flat occiput, wide nose bridge, epicantus along with double sided hydronephrosis and non-closed Bottalo's duct. Karyotype revealed the translocation 45,XY,t(6;13)(p25;q12)dn. Firther Affymetrix Genome-Wide SNP Array 6.0 analysis has revealed approximately 6Mb deletion on chromosome 13(13q11-13q12.12)(chr13:19045719-25196912, GRCh37/hg19) in the patient's genome. No deletion was detected on chromosome 6. However, we cannot excluded that there might be subtelomeric deletion of 6p, which was not detected by any SNP on the array platform due to highly repetitive region. We assume that the input of the 6p deletion might be insignificant comparing with 13q proximal deletion, which includes a number of reliable genes: for example GJB6 is associated with autosomal dominant deafness; FGF9 is associated with multiple synostoses syndrome, which also includes deafness; SGCG associated with muscular dystrophy limb girdle type 2C; and SACS is casing spastic ataxia Charlevoix Saguenay type. Thus, the child may be under a high risk of having deafness, muscular dystrophy and ataxia based on the deleted regions.

Dissecting the genotype in syndromic intellectual disability using whole exome sequencing in addition to genome-wide copy number analysis

V. Riehmer[1,2], *C. F. Classen*[3], *C. Landwehr*[2,4], *A. Kosfeld*[1], *S. Heilmann*[2,5], *C. Scholz*[1], *S. Kabisch*[3,6], *H. Engels*[2], *S. Tierling*[7], *M. Zivicnjak*[8], *F. Schacherer*[9], *D. Haffner*[3,8], ***R. G. Weber***[1,2];
[1]*Department of Human Genetics, Medical School Hannover, Hannover, Germany,* [2]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [3]*Department of Pediatrics, University Hospital, Rostock, Germany,* [4]*Institute of Medical Diagnostics, Berlin, Germany,* [5]*Department of Genomics, Life and Brain Centre, University of Bonn, Bonn, Germany,* [6]*Department of Pediatrics, Division of Neonatology and Intensive Care, University Hospital Hamburg-Eppendorf, Hamburg, Germany,* [7]*Universität des Saarlands, Biowissenschaften, Genetik/Epigenetik, Saarbrücken, Germany,* [8]*Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany,* [9]*Biobase GmbH, Wolfenbüttel, Germany.*

When a known microimbalance affecting multiple genes is detected in a patient with syndromic intellectual disability, it is usually presumed causative for all observed features. Whole exome sequencing (WES) allows questioning this assumption. In this study of three families with children affected by unexplained syndromic intellectual disability, genome-wide copy number and subsequent analyses revealed a *de novo* maternal 1.1Mb microdeletion in the 14q32 imprinted region causing a paternal UPD(14)-like phenotype, and two inherited 22q11.21 microduplications of 2.5Mb or 2.8Mb. In patient 1 carrying the 14q32 microdeletion, tall stature and renal malformation were unexplained by paternal UPD(14), and there was no altered *DLK1* expression or unexpected methylation status. By WES and filtering with a mining tool, a novel *FBN1* missense variant was found in patient 1 and his mother, who both showed clinical features of Marfan syndrome by thorough anthropometric assessment, and a novel *EYA1* missense variant as a probable cause of the renal malformation in the patient. In patient 2 with the 22q11.21 microduplication syndrome, skin hypo- and hyperpigmentation and two malignancies were only partially explained. By WES, compound heterozygous *BLM* stop founder mutations were detected causing Bloom syndrome. In male patient 3 carrying a 22q11.21 microduplication inherited from his unaffected father, WES identified a novel missense variant in the *OPHN1* X-linked intellectual disability gene inherited from the unaffected mother as a possible additional cause for developmental delay. Thus, WES seems warranted in patients carrying microdeletions or microduplications who have unexplained clinical features or microimbalances inherited from an unaffected parent.

Targeted Next Generation Sequencing of TAAD genes using DNA isolated from paraffin embedded tissue

M. Stuhrmann, *B. Keyser, T. Hartmann, A. Schöner, M. Mälzer, J. Schmidtke; Medical School, Hannover, Germany.*

Thoracic Aortic Aneurysms and Dissections (TAAD) may occur isolated or as part of syndromes, like Marfan or Loeys-Dietz syndrome. Mutations in several different genes are known to cause TAAD. Diagnosis is often made during autopsy. If available, paraffin embedded tissue can be used for *post-mortem* genetic testing. However, DNA extracted from this tissue is often degraded. Since next generation sequencing (NGS) with the Illumina MiSeq platform requires DNA fragments around 300 base pairs, it should be possible to analyse DNA isolated from paraffin embedded tissue with this platform.
We isolated DNA from paraffin embedded tissue from six deceased TAAD. Library preparation was carried out using a customized TruSeq Custom Amplicon Kit from Illumina. Sequencing was performed with the Illumina MiSeq.
185 exons of the genes *ACTA2*, *COL3A1*, *FBN1*, *MYH11*, *SLC2A10*, *SMAD3*, *TGFBR1*, and *TGFBR2* have been analysed. The results showed that the quality of the sequences depended directly on the quality of the isolated DNA. When the fixation of the tissue was poor (e.g. unbuffered formalin, no homogenous fixation), the coverage was very low. With good fixation, the sequencing results resembled that of DNA isolated from blood. Between 5% (poor fixation of the tissue) and 91% (good fixation/DNA from blood) of the 185 exons had a coverage greater than the threshold that we set at 50x.
In the six analysed patients, we found some new sequence variations with yet unclear relevance.
In conclusion, DNA from paraffin embedded tissue can be analysed by NGS, when the fixation has been done properly.

Primary Immunodeficiencies (PID) are a heterogeneous group comprising over 150 diseases caused by congenital defects of the immune system. These diseases are mainly characterized by severe recurrent infections, and can often be life-threatening. Diagnosing patients with PID is however challenging, since more than 179 genes are known to cause these diseases.
In this study, we adopted a selector-based sequencing capture assay together with Illumina sequencing, to identify disease-causing mutations in all 179 PID genes simultaneously, and evaluated the usefulness of this targeted assay for molecular diagnosis of PID. The exons of the 179 genes were captured and sequenced in 34 patients, 15 of which had at least one known causal mutation at the onset of the experiment.
Sequencing reads were aligned against the targeted regions, and variants were detected using an in-house developed software tool.
In order to narrow down the number of potential disease-causing mutations per patient, variants were filtered according to read depth, variant allele ratio and variant consequence.
Using the applied criteria, 17 out of 21 (~81%) known single base or short indel variants were detected, resolving of the mutation status for 12 out of 15 individuals (80%).
Sequencing of the unknown samples resulted in the discovery of several new mutations that could be confirmed by Sanger sequencing.
We will present the outcome of our mutation analyses, and discuss the usefulness of the developed assay for first tier cost efficient molecular diagnosis of PID, reducing the number of patients subjected to more expensive exome and genome sequencing.

The Shared Variant Database

*M. Vermaat[1,2,3], H. Mei[1,3], I. F. A. C. Fokkema[1], P. E. M. Taschner[4], **J. T. den Dunnen**[1,2], J. F. J. Laros[1,2,3];*
[1]Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands, [2]Leiden Genome Technology Center, Leiden University Medical Center, Leiden, Netherlands, [3]Netherlands Bioinformatics Centre, Nijmegen, Netherlands, [4]Department of Human Genetics, Leiden University Medical Center, Amsterdam, Netherlands.

DNA diagnostics is based on sharing information on gene variants found in patients with a certain phenotype. Yet, most variants are not shared and valuable information gets lost. This is especially true for exome/genome sequencing projects, where only the results of successful projects and of these only the causing variants identified get published.
We have developed the Shared Variant Database (SVD) to support easy and pre-publication sharing of all variants and phenotypes. Upon submission a report is returned summarizing, per variant, its frequency in the database. To address privacy concerns, data can be submitted as a pooled set. The SVD accepts input in VCF and BED formats for variant calls and coverage respectively. For variants that have a low frequency the submitter has the option to contact submitting colleagues.
The public part of the SVD shows data that were made public by their submitters and summary data from other sources. Variants can be shared with or without links to an individual. Submitters have the option to mark variants that are of special interest. These options should facilitate sharing data of unsolved cases with the intention to initiate a collaboration with others that have similar cases/findings.
An earlier version of the SVD, the Diagnostic Variant Database (DVD), was implemented to support the Dutch medical centers performing exome sequencing, facilitating effective filtering of variants frequently occurring in the Dutch population.

Next Generation Sequencing in molecular diagnostics of previously undiagnosed clinical conditions

A. M. Boguszewska-Chachulska[1], *M. Krawczyk*[2,1], *D. Loska*[2,1], *M. Zagulski*[1];
[1]Genomed SA, Warsaw, Poland, [2]Polish-Japanese Institute of Information Technology, Warsaw, Poland.

Our project is aimed at identifying the molecular bases of previously undiagnosed genetic diseases in Polish patients by Next Generation Sequencing (NGS), mainly whole exome sequencing and multiplex PCR-NGS.
Whole exome sequencing was performed for DNA samples of nine patients, representing undiagnosed clinical cases, and a healthy control. Exome-enriched libraries were prepared and sequenced using the TruSeq chemistry and GA II or HiSeq 2000 instruments (Illumina). The exome analysis was performed using specialised open access, commercial and company-developed bioinformatic tools. A pipeline was designed for data quality analysis, mapping and SNP/indel detection for diagnostic purposes.
As a result of our studies, a previously described heterozygous mutation in the COL1A2 gene (c.1009G>A) was identified as resulting in osteogenesis imperfecta symptomes in one patient, and its inheritance in the patient's family was analysed. Exome data analysis also allowed us to identify two mutations in the CAPN3 gene responsible for the muscular dystrophy symptoms, indicating the Limb-Girdle Muscular Dystrophy type 2A diagnosis. Both mutations are single nucleotide deletions, leading to frameshifts. The first mutation is one of two most common mutation in the CAPN3 gene (c.550delA), the second mutation (c.1642delC) has never been reported before. Polyphen 2 and SIFT analyses suggested its pathogenicity and possible targeting of improperly terminated mRNA for nonsense mediated decay. The biparental inheritence and carrier status of both mutations in the patient's family were analysed.
The results of our studies allow us to propose whole exome sequencing as a tool that can be applied to diagnose Mendelian disorders.

P13.93

Whole-exome sequencing in Altaian families with autosomal recessive nonsyndromic hearing loss (the Republic of Altai, Southern Siberia)

A. Y. Churbanov[1], *O. L. Posukh*[2,3], *T. M. Karafet*[1];
[1]ARL Division of Biotechnology, University of Arizona, Tucson, AZ, United States, [2]Institute of Cytology and Genetics, Novosibirsk, Russian Federation, [3]Novosibirsk State University, Novosibirsk, Russian Federation.

Mutations in more than 70 different genes were found as the causes of hereditary Non-Syndromic Hearing Loss (NSHL). Identification of NSHL-responsible genes is a significant challenge due to extreme genetic heterogeneity of the disorder. Here we explore the utility of whole-exome sequencing (WES) for identifying candidate causal variants in unrelated families from Altai with undiagnosed potentially autosomal recessive NSHL (ARNSHL). We performed WES on 6 siblings, two from each of three Altaian extended families (F#38, F#40, F#54), with proportion of affected to non-affected siblings as 4:5, 4:5, 5:3, correspondingly. Likelihood of mutations compromising *GJB2* gene has been ruled out in these families. Sequence processing and variant calling were performed using standard bioinformatics tools. A custom filtering system was used to prioritize novel variants of candidate genes. We identified a novel missence homozygous mutation (NM_194248.2:c.1111G>C) in gene *OTOF* known in association with ARNSHL (DFNB9) in both affected siblings (F#54) and missence homozygous mutation (NM_030665.3:c.5254G>A) in gene *RAI1* previously associated with Smith-Magenis syndrome (OMIM#182290) and Potocki-Lupski syndrome (OMIM#610883) in four affected siblings (F#38, F#40). Subsequent Sanger sequencing of extended families confirmed cosegregation of homozygous mutations c.1111G>C (*OTOF*) with hearing loss in all affected siblings of F#54, and c.5254G>A (*RAI1*) in all affected siblings in F#38, F#40. Non-affected siblings from all families were either wt/wt or heterozygous for c.1111G>C (*OTOF*) in F#54, and for c.5254G>A (*RAI1*) in F#38, F#40.
Study was supported by grant 2011Y1SA09 from the CAS Fellowship for Young International Scientists, NSFC grant 31150110466 to AC, RFBR grant #11-04-01221-à to OP.

NGS diagnosis on Willebrand disease : about a highly homologous pseudogene ?

M. GIRAUD[1], *P. BOISSEAU*[1], *P. TALARMAIN*[1], *J. HARY*[1], *M. GOURLAOUEN*[1], *C. TERNISIEN*[1], *E. FRESSINAUD*[2], *A. VEYRADIER*[2], *S. BEZIEAU*[1];
[1]CHU Hotel Dieu, Nantes, France, [2]CHU, Clamart, France.

Von Willebrand Disease (VWD) is a common autosomally inherited bleeding disorder which results from a quantitative or qualitative deficiency of von Willebrand factor (VWF), a glycoprotein that is essential to primary haemostasis. The VWF gene (VWF) is located on the chromosome 12, resides within 178 kb of genomic DNA and consists of 52 exons which gives rise to a 9kb mRNA. Systematic identification of the causal VWD sequence variations has been hampered by the large size of the VWF, but the main difficulty resides on a 97% homologous partial pseudogene from exon 23 to exon 35 (21kb of genomic DNA). Cost and time consuming of Sanger method sequencing remain a serious obstacle for most diagnostic laboratories. However, Next Generation Sequencing (NGS) have radically changed the technical perspectives over the last years. Then we have planed to test NGS for VWD diagnosis to evaluate the accuracy of this resequencing technique for this highly homologous region. We have selected the Agilent HaloPlex target enrichment system to prepare sequencing library samples running out on illumina MiSeq platform. The HaloPlex probes library design has been made on the Agilent web-base SureDesign , (free software) and comprised VWF exons, introns, 5' and 3' UTR and the known promoter. This design foresee a coverage rate of 95.84% of the whole gene. 48 patients have been tested and raw datas will be analysed and compared to capillary sequencing. Results will be discussed on the ESHG poster.

Rapid sequencing of clinical samples using the Ion Proton™ system

A. Ameur, *C. Lindau, S. Häggqvist, I. Jonasson, U. Gyllensten;*
Dept. of Immunology, Genetics and Pathology, Uppsala University, National Genomics Infrastructure at Science for Life Laboratory, Uppsala, Sweden.

We are evaluating the Ion Proton™ System (Life Technologies) as a platform for massively parallel sequencing of clinical samples (MPS). This technology has several potential advantages as compared to other platforms for MPS. A sequencing run only takes 3 hours and the mapping and variant calling analysis is completed within 24 hours. Sequencing of human exomes using the Ion PI™ chip typically results in the identification of 60-70,000 SNPs per sample, with ~98% of these overlapping variants reported in dbSNP. We successfully recover known insertions of lengths up to 25 bp and deletions of up to 37 bp. The bioinformatics analysis has been streamlined using in-house database system, based on R and MySQL, where all detected variants from all our exome sequencing runs are stored. This system allows for very efficient filtering of SNPs and indels between any group of samples in a matter a seconds. In addition to exome sequencing, Ion Proton™ is being used for clinical applications such as identification of fusion transcripts from cancer samples, mutation screening using panels of candidate genes and whole-genome sequencing of bacterial or viral human pathogens. The introduction of the Ion PII™ chip will enable whole-genome human sequencing in the time frame necessary to be useful for an increasing range of clinical applications.

A fast solution to NGS library preparation with low nanogram DNA input

P. Liu, *B. W. Langhorst, E. Yigit, L. M. Apone, D. B. Munafo, C. Sumner, F. J. Stewart, G. J. S. Lohman, E. Cantor, T. C. Evans Jr, N. Nichols, E. T. Dimalanta, T. B. Davis;*
New England Biolabs, Ipswich, MA, United States.

Next Generation Sequencing (NGS) has significantly impacted human genetics, enabling a comprehensive characterization of the human genome as well as a better understanding of many genomic abnormalities. By delivering massive DNA sequences at unprecedented speed and cost, NGS promises to make personalized medicine a reality in the foreseeable future. To date, library construction with clinical samples has been a challenge, primarily due to the limited quantities of sample DNA available. To overcome this challenge, we have developed NEBNext® Ultra DNA Library Prep Kit, a fast library preparation method using novel NEBNext reagents and adaptors, including a new DNA polymerase that has been optimized to minimize GC bias. This method enables library construction from an amount of DNA as low as 5 ng, and can be used for both intact and fragmented DNA. Moreover, the workflow is compatible with multiple NGS platforms.

P14.03

Next Generation Sequencing application to challenged sequencing on homologous genes CLCNKA and CLCNKB, implicated in two forms of Bartter syndrome.

L. Mansour-Hendili, *N. Le Pottier, I. Roncelin, X. Jeunemaître, R. Vargas-Poussou;*
AP-HP, Paris, France.

CLCNKA and CLCNKB encode for renal chloride channels ClC-ka and ClC-kb involved in Bartter syndrome (BS), a rare recessive salt-losing tubulopathy. These genes are highly homologous, with a 95% identity and a similar genomic organisation. In order to improve CLCNKB analysis and to sequence CLCNKA, we have developed a NGS protocol for both genes in a same run.
The DNA library was prepared using nebulised specific LR-PCR following manufacturer recommendations. Each patient was tagged with two distinct MIDs, one for each gene. The library was clonally amplified using emulsion PCR, enriched and loaded on a picotiter plate on a GS junior (Roche). Data were analysed with Reference mapper (Roche) and Seqnext (JSI medical). Both genes were sequenced for 7 patients and 3 controls and only CLCNKB in 2 patients and 3 controls. We compared NGS results to Sanger sequencing to determine specificity and sensitivity.
The main obtained coverage varied from 40 to 200. All coding variants found with Sanger analysis were found with NGS. The sensitivity was near 100% for the common regions tested and the analytic specificity was verified by the right match between the reads and reference sequence on the entire chromosome 1.
In conclusion, this study allowed us to develop a whole specific sequencing of the homologous CLCNKA and CLCNKB genes in a same run. The use of NGS in diagnosis requires secure interpretation with two softwares, in order to avoid misinterpretation of contiguous variants and homopolymers regions, and a well defined threshold for variant interpretation.

P14.04

Combination HRM and MLPA for identification of methylation status at the H19 and KCNQ1OT1 DMRs in patients with Beckwith-Wiedemann syndrome

C. Hung[1,2], *C. Lee*[3], *S. Lin*[4], *Y. Su*[2];
[1]*Graduate Institute of Clinical Genomics, National Taiwan University College of Medicine, Taipei, Taiwan,* [2]*Sofiva Genomics, Co., Ltd,, Taipei, Taiwan,* [3]*Department of Obstetrics and Gynecology, Taipei, Taiwan,* [4]*Department of Obstetrics and Gynecology, National Taiwan University Hospital, Hsin Chu Branch, Hsin Chu, Taiwan.*

Methylation alterations in *H19* and *KCNQ1OT1* differentially methylated regions (DMRs) on chromosome 11p15.5 are relatively common in Beckwith-Wiedemann syndrome (BWS). Gain of methylation in *H19* DRM or loss of methylation in *KCNQ1OT1* DMR result in heterogeneous overgrowth which is also associated with high risk for tumor development. The goal of the study was to combine methylation-sensitive high-resolution melting analysis (MS-HRM) and methylation-specific multiplex ligation-dependent probe amplification (MS-MLPA) for the identification of *H19* and *KCNQ1OT1* DMRs methylation status in 43 patients with Beckwith-Wiedemann syndrome. The genotypes of these samples were compared to traditional methylation-specific PCR results. Of 43 BWS samples, 30.2% (13/43) were hypomethylation in *KCNQ1OT1* DMR, 2.3% (1/43) were hypermethylation in *H19* DMR, 2.3% (1/43) were paternal uniparental disomy (UPD), and 65.1% (28/43) were negative. The detection rate for BWS at two DMRs is 34.9%. These two methods produced consistent results regarding methylation status and yielded neither false positive nor false negative results. Moreover, this study provides a representative picture of the distribution of methylation status of *H19* and *KCNQ1OT1* DMRs in clinically ascertained BWS cases in the Taiwanese population. The MS-HRM and MS-MLPA clearly demonstrated that these are significant tools for quantification of methylation in molecular epigenetic diagnosis.

FAVR (Filtering and Annotation of Variants that are Rare): methods to facilitate the analysis of rare germline genetic variants from SOLiD and Illumina datasets

T. Nguyen-Dumont[1], *B. J. Pope*[2], *F. Odefrey*[1], *R. Bell*[3], *S. V. Tavtigian*[3], *A. Lonie*[2], *M. C. Southey*[1], *D. J. Park*[1];
[1]*Department of Pathology, The University of Melbourne, Parkville, Australia,* [2]*Victorian Life Sciences Computation Initiative, The University of Melbourne, Melbourne, Australia,* [3]*Huntsman Cancer Institute, Salt Lake City, UT, United States.*

Characterising genetic diversity through the analysis of massively parallel sequencing (MPS) data offers enormous potential to significantly improve our understanding of the genetic basis for observed phenotypes, including predisposition to and progression of complex human disease. Great challenges remain in resolving genetic variants that are genuine from the millions of artefactual signals.
FAVR is a suite of new methods designed to work with commonly used MPS analysis pipelines, with a focus on relatively rare genetic variants. The most important and novel aspect of FAVR is the use of signatures in comparator sequence alignment files during variant filtering, and annotation of variants potentially shared between individuals. The FAVR methods use these signatures to facilitate filtering of (i) platform and/or mapping-specific artefacts, (ii) common genetic variants, and, where relevant, (iii) artefacts derived from imbalanced paired-end sequencing, as well as annotation of genetic

variants based on evidence of co-occurrence in individuals. We applied conventional variant calling applied to whole-exome sequencing datasets, produced using both SOLiD and TruSeq chemistries, with or without downstream processing by FAVR methods. We demonstrate a 3-fold smaller rare single nucleotide variant shortlist with no detected reduction in sensitivity. The principles described herein were applied in our publication identifying XRCC2 as a new breast cancer risk gene and have been made publically available as a suite of software tools.
FAVR is a platform-agnostic suite of methods that significantly enhances the analysis of large volumes of sequencing data for the study of rare genetic variants and their influence on phenotypes.

Rapid Single Cell Targeted Sequencing: Applications in Tumorigenesis

T. Harkins, *C. Lee;*
Life Technologies, Foster City, CA, United States.

Current sequencing technologies have allowed the genomic community to delve deeper into complex cellular systems on a massively parallel scale. We now, for example, have a better understanding of cancer evolution, as well as the general genomic heterogeneity within a single tumor sample. Rare mutations and copy number variations (CNVs) are known to drive tumorigenesis and disease progression, but the amount of sample DNA required for deep sequencing is a limiting factor. This hindrance means that our understanding of cancer and other cellular systems, such as embryo development, is limited to the sub-population level. A detailed understanding of cellular genomic hierarchies, whether on a temporal or spatial scale, requires an improved capacity to perform quantitative analysis on a single-cell level. In this study, we have developed methodologies using as little as 1 picogram of input material to generate sequence information across 100's to 1000's of amplicons. Sequencing performance did not show any appreciable amplification bias as measured by strand bias and coverage uniformity. Using a custom AmpliSeqTM assay, individual cells from primary and metatstatic ovarian tumors were sequenced at ultra-high coverage (>1000x), allowing us to study low frequency mutations and changes in gene copy numbers, and hence the evolution of ovarian cancer at the cellular level.

P14.07

First experiences with the GS Junior 454 in molecular genetic analysis of patients with hereditary breast and ovarian cancer at the Center of Familial Breast and Ovarian Cancer, University of Cologne

A. Baasner, *B. Bluemcke, J. Hauke, B. Wappenschmidt, E. Hahnen, R. K. Schmutzler;*
Center of Familiar Breast and Ovarian Cancer, University of Cologne, Cologne, Germany.

Mutations in *BRCA1* and *BRCA2* are linked to the development of hereditary breast and ovarian cancer. In 2012, 74.500 women and 600 men got breast cancer and 7.200 women got ovarian cancer in Germany, while a hereditary predisposition is suspected in about 10% of these cases. Family history and age of onset are the most important inclusion criteria for genetic testing. Since August 2012, we have analysed 237 index patients with hereditary breast and/or ovarian cancer using the GS Junior 454 (Roche) and the BRCA kit (BRCA Master™ Dx kit, Multiplicom). The *BRCA1/2* genes contain many homopolymer stretches of at least 6 bp in length. Since these stretches are difficult to detect with the GS Junior 454 platform, we additionally employed a homopolymer assay fragment analysis (BRCA HP, Multiplicom), which allows rapid detection of small insertions/deletions in approximately 30 of these coding homopolymer stretches in *BRCA1/2*. In this cohort, 36 out of 237 index patients were tested positive for pathogenic *BRCA1/2* mutations. Of those, 10 individuals show disease-causing alterations located in homopolymer stretches that were easily detected by homopolymer assay pre-screening. Thus, our results warrant homopolymer pre-screening prior to costly next generation sequencing analyses.

New splicing vector pSAD: Splicing functional analysis of a hybrid "maxi-minigene" with exons 19 to 27 of BRCA2

A. Acedo, *B. Díez, A. Curiel, C. Hernández, M. Infante, M. Durán, E. Velasco;*
Instituto de Biología y Genética Molecular (UVa-CSIC), Valladolid, Spain.

At least 50% of all mutations identified in BRCA genes in breast/ovarian cancer patients are variants of unknown clinical significance (VUS). Several studies have shown the link between disease and splicing disruptions due to mutations, including predicted nonsense or frameshift mutations. We aimed to investigate the role of splicing aberrations of BRCA2 in breast/ovarian cancer.
We followed a simple strategy consisting of bioinformatics analysis with NNSplice and Human Splicing Finder of DNA variants and splicing functional assays of hybrid minigenes. Splicing reporter plasmids allow to perform functional analysis without the need of patient RNA. We designed a new splicing vector, pSAD, which enabled us the creation of a "maxi-minigene" that includes nine exons of BRCA2 (19 to 27, MGBR2_19-27), where exon 27 substituted the second vector exon. The wt minigene produced a mRNA of 2,174 nucleotides. We validated the new MGBR2_19-27 with four splicing variants of the exons 19, 20, 23 and 24, which were tested in a previous report. Thirty-six out of 166 variants reported in these 9 exons were bioinformatically selected and introduced by PCR-mutagenesis in the wt MGBR2_19-27. Fifteen variants (42%) of all types (synonymous, nonsense, frameshift or missense) altered splicing by different mechanisms. Altogether, most variants disrupted the canonical splice sites; one affected a splicing silencer and another the polypyrimidine tract.
Aberrant splicing represents a relevant pathogenic mechanism in hereditary breast/ovarian cancer. Splicing functional assays with the new vector pSAD are valuable tools to discriminate between benign and pathogenic DNA variants of any human disease genes.

A novel technique that distinguishes low-level somatic DNA variants from FFPE-induced artifacts in solid tumors by next-generation sequencing (NGS)

N. Udar[1], *R. Haigis*[1], *T. Gros*[1], *N. Kerry*[1], *B. Barnes*[1], *D. Pokholok*[1], *M. Ross*[1], *A. Lucio-Eterovic*[2], *Q. Zhang*[2], *M. Zenali*[2], *E. Jaeger*[1];
[1]*Illumina, San Diego, CA, United States,* [2]*Institute of Personalized Cancer Therapy, MD Anderson Cancer Center, Houston, TX, United States.*

Several applications, including somatic mutation detection in cancers, require methods that can efficiently detect low-frequency variants (< 10% minor allele frequency, MAF) in DNA extracted from formalin-fixed-paraffin-embedded (FFPE) tissue. We have developed a novel technique that can distinguish true variants from fixation artifacts with high sensitivity and specificity by investigating each of the two DNA strands independently. TruSeq Custom Amplicon technology was used to generate sequencing libraries and deep sequencing was carried out to an average depth of 20,000X with a minimum of 1000X. The targeted re-sequencing assay* investigates ~14 kb of exons in 26 genes commonly mutated in solid tumors. Testing of more than 200 samples with a MAF ≥5%threshold revealed the presence of a large number of potentially false positive calls when data from only one strand of DNA was analyzed, but this number was significantly reduced (e.g. >50% for G>A) when both strands were considered. Conclusion: This technique can distinguish FFPE artifacts from true variants and therefore provides increased accuracy for the detection of low-frequency variants by NGS.

Structural variation in the human genome has gained considerable attention in the recent years as it accounts for much of the variation between human genomes. However, the question of the implication of multi-allelic CNVs in complex traits remains largely open as most of them cannot be genotyped by array technology. Among them, the *RNU2* CNV is missing from the latest human genome assembly. However, this locus has been previously shown to contain a variable number of tandem repeats and to reside close to the breast cancer susceptibility gene *BRCA1.*

We developed new tools to fully characterize it. By FISH analyses on combed DNA, we precised its location 124 kb telomeric of *BRCA1*, we determined for the first time the exact allelic number of repeats in 41 individuals and found a range of 6-82 and a level of heterozygosity of 98%. Analysis of the 1,000 Genome Project data sets confirmed the high degree of polymorphism and concerted evolution of this CNV. By taking advantage of its location within the *BRCA1* linkage disequilibrium block, we studied the *RNU2* array transmission through a large number of generations and found that the *RNU2* CNV displays an unexpected high degree of meiotic stability.

These new approaches extend our knowledge of a recently neglected CNV that could be valuable for evaluating the potential role of structural variations in disease due to its location next to a major cancer susceptibility gene.

P14.11
A novel approach for multiplex ultrasensitive detection of somatic mutations in tumor samples

A. O. H. Nygren*, M. Mosko, E. Flores, A. Nakorchevsky, M. Ehrich, C. Honisch, D. van den Boom;*

Sequenom, San Diego, CA, United States.

Systematic characterization of somatic mutations in cancer genomes has improved our understanding of this multifaceted disease and has provided opportunities for targeted therapeutic development. Despite much progress several analytical challenges remain to be resolved, in particular the detection of low abundance somatic mutations. These genetic events are hard to identify due to the heterogeneous nature of most tumor tissue samples and where the mutation may differ from the highly abundant wild type sequence by only a single nucleotide. A method capable of accurate detection of these rare variants would allow identification of genetic determinants for the initiation and proliferation of tumors at an early stage of disease progression or would serve as a tool for monitoring residual disease.

We have developed a novel approach for ultrasensitive high-throughput multiplex mutation detection and used this technique to detect as low as 0.125% of a mutant sequence in a mixture model. The process consists of multiplex PCR followed by a mutation specific single base extension reaction. The extension reaction utilizes a single mutation specific chain terminator labeled with a moiety for solid phase capture. Captured, washed, and eluted products are interrogated for mass and mutational genotypes are identified and characterized using MALDI-TOF mass spectrometry. For further validation of this methodology, we successfully verified rare mutations in a set of characterized cell-lines with ultra-low fractions of defined somatic mutations. This new method, when compared to next generation sequencing platforms, offers a relatively simple workflow with quick turnaround time and minimal sample input requirements.

Comparative study for the evaluation of a new technology for cystic fibrosis screening

M. C. A. Rongioletti[1], *F. Papa*[1], *C. Vaccarella*[1], *M. B. Majolini*[1], *C. Centrone*[2], *B. Minuti*[2], *A. Luciano*[1], *V. Mazzucchi*[1], *M. Belli*[1], *I. Giotti*[2], *C. Giuliani*[2], *F. Torricelli*[2], *G. M. Liumbruno*[1];

[1]*Clinical Pathology Laboratory, San Giovanni Calibita Fatebenefratelli Hospital, Rome, Italy,* [2]*SOD Diagnostica Genetica, AOU Careggi, Florence, Italy.*

Objectives

Cystic fibrosis (CF) is one of the most frequently diagnosed autosomal-recessive diseases in the Caucasian population. Screening for Cystic Fibrosis Transmembrane conductance Regulator (CFTR) gene mutations, including poly T, is strongly recommended in infertile couples planning a pregnancy by assisted reproductive technology (ART). This study evaluated the performance of the new Nanochip CF70 kit (Savyon Diagnostic, Israel), a microarray assay, and compared it with the Innolipa kits (Innogenetics, Belgium)

Methods

From January to July 2012 we analyzed 392 blood samples with Innolipa and Nanochip technologies that identify respectively 70 and 56 CFTR mutations. Both tests include the most common Italian mutations and the poly-T screening. Discordant results were analyzed with the Devyser CFTR Core Kit (Devyser, AB, Sweden), MLPA (MRC Holland), Direct Sequencing (DS) on the 3730 DNA Analyzer (AppliedBiosystems), and Sequenom's MassArray system (Diatechpharmacogenetics, Italy)

Conclusions

Innolipa and NanoChip were concordant for 371/392 samples. 21/392 (0.5%) discordant results were tested with the aforementioned technologies: DS confirmed Innolipa results in 18/21 samples and Nanochip results in 1/21, while Devyser and Sequenom did not recognize some mutations not included in their panels. DS was essential for the identification of two different homozygous deletions; although they were not present in Innolipa panels, in 2/21 samples Innolipa indicated a mutation with the warning *no interpretation possible*

In this study the Innolipa assay confirmed its reliability and Nanochip showed that it could become competitive with slight changes to the software

P14.13
Induced pluripotent stem cells derived from human chorionic villi

P. Spitalieri*, M. C. Quitadamo, A. Luchetti, L. Saieva, F. C. Sangiuolo;*

Tor Vergata University, Rome, Italy.

Trophoblast cells (TCs) are placenta fetal components that can be isolated from patients undergoing chorionic villi sampling for prenatal diagnosis. In consideration of some of the features of these cells we speculated that TCs could be used to produce induced pluripotent stem cells (iPS). To validate this hypothesis, we employed human chorionic villi and a polycistronic lentiviral vector (hSTEMCCA-loxP) encoding Oct4, Sox2, Klf4 and c-Myc genes necessary to cell reprogramming. Stem cells specific morphological, molecular and immunocytochemical markers (ALP; OCT4; SSEA3; SSEA4; TRA1-60) confirmed the successful reprogramming. Additionally, we evaluated their ability to differentiate into the three embryonic germ layers (ecto, endo and mesoderm) by immunocytochemical characterization and their ability to in vivo form teratomas.

This study was carried out on two different samples: a cystic fibrosis (CF) patient carrying E831X/F508 mutations and a wild type one. Following reprogramming, the presence of the mutations were confirmed in iPS-CFTR cells and then cells were induced to differentiate into alveolar type II cells (ATIICs; a lung cell lineage). Within the cell population generated, the presence of ATIICs was confirmed by molecular analyses.

To date, this represents the first example of iPS cells derived from a very early extra-embryonic fetal tissues like chorionic villi (hiPS-CVS). These data suggest that hiPS-CVS can be considered a valid cell model to accomplish pathogenesis studies and possibly represents a valid tool for future therapeutic applications.

P14.14

Digital PCR modeling for maximal sensitivity, dynamic range and measurement precision

*N. Majumdar, T. Wessel, J. Marks, **D. Woo**;*
Life Technologies, Foster City, CA, United States.

A mathematical framework is developed for modeling a digital PCR system with factors impacting the measurement precision such as the number of available reaction chambers, sample volume reduction (due to a variety of causes), and false negative/false positive rates. This framework is used to develop graphics showing the relationship between precision and the supported dynamic range. The impact of total input sample volume on the lowest limit of detection or sensitivity is also illustrated.
The model predicts an increase in supported dynamic range for the same number of reaction chambers with the use of two dilution points (using half the number of reaction chambers for each dilution). The loss of half the number of reaction chambers to a second dilution point incurs a slight loss in the detectable concentration range. However, this loss is more than offset by the gain in concentrations now detectable because of an overlapping effect of the second dilution point. Beyond two dilutions, gains are not found to be as significant. The results also predict how to leverage available reaction chambers for precise detection of two targets present at largely different proportions. A large subset of the chambers is dedicated to detecting the rare type and the remaining chambers are dedicated to detecting the wild type at a different dilution. The curves showing precision versus concentration will be used to plan two digital PCR experiments for genetic quantification and rare allele detection respectively.

Single cell analysis with QX100 Droplet Digital PCR system

***Y. Jouvenot**, J. Berman, N. Heredia, S. Hodges, C. Litterst, S. Marrs, S. Wang, W. Yang, E. Hefner;*
Bio-Rad Laboratories, Pleasanton, CA, United States.

Over the last decades, it has become increasingly evident that gene expression profiles can vary from cell to cell, even within an apparently homogenous population. The analysis of this heterogeneity has become a focus of interest in various fields of biology, especially in stem cell research. The main obstacle for analysis of gene expression at the single-cell level is the low amount of starting material. This requires a high level of confidence in results obtained from unique samples, making it nearly impossible to be accurately done by traditional quantification methods such as qPCR. Droplet digital PCR (ddPCR) provides absolute quantification of individual molecules with high precision, and without the requirement for standard curves or pre-amplification steps. Using Bio-Rad's QX100 ddPCR system, we developed a method that measures single-cell gene expression with a great accuracy, thus enabling us to simultaneously analyze expression of different targets in material from the same cell. In order to perform this, we carefully evaluated various cell lysis and cDNA synthesis methods and developed a protocol that is fully compatible with ddPCR, easy to use and capable of analyzing gene expression in single cell without pre-amplification. This method allows us to measure the expression of genes of interest in a single cell, minimizing the stochastic effect of sampling and empowering us to accurately and sensitively detect and quantify low-expressing genes in single cells.

Development of a next-generation sequencing approach for molecular diagnosis of dystrophinopathies

***D. Thorel**, D. Méchin, R. Zenagui, M. Claustres, M. Cossée;*
Molecular Genetic Laboratory - CHU de Montpellier - INSERM U827, MONTPELLIER, France.

Duchenne Muscular Dystrophy (DMD) and its milder allelic variant, Becker Muscular dystrophy (BMD) are both caused by mutations in the dystrophin gene (DMD) located on Xp21. The human DMD gene is the largest one spanning >2,200 kb of genomic DNA. It contains 79 exons involving various mutation types and regions. The mutational spectrum includes copy number mutations (CNMs) and point mutations that account respectively for approximately 65% and 35% of DMD mutations. Current diagnostic assays involve a variety of methodologies but theses methods are time-consuming. The main objective of our study was to implement Next Generation Sequencing (NGS) technology for diagnostic applications in DMD or BMD patients. For this purpose, we assisted the Multiplicom Company to develop a multiplex PCR assay of the 79 exons and splice sites (Multiplicom's MASTR™ - Multiplex Amplification of Specific Targets for Resequencing) for further sequencing on the Roche 454 GS-FLX sequencer. We compared data generated by this approach with those obtained by classic Sanger sequencing in a cohort of patients with known and unknown mutations, and tested its quality and reproducibility. The results showed complete consistency between this NGS strategy and Sanger sequencing, with a gain in term of length of experiments and data analyses. Another major interest of this technique is its potential ability to exploit the multiplexed PCR amplicons to determine exonic CNMs. A single technique should allow screening the majority of DMD mutations, reducing therefore costs and diagnostic delay in most cases.

Evaluation of methodologies for the analysis of human exomes using DNA purified from saliva.

***R. M. Iwasiow**, M. Tayeb;*
DNA Genotek Inc, Ottawa, ON, Canada.

Saliva provides a non-invasive sample collection option which can greatly improve the success of a research study by ensuring donor compliance and enabling collections in difficult environments. Saliva collected using Oragene self-collection kits provide results equivalent to blood as demonstrated via published GWAS studies over the last 10 years. In this study we show that DNA from saliva collected using Oragene is a reliable sample for exome arrays and exome sequencing. Furthermore, we compare results between the two platforms. Saliva samples (2 mL) were collected using Oragene self-collection kits. DNA was extracted using the prepIT•L2P kit, an alcohol recipitation-based extraction kit that yields high quality, high molecular weight DNA. Samples were quantified using a Picogreen protocol, A260/A280 ratios were evaluated using a UV spectrophotometer and DNA integrity was assessed using agarose gel electrophoresis. All samples were of sufficient quantity and quality for analysis using the Illumina HumanExome v1.1 arrays and for targeted exome sequencing. Ten samples were processed on the exome arrays and all reported a call rate >99.8%. Three samples were exome sequenced, for which we obtained > 98.5% exome coverage at a mean depth >72x. We then evaluated the variants which are shared amongst the array and target capture platforms and evaluated the concordance between them. Saliva collected using Oragene provided DNA of sufficient quality and quantity for both exome array and targeted sequencing analysis. Data obtained demonstrates the samples perform equally well using either approach and that data is highly concordant across methodologies.

Haloplex, the next generation in exome sequencing

***R. W. W. Brouwer**[1], M. C. G. N. van den Hout[1], F. J. G. T. Sleutels[1], C. E. M. Kockx[1], Z. Ozgur[1], E. Oole[1], E. Brosens[1], B. Eussen[1], Y. Yi[2], F. Dahl[2], H. Johansson[2], M. Isaksson[2], F. G. Grosveld[1], A. de Klein[1], O. Ericsson[2], W. F. J. van IJcken[1];*
[1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Agilent Technologies, Santa Clara, CA, United States.

Exome sequencing allows samples to be sequenced at a fraction of the costs of whole genome sequencing while retaining information on the important protein-coding portions of the genome. Haloplex technology offers a very short (3 day) sample prep time, that combined with the fast Illumina HiSeq2500 and MiSeq sequencers brings the turn-around time of exome sequencing to days instead of weeks. Here, we present the first exome sequencing results obtained with Haloplex capture technology within a week.
We processed 8 samples with the Haloplex exome capture including 1 sample from HapMap. The generated libraries were sequenced on the Illumina MiSeq, HiSeq 2000 and HiSeq 2500 systems. The generated data was com-

pared to SureSelect v4 data from the same samples. Haloplex requires only 200 ng of DNA input amount and provides a two day turn around time for sample preparation. 90% of the exome is covered at 10x using only 4 Gbp of sequencing. The datasets from Haloplex are highly concordant with SureSelect all exon V4 results (99.6% SNP concordance). Haloplex excels at calling insertions and deletions in and near repeats due to the structured nature of the resulting reads but both data sets have specific benefits and strengths which will be described. In conclusion, Haloplex exome capture is a solid platform for exome sequencing. Its short runtime and low input requirements make Haloplex exomes ideally suited for clinical genetics applications.

Determination of transgene copy number in stably-transfected mammalian cells by PCR-capillary electrophoresis assay

I. B. Pruner, V. Djordjevic, M. Gvozdenov, B. Tomic, ***D. Radojkovic****;*
Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia.

The quantitative determination of transgene copy number in stably-transfected mammalian cells has been traditionally estimated by Southern blot analysis. Recently, other methods have been available for appraisal of gene copy number, such as real-time PCR.
We describe here a new method for quantitating the transgene copy number in stably-transfected mammalian cells. Method is based on the relative quantification of amplicons after multiplex PCR reaction in which we used fluorescently labelled primers.The visualisation of amplified fragments was performed by capillary electrophoresis. Sequence specific for our target gene (prothrombin) and internal control originating from genomic DNA (18S rRNA) were amplified in the same PCR tube. We calculated mean peak height ratio of target:control gene with standard deviation for every cell clone sample and used this method to identify stably-transfected mammalian cell clones bearing same copy number of vector containing target gene. The results of our assay were confirmed by real-time PCR. Our study showed that method is equally informative and less expensive compared to traditionally used assay. Apart from saving time and material, this method has the advantage of using a very small amount of DNA. Also, since PCR is carried out in a single tube, any factor affecting the PCR will affect both target and internal control and hence the ratio remains unchanged.
In conclusion, herein described method proves to be fast, reproducible and low-cost and can be used as a rapid screening tool for the determination of gene copy number in basic research of gene expression.

Using biotinylation for plasmid DNA binding to streptavidin-cell-penetrating peptide conjugate

D. S. Polyakov*;*
Institute of Experimental Medicine of the NorthWest Branch of the Russian Academy of Medical Science, St.Petersburg, Russian Federation.

Gene therapy strategies based on plasmid DNA are more preferable than viral-based gene delivery. Plasmids are more stable in vivo and known to be less immunogenic. Retroviral-based vectors integrate in actively transcribed genes that can lead to disruption of tumor suppressor genes. Gene delivery methods based on plasmid DNA are not likely to cause mutagenesis and they do not integrate in chromosomes providing increased safety. Despite the potential advantages of using plasmid DNA, delivery issues with plasmid vectors exist.
One of the ways of plasmid delivery into a cell can be covalent bonding of the plasmid to a cell-penetrating peptide (CPP). However, common covalent linking methods are limited by the concern that the covalent bond between CPP and plasmid may alter the target gene expression. To avoid this, few preselected nucleotides must be linked with CPP. Besides the covalent bond, for this purpose may be used disulfide or biotin-streptavidin interaction.
In this work, we have created a biotinylated circular plasmid DNA to further its binding to the streptavidin-CPP. In one strain of the pEGFP-N3 plasmid we replaced 1-3 thymines by biotinylated uracils. This modification was carried out in previously inserted 30 b.p. sequence between SV40 polyadenylation signals downstream of the EGFP gene and f1 origin for single-stranded DNA production. The presence of biotinylated uracils in purified plasmid was verified in restriction analysis followed by dot blot procedure. Streptavidin-conjugated alkaline phosphatase was used to detect the biotin-uracils. The ability to express EGFP was tested in Hela cell culture.

Human Genome Structural Variation Discovery and de novo Assembly at the Single Molecule Level using Nanochannel Genome Mapping

A. Hastie*, E. Lam, M. Requa, M. Austin, F. Trintchouk, M. Saghbini, H. Cao;*
BioNano Genomics, San Diego, CA, United States.

As a result of the remaining limitations of DNA sequencing and analysis technologies_even ten years after the completion of the human genome project_there remain about 400 gaps in the human reference sequence assembly, hundreds of millions of unassembled bases in those regions, and no effective tools to comprehensively characterize the structural variation in an individual's genome. Despite the ungapped reference sequence being of extremely high quality, it is not feasible to create similarly high quality assemblies of individuals to detect and interpret the many types of structural variation that are refractory to high throughput or short-read technologies. We present a single molecule genome analysis system (Irys) based on NanoChannel Array technology that linearizes extremely long DNA molecules for direct observation. This high-throughput platform automates the imaging of single molecules of genomic DNA hundreds of kilobases in size to measure sufficient sequence uniqueness for unambiguous assembly of complex genomes. High-resolution genome maps assembled de novo preserve long-range structural information necessary for structural variation detection and assembly applications. We have used Irys genome mapping for the assembly and characterization of two human genomes. From these assemblies, we have spanned many of the remaining gaps, identified known and novel structural variants and phase some haplotype blocks, including in the MHC region. We also resolve and measure long tandem repeat regions that are likely impossible to assemble by other methods.

Antisense therapy is a powerful tool for post-transcriptional gene silencing suitable for downregulating target genes associated to disease. Gold nanoparticles (AuNPs) have been described as effective intracellular delivery vehicles for antisense oligonucleotides providing increased protection against nucleases and targeting capability via simple surface modification. We constructed an Antisense Gold-nanobeacon consisting of a stem-looped oligonucleotide double labelled with 3'-Cy3 and 5'-Thiol-C6 and tested for the effective blocking of gene expression in colorectal cancer cells. Due to the beacon conformation, gene silencing was directly detected as fluorescence increases with hybridisation to target. Vectorisation via the AuNPs circumvents the need of transfection agents but with comparable silencing efficiency to that of commercial RNAi strategies with the advantage that AuNPs provide additional protection against circulating RNases. An integrated toxicology evaluation was performed based on acute cell toxicity, genomic DNA damage and proteome profiling showing that the proposed nanotheranostics tool does not exhibit significant toxicity, which is extremely relevant when translating into in vivo systems.

Reprogramming through the pluripotent state as a new paragigm for human cell rejuvenation

*L. Lapasset[1], O. Milhavet[1], A. Prieur[1], E. Bernard[1], A. Babled[1], N. Aït-Hamou[1], J. Leschick[1], **F. Pellestor**[2], J. Ramirez[3], J. De Vos[3], S. Lehmann[4], J. Lemaitre[1];*
[1]Team INSERM „Plasticité du Génome et Vieillissement", IGF, Montpellier, France, [2]Chromosomal Genetics Laboratory, CHRU, Montpellier, France, [3]IRB, Hopital St Eloi, Montpellier, France, [4]IGH, Montpellier, France.

Direct reprogramming of somatic cells into induced pliripotent stem cells (iPSCs) provides a unique opportunity to derive patient-specific stem cells with potential application in autologous tissue replacement therapies and without the ethical concerns of embryonic stem cells (hESC). However, cellular senescence which contributes to aging and restricted longevity, has been described as a barrier to the derivation of iPSCs, suggesting that aging might be an important limitation for the derivation of iPSCs for therapeutic purposes from elderly individuals. Recently, we developped an optimized 6 factor based reprogramming protocol that may cause efficient reversing of cellular senescence and reprogramming into iPSCs. We demonstrated that iPSCs derived from senescent and centenarian fibroblasts have reset telomere size, gene expression profiles, oxidative stress and motochrondrial metabolism, and are undistinguishable from hESC. Finally, we further demonstrates that re-differentiation led to rejuvenated cells with a reset cellular physiology, defining a new paradigm for human cell rejuvenation. These results provide new insights into iPSC technology and pave the way for regenerative medicine for aged patients.

A rapid and simple method for NGS library normalization

***G. Roma**, S. Roman, C. Van Loy, D. Topacio, K. Rhodes, M. Andersen;*
Ion Torrent Systems, Inc., a Division of Life Technologies Corporation, Carlsbad, CA, United States.

Library preparation is a major contributor to labor and reagent costs for Next Generation Sequencing (NGS). This is particularly true for higher throughput applications, such as targeted re-sequencing, where many samples are prepared in parallel. NGS platforms require careful quantification of libraries, and sets of barcoded libraries require normalization prior to pooling. We present a simple method for NGS library normalization that obviates the need for library quantitation and dilution. Five DNA samples (1 matched lung normal/tumor pair, 1 FFPE DNA, and 2 high molecular weight DNAs) were carried through a 207-plex amplicon library preparation workflow with 5, 10, and 20ng of DNA input. Libraries were prepared in triplicate for each sample at each input level. After library construction and normalization, 45/45 (100%) of libraries were within a two-fold concentration range (115 - 204 pM, average 156 pM, SD 16.5 pM), when measured by qPCR. Sequencing of these libraries showed no adverse effects on accuracy (>99.5%), uniformity of amplicon representation (>99%), or bases with no strand bias (>99%) compared to control libraries (non-normalized, individually diluted). The method has been shown to be highly tunable, making it applicable to a variety of NGS platforms.

P14.26

Hyperspectral Imaging for Label Free High Resolution Characterization of Chromosomes

***S. Luckow-Markgraf**, A. Lorenz, K. Rebner, R. W. Kessler;*
Reutlingen Research Institute, Reutlingen, Germany.

In Cytogenetics the specific structure of chromosomes is routinely identified by expensive and time consuming staining techniques like GTG (G- banding by trypsin using Giemsa) banding or FISH (Fluorescence Insitu Hybridisation). In both cases a broad expert knowledge is necessary to understand and diagnose complex diseases and particularly to visualize small structural aberrations.
We have made efforts to substitute the state of the art karyotyping technique to a fast low-cost and automatic label-free karyotyping procedure using absorption and stray light spectroscopy in the UV-VIS range combined with classical light microscopy. Therefore we designed a hyperspectral imaging system with a scanning software for marker free karyotyping. This system allows visualizing the stray light interference pattern of unstained chromosomes resulting from small variations in size, thickness, refractive index and field of chromatin condensation of chromosomal substructures on a nanoscale. Up to 150 individual spectra along the chromosome are registered. The spatial pixel resolution can therefore be as small as 50nm. The spatial location is indeed limited to the diffraction limit of microscopy (5Mb), but the detected substructures remain in the spectra and even can be optically resolved using Scanning Near-Field Microscopy (SNOM).
The complex spectral signature can be analyzed by means of Multivariate Curve Resolution (MCR) or Principle Component Analysis (PCA) which is now integrated in our scanning software. The unique banding pattern of unstained chromosomes can be visualized in a novel high resolution karyogram resulting from the hyperspectral data analysis.

WildFire: an In-situ Isothermal PCR Method forming Billions Monoclonal Colonies for NGS

***K. Q. Lao**;*
Life Technologies, Foster City, CA, United States.

We have developed a new massive parallel monoclonal technology, called "WildFire", where sequencing libraries are *in-situ* isothermal amplified directly on the surface of a 5500 flowchip. Sequencing libraries (~ 40 uL per lane) are added directly to the 5500-series Genetic Analyzer flowchip, whose surfaces have been coated with a special library-adaptor capture oligonucleotide. A DNA polymerase reaction mix is added, and in a single isothermal step lasting ~ 30 minutes, single templates are amplified *in-situ* on the flowchip. The net density of sequencing-colonies created in this manner far exceeds anything currently utilized in next-generation sequencing, reaching ~ 1.5 million colonies per mm^2 per flowchip surface. During *in-situ* amplification, the capture oligonucleotide is "consumed", and each individual nucleic-acid fragment "spreads" (like a WildFire) inside the flowchip until reaching an adjacent library fragment(s). When the individually-growing fragments "meet", the amplification step terminates, because all of the surface-bound primer was consumed. These "self-assembled", spatially resolved, monoclonal colonies, are then sequenced by SOLiD chemistry. The resulting colony-sequencing reads maintain the same high accuracy as our bead-based method. Full genomes (from bacterial to human), exomes (human), and transcriptomes (human) have now been sequenced using WildFire technology. WildFire technology greatly improves NGS workflow, increases throughput, and significantly decreases net cost-per-genome.

P14.28

Non - destructive aDNA extraction from museum specimens

***T. M. Dobosz**;*
Medical University, Wroclaw, Poland.

Museum collections contains valuable genetic information. Most of them haven't been available, mainly because specimens should be intact. The possibility of obtaining DNA by non- destructive way from conservation fluid allows to explore these valuable specimens.
Analysis include exhibits, which were stored in two types of preservative fluids: ethanol/glycerol and ethanol/glycerol/formalin. Specimens are dated from first decade of XIX century to the second half of the XX century. Method starts from vacuum filtration of the conservation fluid. DNA were isolated from the filters, contained small fragments of tissue and whole and fragmented cells. DNA was isolated according Ivanow's method with our own modifications, then evaluated using agarose gel and Quantifiler real time - PCR test. Next, in view of the genetic material's age and the degradation stage, the samples were tested by multiplexing STR or SNP. In order to verify the results, two various tests which ranges overlaped, were used.
The obtained results allow to accept these method as reliable. This approach may be useful for researches as well as for museum curators because recovery of DNA may be connected with necessary periodical conservation and

complementation of conservation fluids. The conclusion: it is possible to obtain valuable researching genetic material without the necessity to damage or destroy the museum exhibits.

Familial recurrence of an extreme phenotype of infantile anorexia in a Caucasian isolate in Reunion Island led us to suspect autosomal recessive inheritance of this rare progressive encephalopathy. Here, we report homozygosity mapping of the locus of this syndrome, called Ravine. Complete DNA sequencing of the 400-kb linkage locus reveals a point mutation in a primate-specific retrotransposon that is transcribed as part of a unique long non-coding RNA, SLC7A2-IT1A/B, which is expressed in the brain. Silencing this RNA whether by siRNA or antisense leads to increased neuronal apoptosis, consistent with the inappropriate dosage of this RNA in vivo and with the phenotype. Structural analysis of the sequence reveals homology to piRNA as well as a small RNA-like hairpin. We assess the global impact of the mutation by transcriptomic analysis of brain samples, and discuss the different mechanisms that could underlie the effect of the mutation. We believe that this work could contribute in the understanding of the significance of subtle variations in retrotransposons.

Towards a Theory of Science Policy for Genetics

***E. M. Meslin**[1,2], A. Blasimme[2];*
[1]Indiana University, Indianapolis, IN, United States, [2]UMR U 1027, Inserm, Université Toulouse III - Paul Sabatier, Toulouse, France.

Many politically charged topics in Western liberal democracies have science at their core: embryonic stem cell research, climate change, GM crops, or alternative energy strategies. But science has always been politically charged -- from the early 17th century academies advising governments, to the Horizon 2020 budget debate in Europe and the "fiscal cliff" in the United States. We argue that science has become especially challenging for policy-making precisely because liberal democracies lack a coherent way to accommodate pluralistic views about scientific innovation. Indeed, given the importance of science in society, it is surprising that so little attention has been given to providing a coherent approach that would explain the way science policy works. Such an approach, if it could be developed as theory, might help systematize public decision making about science and more effectively contribute to desirable social goals. Human genetics is only the most recent of many science policy topics where comprehensive ethical analysis has been brought to bear (rightly) on key issues such as informed consent, privacy, and governance. This may be why regulation of direct-to-consumer genetic testing, establishing consent protocols for biobanks, or constructing privacy protections for GWAS studies does not admit of harmonized policy. It may also be that insufficient effort has been made to articulate the fundamental political values that underpin progress in science policy. To supplement the role that ethical theory has played in genetics, we sketch the basic features of a theory of science policy using political philosophy to engage these normative problems.

Breakpoint characterization of large deletions using PacBio and Illumina sequencing technologies

*J. Meienberg[1], M. Okoniewski[2,3], A. Patrignani[2], A. Szabelska[2,4], Y. Tsai[5], S. W. Turner[5], J. Korlach[5], R. Schlapbach[2], **G. Matyas**[1];*
[1]Center for Cardiovascular Genetics and Gene Diagnostics, Schlieren ZH, Switzerland, [2]Functional Genomics Center Zurich, Zurich, Switzerland, [3]Department of Neuroimmunology and Multiple Sclerosis Research, Neurology Clinic, University Hospital, Zurich, Switzerland, [4]Department of Mathematical and Statistical Methods, Poznan University of Life Sciences, Poznan, Poland, [5]Pacific Biosciences, Menlo Park, California, CA, United States.

The characterization of large deletions identified by multiplex ligation-dependant probe amplification (MLPA) or microarray analyses can be challenging. Here, we present the applicability of single-molecule (PacBio RS) and second-generation (Illumina) sequencing technologies to the characterization of large genomic deletions. The three DNA samples used in this study harbor hemizygous deletions previously characterized using a Sanger approach. Deletions in two samples of length 26,887 bp and 302,580 bp, respectively, affect the *FBN1* gene in patients with Marfan syndrome, whereas a deletion of 3,408,306 bp comprises the entire *COL3A1* gene in a patient with Ehlers-Danlos syndrome vascular type (EDS IV). By testing these DNA samples, our methods determined that both next-generation sequencing platforms were able to identify the position of deletion breakpoints. Our results point out various advantages of next-generation sequencing platforms when characterizing genomic deletions. However, special attention must be paid to identical sequences flanking the breakpoints, such as poly(N) motifs. Consequently, for the characterization of large deletions an alternative procedure is provided by our approach, which can be performed with reasonable DNA amount and is less work intensive and time consuming than a Sanger approach.

Next generation sequencing: aligning the futures of genomic medicine

***A. Blasimme**;*
INSERM, toulouse, France.

Genomic approaches to cancer treatment are already informing a number of clinical trials in oncology (e.g. microarray-based cancer signatures trials). This is animating powerful visions about the development of increasingly personalised and effective cancer therapies.
However, in this paper we show that next-generation high-throughput technologies, offering an unprecedented level of genomic resolution, are likely to steer the emergent sociotechnical phenomenon of cancer genomics even further into as yet uncharted territories.
Our paper will draw on the authors' direct engagement with an International Cancer Genome Consortium project (CAncer GEnome of the KIDney - CAGEKID) and a number of other European projects in the field of high-throughput genomics. We will provide first-hand ethnographic analyses of the anticipatory orientations of early actants in cancer post-genomics.
What are the traces of this imagined future in present day practices of cancer post-genomic research? What sociotechnical relationships are being reconfigured, and how? What material practices, biomedical platforms and actor-networks are being mobilized to design the future of post-genomic clinical oncology? Our inventory will reconstruct the assemblage of a sociotechnical infrastructure made of new actors, circulating samples, shared databases, collaborative projects, but also of restructured ordering tools such as new informed consent forms and feedback practices.

The challenges of quantifying the use of bioresources in genetic research

***A. Cambon-Thomsen**[1,2], L. Mabile[1,2], M. Thomsen[1,2], E. Rial-Sebbag[1,2], &. BRIF working group[3];*
[1]Inserm, UMR1027, Epidemiology and analyses in public health, Toulouse, France, [2]Université de Toulouse III Paul Sabatier, UMR 1027, Toulouse, France, [3]The GEN2PHEN and the BioSHaRE-EU consortia, Toulouse, France.

Sharing data and bioresources is essential for optimising knowledge production. However, establishing a valuable bioresource that can be used for various genetic researches over time requires considerable time and efforts that often lack proper recognition. To address this issue, one approach is to develop adequate tools to assess bioresource uses and their specific contribution in the development of novel scientific knowledge. The concept of a Bioresource Research Impact Factor (BRIF) was introduced in 2003], and later further developed [1]. BRIF aimed to be a quantitative indicator filling a

gap in the complex environment of scientific production assessment. Rather than a fixed indicator we tend to propose a framework for measuring bioresource impact that could be used for valuing the activity of a bioresource over time.
The methodology of Requirement Engineering (RE) was used to formalise the steps towards the development of a BRIF instrument. The requirement analysis resulted in the following entities/ideas to be assessed:
- Defining obstacles to sharing samples and data
- Pointing to specific issues regarding genetic use
- Choosing adequate identifier scheme for bioresources
- Identifying and weighing parameters to be considered in various metrics
- Analysing the role of Journal guidelines and policies for resource citing and referencing
- Assessing policies for resource access and sharing and how they influence the bioresource use.
This work allows proposing a framework for the operational development of BRIF. It still requires input from stakeholders within the biomedical community. Nat Genet 2011, **43**(6):503-4.

P14.34
Detection of mRNA knockdown in live cells using a novel nanoparticle technology

D. Weldon[1], *D. Giljohann*[2], *A. Ko*[1], *L. White*[1], *Y. Williams*[1], *S. Le Dall*[3], *G. Johnston*[1];
[1]*Merck Millipore, Temecula, CA, United States,* [2]*AuraSense, Skokie, IL, United States,* [3]*Merck Millipore, Molsheim, France.*

Modulation of gene expression using techniques such as RNAi has become a fundamental tool in the study of gene function and biological pathways. To determine the efficiency of gene knockdown using most widely used detection methods, cell samples must be sacrificed by lysis or permeabilization and fixation. In addition to sample destruction, another disadvantage of these techniques is that they yield results that only reflect the average expression of the gene in the collected cell population. One nondestructive option is the use of transfected reporter constructs. However, although the cells remain alive, the technique cannot reveal endogenous gene expression and can have negative effects on cell health. An ideal RNA detection agent provides a noninvasive approach to interrogating gene expression while enabling sorting of live cells that can be separated and directly used for downstream studies.
Here we describe the detection of Survivin mRNA levels in LNCap and SCC12 with and without the presence of Survivin siRNA treatment. The changes in gene expression can be determined in the cells while they remain in cell culture in real-time, providing more physiologically relevant data in living cells. This technique utilizes a fluorescent reporter that can be detected using fluorescent microscopy for visualization or flow cytometry for single cell resolution and quantification. This allows for a more dynamic understanding of knockdown efficiency.
The ability to specifically detect RNA levels in live cells on a cell–by-cell basis provides new opportunities to link biological pathways and physiological processes to gene functions.

The thiopurine methyltransferase (TPMT) is a crucial enzyme in metabolism of thiopurine drugs: azathioprine and 6-mercaptopurine which are used in the treatment of leukemia or inflammatory bowel diseases (IBD). Genetic polymorphism of the TPMT gene correlates with activity of this enzyme which determines an individual reaction and dosing of thiopurines. The three main TPMT alleles: TPMT*2 (c.238G>C), *3A (c.460 G>A, c.719A>G) and *3C (c.719A>G) accounting for 80% to 95% of inherited TPMT deficiency in different populations in the world. The aim of the study was to establish a rapid and highly sensitive method for analysis of these three major TPMT alleles. Here we present the molecular test based on multiplex high melting resolution analysis (HRMA) for genotyping of c.238G>C, c.460 G>A and c.719A>G.
We analyzed DNA samples from 100 clinically diagnosed IBD patients treated with thiopurine drugs and known genotypes at codons 238, 460 and 719 of the TPMT gene. One probe was TPMT *1/*2, one *3A/*3A, seven *1/*3A and other 91 wild type *1/*1. Our results obtained with multiplex HRMA indicated 100% accuracy compared to data from classical sequencing and RFLP. We conclude that multiplex HRMA can be used as a sensitive and efficient alternative diagnostic method compared to conventional techniques for determination of TPMT*2 and *3 alleles.

Whole Genome Sequencing of a Family Trio Using DNA Extracted from Saliva

M. Tayeb, *S. Rabuka, R. M. Iwasiow;*
DNA Genotek Inc, Ottawa, ON, Canada.

Saliva collected using Oragene is a non-invasive sample type and an alternative to blood that provides large amounts of high quality genomic DNA, as demonstrated through published GWAS studies over the last 10 years. In this study we show that DNA extracted from saliva is a reliable sample for whole genome sequencing and performs similarly to DNA from blood. Saliva samples were collected from a family trio consisting of a mother, father and male child. Saliva was collected using Oragene self-collection kits. The DNA was extracted using the prepIT•L2P kit, an alcohol precipitation-based extraction kit that yields high quality, high molecular weight DNA. Library preparation, sequencing and assembly were performed at Complete Genomics (CGI). Sequencing performance of DNA from saliva was compared against a publicly available trio data set sequenced from blood DNA, sequenced by CGI. There was no statistical difference between the number of known variants (p=0.064), novel variants (p=0.243), indels (p=0.069) and frameshifts (p=0.075) called among saliva samples compared to blood samples on average. In saliva, we observed minor differences in synonymous reference mismatch calls, missense variants and total sites called. These differences are likely due to differences in donors and sequencing coverage between the saliva and blood samples, work is ongoing to determine the cause. Data obtained from the family trio indicated excellent sequencing performance of all three samples confirming that saliva collected using Oragene is an excellent source of DNA for whole genome
sequencing.

Computer-aided facial recognition of individuals with X-linked hypohidrotic ectodermal dysplasia

K. M. Huttner[1], *L. Karlinsky*[2], *S. Hadj-Rabia*[3], *L. Wolf*[2,4], *M. Shohat*[2,4,5], *D. K. Grange*[6], *O. D. Klein*[7], *H. Schneider*[8], *E. Navarro*[9], *V. López-González*[9], *C. Bodemer*[3], *L. Basel-Vanagaite*[2,4,5];

[1]Edimer Pharmaceuticals, Inc., Cambridge, MA, United States, [2]FDNA Ltd., Herzlyia, Israel, [3]Department of Dermatology, French reference centre for genetic skin disorders (MAGEC) Necker Enfants Malades Hospital, APHP, Paris Descartes University, INSERM U 781, Paris, France, [4]Tel Aviv University, Tel Aviv, Israel, [5]Schneider Children's Medical Center of Israel, Raphael Recanati Genetics Institute, Rabin Medical Ctr and and Felsenstein Medical Research Center, Petah Tikva, Israel, [6]Washington Univeristy in St. Louis, St. Louis, MO, United States, [7]University of California San Francisco, San Francisco, CA, United States, [8]University of Erlangen-Nürnberg, Erlangen, Germany, [9]Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain.

X-linked hypohidrotic ectodermal dysplasia (XLHED) is a genetic disorder characterized by hypohidrosis, hypotrichosis and hypodontia. Early diagnosis of XLHED is a key factor in reducing the risk for severe hyperthermia and pulmonary infections. Patients display a distinct craniofacial phenotype characterized by retruded appearance of the midface with maxillary hypoplasia and mandibular prognathism. In this study, a novel facial dysmorphology analysis system based on 2D photographs (FDNA®) was used to identify XLHED-affected individuals.

Following photograph acquisition from male patients with clinically and/or genetically-confirmed XLHED (n=27 newborns, n=64 age 1-10 yrs, n=42 age 11+ yrs, plus controls), 130 facial fiducial points were localized per photograph and their geometrical relationships determined. The final classification was based on these measurements as well as on a global „gestalt" detector. Cross validation of the recognition capability involved 20 rounds of analysis with the data split randomly to training and testing data.

In this proof-of-concept study, the statistical power of the test in identifying XLHED patients using average area under the ROC curve was 96% for individuals >11 years; 97% for children 1-10 years, and 98%-99% for newborns. Overall, the system had a high level of specificity (97-100%) at 90% sensitivity across all age groups.

These results demonstrate the strength and utility of computer-based facial analysis utilizing ordinary photographs in the identification of XLHED-affected patients. With further refinement, a universal newborn screening platform is plausible that will alert families to this clinical condition. Early diagnosis may also be critical for successful ectodysplasin therapy in this disorder (NCT01775462).

Investigation of intra individual gene expression variations in venous blood from healthy volunteers

S. Lehnert, *M. Jaspers, H. Cuppens;*
Center for Human Genetics, Leuven, Belgium.

High-throughput sequencing techniques as RNA-Seq may soon be used to discover diseases with diagnostic tests at the earliest possible onset. RNA-Seq techniques create a high resolution readout of transcript levels. The Gene-expression profiles have a near digital character, which exceed sensitivity and dynamic range of the hybridization-based array technologies. In order to discover small changes in transcript abundance that may lead to a disease, within individual variability, but also technical and statistical biases of high-throughput sequencing need to be well described. Pipelines as the Tophat Cufflinks offer the user a number of custom settings to fine-tune the analyses result. We will investigate the impact of these settings on the prediction of transcript abundance systematically and describe variation with technical replicates and autologous day-to-day samples further. Consolidated guidelines will be generated and applied in subsequent analyses together with further samples from later-time points within the same individual.

Human venous blood samples will be collected from 3 healthy volunteers on a day to day, week to week and month to month basis over 2 years. Multiplexed polyadenylated RNA samples were run on the Illumina HiSeq system and analyzed with a Tophat Cufflinks pipeline.

Characterizing the dynamic range of intra-individual transcriptomes on the basis of statistical, chemical and biological variations is a crucial step in applying RNA-Seq in diagnostics. Here, we will analyze if current statistical methods can result in biological different answers within one individual and will provide recommendations for RNA-Seq studies.

Comparative genome-wide analysis using whole-genome sequencing and high-density SNP genotyping array data

M. Noukas[1,2], *K. Mannik*[1,3], *R. Magi*[2], *R. Tamm*[1,2], *A. Macé*[4,5], *A. Kurg*[1], *Z. Kutalik*[4,5], *A. Reymond*[3], *A. Metspalu*[1,2];

[1]Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, [2]Estonian Genome Center, University of Tartu, Tartu, Estonia, [3]Center of Integrative Genomics, University of Lausanne, Lausanne, Switzerland, [4]Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland, [5]Swiss Institute of Bioinformatics, University of Lausanne, Lausanne, Switzerland.

Next-generation sequencing and array-based high-density genotyping are both powerful approaches to study genetic variation that affect disease development, tumorigenesis, response to drugs etc.

In our study, the aim is to (i) develop a workflow to compare CNVs obtained from high-coverage whole-genome sequencing to the ones from high-density SNP genotyping array data; (ii) accurately detect rare CNVs with effect on health in a longevity cohort collected by Estonian Genome Center of Tartu University of Estonia.

We report a cohort of 49 unrelated individuals older than 83 years. Whole-genome sequencing experiment was performed using TruSeq DNA Sample Preparation Kit and HiSeq 2000. For genome-wide SNP genotyping we used HumanOmni2.5-8v1 BeadChips (Illumina, Inc).

Our study includes the estimation of efficiency and accuracy of calling structural variants from sequencing data and comparison of the concordance with CNV information obtained from SNP genotyping. To test if rare variants could affect ageing and age-related diseases, we will compare the state and frequency of genomic alterations between different age groups and geriatric subjects. By integrating both sequencing and SNP genotype data we will characterize some of the functional spectrum of genetic variation in our study cohort.

Exon-level aCGH in over 2000 patients from the Deciphering Developmental Disorders Project.

T. W. Fitzgerald, *M. E. Hurles;*
Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

The Deciphering Developmental Disorders (DDD) project is a family based study focused on rare genetic variants in patients with undiagnosed developmental delay. The majority of probands have been pre-screened by clinical microarray, which limits the enrollment of patients to those whose phenotypes cannot be easily explained by large copy number events. Exome sequencing and array comparative genomic hybridization (aCGH) are used to scan patient genomes for a wide range of genomic variation. The primary source for copy number (CNV) discovery in the DDD project is high-resolution (exon-level) aCGH. This platform comprises of 2x1Million probe Agilent arrays and is heavily targeted towards exons and conserved regions while retaining median backbone coverage of 3Kb. For the detection of CNV we have developed a high performance change point detection pakkage CNsolidate, which makes use of multiple weighted algorithms. Using this approach, we are able to rank detections based on differential weighting functions between component algorithms. To facilitate the direct reporting of patient variants back to the NHS via the DECIPHER database, we have implemented a dedicated clinical reporting pipeline. We compare patient CNVs to high quality CNV reference sets containing population frequency estimates (CNV Consensus) and a manually created list of developmental disorder genes (DDG2P). We applied CNV detection and clinical variant filtering to over 2000 patients from the DDD project. Here we assess the performance and detection rates using CNsolidate, describe a global CNV burden analysis

and present some examples of variants classified as pathogenic using the clinical reporting pipeline.

3DM: Data integration and next-generation variant effect predictions

B. Vroling, *T. van den Bergh, R. Kuipers, H. Joosten;*
Bio-Prodict, Castellastraat 116, Nijmegen, Nijmegen, Netherlands.

Many point mutations are located in protein-coding regions of the human genome. Determining their effects on the structure and function of a protein remains a very difficult problem, as is illustrated by the poor performance of tools such as PolyPhen and SIFT. In response to the growing demand for high-quality variant effect predictions we present 3DM; a data integration & mutation prediction platform for protein families. 3DM relieves many of the burdens that researchers face in dealing with the growing amounts and complexity of biomedical data. For each protein family a large amount of information that is extracted from protein structures, alignments and scientific literature, among others, is available. All this information is integrated and validated, and can be analysed via a number of different methods and tools.
By intelligently combining all this heterogeneous information 3DM is able to provide state-of-the-art predictions about the effects of genetic variations.
On a set of > 800 validated LongQT syndrome related variants (~200 neutral variants, ~600 pathogenic variants), 3DM was able to reach an accuracy of more than 95%. In contrast, PolyPhen was able to correcty predict only ~65% of the variants. The extremely accurate predictions made by 3DM shows that the availability of high-quality, integrated data is essential for assessing the effects of mutations.

GS data online treatment : a 454 dedicated tool to facilitate quality assessment, variation selection and annotation

D. Baux[1], *T. Besnard*[2,3], *G. Garcia-Garcia*[3,4], *M. Claustres*[1,2,3], *A. Roux*[1,3];
[1]*Laboratoire de génétique moléculaire - CHU, Montpellier, France,* [2]*Univ, Montpellier I, Montpellier, France,* [3]*Inserm U827, Montpellier, France,* [4]*Instituto de Investigación Sanitaria IIS-La Fe and CIBERER, Valencia, Spain.*

Following the improvements of second generation sequencing technologies, benchtop sequencers are now available to a number of laboratories. 454 sequencing is the oldest of these technologies and its pros and cons are now well characterised. However, it does not really benefit from the burst of academic implementations of bioinformatic software. Identifying mutations in the clinical context of genetic heterogeneous disorders represents a promising approach. These conditions often require the sequencing of several genes before the identification of pathogenic genotypes, and therefore could benefit from medium-throughput methods. Usher syndrome is characterised by a congenital deafness associated with retinitis pigmentosa. We designed the liquid capture of the 9 responsible genes coupled with 454 sequencing. Given the lack of analysis tools and the weaknesses of the built-in software concerning the identification of some major disease causing alterations, we implemented GSdot, a web-based application available at https://neuro-2.iurc.montp.inserm.fr/454/, designed to assess, filter and annotate variants identified by the process. GSdot, launched right after base-calling and alignment, assesses some quality scores and computes the average depth of coverage for each analysed region. It also applies some simple rules to the candidate variations to eliminate a maximum of artefacts, and adds annotations (HGVS nomenclatures, gene and exons localisations) to the remaining candidates using the third-party software Annovar and Mutalyzer. A comparison of hundreds of variants previously identified by Sanger among the same cohort showed that GSdot treatment does not produce any false negative, and therefore can be used as an efficient tool to study genetic heterogeneous disorders.

Detection of allele-specific gene expression on next generation sequencing data

V. Mijatovic[1], *L. Xumerle*[1], *E. Trabetti*[1], *P. Prandini*[1], *C. Zusi*[1], *G. Buson*[2], *A. Ferrarini*[2], *A. Zamò*[3], *M. Delledonne*[2], *P. F. Pignatti*[1], *G. Malerba*[1];
[1]*Dept. of Life and Reproduction Sciences,University of Verona, Verona, Italy,* [2]*Dept. of Biotechnology, University of Verona, Verona, Italy,* [3]*Dept. of Pathology and Diagnostics, University of Verona, Verona, Italy.*

Some studies observed that variation of gene expression between alleles is common, and this variation may contribute to human variability of several traits. The goal of our study is to develop a statistical framework aiming to measure and detect allele-specific gene expression (GE) differences from global GE experiments conducted using next generation sequencing (NGS) technology. Our method for identification of allele-specific differential expression (ASDE) is based on the likelihood estimation of the observed data depending on the parameter Θ (the relative amount of the reference allele with respect to the alternative allele). ASDE was estimated by a Likelihood Ratio Test (LRT). Only genes with at least two heterozygous sites were selected. Currently we tested the method on a total of 7 mantle cell lymphoma samples (MCL), 12 muscle cell samples (MC) and 15 lymphoblastoid cell lines samples (LCL). Using an arbitrary threshold of LRT > 250 we observed 15, 22 and 33 ASDE genes for MCL, MC and LCL, respectively, on a total of 10910, 8357 and 13328 expressed genes. For MCL samples we observed 3 and 1 ASDE genes in common with MC and LCL, respectively. No common ASDE genes were observed between MC and LCL. We plan to improve the method to identify haplotypes underlying ASDE, and to investigate the correlation between ASDE genes and their chromosomal location or specific classes of functionality. These bioinformatic results should be confirmed by wet lab experiments. In conclusion we developed a simple method to detect ASDE genes from NGS data.

P15.07

Cafe Variome: Connecting Diagnostic and Disease Networks by Enabling 'Open Discovery' of Data, Without Sharing Of Data

O. Lancaster[1], *R. Dalgleish*[1], *D. Atlan*[2], *A. J. Brookes*[1];
[1]*University of Leicester, Leicester, United Kingdom,* [2]*PhenoSystems, Bruxelles, Belgium.*

Diagnostics laboratories assess DNA from many patients affected by inherited disorders. To infer the likely pathogenic role of sequence variants identified in such settings, it would be useful to check whether the same changes had previously been seen by other laboratories/patients with related phenotypes. However, this option is precluded due to difficulties of data sharing between labs, or with others. Typically, any information exchange that does take place occurs on a one-to-one basis, via telephone or email contact.
To address this deficiency the novel ‚Cafe Variome' platform has been developed to enable ‚open discovery' of the existence (rather than actual substance) of relevant mutation data. By enabling networks of labs to easily query for the existence of variants, without necessarily revealing the underlying data, this overcomes issues of patient confidentiality.
Hence, Cafe Variome is not a database but is a searchable ‚menu'. The platform enables data owners/submitters to specify and update lists of who can search for records of interest (using various search parameters), and to determine how results are returned to those users: either as core data, or links to data at source, or via computationally facilitating data access requests.
The core ‚open discovery' concept underlying Cafe Variome could be deployed in many other settings - and the underlying technology is sufficiently generic and flexible to enable this. Therefore, as well as currently piloting the system with networks of diagnostic labs, we would welcome further collaborations in any and all potential areas of application.

P15.08

System and pathway analysis of variants associated with immune cell levels

W. I. Mentzen[1], *M. Floris*[2], *V. Orrù*[1], *M. Steri*[1], *G. Sole*[1], *S. A. M. Urru*[2], *S. Olla*[1], *F. Virdis*[1], *M. Dei*[1], *S. Lai*[1], *E. Fiorillo*[1], *S. Sanna*[1], *F. Cucca*[1];
[1]*IRGB-CNR, Monserrato (CA), Italy,* [2]*CRS4, Pula (CA), Italy.*

Bioinformatic analyses aiming to discern causal polymorphisms, underlying regulatory mechanisms, pathways and protein interaction networks, were performed for a set of SNPs found to be associated with levels of 95 immune cell types in the SardiNIA study. These immune traits, representing the ma-

jority of leukocyte cell populations (monocytes, T and B cells, Natural Killer cells, regulatory T cells, dendritic cells, and their subsets), were assessed by polychromatic flow cytometry in a sample of 1,629 individuals, and analyzed by genome-wide association scan.
The data, comprised of 81 variants, associated genes, traits and autoimmune diseases, were visualized in network setting in Cytoscape, allowing for better exploration of the multi-way relationships among them. The genes, to which the lead variants and those in linkage disequilibrium map, were inspected in a context of protein network and analyzed for the enrichment of pathways, Gene Ontology terms and semantic interconnections. The SNPs effects were assessed both in terms of an impact on the gene product and of potential regulatory function, taking advantage of genome-wide data on genomic and epigenetic features and 3D chromatin structure, made available through ENCODE project.
The results point to genes and processes with well established role in hematopoiesis and immune system, but also to involvement of an extensive part of signaling network. Regulatory function of DNA fragments containing several variants have been hypothesized, including looping to promoter regions of surrounding genes, enhancer or insulator function, or transcription factor binding.

Whole genome methylation profile of patients with Balkan endemic nephropathy

R. Staneva[1], *B. Rukova*[1], *S. Hadjidekova*[1], *D. Nesheva*[1], *O. Antonova*[1], *P. Dimitrov*[2], *V. Simeonov*[3], *R. Cukuranovic*[4], *J. Cukuranovic*[4], *V. Stefanovic*[4], *M. Polenakovic*[5], *I. Dimova*[1], *R. Hlushchuk*[6], *V. Djonov*[6], *A. Galabov*[7], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria,* [2]*National Center of Public Health and Analyses, Sofia, Bulgaria,* [3]*Vratza District Hospital, Vratza, Bulgaria,* [4]*Faculty of Medicine, Institute of Nephrology, University of Nis, Nis, Serbia,* [5]*Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of,* [6]*Institute of Anatomy, Bern University, Bern, Switzerland,* [7]*Institute of Microbilogy, Bulgarian Academy of Sciences, Sofia, Bulgaria.*

Background: Balkan endemic nephropathy (BEN) represents a chronic progressive interstitial nephritis in striking correlation with uroepithelial tumors. The disease has endemic distribution in several Balkan countries and shows predominance of affected females.
DNA methylation is a primary epigenetic modification that is involved in cancerogenesis, genomic imprinting, gene silencing etc. The significance of CpG-island methylation in normal development, cell differentiation and gene expression is widely recognized.
Methods: We performed whole genome DNA methylation analysis on pool-DNA blood samples from 159 affected individuals and 170 healthy controls. We determined the methylation status of 27000 CpG-islands throughout the whole genome in healthy controls and BEN patients (Agilent DNA-methylation array 1x244k). We obtained the methylation profile of BEN patients from Serbian and Bulgarian endemic regions. Results were processed by Agilent Genomic Workbench Lite software v.6.5.0.18.
Results: Comparison of the methylation profiles of BEN patients and corresponding controls revealed the differentially methylated regions (DMRs). We then compared the DMRs between all patient-control pairs to determine common disease associated changes in the epigenetic profiles
SEC61G, IL17RA, HDAC11 were found to be differently methylated throughout all patient-control pairs. The CpG-islands of all 3 genes were hypomethylated in patients and hypermethylated in controls. Dysregulation of these genes could be common mechanism in BEN in both endemic regions and in both genders.
Conclusion: Our data strongly suggests that immunologic alterations have a significant role in BEN etio-pathogenesis. These results are in accordance with major BEN pathological characteristics.
Acknoledgements: funded by BNSF grant DMY 03/35, SNSF-SCOPES grant IZ73ZO_127949

P15.10
Epigenetic alterations as a pathomechanism of genetic disease, example of Beckwith-Wiedemann Syndrome.

Z. Gencik-Guillier;
diagenos, Osnabrück, Germany.

Beckwith Wiedemann syndrome (BWS) is a model disorder for the study of epigenetic mechanisms.
BWS is a pediatric overgrowth disorder involving a predisposition to tumor development. The clinical presentation is highly variable, some cases lack the hallmark features of exomphalos, macroglossia and gigantism (EMG syndrome).
The molecular etiology of BWS syndrome is rather heterogenous. Dysregulation of imprinted genes found within a genomic region on human chromosome 11p15 results in the BWS phenotype through a number of different mechanisms leading to either primary epigenetic alterations or genetic alterations that change the relative contributions of parental alleles. Clinically, the BWS molecular subgroups are associated with different recurrence risks and mostly important with different predispositions to embryonal tumors, which necessite different current tumor surveillance.
We present the results of our around 200 examined patients with clinical suspicion of BWS syndrome and the different molecular subgroups. Up to 50% of BWS patients with positive molecular fiding have biallelic rather than monoallelic expression of the insulin-like growth factor 2 (IGF2) gene. Another 50% of patients have an epigenetic mutation resulting in loss of imprinting in this region.
Unique observations in this disorder point out to an important embryonic developmental window, relevant for example to the obsevations of monozygotic twinning which seems to predispose for the epigenetic dysregulations. Another actual topic is the higher rate of epigenetic dysfunction after assisted reproduction.
We discuss the insights of how the study of BWS has contributed to our understanding of the mechanisms of growth control, oncogenesis and genomic imprinting.

Genome-wide association scanning for asymmetry of the human planum temporale

T. Guadalupe[1], *M. Zwiers*[2], *K. Wittfeld*[3], *A. Teumer*[4], *A. Arias Vasquez*[5], *M. Hoogman*[1], *P. Hagoort*[1,2], *G. Fernandez*[2,5], *J. Buitelaar*[5], *B. Franke*[5], *S. E. Fisher*[1,2], *H. J. Grabe*[3,6], *C. Francks*[1,2];
[1]*Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands,* [2]*Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands,* [3]*Department of Psychiatry and Psychotherapy, University of Greifswald, Greifswald, Germany,* [4]*Interfaculty Institute for Genetics and Functional Genomics, University of Greifswald, Greifswald, Germany,* [5]*Radboud University Nijmegen Medical Center, Nijmegen, Netherlands,* [6]*German Center for Neurodegenerative Diseases (DZNE), Greifswald, Germany.*

The Planum Temporale (PT), a triangular shaped surface on the upper part of the temporal lobe, is for most people larger on the left hemisphere than the right. The degree and direction of this asymmetry has been linked to gender, handedness and language dominance. Although present to a degree in other primates, PT asymmetry is pronounced in the human brain and is already visible at 31 weeks of gestation. While this suggests a role for genetic mechanisms, nothing is known about the specific genes that determine this landmark brain asymmetry.
We performed a genome-wide association meta-analysis of PT asymmetry in three population cohorts: the Brain Imaging Genetics cohort from the Netherlands, and two Study of Health in Pomerania cohorts from Germany. A grey matter volume asymmetry measure was derived from T1-weighted MRI scans.
Our combined sample of 3100 subjects showed a genome-wide significant association on chromosome 2q32.2. Because of the sexual dimorphism of PT asymmetry, we subsequently used the meta-analyzed GWAS results to test for enrichment of association in sex-hormone related pathways. We found that, after correcting for the multiple pathways tested, the ´steroid hormone receptor activity´ pathway was significantly associated with PT asymmetry.
This study is the first genome-wide scan for genetic effects on PT asymmetry. Variants in the genes and pathways identified may affect the development of this structure and its role in cognition.

P15.12

Fast detection of de novo copy number variants from case-parent trio SNP arrays.

I. Ruczinski;
Johns Hopkins University, Baltimore, MD, United States.

To infer de novo copy number variants from SNP arrays for case-parent trios, we exploit the trio design and define a statistic called „minimum distance" to capture differences in copy numbers between offspring and parents using genome wide SNP array data. We show that this approach reduces technical variation from probe effects and genomic waves, which is the major source of false positive identifications in copy number analyses. Following segmentation of the minimum distance by circular binary segmentation, final inference regarding de novo copy number events is based on a posterior calling step. We apply both the „MinimumDistance" approach and the joint HMM implemented in PennCNV to a study of oral clefts, validate several detected de novo regions by qRT-PCR, and assess the overall concordance of these two algorithms. Our analysis of the oral cleft trios reveals that genomic waves represent a substantial source of false positive identifications in the joint HMM, despite a wave-correction implementation in PennCNV. The minimum distance is an effective statistic for reducing technical variation contributing to such false de novo discoveries. Computationally, MinimumDistance provides a nearly 8-fold increase in speed relative to the joint HMM. Using trios not selected for phenotype as controls, we identify a region on chromosome 7p14.1 with a (genome-wide) significantly higher number of de-novo deletions in the case-parent trios ascertained through an oral cleft.

P15.13

Comparison of copy number variation (CNV) calling performance in large numbers of technical replicate SNP array data using three different, widely-used CNV calling algorithms

S. Herms[1,2], *A. Hofmann*[2,3], *L. Priebe*[2,3], *F. D. Degenhardt*[2,3], *T. W. Mühleisen*[4], *M. M. Nöthen*[3,2,5], *S. Cichon*[1,3,4], *P. Hoffmann*[1,2,4];
[1]*Division of Medical Genetics, University Hospital Basel; Department of Biomedicine, University of Basel, Basel, Switzerland,* [2]*Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany,* [3]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [4]*Institute of Neuroscience and Medicine (INM-1), Research Center Jülich, Jülich, Germany,* [5]*German Center for Neurodegenerative Diseases, Bonn, Germany.*

Copy number variants (CNVs) have been shown to explain part of the heritability in various multifactorial diseases. Many of these findings are derived from SNP-array data generated in the course of large genome-wide association studies (GWAS). This is not without challenges, however: SNP-arrays contain an ever increasing density of probes which results in a decreased signal-to-noise ratio. The latter causes problems for automated CNV calling algorithms and is a major cause for the unambiguous calling of smaller (<350kbp) and/or low frequency CNVs. Recent studies have therefore focused on the much more reliable calling of larger CNVs (number of consecutive marker or length) and often considering the easier to detect deletion events only.
This study compares the performance and differences in CNV calling using three widely-used CNV calling algorithms: CNVPartition, QuantiSNP2 (v2.2), and PennCNV. As SNP array data a large number of technical replicates (n>500) all genotyped at the University of Bonn on Illumina's HumanOmni-Express- and HumanOmni1M-arrays were used.
We observed an unexpectedly high fluctuation in the prediction of cnv events throughout the three algorithms. All gave comparable findings for larger findings (> 1Mbp) but suffered to give consensus results for smaller variants. Since the replicates were typed on the same array type, this allowed to evaluate effects of the chemistry or the operator in the lab. Results will be shown and based on that parameters will be presented that allow for a better evaluation of the quality of CNV callings from SNP array data.

CNVs and de novo deletion identified in GSTM1 gene in Rheumatoid Arthritis

M. S. Ben Kilani[1], *L. Michou*[2], *T. Bardin*[3], *F. Cornelis*[4], *V. Chaudru*[1], *E. Petit-Teixeira*[1];
[1]*GenHotel-EA3886, Université d'Evry-Val-d'Essonne, Evry-Genopole, Evry, France,* [2]*Département de Médecine, Université Laval, Service de Rhumatologie et Centre de Recherche du CHU de Québec, Québec, QC, Canada,* [3]*Fédération de Rhumatologie, Pôle Appareil Locomoteur, Hôpital Lariboisière, Assistance Publique-Hôpitaux de Paris, Paris, France,* [4]*GenHotel-Auvergne, EA4679, Université d'Auvergne, Service de Génétique Clinique, CHU Clermont-Ferrand, Clermont-Ferrand, France.*

Introduction: At least 12% of the human genome has been identified as copy number variable (CNV). We analysed CNVs of Glutathione S-Transferase Mu 1 class gene (GSTM1), a candidate gene in Rheumatoid Arthritis (RA). Three methods for identifying CNVs were compared in trio families with RA.
Patients and Methods: Nine trio families were genotyped using a multiplex standard PCR (mPCR), which lead to identify three genotypes (-/-, -/+, and +/+) of the gene. Two methods of CNVs quantification were used: a quantitative PCR (qPCR, Life Technologies) for a relative quantification and Droplet Digital PCR (DDPCR, BioRad) for an absolute quantification using up to 20,000 reactions for one sample.
Results: mPCR identified genotypes -/- and -/+. qPCR and DDPCR revealed zero to two copies of the gene. All samples with two copies were heterozygous for GSTM1 deletion (-/++). A de novo deletion of a GSTM1 copy was observed in a RA patient. qPCR analysis using a calibrator with a known CN or the Most Frequent CN (MFC) could have generated heterogeneous results. DDPCR did an absolute quantification of CNVs with a high number of replicates and no calibrator or MFC was needed.
Conclusion: Comparison of technologies identifying CNVs of this candidate gene lead us to conclude that DDPCR is the best method to use in this field of investigation. We highlighted then rare events such as de novo deletion in families of RA patients. Further analyses on larger samples are required to better understand the impact of GSTM1 CNVs in RA.

Variant discovery in BRCA1 and BRCA2: Comparison of the efficiency of NextGENe software and the Torrent Suite Variant Caller plugin

I. Popov[1], *D. Dacheva*[1,2], *R. Dodova*[1,2], *T. Goranova*[1], *A. Mitkova*[1,2], *R. Kaneva*[1,2], *V. Mitev*[1,2];
[1]*Molecular Medicine Center, Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria.*

Second-generation sequencing technologies are now widely used in a research setting to screen large numbers of samples for known variations, or as primary detection for new ones. Computational methods that rate the discovered variations and separate the sequencing errors from the real SNPs and mutations are an inseparable part of every NGS pipeline.
In our study the BRCA1 and BRCA2 genes were sequenced in 16 patients with breast cancer on a single Ion 316 chip, using the Ion Torrent PGM platform. The native Ion Torrent Variant Caller and the NextGENe software by SoftGenetics were used separately to analyze the results. The calls that appeared in both analyses were forwarded for confirmation with Sanger sequencing.
NextGENe reported a smaller total number of variations over all 16 patients (224) in the sequenced regions than the Variant Caller (312), which was due to the strict settings of the mutation filter. 106 of those variants were common for the two groups. The filtering was tuned down in two steps, yielding two more NextGENe result sets with 325 (123 common) and 1951 (201 common) variants, respectively. The 201 common variants had a higher frequency than the calls made by Variant Caller alone, and higher scores than those made by NextGENe only. This shows that the combined use of the two filters can increase the quality of the final results, even when they are set to register almost all variations in the data, as in the case of de novo variant discovery.

P15.17

Evaluation of DNA methylation in breast cancer patients

I. Zmetakova, *V. Kajabova, B. Smolkova, T. Krivulcik, I. Fridrichova;*
Cancer Research Institute of Slovak Academy of Sciences, Bratislava, Slovakia.

Epigenetic alterations, in addition to the highly characterized genetic changes, are key contributors to breast carcinogenesis. Altered DNA methylation is commonly observed in the tumorigenesis. The aberrant promoter hypermethylation of cancer-related genes in tumour-derived DNA from plasma samples was presented as a useful tool for detecting and monitoring cancer.
The purpose of our study is to investigate relationship between DNA methylation and breast cancer progression. Quantitative DNA methylation analysis of 11 genes (APC, ADAM23, CXCL12, ESR1, PGR B, CDH1, RASSF1A, SYK, TIMP3, BRMS1 and SOCS1) was performed by pyrosequencing. For determining of methylation levels we analysed DNA isolated from paraffin-

embedded tumour tissues, plasma and blood cells from 37 sporadic breast cancer patients and plasma and blood samples of 50 healthy controls.
We have observed DNA methylation in nearly half of investigated patients in RASSF1A, APC, ADAM23, CXCL12 and SYK genes in tumour samples. Cumulative methylation results showed different methylation levels in tumour and plasma samples where notable higher portion of methylation was found in tumour. Differences between DNA methylation in plasma samples of patients and healthy controls were not significant. This finding cast some doubts on the utility of DNA extracted from plasma samples to identify hypermethylation of specific gene promoters for diagnosis and prognosis of cancer. Preliminary results suggest that DNA methylation in the several studied genes in tumour tissues could be useful biomarkers for the identification of breast cancer with metastasizing potential.
This study was funded by projects: APVV-0076-10; no.26240220058, Research and Development Operational Programme (ERDF) and VEGA-2 /0120/13.

P15.18
The Association Between TWIST, RARβ2, ESR1 Gene Promotor Hypermethylation and the Histopathologic Type of Breast Cancer in Turkish Population

O. EROGLU[1], *B. DURAK ARAS*[2], *S. ARTAN*[2], *M. OZDEMIR*[2], *O. CILINGIR*[2];
[1]*Bilecik Seyh Edebali University, Molecular Biology and Genetics Department, Bilecik, Turkey,* [2]*Eskisehir Osmangazi University, Medical Faculty of Medical Genetics, Eskisehir, Turkey.*

Backround: Breast cancer is the most common cancer in women. Histopathology plays an important part in determining the treatment strategy for women with breast cancer.
TWIST expression in breast tumors correlate with increased disease recurrence, metastasis and poor disease-free survival. Steroid receptor gene family members such as RARβ2 and ESR1 genes are methylated and silenced in a fraction of breast cancer.
Method: In this study the promoter methylation levels of TWIST, RARβ2 and ESR1 gene which are associated with breast cancer were investigated by Quantitative Methylation Sensitive High Resolution Melting Analysis (QMS-HRM).We analysed primary tumor core biopsies from 80 high-risk primary breast cancer patients (tumors ≥2 cm and/or lenfatic metastase and/or distant metastases and/or under 40 years) and their histopathologic types were associated with the methylation levels.
Results: In our study the promoter hypermethylation status were observed at different rates; TWIST, RARβ2 and ESR1 methylation frequencies were 25%, 88.75 and 72.5%, respectively. The promoter hypermethylation levels of the genes found to be significant with lymph node positivity, ER positivity and HER2/neu negativity.
Conclusions: Our study is important as being the first study that analyzes the association between histopathologic type of breast cancer and TWIST, RARβ2, ESR1 gene promotor methylation status in Turkish population.
Key words: Breast cancer, Histopathologic Type, TWIST gene, RARβ2 gene, ESR1 gene, Methylation, MS-HRM Analysis

P15.19
Analysis of Apoptosis regulatory pathway in sporadic breast cancer through Gene Regulatory Network

S. Haider[1], *k. Ponnusamy*[2], *R. N. K. Bamezai*[3];
[1]*Department of Biotechnology, Jamia Millia Islamia, New Delhi, India,* [2]*National Centre of Applied Human Genetics, School of Life Sciences, Jawaharlal Nehru University, New Delhi, India,* [3]*National Centre of Applied Human Genetics, School of Life Sciences,Jawaharlal Nehru University, New Delhi, India.*

In multicellular organisms, gene regulatory networks along with transcriptional factors (TF) control the global gene expression and the dynamics of protein output in living cells. An extensive analysis of networks facilitates to analyze coordinated gene expression changes to find altered molecular pathways and genes in cancer development. The aim of the study was to predict the innovative biological networks that describe transcriptional alteration (up or down regulation) in genes/pathways which could contribute to the pathogenesis of cancer and other associated disease. The expression of several candidate genes (MDR1, ATM, BCL2, CASP3, CASP8, CHK2, TR10C, TR10D, TR10B, CFLAR, H2AX, IFNG, IL10, IL4, IL6, P53, MDM2, TGFB1, TNFA, TNF10, BRCA1 and BRCA2), as a part of another study in sporadic breast cancer was used for constructing the biological network which comprised of both transcriptional regulatory relationships and integrated the protein interactome. We also developed a set of TF-gene regulatory relationships, using UCSC genome browser. The human cancer combinatory gene regulatory network was found to be a hierarchical scale-free network with PAX4-transcription factor as the most important regulators. It is known that PAX4 functions as a potent tumor suppressor and plays a critical role in Cancer growth as well as in the functional morbidity causes Diabetes, which also provides a logical link between cancer and diabetes. We believe our work provides a scaffold combinatorial gene regulatory network allowing systematic study of apoptotic gene regulation, and provides a pipeline which could be extended to reveal conditional combinatorial regulatory landscapes correlating with specific cellular contexts.

P15.20
Methylation analysis of NFkB-related genes in celiac gut mucosa

N. Fernandez-Jimenez[1], *X. Elcoroaristizabal*[2], *L. Plaza-Izurieta*[1], *A. Jauregi-Miguel*[1], *T. Lopez-Euba*[1], *I. Irastorza*[1], *M. M. de Pancorbo*[2], *J. Bilbao*[1];
[1]*BioCruces Reserch Institute/UPV-EHU, Leioa, Spain,* [2]*BIOMICs Research Group / UPV-EHU, Vitoria-Gasteiz, Spain.*

Celiac disease (CD) is a complex, immune-mediated enteropathy caused by ingested gluten with strong genetic and environmental risk determinants, and is an excellent target for the study of gene methylation. IL6 has been shown to induce nuclear translocation of DMT1 through NFkB and JAK/STAT pathways and to alter CpG island methylation. In this work, we studied the methylation pattern of the promoter regions of several NFkB-related genes.
Using pyrosequencing of bisulfite treated DNA, we analyzed 4-6 CpG islands in 8 NFkB-related gene promoters in 17 celiac biopsy pairs (at diagnosis and after >2 years on gluten free diet) and 13 non-celiac biopsies. We also studied IL6 expression. Additionally, samples from 8 patients at diagnosis and 8 treated patients were incubated for 12 hours with gliadin, with a modulator of NFkB pathway, with both compounds or without any of them.
Compared to controls, RELA presented lower methylation levels at diagnosis while MAP3K7 and TRADD showed the opposite pattern. Treated patients presented intermediate methylation percentages, suggesting a partial reversion of the aberrant methylation induced by active disease. Methylation levels of different genes showed significant linear correlation in patients but not in controls. Methylation percentages did not correlate with IL6 RNA levels, although IL6 was overexpressed in active CD. Preliminary results suggest that incubation of biopsies from treated patients alters methylation in several genes, and NFkB modulation seems to partially reverse gliadin effects. Correlation between different genes was not observed in these samples, pointing to cell subtype selection underlying the observed events.

P15.21
Genome-scale DNA Methylation Analysis of Sporadic Colorectal Cancer by Infinium HumanMethylation 450 BeadChips.

V. Naumov, *E. Generozov, N. Zakharzhevskaya;*
Research Institute of Physico-Chemical Medicine, Moscow, Russian Federation.

Infinium HumanMethylation 450K BeadChip arrays were used to examine genome-wide DNA methylation profiles in 22 sample pairs of colon cancer (CRC), adjacent tissues and 19 colon tissues samples from cancer-free donors. We show that tumor and both normal methylation profiles can be clearly distinguished from one another and that the main source of methylation variability is associated with disease status. Although we have identified a number of genes potentially involved in the field cancerization their total impact on methylation in normal tissue is rather low.
At CpG sites level we showed that common CRC-specific methylation patterns consist of at least 15,667 CpG sites significantly different from both versions of the norms. 10,342 of them were hypermethylated and 5,325 hypomethylated. Hypermethylated sites were common in maximum number of sample pairs, located mostly in CpG islands and significantly enriched for known cancer-specific differentially methylated regions, while hypomethylated were mostly located in CpG Shores and were generally sample-specific.
Despite of considerable variability in methylation data we selected a panel of 14 highly robust candidate methylation markers located in genes SND1, ADHFE1, OPLAH, TLX2, C1orf70, ZFP64, NR5A2 and COL4A. This set was

successfully cross-validated using methylation data of 247 CRC samples from The Cancer Genome Atlas consortium (AUC = 0,981(95% CI: 0.9677-0.9939), sensitivity = 100%, specifity = 82%).
In summary, our results demonstrate the significance of aberrant DNA methylation in CRC tumorigenesis and report a large number of novel differentially methylated loci some of which may serve as candidate markers for diagnostic purposes.

P15.22
Facing the challenge of increased genetic and clinical heterogenities

M. L. Chauvet[1], S. Hanein[1], C. Mugnier[2], C. Turleau[1], P. Gastineau[1], M. Girard[1], A. Legendre[3], F. Cartault[1], A. Munnich[1], J. P. Jais[4], Y. Kergosien[5], M. Le Merrer[6], ***A. Henrion Caude[1]****;*
[1]Inserm U781, Paris, France, [2]Université Paris Descartes, Paris, France, [3]Service de cardiologie pédiatrique, Paris, France, [4]Service de biostatistique, Paris, France, [5]Universite de Cergy-Pontoise, Cergy, France, [6]Service de Génétique - Hôpital Necker-Enfants Malades, Paris, France.

With next-generation sequencing techniques, geneticists are in great need of bioinformatic solutions to face the deluge of literature and gene identifications. A challenge is thus to provide both the medical and the scientific audiences with ready and easy access to high-quality synthesized information on rare human diseases in relation with the genes. Originally founded in 1986, GenAtlas is a world-reference database of genes and diseases that has ever since been constantly maintained and updated. It provides a flow of information from gene structure to expression, protein structure to expression and function, mutations to gain or loss-of-function consequences. Reciprocal links are established with different databases such as Ensembl, HGNC, Genecards, UniGene, NCBI Gene and Refseq, HGMD as well as OMIM, UniProt, OrphaNet, GeneReviews, confirming international recognition. The specificity of GenAtlas is that it records data manually extracted from scientific papers and annotated, making it a genuine compilation of genetic diseases with updated and curated links to relevant original articles. Through proof-of-concept cases, we will present how the new web-interface can help facing the challenge of clinical and genetic heterogeneity, as well as the characterization of non-coding RNA genes, i.e. microRNA and long non-coding RNA as bona fide causal genes.

P15.23
Qualifying the role of genes in the determination of diseases: a new service of Orphanet

A. M. Rath*, C. Gonthier, A. Olry, S. Aymé;*
Inserm, US14, Paris, France.

The identification of genes related to diseases is growing exponentially. However, relationships between genes and diseases are not always explicit. There is no standardised, systematic annotation of gene-disease relationships in genetic databases that is easy to use for research purposes. Orphanet has maintained a database of genes linked to rare diseases since 2007. Genes are also entered in the database if tests are available in order to search for susceptibility factors for non-rare diseases. There are currently 2,498 genes linked to diseases in the database. Each gene-disease relationship is assigned one the following categories: germline or somatic causing mutations, part of a fusion gene, major susceptibility factor, modifying gene or gene playing a major role in the phenotype (of a chromosomal abnormality). The evidence is established from the literature, by cross-referencing with other genetic databases (i.e. OMIM, Geneatlas), by seeking expert advice or by collective decisions made by the scientific staff at Orphanet in very difficult cases. Whether the information has been assessed or not is indicated in the website by a visual pictogram as well as in the downloadable files.
The *gene-relationship-disease* triples can be visualised via the Orphanet website (www.orpha.net) by disease or gene search, or extracted from Orphadata (www.orphadata.org). They will be used in innovative bioinformatics projects (for instance, OpenPHACS) as nanopublications.

P15.24
Automating the collection and quality control of clinical variant data.

M. J. Cornell, K. Robertson, ***A. Devereau****;*
National Genetics Reference Laboratory, Manchester, Manchester, United Kingdom.

The diagnostic mutation database (DMuDB https://secure.dmudb.net) was established in 2005 to allow the secure sharing of diagnostic variant data. Currently the database contains 45117 variant reports from 78 genes. Since 2011 DMuDB has been available to diagnostic laboratories worldwide and is now used by 105 laboratories.
As DMuDB has grown, the need for ensuring data quality has become more apparent. To identify incorrect nomenclature we have developed a quality control pipeline using the Taverna Workflow Management System (http://www.taverna.org.uk/) and the Mutalyzer web service (https://mutalyzer.nl/). In addition, we have identified instances where the pathogenicity of a variant differs between submissions. This has required us to establish protocols for re-contacting users regarding their submissions.
Much of the data submitted to DMuDB is in the form of users spreadsheets that require reformatting prior to database submission. This is time consuming and inappropriate for next generation sequencing (NGS) data. We are developing mechanisms for incorporating submission to DMuDB into laboratories LIMS systems. We are enabling the input of patient phenotype data using standards such as Human Phenotype Ontology (HPO). Capturing phenotype data will increase the usefulness of variant data to the clinical community. This particularly applies to variants identified by NGS, which may have been identified by the sequencing of large gene panels.
Our experience of databasing clinical variants suggests that future development of large variant data repositories will require a "hands on" approach by database curators in order to maintain data quality.

M.J. Cornell: None. **K. Robertson:** None. **A. Devereau:** None.

P15.25
Estimation of the timing and rate of *de novo* mutagenesis in a healthy monozygotic twin pair

G. M. Dal*[1], C. Alkan[2], M. S. Sagiroglu[3], B. Erguner[3], T. Ozcelik[1];*
[1]Department of Molecular Biology and Genetics, Bilkent University, 06800, Ankara, Turkey, [2]Department of Computer Engineering, Bilkent University, 06800, Ankara, Turkey, [3]TUBITAK - BILGEM - UEKAE, 41470, Gebze, Kocaeli, Turkey.

Characterizing *de novo* mutations regarding their origin, timing and rate has great importance in terms of providing insights into mutational processes, human diseases and evolution. Outstanding progress of the next generation sequencing technologies has facilitated the investigation of *de novo* mutations and led to the estimation of human *de novo* single nucleotide variant (SNV) rate at ~1.2 × 10−8 bp/generation. However, the timing of these *de novo* mutations is still unknown. Hence, we performed deep whole genome sequencing of a male monozygotic twin pair and their parents at (21-41x) and identified ~3.2 million SNVs for each individual. Through the comparative analysis of the genotypes of both twins and their parents for each of these SNVs in a synchronized manner, we discovered a total of 97 *de novo* SNVs. Among them, 46 were shared by the twin pair indicating a parental or pre-twining zygotic origin. We found 37 *de novo* SNVs to be specific for twin-I and 14 for twin-II, which indicates that these SNVs had occured in the post-twinning embryo, particularly in the mesoderm from which the blood cells derived. To date, we validated 12 pre-twinning and 2 post-twinning *de novo* SNVs using Sanger sequencing, while other candidates are currently being tested at the time of this abstract submission. Our findings provide knowledge about the rate and timing of *de novo* mutagenesis in healthy individuals; and further reiterate the importance of post-zygotic mutations leading to somatic mosaicism in what could be a wide spectrum of human diseases.

P15.26
Locus Reference Genomic sequences: reference sequences for the reporting of clinically relevant sequence variants.

J. A. L. MacArthur*[1], J. Morales[1], R. Dalgleish[2], A. Astashyn[3], L. Gil[1], W. M. McLaren[1], R. E. Tully[3], E. Birney[1], P. Flicek[1], D. R. Maglott[3], F. Cunningham[1];*
[1]European Bioinformatics Institute, Cambridge, United Kingdom, [2]University of Leicester, Leicester, United Kingdom, [3]National Center for Biotechnology Information, Bethesda, MD, United States.

Locus reference genomic (LRG) sequences are internationally recognized reference sequences designed specifically for the reporting of clinically relevant variants. An LRG provides a stable genomic DNA sequence for a region

of the human genome which will never be changed and so is not versioned. They are compiled and maintained by the NCBI and EBI, as part of the GEN2PHEN and RefSeqGene projects (www.ncbi.nlm.nih.gov/refseq/rsg), in collaboration with the community of diagnostic and research labs, locus specific database (LSDB) curators and mutation consortia. The LRG project aims to create an LRG for every clinically relevant genomic locus. Over 600 LRGs have been created so far.

All information relating to an LRG is contained within a single XML file, which comprises separate sections for the fixed and updatable annotation. The fixed (stable) section contains the genomic sequence and annotation for transcripts and exons used as reference standards. The updatable section contains mapping information for the LRG sequence, as well as annotation of additional transcripts, co-located genes, LSDB information, and alternative exon and amino-acid numbering systems.

The stable nature of these reference sequences enables unambiguous reporting of variants in LRG coordinates, as recommended by the Human Genome Variation Society (HGVS) and European Molecular Genetics Quality Network (EMQN). LRGs can be viewed in the Ensembl and NCBI genome browsers and databases. Tools such as Mutalyzer (https://mutalyzer.nl) and Variation Reporter (http://www.ncbi.nlm.nih.gov/variation/tools/reporter/) also support LRGs.

All LRG records are available on the LRG website (http://www.lrg-sequence.org), which also provides instructions on requesting LRGs and the complete LRG specification.

Rapid Identification of Clinically Relevant Variants from Human Sequencing Data

D. Richards, *T. Bonnert, R. Flannery, A. Kramer, A. Kutchma, J. Lerman, J. Leschly, S. Majumdar, N. Marshall, M. Molloy, A. Muthiah, A. Ning, R. O'Connor, K. Patel, V. Rajaraman, R. Rebres, A. Sarver, D. Bassett;*
Ingenuity Systems, Redwood City, CA, United States.

Biological interpretation of thousands of potentially deleterious variants is a bottleneck in discovering valuable causal insights from DNA resequencing studies, often requiring months of effort after completion of the variant calling step. Ingenuity® Variant Analysis (www.ingenuity.com/variants) is an application that leverages an extensive knowledge base of millions of expert-curated mutation and biomedical findings from the literature and integrated reference information to enable real-time interactive filtering and rapid prioritization of variants. We have extended it to compute a synthesis of the current knowledge about variants to provide automated initial clinical assessments, identify variants implicated in diseases consistent with observed clinical features, and extensive coverage of pharmacogenetic impacts. Aside from empowering clinical researchers to immediately identify reportable variants in medical genomes, we have optimized gene-level burden tests on the order of 100x faster than conventional methods while delivering consistent results, and pathway level causally-consistent algorithms to find the few variants that are most compelling for follow-up in multi-sample studies. Using a combination of causal analytics, statistical and genetic analysis at the variant, gene, and pathway levels, and the ability to visualize how variants impact disease progression, we will demonstrate the application of a context-rich knowledge base to discover clinically relevant cancer driver variants and novel causal variants for human genetic disease.

High-throughput screening of animal venoms for isolation of novel drug leads

J. Trivino[1], *R. Minambres*[1], *R. Rodríguez-dePablos*[1], *M. Gil*[1], *P. Escoubas*[2], *M. Verdenaud*[3], *F. Ducancel*[3], *S. Zuniga*[1];
[1]*Sistemas Genomicos, Valencia, Spain,* [2]*Venometech, Valbonne, France,* [3]*Laboratoire d'Ingénierie des Anticorps pour la Santé (LIAS), CEA Saclay, Paris, France.*

Multiple studies have shown the potential of some animal venom compounds for the treatment of different diseases where medical needs are not properly addressed by the current available treatments. Animal venoms are small effective molecules with extraordinary target selectivity and low side effects with huge natural and chemical diversity. These properties make animal venoms especially suitable as sources for drug development. Due to technical and economical limitations in traditional peptide screening techniques little work has been done so far in venom-based research for drug therapy. With the advent of Next-Generation Sequencing platforms novel and more efficient strategies for drug discovery are now feasible to improve Human Health.

Here we describe the results of the first pilot project that was performed to reconstruct and characterize three venom transcriptomes that were sequenced on two different NGS platforms. We functionally compared the results of the different datasets to provide new insights into venom composition. Our results are part of a comprehensive international project aiming at full venom toxin identification for drug lead discovery and drug development. The VENOMICS project is a FP7 HEALTH initiative which aims to analyze 200 venoms using the most advanced proteomics and transcriptomics techniques to obtain a collection of 10,000 venom peptides that will be further used for drug development to target different metabolic diseases such as obesity and diabetes.

DNA-methylation changes at multiple loci in patients with imprinting disorders due to epimutations and in children born small for gestational age

J. Kolarova*[1], *S. Bens*[*1], *A. Haake*[1], *J. Richter*[1], *J. Leohold*[1], *F. Riepe*[2], *I. Tangen*[1], *T. Eggermann*[3], *K. Buiting*[4], *S. Thiele-Schmitz*[5], *G. Gillessen-Kaesbach*[6], *D. Prawitt*[7], *O. Ammerpohl*[1], *B. Horsthemke*[4], *A. Caliebe*[1], *R. Siebert*[1];
[1]*Institute of Human Genetics, Christian-Albrechts-University Kiel & University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany,* [2]*Department of Pediatrics, Christian-Albrechts-University Kiel & University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany,* [3]*Institute of Human Genetics University Hospital Aachen, Aachen, Germany,* [4]*Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany,* [5]*Klinik für Kinder- und Jugendmedizin Universität zu Lübeck, Lübeck, Germany,* [6]*Institut für Humangenetik Lübeck, Universität zu Lübeck, Lübeck, Germany,* [7]*Section of Molecular Pediatrics University Medical Centre of the Johannes Gutenberg-University Mainz, Mainz, Germany.*

A subset of patients with imprinting disorders due to epimutations shows DNA methylation defects at multiple loci (MLMD). Within the German "Imprinting Network" we analyzed the methylation pattern at imprinted loci in 127 patients with imprinting disorders caused by epimutations and 98 children born small for gestational age (SGA). In a step-wise screening approach we first determined peripheral blood DNA methylation patterns of 10 imprinted loci in all patients by bisulfite pyrosequencing and compared them to those of 50 healthy controls. In addition to 6/127 patients previously diagnosed with MLMD, bisulfite pyrosequencing suggested aberrant DNA methylation at multiple loci in additional 15/127 patients with classical imprinting disorders. No SGA born child showed MLMD (Bens et al, EJHG, 2012).

All patients suggestive for MLMD in pyrosequencing with left over material (n=19), one "positive control" for each classical imprinting disorder (n=6) and all children born SGA were further analyzed using the HumanMethylation450k BeadChip (Illumina) interrogating genome-wide DNA-methylation patterns at 485,577 CpG loci. Results were compared to those of 20 healthy controls. MLMD was confirmed in all previously diagnosed cases, 3 patients suggestive for MLMD in pyrosequencing, one SGA born child and one "positive control". The extent of methylation changes varied with the *KCNQ1* locus being most frequently affected consistent with the clinical phenotype of BWS in 3/11 cases. This study also revealed that multiple imprinting defects are more frequent in growth disorders than in neurogenetic disorders caused by imprinting defects.

P15.30
Association of IGFBP-5 exon-I methylation and gene expression in breast cancer

***S. Karabulut**, Z. Kaya, G. Güllü, &. Peker, T. Özmen, C. Erzik, A. Özer, M. Akkiprik;*
Marmara Unıversıty, İstanbul, Turkey.

Breast cancer is the most frequently diagnosed oncological disease. Insulin-like growth factor binding protein-5 (IGFBP-5) is one of the critical members of IGF system in both normal cell physiology and tumorigenesis. IGFBP5 expression shows diversity in breast cancer patient tissues. Aberrant CpG methylation in regulator sequences of this gene could be responsible for the difference of IGFBP-5 expression pattern in breast tumor.
The aim of our study was to evaluate the significance of IGFBP-5 exon-1 methylation status on expression level of IGFBP-5 mRNA in patients with breast cancer. Thirty pairs of breast carcinomas and their normal breast tissue counterparts from the same patients were randomly selected for methylation-specific PCR (MSP) experiment. Methylation status of first exon and its transcriptional effect were evaluated using a MSP and expression level by real time PCR, respectively.
According to our results, different methylation patterns of the region were detected between healthy and cancer tissues of 4/30 patients. Gene expression and methylation status were correlated in two of these patients, whereas in one there was no correlation. In the fourth patient tissues, in which methylation and unmethylation were detected in healthy and cancer tissue, respectively, the expression data is not available yet.
In conclusion, methylation level of IGFBP-5 exon-1 region has been shown to be rarely present in breast cancer tissue, but it may affect mRNA expression level of the gene. Further studies are needed to confirm these findings. Ongoing studies about promoter sequence methylation of IGFBP-5 gene are being conducted.

SNVs and indels derived from exome sequencing are usually filtered by minor allele frequency and mode of inheritance in order to identify candidate variants for Mendelian disease. We developed a database that stores both pedigree information and variant data generated by an analysis pipeline. A corresponding web frontend allows to filter the data in an interactive way. Standard queries include searches for rare heterozygous, compound heterozygous, homozygous, de novo and somatic variants. Variants are connected with a number of annotations such as position in transcripts, amino acid change, functional predictions, and presence in dbSNP, HGMD and the 1000 Genomes data. Furthermore, quality scores, and read depth and links to external databases are provided. In addition to publically available frequency data, variants identified in in-house exomes of individuals with unrelated phenotypes are used as controls.
In addition to frequency based searches, one can also perform gene and disease-based searches, thus displaying the variation content of genes or focusing the search on known disease genes or HGMD mutations.
The database also contains data about the average read depth per exon and the proportion by which each exon is covered at least 20-times. These data can be used in a diagnostic context to define the regions of a gene which have been appropriately analyzed and to identify genes which possibly carry deletions of entire exons.
Lastly, the database is connected with a LIMS and provides basic quality statistics, such as sequence amount, read depth, sample contamination and discordance between specified and identified sex.

GeneTalk: a compound heterozygotes filter for exome data

***T. Kamphans**[1], P. Krawitz[2], P. Sabri[2], A. Knaus[2];*
[1]Smart Algos, Berlin, Germany, [2]Medical Genetics and Human Genetics, Berlin, Germany.

The identification of disease causing mutations in next-generation sequencing (NGS) data requires efficient filtering techniques. We developed a web-based compound heterozygous filter that is suited for data from NGS projects and that is easy to use for non-bioinformaticians. We analyzed the power of compound heterozygous mutation filtering for rare recessive disorders in single individuals, trios and more complex pedigree structures based on exome data of more than 10,000 individuals from 10 different population backgrounds. Depending on the ethnicity there are characteristic sets of highly variable genes that can be used to filter candidate genes. Compound heterozygous filtering rules in combination with population frequency data yield a highly effective prioritization in disease gene discovery.

Gene-centered viewing, storing and sharing of exome/genome variant and phenotype data

***P. Taschner**, I. Fokkema, I. Lugtenburg, J. Hoogenboom, Z. Tatum, G. Schaafsma, M. Vermaat, J. Laros, J. den Dunnen;*
Center for Human and Clinical Genetics, Leiden, Netherlands.

The favourite view of sequence variant data in DNA diagnostic centers is gene-centered. We have developed a new version of the LOVD platform (Leiden Open-source Variation Database, http://www.LOVD.nl) facilitating the analysis of exome and genome sequence data. During installation, web services retrieve gene and transcript information on the fly. Imported variant data are stored using chromosomal nucleotide positions as a reference. Data can be stored and displayed in several ways: variant-by-variant or all connected to one individual. Using the existing LOVD functionality, users have the option to perform query per gene or individual, to link to other resources of interest, to get genome browser views of the data and to using web services to access variants stored in other gene variant databases. LOVD 3 has the unique option to independently store both the phenotypes screened and the variants detected. This gives submitters the chance to share inconclusive results, allowing collaborators with matching data to join the gene identification project and crack the case together. In addition, LOVD3 has a new access level, designated “collaborator”, allowing submitters to share otherwise non-public data with other submitters, e.g., to share detailed phenotype information with other diagnostic labs only.

Circadian rhythm is approximately 24-hour cycle in behavioural, physiological and biochemical processes in diverse living organisms. One of underlying principles of successful rhythmicity is cycling gene activation, which leads to the changes in the transcriptome of different tissues. We investigated gene expression in the peripheral blood lymphocytes as a function of time of the day when the blood sample was taken. In total mRNA samples from1086 individuals were analysed using Illumina HumanHT-12 v3 BeadChip arrays. We found 181 statistically differentially expressed transcripts throughout the day (from 9 am to 18 pm), including previously known rhythmic genes as well as novel candidate genes that might be related to circadian rhythms of blood. These results were replicated in KORA cohort samples, although in shorter time-span. This finding demonstrates daytime-dependent effect on gene expression of whole blood cells, indicating potentially functional circadian clock in peripheral blood cells.

The acute respiratory distress syndrome (ARDS) is a severe inflammatory disease characterized by pulmonary edema and hypoxemia. It commonly affects critically ill patients following insults such as sepsis. The only effective treatment is mechanical ventilation (MV) using low tidal volumes (LTV), although it is unclear how it exerts its protective effects. To identify the molecular mechanisms modulated by MV, we performed microarray gene expression analysis using a clinically relevant model of sepsis-induced ARDS by cecal ligation and puncture in male Sprague-Dawley rats. Following this first injury, rats were exposed to different MV regimes, using high tidal volume, LTV, or simply non-MV. Total lung RNA was extracted, DNase digested, integrity evaluated and hybridized to microarrays. Comparisons against the non-septic control rats revealed a total of 2038 deregulated genes (at 5% false discovery rate) in the overall experiment. Functional predictions in the 1013 deregulated genes of the LTV group supported the involvement of chemotaxis, proliferation and cellular differentiation, lung development, cell matrix adhesion, water transporter channels, neuronal development and axonogenesis, processes related to edema formation and pulmonary fibrosis commonly observed in the lungs of ARDS patients. We expect that further integrative analysis of this data along with existing human genomic information from this and other respiratory conditions will provide valuable candidate genes for downstream association studies of genetic variants with ARDS pathogenesis.

DNA methylation is one of the main epigenetic mechanisms regulating the activation and inactivation of genes in a tissue specific manner. Although it is well-known that DNA methylation is essential for the regulation of gene expression, so far no epigenome-wide study is published that has analyzed the influence of the methylation state on transcript levels in whole blood leucocytes.

We analyzed 732 individuals from the population-based KORA F4 cohort with whole blood DNA methylation data measured on the Illumina HumanMethylation450 BeadChip and whole blood gene expression data on the Illumina Human HT-12 v3 Expression BeadChip. After quality control we applied a linear regression model using methylation intensity values (M-values) for 460.000 CpG sites and almost 30.000 expression probes. We obtained more than 12 million significant associations when using the Bonferroni threshold of 3.7E-12 including 76,720 CpG sites and 5,145 expression probes. To our surprise, more than 80% of the associations were between CpG sites and transcripts across different chromosomes. On the one hand, this might suggest a high degree of inter-chromosomal interactions; however, on the other hand, the extremely high proportion of non-cis interactions questions the biological significance of the identified associations and needs to be verified. Future strategies include replication, adjustment for leucocyte subtypes and genetic variants, stepwise exclusion of sites and transcripts with multiple hits, and functional annotation of the significant hits. This study suggests a complex relationship between the methylation state and transcript levels and demonstrates the challenges in interpreting results from multi-omics analyses.

Architecture of aging-regulated genome-wide expression profiles in humans

M. Gheorghe[1], *J. J. Goeman*[2], ***V. Raz***[1];

[1]*Department of Human and Clinical Genetics, Leiden University Medical Centre, Leiden, Netherlands,* [2]*Department of Medical Statistics, Leiden University Medical Centre, Leiden, Netherlands.*

Summary: During adulthood physiological ability declines with age and is associated with genome-wide changes in gene expression profiles. Genome-wide age-regulated expression trends could provide an unbiased description of temporal changes during aging. We developed a robust statistical methodology to identify age-regulated expression trends in human cross-sectional datasets, and we show that the pattern of aging-associated changes in expression profiles differ between tissues. We identified that in *Vastus lateralis* muscles and in brain cortex molecular aging starts already during early midlife and is progressed through two distinct checkpoints. In contrast in Kidney cortex and in blood changes starts only around the eighth decade. Our results suggest that in human molecular aging progresses through at least two checkpoints, which are temporally and spatially distinct between tissues. This open new hypothesis for how aging is initiates and progressed in humans.

SNP detection by RNA-seq

L. Xumerle[1], *I. Iacobucci*[2], *V. Mijatovic*[1], *A. Mori*[1], *G. Martinelli*[2], *P. F. Pignatti*[1], *G. Malerba*[1];

[1]*Biology and Genetics, Verona, Italy,* [2]*Department of Hematology and Oncological Sciences „L. e A. Seràgnoli", Bologna, Italy.*

The massively parallel sequencing of the transcriptome (RNA-seq) produces several millions sequences (reads) that are usually used to quantify digitally the genes expression over the trascriptome. Since RNA-seq is based on sequencing, it's possible to identify loci that are likely to be polimorphic using alignment mismatches between the tested sample and the reference genome sequence. The goal of this study is to compare the most common alignment programs (bowtie2, tophat2, bwa, gsnap) to verify the reliability of SNP detection in RNA-seq samples. For the analysis were used data of 5 RNA-seq samples from individuals (2 leukemia and 3 chronic myeloproliferative syndrome) previously genotyped with the Affymetrix Chip GenomeWideSNP 6. After alignment, genotypes of polimorfic loci were detected directly from the pileup computed by the program samtools. More than 10000 polymorphic loci were detected by RNA-seq and were in common with the corresponding loci on the Chip. In the first analysis an allele was considered a true variant if called by at least five reads. Using this threshold the average genotype error rate between RNA-seq and Chip is ~10%. The same computation performed with no threshold value (1 read was enough to call the alternative allele) shows an error rate of ~ 0,03%. The results suggest that SNP detection is possible using RNA-seq and that variants called by few reads have to be interpreted as true variant and not as background noise. A more detailed study on differential allele counts needs to be performed to ascertain possible biases of RNA-seq.

SH-imi-goldnanoparticles a possible drug target carrier: an evaluation using epigenetic histone dimethylation levels

A. Polverino[1], *A. Iuliano*[1], *M. Frucci*[1], *A. Longo*[2], *G. Carotenuto*[2], *D. Drongitis*[3], *M. Piscopo*[3], *L. Fucci*[3], *E. Vitale*[1];
[1]*CNR Cybernetics, Pozzuoli, Italy,* [2]*Institute of Biomaterials CNR, Portici Napoli, Italy,* [3]*Department of Structural and Functional Biology University of Naples, Naples, Italy.*

This study refers a 2-mercapto-1-methylimidazole (SH-imi) gold nanoparticles (AuNPs)-conjugated synthesis, their interaction within different cell lines and epigenetic effect after cell internalization. We describe SH-imi-AuNPs cell intake following H3K4 and H3K9 dimethylation analysis in three different cell lines: human neuroblastoma cells SH-SY5Y, androgen-responsive lymph node prostate cancer cell line LNCaP, and DU-145 cells, a non-androgen sensitive cell line. Specifically we study the level of dimethylation in H3K4 as epigenetic marker of euchromatin, and dimethylation in H3K9 as transcriptional repression marker.
After an hour of treatment with SH-imiAuNPs, histones were extracted and dimethyl-H3K4 and -H3K9 evaluated. The three cell lines all show decreased levels of H3K4me2 and increased levels of H3K9me2. Additionally we observe a general chromatin closing trend within the three cell lines with minor different effect.
To better understand the nanogold biological interaction we incubated SH-SY5Y for an hour using decreased concentration of SH-imiAuNPs, within the range of 100 ng/ml to1 ng/ml. We found that cell damage decrease with the concentration of gold nanoparticles. Fluorescent microscopy and binarization algorithm based on thresholding process with an RGB input image, still show the presence of SH-imiAuNPs into cells. In particular, our results underline that lower concentration of nanoparticles lead to a new characteristic nano-phenotype in which the cells reached a new steady-state healthy condition. Further, under these conditions SH-SY5Y cell lines are able to rescue cell phenotype making the system suitable for drugs nano-carrier studies.

High-resolution HLA Typing of HapMap NGS Samples From 1000 Genomes Paired Illumina Reads

A. Berces*, E. Major, K. Rigo, S. Juhos;*
Omixon Biocomputing, Budapest, Hungary.

HLA typing from NGS data is gaining importance as the cost of sequencing and sample preparation is falling rapidly. Since the MHC is the most polymorphic region of the human genome with significant segmental duplication this makes the usual NGS analysis, which includes reference-alignment of the NGS reads highly unreliable.
Omixon has developed algorithms to solve HLA typing by directly mapping NGS reads to the IMGT/HLA database to determine the best matching HLA type from whole genome and whole exome data. We are presenting methods to determine HLA types up to four field if possible from public data using paired Illumina reads of the 1000 Genomes (KG) samples. Data from 218 samples of the HapMap set (137 Coriell IDs) with known HLA types (A,B,C) were used for validation. Criteria for typing confidence and accuracy is also presented. Automated filtering and typing of a single sample takes minutes on a commodity PC with our database-driven search algorithm. Results show that although the KG data was not intended to use for high-resolution HLA typing, read sets with proper read-length and quality can provide the correct types above 90% concordance.

Exome sequencing in a family with hypertrophic cardiomyopathy

U. B. Esslinger[1], *C. Perret*[1], *C. Proust*[1], *P. Charron*[2,3], *P. Richard*[4], *M. Komajda*[2,3], *F. Cambien*[1], *E. Villard*[2,3];
[1]*INSERM UMR-S937, Paris, France,* [2]*INSERM UMR-S956, Paris, France,* [3]*Institute of Cardiology, Department of Genetics, AP-HP, Hôpital Pitié-Salpêtrière, Paris, France,* [4]*Cardiogenetics and Myogenetics Unit, Biochemistry Lab, AP-HP, Hôpital Pitié-Salpêtrière, Paris, France.*

Hypertrophic cardiomyopathy (HCM) is a heart muscle disease with a prevalence of 1:500 in the general population. It is an inherited autosomal-dominant disease, characterized by left ventricular hypertrophy. Mutations in one of the known sarcomeric genes are identified in 50-60% of cases. However, in the remaining genetic cause leading to HCM is unknown.
The aim of the study was to identify the genetic cause of HCM in a family with no identified mutation. We sequenced the exome of three affected distant relatives. Exome libraries were prepared using the TruSeq Exome Enrichment Kit (Illumina) and sequenced on Illumina HiSeq2000. On average, 4.5 Gb, corresponding to 65,000,000 reads of sequence (12% duplicate reads) were generated per exome. Alignment was done using BWA v.0.5.9 against the human reference genome GRCh37/hg19. Approximately 70% of the bases were covered at least 20-fold. For variant calling, the GATK pipeline (Broad Institute) was used. For putative mutation identification, we selected only variants shared by the three sequenced individuals and which were novel (absent in dbSNP135) and heterozygous (dominant inheritance). After filtering, we identified 12 variants in 12 different genes. All were genotyped in the whole pedigree (8 affected, 3 unaffected individuals) to check for co-segregation. Two variants in genes not previously reported to be associated with HCM remain candidates. None of them is obviously related to cardiac dysfunction suggesting a new mechanism leading to HCM in this family. Current resequencing of the two genes in 200 unrelated HCM cases should definitely identify the causative gene.

An integrated 'imputation in a box' pipeline for GWAS studies

A. Kanterakis[1], *P. Deelen*[1], *F. van Dijk*[1], *G. Byelas*[1], *M. Dijkstra*[1], *H. Westra*[2], *G. GoNL imputation team*[3], *M. A. Swertz*[1];
[1]*Genomic Coordination Center, Department of Genetics, UMCG, Groningen, Netherlands,* [2]*Department of Genetics, UMCG, Groningen, Netherlands,* [3]*BBMRI-NL, Leiden, Netherlands.*

Genetic imputation has been a major component of many bioinformatics analysis pipelines including GWAS, signal refinement and meta-analysis. Moreover, modern genomic research moves towards identification and discovery of novel markers that contribute to complex diseases. These markers often belong to the lower side of the frequency spectrum. In order to impute these sufficiently we need vast amounts of data both in the study and the reference panel. Hence imputation tend to be very laborious, complex and demand modern High Performance Computing (HPC) environments. Finally very limited work has been done to improve comparability, reproducibility and sharing of existing pipelines.
Here we propose a web application that contains analysis pipelines for almost all imputation software (mach/minimach, impute2 and beagle). The pipelines include protocols for format conversion, sample and chromosome chunking, quality check, accuracy metrics and visualization, all in simple CSV format and as editable elements in a database. It also includes the widely used reference panels of 1000 Genomes (GIANT release), HapMap2 and tools for creation of custom panels. The application supports various flavours of HPCs including local server, (pbs) cluster, grid and cloud infrastructure. The complete computation can be monitored and managed through a web interface or commandline interface.
The proposed approach can be conceptualized as an "imputation in a box" application that belongs to the family of MOLGENIS 'compute' ecosystem that also includes NGS and GWAS pipelines. All has been used successfully for imputation in the BBMRI-NL Genome of the Netherlands. Availability: http://www.molgenis.org/wiki/ComputeStart

Bioinformatic approaches for predicting the development and progression of inflammatory bowel disease

P. Perin[1,2,3], *G. Štiglic*[1,4], *M. Mitrovič*[5,6], *U. Potočnik*[2,3];
[1]*Faculty of Health Science, University of Maribor, Maribor, Slovenia,* [2]*Faculty of Chemistry and Chemical engineering, University of Maribor, Maribor, Slovenia,* [3]*Faculty of Medicine, University of Maribor, Maribor, Slovenia,* [4]*Faculty of Electrical Engineering and Computer Science, University of Maribor, Maribor, Slovenia,* [5]*Faculty Medicine, University of Maribor, Maribor, Slovenia,* [6]*University Medical Centre Groningen and University of Groningen, Groningen, Netherlands.*

So far, genome wide association studies identified 167 loci which contribute the IBD development. Scientists use different statistic methods for evaluating markers, however, no one have reached sufficient specificity and sensitivity to transfer genetic tests in clinical practice. To confirm previously identified SNPs in Slovenians, we genotyped 635 patients and 276 controls. A robust evaluation technique using repeated cross-validation was performed to identify the number of SNPs needed for optimal performance. Recur-

sive Feature Elimination (RFE) using Support Vector Machines (SVM) was used to assess the effectiveness of classification for different SNP combinations. SVM-RFE (evaluated using 20 runs of 10-fold cross-validation) identified a combination of approximately 19 SNPs that can be used for optimal performance in terms of area under the ROC curve (AUC). Using an optimal set of SNPs we were able to achieve AUC of 0.828, sensitivity of 0.515 and specificity of 0.900. By designing risk profiles, based on different number of SNPs, and deriving relative risk from odds ratio we could poorly predict who will develop IBD and who will not, however we reached predictive value up to 70 % to distinguish between two major sub-phenotypes and up to 96 % to predict which Chron's disease patients will require biological therapy. Results of our study hold a great promise and hope for application of SNPs as biomarkers in clinical practice. Predictive models, based on genetic characteristics may be used as diagnostic and prognostic tests of each individual, encourage positive lifestyle and guide clinical decisions in the near future.

Placing landMarks in the Knowledge Space: crowd-sourcing landmark publications for benchmarking text-mined predictions

H. van Haagen, *M. Thompson, E. A. Schultes;*
LUMC, Leiden, Netherlands.

Data production and the volume of biomedical literature are growing faster than human comprehension. Keeping up to date with new discoveries even within one's own field of expertise is no longer possible. To make it easier for researchers to keep up with landmark biomedical discoveries, we introduce a simple, a web-based tool called LandMark, that allows researchers to log their newly discovered gene-disease associations, drug-disease associations, and protein-protein interactions. The interface is a minimal web-form that takes only minutes to complete, but then archives the discovery in a public database making it easy for the research community to monitor and cite new discoveries. Users who file a new discovery at LandMark will receive a brief report about their concepts based on our semantic analysis of MEDLINE abstracts. Furthermore, by registering at the web site, users will receive automatic updates for future discoveries involving the diseases, genes, proteins or drugs of their choice. LandMark allows individual researchers, institutions and publishers to publicly claim landmark discoveries and serves as a transparent service to help resolve conflicts about priority in landmark discovery. LandMark stores information using the novel semantically enabled nanopublication format, allowing automatic interoperability with other semantic data and proper attribution. Over time, LandMark will result in a gold-standard test set of discoveries for benchmarking text-mining and automated knowledge discovery systems. LandMark can be accessed at: http://nanopub.org/landmark/

Macrosatellite repeats (MSRs) belong to the largest repeat structures in the human genome and usually span hundreds of kilobases of genomic DNA. Because of their polymorphic nature, MSRs represent an extreme example of copy number variation. Their structure and function however, is poorly understood. We studied six autosomal and two X chromosomal MSRs among 270 HapMap individuals from Central Europe, Asia and Africa for copy number variation, stability and genetic heterogeneity.
Repeat array size distribution analysis indicates that all MSRs are highly polymorphic. The most genetic variation was observed among Africans and the least among Asians. A mitotic mutation rate of 0.4-2.2% was detected, which exceeds meiotic mutation rates of MSRs and possibly explains the large size variability typically observed for these MSRs. By means of a novel Bayesian approach, statistical support for a distinct multimodal rather than a uniform allele size distribution was detected in all but one MSRs, with evidence for equidistant intervals between the modes.
These results suggest that MSRs are restricted in their configurations and that deviations thereof may cause disease, as is the case for facioscapulohumeral muscular dystrophy, which is most often caused by contraction of the D4Z4 MSR below a threshold of 10 units. This study represents the first comprehensive study of MSRs in different human populations and identifies commonalities and differences in their organization and function of the human genome.

Inter-individual methylation variability in differentially methylated regions between maternal whole blood and first trimester CVS

M. Ioannides[1], *E. Tsaliki*[2], *A. Keravnou*[2], *C. Spyrou*[2], *A. Chrysostomou*[3], *M. Hadjidaniel*[1], *G. Koumbaris*[2], *C. Sismani*[1], *E. Papageorgiou*[2], *P. Patsalis*[1,2];
[1]*The Cyprus Institute of Neurology and Genetics, Agios Domedios, Cyprus,* [2]*NIPD Genetics Ltd, Engomi, Cyprus,* [3]*University of Cyprus, Nicosia, Cyprus.*

DNA methylation is the most studied form of epigenetic regulation, a process by which chromatin composition and transcription factor binding is altered to influence tissue specific gene expression and differentiation. Such tissue specific methylation patterns are investigated as biomarkers for cancer and cell-free fetal DNA using various methodologies. We have utilized methylDNA immunoprecipitation (MeDIP) and real-time quantitative PCR to investigate the inter-individual methylation variability of 22 differentially methylated regions (DMRs) in fifty 1st trimester Chorionic villus samplings (CVS) and fifty female peripheral whole-blood (WB) samples. qPCR results from MeDIP and genomic DNA (Input) assays were used to calculate fold enrichment values for each DMR. For all regions tested MeDIP enrichment was higher in CVS than in WB samples as expected, and mean average enrichment values across all regions tested was 2.9 and 0.2 respectively. The variability of the two datasets was assessed using their mean coefficients of variation, giving a score of 0.4 for CVS and 0.9 for the WB cohorts. Despite the inter-individual variability noted for these regions, mean enrichment values for CVS were significantly different than those for WB in all DMRs tested ($p<0.001$). This observation is reinforced by the absence of overlap in CVS and WB enrichment value distributions for 16 of 22 DMRs. Our data indicate that inter-individual variation in methylation is an important variable to consider during biomarker discovery, yet the difference in methylation status across tissues is large enough to allow for robust tissue specific methylation identification.

Background: Recent studies have revealed general age- and sex-related patterns in metabolite profiles, but have not provided information on serum lipid markers or specifically addressed menopause as a factor affecting metabolite levels. After menopausal transition, women rapidly lose their advantage in cardiovascular disease risk compared to age-matched men, which has partly been explained with pro-atherogenic alterations in serum lipids. We aimed to analyze menopause- and age-related changes in the metabolite profiles of a Finnish population cohort.
Methods: Our study sample consisted of 7060 non-diabetic and non-lipid medicated individuals from FINRISK 1997. The levels of over 100 NMR-measured serum metabolites were individually treated as dependent variables in linear regression analysis with BMI and smoking taken into account. The transcriptomic changes in menopause were analyzed in a similar

linear analysis of 518 individuals of FINRISK 2007.
Results: Our results highlight a systematic, consistent shift towards a more atherogenic lipid profile by age, observed in all Apolipoprotein B-100 parameters. In women, the steepest slope of change strictly overlaps the time of menopausal transition, whereas in men the pattern shows a gradual change beginning already at early middle age. In transcriptomic analysis, the expression levels of several liver lipid-related genes were observed to vary with menopausal status.
Conclusions: Our results provide population-based knowledge on detailed lipid measures which may add valuable insights to CVD-risk assessment especially in women, emphasizing the need to stratify analysis by sex and the importance of menopausal status alongside age in all CVD- and lipid-related risk analysis.

P15.50
Whole genome bisulfite sequencing of acute lymphoblastic leukemia cells

P. Wahlberg[1], *A. Lundmark*[1], *J. Nordlund*[1], *O. Karlberg*[1], *E. Forestier*[2], *G. Lönnerholm*[3,4], *A. Syvänen*[1];
[1]*Molecular Medicin, Department of Medical Sciences, Uppsala University, Uppsala, Sweden,* [2]*Department of Medical Biosciences, University of Umeå, Umeå, Sweden,* [3]*Department of Children's and Women's Health, Uppsala University, Uppsala, Sweden,* [4]*For the Nordic Society of Pediatric Hematology and Oncology (NOPHO), Uppsala, Sweden.*

Acute lymphoblastic leukemia (ALL) is the most common pediatric cancer in the developed countries. DNA methylation of CpG sites plays an important role in cell differentiation and establishment of cell identity by regulation of gene expression. Aberrant patterns of methylation have been associated with a wide variety of diseases including cancer. We and others have previously documented large differences in the patterns of ALL epigenomes compared to control immune cells and common patterns have been identified in different subtypes of ALL. Because of its biological importance, abnormal methylation patterns could play a major roll in the establishment and malignancy of ALL. Hence, methylome analysis can shed light on the molecular mechanisms involved in ALL pathogenesis.
Bisulfite treatment of DNA coupled to high-though sequencing offers a unique possibility to unravel the genome-wide cytosine methylation landscape at base-pair resolution. In addition, bisulfite sequencing can give information relating to haplotype specific methylation. To investigate the distribution of methylation in ALL cancer cells, we have generated whole genome bisulfite sequencing data at high coverage to characterize the methylomes of four samples, belonging to different subtypes of ALL. We will present a detailed view of the methylation patterns in the four ALL patients together with analysis of RNA-Seq data that we will use to infer how methylation affects gene transcription. Furthermore, we will also investigate the occurrence of allele-specific methylation and how it is connected to allele-specific gene regulation.

P15.51
DNA Methylation Patterns Associated with Smoking in Twins Discordant for Smoking Status

M. Lee[1,2], *S. Yang*[1,2], *J. Sung*[1,2];
[1]*Institute of Health and Environment, Seoul National University, Seoul, Korea, Republic of,* [2]*Complex Disease Genome Epidemiology Branch, Graduate School of Public Health, Seoul National University, Seoul, Korea, Republic of.*

It is well established that methylation changes in DNA at cytosine bases, constitutes an important part of epigenetic regulation of human gene expression. Although even monozygotic twin pairs havedifference in their methylation patterns which grow with aging, the specific factors associated with DNA methylation profiles are not well understood. Smoking is one of the most important health determinants associated with numerous diseases. While interactions between smoking habits and genetic susceptibilities are a priority health issues, epigenetic angles regarding such interaction mechanisms are not well understood. In this study we have selected 11 pairs of monozygotic twins in a Korean twin-family cohort study, The Healthy Twin Study. Monozygotic twin pairs consisting of "never smoker" and "current smoker" by self-administered questionnaire were further validated by urine cotinine level. 4 pairs with conflicting information between questionnaire and cotinine levels were excluded. Average age of twins were 43 (7 male and 4 female pairs), and the cumulative smoking of the smokers were 14.7 pack-years. Illumina 450K genome-wide methylation array was used for analysis, and 484,130 probes passed QC (detection p<0.05) to be used in this analysis. Beta value of methylation for each probe, and gene-based methylation score were used for analysis. Wilcoxon Signed Rank Test was used for screening reactive methylation regions. When we checked for the regions responsible for the smoking difference, 250 regions from 232 genes showed significant differences (p<0.001) between smokers and non-smokers. Several regions were suggested for possible candidate regions of "smoking methylation" hot spots.

Introduction: DNA methylation is one of the basic molecular mechanisms involved in the spatial regulation of gene activity and maintaining the genomic integrity. To complement the current knowledge of normal human DNA methylation, we have analyzed DNA methylation in 17 somatic tissues from four individuals using Infinium HumanMethylation 450 BeadChips (Illumina, San Diego, USA) that covers 486,428 CpG sites all over the genome.
Results: The related tissues (e.g. spleen artery, coronary artery and aorta) successfully co-clustered in the hierarchical clustering analysis. Of the 17 tissues studied, only a small number of CpGs (2%; 10 707 CpGs) were fully methylated in all the analysed tissues and these genes have mostly functions in the reproductive system. The always-methylated CpGs were mostly located in gene body regions. On contrary, the mostly unmethylated CpGs (15%; 72 444 CpGs) were located in the proximity of transcription start sites of the genes that are involved in different cellular processes. We have correlated the DNA methylation patterns with available gene expression data and discovered a number of tissue-specific differentially methylated DNA regions. We have used Sanger sequencing to confirm the differential DNA methylation at selected regions of the genome.
Conclusions: Our results show that human somatic tissues have distinct DNA methylation patterns. There are also general similarities in the location of methylated and unmethylated CpG-s, independent of tissues and genes. Our data may also help in understanding the role of gene-body methylation and methylation of CpG island shores.

Genome-wide DNA methylation profiling in myocardial infarction

A. Russo[1,2], *S. Guarrera*[1], *G. Fiorito*[1,2], *C. Di Gaetano*[1,2], *F. Ricceri*[1,2], *F. Rosa*[1], *A. Allione*[1], *F. Modica*[1], *L. Iacoviello*[3], *M. Giurdanella*[4], *R. Tumino*[4], *S. Grioni*[5], *V. Krogh*[5], *A. Mattiello*[6], *S. Panico*[6], *P. Vineis*[1,7], *C. Sacerdote*[1,8], *G. Matullo*[1,2];
[1]*Human Genetics Foundation, Torino, Italy,* [2]*University of Turin, Torino, Italy,* [3]*Catholic University, Campobasso, Italy,* [4]*''Civile-M.P. Arezzo'' Hospital, Ragusa, Italy,* [5]*Fondazione IRCSS Istituto Nazionale dei Tumori, Milano, Italy,* [6]*Federico II University, Napoli, Italy,* [7]*Imperial College, London, United Kingdom,* [8]*CPO-Piemonte, Torino, Italy.*

Methylation of CpG islands is an important epigenetic regulation mechanism in organ development and differentiation, aging and several diseases. To investigate the role of differential methylation on myocardial infarction (MI) risk, we examined the methylation levels of more than 450K CpG sites in 206 cases and 206 matched controls belonging to the Italian section of the EPIC cohort. EPIC healthy volunteers were recruited between 1994-98 and followed up for MI and other diseases. For the CpG methylation level assessment on blood DNA we used the Illumina HumanMethylation450 BeadChip. Data were analyzed according to standard procedures (MethyLumi, Bioconductor). To account for sex specific methylation and risk profiles, logistic regression analyses were conducted separately for males and females. All analyses were corrected for matching variables (age, season, center of recruitment) and cardiovascular risk factors when significantly different between cases and controls (smoke, BMI, waist/hip ratio). No significant association of single CpG methylation change has been found at the genome–wide significant threshold (p<10-7) with MI risk. However, in a

genome-wide "regional" association analysis, we found multiple significant signals (p<10-7) of differential methylation between cases and controls in 2 genomic regions for females (Chr5, Chr1) and in 4 regions for males with borderline significance (Chr6, Chr7, Chr11, Chr17). QTLs associated to MI, blood pressure regulation and metabolic disorders have been described in these regions. These results suggest that different methylation profiles between cases and controls can be involved in the regulation of these regions and in the modulation of MI risk.

Contribution of methylomic and proteomic approaches to deciphering the pathophysiology of nasal polyposis, a model of chronic inflammatory diseases

L. JEANSON[1], *B. COPIN*[2], *J. F. PAPON*[3,4], *E. ESCUDIER*[1,2], *C. GUERRERA*[5,6], *P. DUQUESNOY*[1], *E. KOTT*[1], *F. DASTOT-LE MOAL*[2], *M. LEGENDRE*[1,2], *A. COSTE*[3,4], *A. EDELMAN*[5,6], *S. AMSELEM*[1,2];

[1]*UMR_S933 Inserm/UPMC, Paris, France,* [2]*Service de Génétique et Embryologie Médicales, Hôpital Trousseau, Paris, France,* [3]*UMR_S955 Inserm/UPEC, Paris, France,* [4]*Service d'Oto-Rhino-Laryngologie et de Chirurgie Cervico-Faciale, Hôpitaux Henri Mondor (AP-HP) et Intercommunal, Paris, France,* [5]*UMR_S845 Inserm/Paris 5, Paris, France,* [6]*Plateau Protéome Necker IFR94/Paris 5, Paris, France.*

Nasal polyposis (NP), a chronic inflammatory disease affecting the upper airways, represents an accessible model to investigate the mechanisms underlying chronic inflammation. To test a possible implication of DNA methylation in NP, we combined proteomic (iTRAQ/nano-LC-MALDI-TOF-TOF) and methylomic (Illumina-450K-methylation array) approaches in human nasal epithelial cells from patients with NP (n=3) compared to control (n=3). Considering methylomic and proteomic data for which we found a +/- 30% difference between NP patients and controls, we identified 640 genes with differential CpG methylations; for 20 of them, we quantified the corresponding protein by proteomic analysis. Twelve of these genes displayed a methylation status that correlated perfectly with the expression level of the corresponding proteins: (i) nine genes encoding proteins overexpressed in NP contained one or several undermethylated CpG (DUOX1, POSTN, PRDX3, TXNDC17, HSPG2, LASP1, TAP1, LGALS7 and HLA-DRB1) and (ii) three genes encoding underexpressed proteins contained one or several overmethylated CpG (RASA3, HLA-DQA1 and HLA-C). Interestingly, it turned out that these 12 genes were known to play a role in inflammation, oxidative stress or tissue remodeling, four of which having already been implicated in NP (DUOX1, POSTN, HLA-DRB1 and HLA-DQA1). Moreover, 39 additional genes with differential methylation status would also play a role in chronic inflammation. These first results, which are currently validated by the use of demethylating agents, underline the interest of this promising strategy based on the combination of global methods for studying the possible role of DNA methylation in chronic inflammatory diseases.

The development of bioinformatics pipelines for the analysis of genetic variant data in a cloud environment.

M. J. Cornell[1], *R. Haines*[2], *M. Donepudi*[3], *H. Hulme*[2], *S. Sufi*[2], *A. Brass*[2], *A. Devereau*[1], *A. Devereau*[1], *A. Ureta-Vidal*[3], *C. Goble*[2];

[1]*National Genetics Reference Laboratory, Manchester, Manchester, United Kingdom,* [2]*School of Computer Science, University of Manchester, Manchester, United Kingdom,* [3]*Eagle Genomics Ltd., Cambridge, United Kingdom.*

Next generation sequencing technologies have been rapidly assimilated into genetic diagnostics, enabling the development of a new range of diagnostic tests encompassing large numbers of genes. Inevitably, such tests identify many more variants than "traditional" testing. Only one of these may be disease causing but all must be evaluated to identify this mutation, greatly increasing the workload on the clinical scientists.

To address this problem, we are developing reusable bioinformatics workflows using the Taverna Workflow Management System (http://www.taverna.org.uk/). These workflows group variants according to their positions within genes (i.e. exonic, intronic and near intron/exon boundaries), compare variants to data from 1000 Genomes and NHLBI exome sequencing projects and web services such as Mutalyzer, Pubmed, Ensembl and WAVe are used to evaluate variant pathogenicity and provide a report for clinical scientists.

Developing workflows using Taverna enables sharing with other bioinformaticians via myExperiment (http://www.myexperiment.org/). As well allowing workflows to be reused, this will improve the quality of shared data by allowing the analysis methods to be shared along with variants.

Deploying the workflow in a cloud infrastructure (Amazon Web Services) ensures the solution can scale up to the increasing workload. Software consumes IT resources on-demand and executes the workflow concurrently for any number of tests with a minimal overhead. The development of a cloud infrastructure for NGS will enable the sharing of data, bioinformatics and computing resources between researchers and should promote the standardisation of analysis across the molecular diagnostics community.

Statistics and observations on 200 exomes: the de Duve Institute (UCL) NGS platform

R. Helaers, *M. Amyere, M. Vikkula;*

De Duve Institute (Université catholique de Louvain), Brussels, Belgium.

The field of human genetics is being revolutionized by exome and genome sequencing. A massive amount of data is being produced, always faster. For example, targeted exome sequencing can be completed in a few days using NGS, allowing new variant discovery in a few weeks. The *Université catholique de Louvain* acquired such a next generation sequencing platform, installed in the Laboratory of Human Molecular Genetics at de Duve Institute. The platform is composed of a Solid 5500XL (Life technologies), a Personal Gene Machine (Ion Torrent, Life technologies) and a cluster for bioinformatics processing. The platform offers services such as exome sequencing and RNA Seq, accessible to the Belgian research community.

Here we present statistics and observations on the 200 exomes that have been analysed since September 2011 (150 exomes generated by our Solid 5500XL and 50 exomes generated by an Illumina HiSeq 2000). We present statistics on runs (effects of run parameters on coverage, proportion of duplicates, ...), variants (number of variants called, number of stops gained according to the calling software) and gene coverage (number and efficiency depending on the enrichment kit). Observations include comparison between pair-end and ECC runs, description of the reasons why we lose coverage compared to the expectations, effects of running the same experiment multiple times on coverage, proportion of variants that can be eliminated using paired blood when searching for somatic variants in tissues, and how some false positive variants (due to systematic errors or homologous regions) can be automatically detected.

R. Helaers: None. **M. Amyere:** None. **M. Vikkula:** None.

VariantDB : A flexible annotation and filtering portal for NGS data

G. Vandeweyer[1], *L. Van Laer*[1], *F. Kooy*[1], *T. Van den Bulcke*[2];

[1]*Universiteit Antwerpen, Edegem, Belgium,* [2]*Universitair Ziekenhuis Antwerpen, Edegem, Belgium.*

Background:

Causes of many hereditary disorders can be identified through detailed inspection of the patients' genome using Next Generation Sequencing technologies. However, interpretation of the vast amount of data, typically over 20.000 variants per patient, became a bottleneck for routine implementation. To help streamlining NGS data analysis through various trimming, mapping, annotation and filtering tools, centralised web-based interfaces, such as the Galaxy platform, have been developed. Although Galaxy provides many bioinformatic tools, it lacks flexibility in downstream annotation and filtering of the resulting variants.

Methods & Results:

We built VariantDB, a versatile annotation and filtering database implemented in MySQL, with a PHP/CGI frontend. Data added from Galaxy or FTP-upload are private, but can be shared with collaborators. Automatic annotation by ANNOVAR and snpEff, includes allele frequencies (1000g/ESP6500/dbSNPv135), functional impact (RefSeq/Ensembl/UCSC) and pathogenicity predictions (SIFT/MutationTaster/PhyloP/Polyphen2/gerp++/LRT). Custom annotation sources can be added to the xml-based configuration. Family relations allow filtering for de novo or segregating variants. Results are

presented in a tabular overview, with selected annotations and hyperlinks to IGV, or exported as text files.
Conclusions:
VariantDB allows on-demand variant filtering based on the implemented annotations. The intuitive web-interface is a very powerful tool for the interpretation of NGS data.

Store, align and explore your genome outside the Cloud, at home, on your PC

B. Wolf[1], *P. Kuonen*[1], *T. Dandekar*[2], *J. T. den Dunnen*[3], *D. Atlan*[4];
[1]*University of applied sciences and arts western switzerland, Fribourg, Switzerland,* [2]*Julius Maximilians Universität Würzburg, Würzburg, Germany,* [3]*Leiden University Medical Center, Leiden, Netherlands,* [4]*Phenosystems SA, Lillois Witterzée, Belgium.*

Cost of whole genome sequencing is rapidly approaching 1000 euro, putting it within reach of amateur geneticists, scientifically curious consumers as well as teachers developing hands-on *omics training courses. Current direct-to-consumer offers do not give consumers the possibility to analyse the actual data, try various alignment algorithms and their parameters nor with the thresholds for calling variants. The raw sequence data remain at the provider and the algorithms used are a black box.
Consumers like amateur geneticists and training course developers prefer to have control of the analysis pipeline for didactic or other purposes and thus need easy to use, flexible software that runs on standard PC's. We present GensearchNGS which we developed to analyse a whole genome on standard PC/Mac, from read alignment to variant detection and annotation. It includes an easy to use graphical user interface, integrating various public and proprietary alignment algorithms through plugins. Open file format standards offer the freedom to exchange data, with for example LOVDs gene variant database to view/query the database with its own associated functionality.
Using only 2 machines we aligned a ~30x coverage whole genome dataset in 40 hours, detected SNPs and short indels, measured coverage and annotated variants with information from Ensembl. To further annotate variants, we connect to the Variant Database archive in the Netherlands, which allows collecting frequency information on the detected SNPs.
This system will allow private exploration and analysis of whole genome raw read data, requiring nothing more than one or two desktops or laptops.

Next-generation sequencing (NGS) based methods, such as exome analysis, are currently being introduced as a tool for mutation detection into routine diagnostics. This increases the need for platform-independent methods of quality control. To date, quality scores have been used on a base- or genotype-level to indicate the reliability of single base or variant calls. However, the great variety of NGS platforms and analysis pipelines hinders the direct comparison of genotype-specific quality scores between platforms or for entire data sets and currently no criteria exist for assessing the overall quality of an exome. We present a genotype-weighted metric to compare all exome variants identified in a single sample together to an appropriate high-quality reference data set, with which we estimate the exome-wide genotyping accuracy based simply on the reported variants and without any further knowledge about the data generation. Our method represents a new way to evaluate the quality of entire whole-exome sequencing data in addition to current recommendations for sequencing depth and genotype likelihoods. The distance value of our metric corresponds to a quality parameter for an entire exome and allows comparing the quality of multiple exome datasets from the same or different NGS platforms.

P15.61
Single Base Resolution DNA Methylomes from Circulating Cell Free DNA as a Basis for Comparative Analyses

T. J. Jensen, *S. Kim, Z. Zhu, C. Chin, T. Lu, C. Deciu, D. van den Boom, M. Ehrich;*
Sequenom Center for Molecular Medicine, San Diego, CA, United States.

Circulating cell-free (ccf) DNA is present in the plasma of healthy individuals; however, distinct physiological and disease conditions, including pregnancy and cancer, contribute additional nucleic acids into the ccf DNA pool. Differential DNA methylation is a method of differentiating the DNA added from the inherent ccf DNA. Whole genome bisulfite sequencing (WGBS) was performed on a set of unmatched samples including ccf DNA from 9 non-pregnant (NP) female donors, genomic DNA from 7 buffy coat and 5 placenta samples, and ccf DNA from 7 pregnant females. We first created a methylome map of ccf DNA from non-pregnant donors at single base resolution. We found CpG cytosines within longer fragments were more likely to be methylated, linking DNA methylation and fragment size in ccf DNA. Next, we performed a series of pairwise comparative analyses to identify differentially methylated regions (DMRs). Comparison of the methylomes of placenta and NP ccf DNA enabled the detection of greater than 50000 DMRs, the majority resulting from of placenta hypomethylation. Further investigation revealed the presence of domains exhibiting consistent hypomethylation in placenta samples relative to NP ccf DNA spanning megabases. DMRs identified when comparing placenta to NP ccf DNA were recapitulated when comparing methylation patterns in pregnant ccf DNA to NP ccf DNA, confirming the ability to detect differential methylation in ccf DNA mixtures. Collectively, these data advance the biological understanding of ccf DNA and detail the ccf DNA methylome at single base resolution, serving as the foundation for future testing based upon ccf DNA.

Omics Connect Toolbox: A management, validation and visualisation toolkit for complex omics data

R. K. Hastings[1], *J. Van der Velde*[2], ***A. J. Brookes***[1], *M. Swertz*[2];
[1]*Department of Genetics, University of Leicester, Leicester, United Kingdom,* [2]*University Medical Center Groningen, Groningen, Netherlands.*

Data generated from the panoply of modern omics technologies are large and complex, making it difficult for researchers to integrate and explore such information. Here we present the 'omics connect toolbox': a set of user-friendly software tools that can be deployed locally in research and biobank environments to assist with omics data validation, management, viewing and sharing.
The 'Automated Bio-Curator' (ABC) tool is designed to help researchers validate and curate their data. This software is built upon a pre-existing data validation engine (cutplace), enhanced to process biological datasets against a set of user-defined rules. The output of ABC highlights data rows and fields that are defective in some way, and suggests and automates corrections.
For core Omics Connect databasing, we have implemented the Observ-OMX data model via the MOLGENIS platform. This allows highly flexible but powerful multi-omics data management, browsing and filtering including mo-

dules for xQTLs, GWAS, NGS, big data pipelines, and sharing. A straightforward tabular data format allows researchers to exchange data without the need for technical know-how on top of ABC.
Most critically, Omics Connect enables direct co-visualisation of various types and scales of omics data via a customised dalliance genome browser. Users can add, delete, edit, or disable tracks to suit their needs. The system employs DAS to serve data sourced from diverse local or online sources to view in the context of other private or publically available data using the Omics Connect browser or other DAS enabled browsers, to facilitate complex data integration and interpretation.

Phenotype terminologies in use for genotype-phenotype databases: need for a standardisation

L. Martin-Chanas, *A. Rath, J. Chahine, S. Aymé;*
ORPHANET - INSERM US14, Paris, France.

The community requires stable standardised terminologies in order to achieve interoperability between databases intended for clinical research that include phenotype descriptions. This is crucial in interpreting genomic rearrangements as well as future high-throughput sequence data. Relevant terminologies used by different communities to describe phenomes were cross–referenced: PhenoDB (2846 terms), London Dysmorphology Database (LDDB; 1318 terms), Orphanet (1243 terms), Human Phenotype Ontology (9895 terms, 22/08/2102), Elements of Morphology (AJMG; 423 terms), ICD10 (1230 terms), as well as medical terminologies in use: UMLS (7,957,179 distinct concept terms), SNOMED CT (>311,000 concepts), MeSH (26,853 concepts) and MedDRA (69,389 concepts). We established a strategy to compare them in order to find commonalities and differences, using ONAGUI as a tool to detect exact matches. The non-exact matches were verified manually by an expert. This exercise showed that, given the multitude of needs and applications in the field of rare diseases, it is not currently realistic or even desirable to have one terminology for all applications. Prominent terminologies have different focuses and user bases. We propose: either to build a consensual terminology using the concepts shared by existing terminologies to describe phenotypes, or to publish the cross-referencing between the existing terminologies, as it has been done for disease nomenclatures. This would ease the interoperability of databases without disturbing the habits of different user groups. The best option would be to implement both.

P15.65
KD4v: Comprehensible Knowledge Discovery System for Missense Variant

H. Nguyen, *T. Luu, V. Walter, J. Muller, J. Thompson, O. Poch;*
IGBMC, Illkirch, France.

Understanding the effects of genetic variation on the phenotype of an individual is a major goal of biomedical research, especially for the development of diagnostics and effective therapeutic solutions. The KD4v (Comprehensible Knowledge Discovery System For Missense Variant) server allows to characterize and predict the phenotypic effects (deleterious/neutral) of missense variants. In this work, we describe the use of a recent knowledge discovery from database (KDD) approach using Inductive Logic Programming (ILP) to automatically extract knowledge about human diseases. We extracted background knowledge from MSV3d, a database of all human missense variants mapped to 3D protein structure. We identified 9000 mutations with known three-dimensional structure that were known to be involved in human disease. After using ILP for learning, we obtained a set of rules that classify a mutation as 'deleterious' or 'neutral' and that can be interpreted by both computer and humans. We then performed a clustering analysis to reduce the number of rules, by combining rules that covered similar mutation sets. The results of this analysis help to improve our understanding of the relationships between structural, functional or evolutionary features and deleterious mutations. Inferred rules can also be applied to predict the impact of any single amino acid replacement on the function of a protein. The web server is available at http://decrypthon.igbmc.fr/kd4v.

P15.66
Cis- and *trans*- Gene Regulation Patterns over Obesity-associated Proteins

D. Kim[1], *S. Yang*[1], *J. Kim*[1], *J. N. Choi*[2], *N. Y. Hong*[2], *K. P. Kim*[2], *J. Sung*[1,3];
[1]*Complex Disease and Genome Epidemiology Branch, Department of Epidemiology, School of Public Health, Seoul National University, Seoul, Korea, Republic of,*
[2]*Department of Molecular Biotechnology, Konkuk University, Seoul, Korea, Republic of,*
[3]*Institute of Environment and Health, School of Public Health, Seoul National University, Seoul, Korea, Republic of.*

Understanding how genes regulate complex traits is still elusive. The architecture of genetic control over gene-expression levels was dissected by e-QTL previously. We attempted to extend the e-QTL study to proteomics level, by selecting proteins related to obesity. At 1st stage, 5 obesity-discordant monozygotic twin pairs (MZ) were selected, and sera of lean and obese cotwins were pooled; after removing 6 major proteins, 128 proteins were identified showing significant differences in both groups by liquid chromatography (LC) tandem mass spectrometry (MS/MS) . At 2nd stage, 261 individuals from 35 families (28 MZ) with varying degree of obesity were screened for 128 proteins using a quantitative LC- multiple reaction monitoring (MRM) mass spectrometry (MS) as a tool for the quantification of proteins. Finally, GWA analysis on 38 proteins identifiable in individual MRM proteomics assay, were conducted (Affymetrix Genechip v6). Heritability (h2) estimates of most proteins ranged between 0.37 and 0.59, showing moderate to high level of genetic control. GWA analysis (GenABEL) revealed that most proteins are under multiple genetic control (p<10E-6), while some proteins do show evidence of *cis*-regulation (p<10E-3, *Hemoglobin subunit epsilon; C4b-binding protein; Apoprotein A-I*). *Ecto-NOX disulfide-thiol exchanger 2* (*X* chromosome) showed the strongest association with ectopic genes, *RSU1* on chromosome 10 (P<10E-26). Our findings suggest that network from genes to proteins are already extremely complex indicated by ubiquitous multiple trans-regulations; and that multi-omics analysis would be able to make up "missing heritability" considering evidence of stronger genetic controls over protein levels than on obesity phenotypes.

Epigenetic analysis in the BMPR2 gene promoter region in patients with pulmonary arterial hypertension

G. Pousada[1], *L. De Chiara*[1], *A. Baloira*[2], *C. Vilariño*[3], *D. Valverde*[1];
[1]*Dpto. De Bioquímica, Genética e Inmunología, Facultad de Biología, Universidad de Vigo, Vigo, Spain,* [2]*Servicio de Neumología del Complejo Hospitalario de Pontevedra, Pontevedra, Spain,* [3]*Servicio de Neumología del Complejo Hospitalario de Vigo, Vigo, Spain.*

Pulmonary arterial hypertension (PAH; OMIM 178600) is a rare and progressive vascular disorder characterized by increased pulmonary vascular resistance, vascular remodelling and right heart failure. The gene mainly related to PAH is the bone morphogenetic protein receptor type II (*BMPR2*). DNA methylation is an epigenetic mechanism characterized by the presence of CpG islands mainly on the promoter regions. These modifications are associated with transcriptional silencing of associated genes. Given the complex and multifactorial nature of PAH, it seems likely that epigenetic events could influence the establishment or progression of PAH.
Forty one patients with familial, idiopathic and secondary PAH and 21 controls were included in this study. Genomic DNA, obtained from peripheral blood, was modified with sodium bisulfite. We searched for CpG islands in 5000 bp upstream the 3´UTR region of *BMPR2* using the Methyl Primer Express v1.0 software.
We found one CpG island of 750 bp containing 57 CpG sites, proximate to the 3´UTR region. To analyse the methylation status within this region we designed 3 pairs of methylation- and unmethylation-specific primers. No differences in the methylation status were observed between patients and controls.
In conclusion, methylation does not seem to be related to PAH, at least in the region of *BMPR2* studied.

P15.68
Determining the quality and complexity of next-generation sequencing data

S. Y. Anvar[1,2], *L. Khachatryan*[1], *M. van Galen*[2], *I. Pulyakhina*[1], *M. Vermaat*[1,3], *K. Kraaijeveld*[2,4], *P. A. C. ,t Hoen*[1], *J. T. den Dunnen*[1,2], *P. de Knijff*[3], *J. F. J. Laros*[1,2];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Leiden Genome Technology*

Center, Leiden, Netherlands, [3]Netherlands Bioinformatics Center, Nijmegen, Netherlands, [4]University of Applied Sciences, Leiden, Netherlands.

Current methodologies for determining the quality and complexity of next-generation sequencing (NGS) data are rather limited as they heavily rely on reference-based quality measures and screening for a set of potential artefacts. To address these limitations, we have developed a new methodology (kLib) that is independent of a reference sequence in determining the complexity and quality of NGS data and allows for pairwise comparison across a series of samples. We have applied kLib on four cohorts of NGS data that consist of 59 targeted resequencing, 43 whole-exomes, 49 full-genomes, and 465 RNA-Seq. In each cohort, kLib could precisely detect and separate various technical variations that were introduced during sample prep or sequencing such as high duplication rate, high number of off-target reads, low capture performance, differing capture protocols, bimodal insert-size distribution, high amount of library chimaeras, and sample mix-up. Notably, some of the aforementioned artefacts could only be characterised after vigorous quality assessments and would have otherwise been missed. These often hidden artefacts undermine the potential application of NGS in clinical diagnostics as they may result in obscured downstream analysis. In addition, we show that kLib allows for estimating the complexity of NGS data, a vital property of NGS in diverse studies ranging from de novo assembly applications to detection of a shift in bacterial abundance in a series of metagenomes. The various techniques that constitute this new paradigm in robust evaluation of the quality and complexity of NGS data allows for a transition from basic research to clinical diagnosis.

ADAR Regulates RNA Editing, Splicing and Transcript Stability As Revealed by Genomic and Molecular Analyses

***I. X. Wang**, S. Liu, E. So, V. G. Cheung;*
University of Pennsylvania, philadelphia, PA, United States.

ADAR adenosine deaminases mediate A-to-G RNA editing. We carried out DNA and RNA deep sequencing, RNA interference, RNA-immunoprecipitation and mass spectrometry in human B-cells to examine the functions of ADAR proteins. We uncovered over 50,000 previously unknown A-to-G editing sites. These editing sites reside in mRNA and long non-coding RNAs (lncRNAs). ADAR gene knockdown abolished editing at most sites, thus validated A-to-G editing at these sites. In addition, ADAR knockdown affects expression levels of several thousand genes, in an editing-independent manner, suggesting ADAR plays roles in processes other than editing. We subsequently identified more than 100 proteins in the ADAR protein complex, including splicing factors, heterogeneous ribonucleoproteins and other proteins involved in RNA processing. We showed that ADAR and RNA-binding proteins, such as HuR, bind to common transcripts and co-regulate RNA stability. Moreover, ADAR plays a role in modulating alternative splicing. Our findings underscore the complexity of RNA editing and processing and interactions between different steps.
In this presentation, I will describe results from genomic, transcriptomic and proteomic analyses which allowed us to identify tens of thousands of unknown A-to-G editing sites and to characterize ADAR's roles in gene regulation. The presentation will focus on findings that underscore the complexity of RNA processing and suggest that there are co- or post-transcriptional mechanisms yet to be determined.

Transcriptome sequence genomic analysis in three tissues of a twin cohort reveals complex causes of allelic expression

***A. Buil**[1,2,3], A. Brown[4], A. Viñuela[5], M. Davies[5], K. Small[5], M. Gallardo[6], D. Glass[5], M. Blasco[6], R. Durbin[4], T. D. Spector[5], E. T. Dermitzakis[1,2,3];*
[1]University of Geneva, Geneva, Switzerland, [2]Institute of Genetics and Genomics in Geneva, Geneva, Switzerland, [3]Swiss Institute of Bioinformatics, Geneva, Switzerland, [4]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [5]King's College London, London, United Kingdom, [6]Spanish National Cancer Centre, Madrid, Spain.

In this study we used RNA-seq data in three tissues: fat, LCLs and skin in a sample of ~400 female twin pairs (2330 RNA-seq samples in total) to address the question of tissue specificity of genetic regulation and to dissect the underlying causes of allelic expression. We found 9861 genes with at least one significant cis eQTLs for fat, 10015 for LCL and 9243 for skin (FDR=10%). We also found that between 75% and 80% of the eQTLs are shared among two tissues and that 50% are shared by the three tissues. RNA-seq data allows the quantification of allele specific expression (ASE). At a 10% FDR we observed that 9.5%, 9.3% and 9.1% of the heterozygous sites had a significant ASE effect in fat, LCL and skin. The observed ASE can be caused by genetic or epigenetic /environmental factors. To quantify how much variation in allelic expression is due to genetic factors we estimated the heritability of ASE ratios. We found a heritability of 42% for fat, 45% for LCL and 66% for skin, suggesting that epigenetic / environmental factors have a substantial effect on allelic expression. We also observed that cis genetic effects explain just a fraction (68% in fat, 37% in lcl, and 44% in skin) of the total genetic effects, suggesting potential epistatic effects between trans and cis genetic variants. These results demonstrate a complex genetic architecture for allelic expression. We are exploring further to find putative GxG and GxE interactions affecting allelic expression.

Shift and night work may shape the DNA methylome in human

***J. Gutwein**[1], C. Dalgård[2], K. Kyvik[3], D. Olbrich[4], M. Dittmar[4], R. Siebert[1], O. Ammerpohl[1];*
[1]Institute of Human Genetics, Christian-Albrechts-University Kiel, Kiel, Germany, [2]Institute of Public Health, University of Southern Denmark, Odense, Denmark, [3]Institute of Regional Health Research, University of Southern Denmark, Odense, Denmark, [4]Department of Human Biology, Zoological Institute, Christian-Albrechts-University Kiel, Kiel, Germany.

Due to modern life style people feel increasingly compelled to work at times which are incompatible with their biological day-night rhythms. Numerous studies reported a link between night and shift work and diseases like sleep problems, the metabolic syndrome and an increased risk for several cancer entities.
Since DNA methylation allows adaption of genetic information according to environmental conditions, we wondered whether night and shift work might be reflected by specific changes in the DNA methylome of those workers.
To avoid genetic contributions we applied DNA methylation analysis using the Infinium HumanMethylation450k BeadChip preferentially on twin pairs discordant for working times, one twin working at shift or night and the other twin working regularly at daytime. The participating twins were selected from the GEMINAKAR twin follow-up study recruited from the Danish Twin Registry. For the majority of the subjects DNA was available from a previous study conducted during 1997-2000 allowing analysis of long-term effects of different working times on the DNA methylome.
By now, we have hybridized the DNA of 32 monozygotic and 39 dizygotic twins to the microarray, allowing the parallel interrogation of more than 450,000 CpG loci.
An interims analysis based on 17 samples revealed 407 CpG loci corresponding to 262 genes differentially methylated between individuals working at day time or with night shift ($p<0.001$).
Hence, shift work may shape the DNA methylome.
As part of the SAME project this study is co-financed by INTERREG 4 A programme Syddanmark-Schleswig-K.E.R.N. by EU funds from the European Regional Development Fund.

Comparison and validation of loss of function variants called by different GATK methods

***F. Lescai**[1], E. Marasco[2], C. Bacchelli[1], V. Mantovani[2], P. Beales[1];*
[1]GOSgene - Institute of Child Health, University College London, London, United Kingdom, [2]CRBA Centro Ricerca Biomedica Applicata, Azienda Ospedaliero-Universitaria Policlinico S. Orsola – Malpighi, Bologna, Italy.

The choice of an appropriate variant calling pipeline for exome sequencing data is becoming increasingly more important in translational medicine projects and clinical contexts. Within GOSgene, which facilitates genetic analysis as part of a joint effort of the University College London and the Great Ormond Street Hospital, we performed a comparison between the variant calls generated by the classic GATK caller UnifiedGenotyper and the new variant discovery tool HaplotypeCaller. We performed an experimental validation of the loss-of-function (LoF) variants called by the two methods using Sequenom technology. UnifiedGenotyper showed a total validation rate of 97.6% for LoF SNPs and 92.0% for insertions or deletions (INDELs) while HaplotypeCaller was 91.7% for SNPs and 55.9% for INDELs. We conclude

that in our working environment, UnifiedGenotyper remains the caller of choice, being an accurate method, with a high validation rate of error-prone calls like loss-of-function variants.

Table 1: Validation of variants by caller comparison

	Outcome	Inter-section	Unified Genotyper only	Haplotype Caller only
SNPs	Validated	97 (98.0%)	27 (96.4%)	2 (22.2%)
	Not validated	2 (2.0%)	1 (3.6%)	7 (77.8%)
	Fail	3	0	1
	Total number of assays	102	28	10
	Total number of working assays	99	28	9
INDELs	Validated	35 (92.1%)	11 (91.7%)	3 (10.0%)
	Not validated	3 (7.9%)	1 (8.3%)	27 (90.0%)
	Fail	4	0	12
	Total number of assays	42	12	42
	Total number of working assays	38	12	30

The validation rates of LoF SNPs and INDEL calls from both methods (Intersection) or uniquely called by UnifiedGenotyper or HaplotypeCaller. The failure rate of validation assays (fail) on the genotyping chip is given.

Whole genome TRIO analysis using CLC Genomics Workbench

S. Guedes, *A. Joecker, U. Appelt, N. Thomson, S. Mønsted, J. Grydholt, B. Knudsen, M. Bundgaard, J. Buur Sinding, H. Handberg, A. K. Hein, M. Nygaard Ravn, A. Joecker, M. Værum, R. Forsberg;*
CLC bio, Aarhus, Denmark.

The increasing use of next generation sequencing in medical genomics settings uncovers the fact that bioinformatics analysis is still a bottleneck. This especially holds true if whole genome sequencing is applied. CLC bio's Genomics Workbench provides efficient and accurate algorithms capable of analyzing such large data sets. In the presented work we describe how the "Trio Analysis" tool of CLC bio's Genomics Workbench can be used to analyze and compare an Illumina Platinum CEO trio data set composed of mother, father and son.

Our strategy for re-sequencing approaches is based on CLC bio's optimized resources and time efficient mapper, its algorithms to uncover variants and annotate them with data from public resources and its further downstream tools to compare and filter variants. The analysis results can be visualized by built-in solutions.

Here, we present the full workflow performed in CLC bio's Genomics Workbench to identify *de novo* variants in a trio dataset. This strategy can be applied to other families to provide insights into inheritance mechanisms, such as the inheritance of recessive variants, and detect possible health consequences.

Characterising the genetic architecture of the miRNA response to Mycobacterium tuberculosis

K. J. Siddle[1], *L. Tailleux*[2], *Y. Nédélec*[3], *E. Patin*[1], *L. Barreiro*[3], *L. Quintana-Murci*[1];
[1]*Institut Pasteur, Unit of Human Evolutionary Genetics, Paris, France,* [2]*Institut Pasteur, Unit of Mycobacterial Genetics, Paris, France,* [3]*CHU Sainte-Justine, University of Montreal, Montreal, QC, Canada.*

Tuberculosis is a major public health problem, with 1.7 million deaths annually worldwide. Despite evidence to suggest there is a heritable component to susceptibility to Tuberculosis, little is known about the underlying genetic and epigenetic factors. In recent years, expression quantitative trait loci (eQTL) studies have provided abundant information about both the genetic basis of variation in gene expression and inter-individual regulatory variation, offering new insight into the aetiology of susceptibility to complex disease. However, despite their critical role in the immune response, the characterisation of the genetic architecture of miRNAs remains comparatively unexplored. Here we aimed to understand variation in miRNA expression in the presence/absence of Mycobacterium tuberculosis (MTB), the aetiological agent of TB, and to dissect the genetic basis of such variation. To this end, we profiled miRNA expression, by microarray, in dendritic cells before and after MTB infection for 18 hours in 65 individuals. We observed a significant change in expression for 40% of miRNAs upon infection, as well as a marked shift in the distribution of correlations between miRNA and, previously characterised, mRNA profiles, implying extensive remodelling of regulatory networks. To understand the genetic architecture of this response we mapped miR-eQTLs before and after infection, by combining our expression data with whole-genome genotyping of the same individuals. We found over 3% of miRNAs to be associated with a cis-eQTL, including 2 infection-dependent associations. One of these miRNAs, miR-326, was also significantly dysregulated upon infection, providing a novel candidate for influencing variability in the response to MTB.

PON-P, accurate predictor for variation pathogenicity

M. Vihinen[1], *A. Niroula*[1], *S. Urolagin*[1], *J. Väliaho*[2];
[1]*Lund University, Lund, Sweden,* [2]*University of Tampere, Tampere, Finland.*

High throughput sequencing data generation demands the development of methods for interpreting the effects of genomic variants. Numerous computational methods have been developed to assess the impact of variations because experimental methods are unable to cope with both the speed and volume of data generation. We have developed Pathogenic-Or-Not-Pipeline (PON-P), which provides higly accurate predictions for the effects of missense variants. The accuracy is 0.90 when the prediction reliability is 0.95. The method is based on machine learning and utilizes random forest classfier. It has been trained and tested with a dataset of some 32 000 experimentally verified disease-causing or benign cases available in VariBench, database for variation benchmarks. The original version (Olatubosun et al., 2012) has been further developed. A related tool is available for mismatch repair (MMR) repair gene variations (Ali et al., 2012). PON-MMR has accuracy of 0.87. When applied to 758 unclassified variants in InSiGHT database, it could classify 248 cases (40.3 %) as pathogenic or benign. The tools are available at http://bioinf.uta.fi/PON-P/ and http://bioinf.uta.fi/PON-MMR/. The tools are freely available and can handle large numbers of cases. PON-P can be used for screening and prioritizing variants in order to determine deleterious ones and for further experimentation.

Investigation of genome-wide DNA methylation marks associated with FV Leiden mutation in patients with venous thrombosis

D. Aïssi[1], *J. Dennis*[2], *F. Gagnon*[2], *P. Morange*[3], *D. Trégouët*[1];
[1]*INSERM UMRS 937, Paris, France,* [2]*Dalla Lana School of Public Health, Toronto, ON, Canada,* [3]*INSERM UMR_S 1062, AP-HM, Marseille, France.*

Several lines of evidence are emerging to suggest that DNA methylation marks are involved in the susceptibility of various complex human diseases including thrombosis-related disorders. As part of a general project aimed at identifying DNA methylation-sensitive regulatory mechanisms associated with biomarkers of the fibrinolysis/coagulation cascade, we measured genome-wide DNA methylation levels in peripheral blood samples of 349 patients with venous thrombosis (VT) using the dedicated Illumina HumanMethylation450 bead array. In the current study, we undertook a genome-wide analysis of 485,577 CpG sites to assess whether patients carrying the FV Leiden mutation might be associated with specific DNA methylation profiles. We identified a locus on chromosome 1 characterized by two CpG sites whose DNA methylation levels differed significantly ($p = 6.12\ 10\text{-}12$ and $7.24\ 10\text{-}11$) between carriers (N = 98) and non-carriers (N = 251). Of note, the smallest p-value observed at the F5 gene, also on chromosome 1, was $p = 0.571$. We further tested whether these two CpG sites were associated

with a biomarker of VT risk known to be under the strong influence of FV Leiden mutation, the agkistrodon contortrix venom (ACV) test that explores the Protein C anticoagulant pathway. Strong associations were observed (p = 9.47 10-10 and p = 3.02 10-7) which subsequently vanished (p > 0.10) after adjusting for FV Leiden mutation. These results, if confirmed in independent samples, would add novel insights into the epigenetic regulation of the coagulation cascade.

Correlation between Apolipoprotein E gene polymorphisms and the dose for acenocoumarol maintenance in Bulgarian patients

*R. Tzveova[1,2], A. Dimitrova – Karamfilova[3], Y. Patokova[3], T. Solarova[3], I. Petrova[3], G. Naydenova[4], **R. Kaneva**[1,2], G. Nachev[3], V. Mitev[1,2];*
[1]Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria, [2]Molecular Medicine Center, Medical University, Sofia, Bulgaria, [3]"St. Ekaterina" University, National Multi-profile Active Treatment Hospital, Sofia, Bulgaria, [4]Second Department of Cardiology, UMATH „Dr. G. Stansky", Pleven, Bulgaria.

Acenocoumarol is an anticoagulant which acts through interference with the recycling of vitamin K in the liver, leading to reduced activation of several clotting factors. Apolipoprotein E plays a central role in the uptake of the lipid-soluble vitamin K.
The aim of this study was to evaluate whether variations in the ApoE gene influence acenocoumarol maintenance dose in Bulgarian patients on anticoagulant therapy.
The genotypes of 64 patients with acenocoumarol treatment in maintenance doses were determined by High Resolution Melting assay. The doses for acenocoumarol maintenance were compared among patients with different genotypes.
In the group of patients, the frequencies of ε2/ε3, ε2/ε4, ε3/ε3, ε3/ε4, ε4/ε4 genotypes were 9.4%, 1.6%, 1.5%, 67.2%, 20.3%, 1.6%, respectively. The acenocoumarol maintenance dose showed a genotype related effect. The acenocoumarol dose of group ε2 (ε2/ε3) was 5.78 ± 0.37 mg/d, higher than that of group ε3 (ε3/ε3, 2.87 ± 0.41 mg/d, P=0.013) or group ε4 (ε4/ε4, ε3/ε4, 2.43 ± 0.58 mg/d, P=0.002). ApoE genotype explains 9.9% of acenocoumarol dose variance (analysis of variance, P=0.01). However, the regression analysis of ApoE together with data on VKORC1*2, CYP2C9*2 and CYP2C9*3 polymorphisms show that only VKORC1*2 and CYP2C9*2 are significantly associated with the acenocoumarol maintenance dose.
In conclusion, our study results show that ApoE polymorphisms have a minor influence on the individual dose for acenocoumarol maintenance in Bulgarian patients on anticoagulant therapy.

Association of LOXL1 and HTRA1 genes polymorphisms with both forms of advanced age-related macular degeneration in Turkish patients

***M. Yılmaz**[1], D. Yücel-Yılmaz[2], R. Özgül[3];*
[1]Hacettepe University Institute of Neurological and Pyschiatrical Sciences, Ankara, Turkey, [2]Hacettepe University Department of Pediatrics, Metabolism Unit, Ankara, Turkey, [3]Hacettepe University, Institute of Child Health,Department of Pediatrics, Metabolism Unit, Ankara, Turkey.

Age related macular degeneration (AMD) is clinically heterogenous disorder and the most frequent cause of irreversible blindness in the elderly population. Several single nucleotide polymorphisms (SNPs) have been linked to the risk of developing AMD. Complement Factor H (CFH) and ARMS2/HTRA1 genes were shown to be associated with a distinct component of the AMD phenotype. Recently, lysyl oxidase-like 1 (LOXL1) gene was shown to be involved in a significant fraction of exudative AMD in Japenese populations. Y402H variant in CFH and A69S polymorphism in ARMS2 genes were shown to be associated for both types of end stage AMD in Turkish patients in our previous studies. The purpose of this study is to determine whether polymorphisms in the HTRA1 and LOXL1 gene are associated with advanced AMD in Turkish patients.
Genotyping of 87 age-matched healthy individuals and 95 unrelated late AMD patients were performed by direct sequence analysis. Both genes were analyzed for deviations from Hardy-Weinberg equilibrium and no significant deviations were detected (HTRA1 controls p=0.92 HTRA1 cases p=0.15; LOXL1 controls p=0.05 LOXL1 cases p=0.14). The association between AMD and genotypes were evaluted and analyzed by logistic regression method. According to the statistical analysis, HTRA1 AA genotype is found to be highly associated with AMD (AA genotype OR=5.33,1.95-14.58%CI;p= 0.001) when compared to GG genotype. However, LOXL1 genotypes did not show any significant association with AMD (P=0,847). This study suggest that HTRA1 rs11200638 polymorphism is highly associated for both types of end-stage AMD in Turkish populations whereas LOXL1 is not.

Effect of Gas6 c.834+7G>A polymorphism and the interaction of known risk factors on age-related macular degeneration pathogenesis in Hungarian patients

***I. Balogh**[1], A. Vajas[1], L. Takács[1], E. Dzsudzsák[1], Á. Fekete[1], É. Márhoffer[1], L. Kardos[2], É. Ajzner[3], B. Hurtado[4], P. Garcia de Frutos[4], A. Berta[1], G. Losonczy[1];*
[1]University of Debrecen, Debrecen, Hungary, [2]Kenézy Gyula County Hospital, Debrecen, Hungary, [3]Jósa András Teaching Hospital, Nyíregyháza, Hungary, [4]Institute of Biomedical Research of Barcelona, Barcelona, Spain.

Age-related macular degeneration (AMD) is the leading cause of blindness in the elderly in the developed world. Numerous genetic factors contribute to the development of the multifactorial disease. We performed a case-control study to assess the risk conferred by known and candidate genetic polymorphisms on the development of AMD. We searched for genetic interactions and for differences in dry and wet AMD etiology.
213 patients with exudative, 67 patients with dry AMD and 106 controls were tested for 12 polymorphisms in Apolipoprotein E, complement factor H, complement factor I, complement component 3, blood coagulation factor XIII, HTRA1, LOC387715, Gas6 and MerTK genes. Gas6 c.834+7G>A polymorphism was found to be significantly protective against wet type AMD (OR=0.50, 95%CI:0.26-0.97, p=0.04). Multiple regression models revealed a genetic interaction in the dry AMD subgroup. In the absence of C3 risk allele, mutant genotypes of both CFH and HTRA1 behaved as strong risk factors (OR=7.96, 95%CI:2.39-26.50, p=0.0007, and OR=36.02, 95%CI:3.30-393.02, p=0.0033, respectively), but reduced to neutrality otherwise. The risk allele of C3 was observed to carry a significant risk in the simultaneous absence of homozygous CFH and HTRA1 polymorphisms only, in which case it was associated with a near-five-fold increase in the odds of dry AMD (OR=4.93, 95%CI:1.98-12.25, p=0.0006). Our results suggest a protective role of Gas6 c.834+7G>A polymorphism in exudative AMD development. In addition, novel genetic interactions were revealed between CFH, HTRA1 and C3 polymorphisms that might contribute to the pathogenesis of dry AMD.

Variant Association Tools (VAT) for association analysis of large scale sequence and exome genotyping array data

*G. Wang[1], B. Peng[2], **S. M. Leal**[1];*
[1]Baylor College of Medicine, Houston, TX, United States, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, United States.

Currently there is great interest in detecting rare variant associations with complex traits. The vast majority of methods developed to test for rare variant associations aggregate variants across a region, which is usually a gene. We developed variant association tools (VAT), a tool-set that implements a quality control and association analysis pipeline for rare variant association studies using sequence or genotyping array data. Highlights of VAT include variant site/call level quality control, summary statistics (HWE, Ti/Tv, etc), phenotype/genotype based sample selections, variant annotation, selection of loci for analysis and a number of rare variant association methods for analysis of qualitative and quantitative traits. The association testing framework implemented in VAT is regression based which readily allows for flexible construction of association models with multiple covariates, weighting (based on allele frequencies or predicted functionality), interactions terms and models for pathway analysis. VAT is capable of rapidly scanning through data using multi-processes computation, adaptive permutation and conducting multiple association tests simultaneously. Additionally a programming interface is provided to readily facilitate user implementation of novel association methods. The VAT pipeline can be applied to sequence data, imputed data and genotyping array data, e.g. exome chip. VAT is highly beneficial in performing association analysis on small to large scale studies of complex traits making use of the latest genotyping and sequencing technologies.

Expression of CTLA4 isoforms is altered in patients with childhood asthma and is changing during treatment with inhaled corticosteroids and leukotriene receptor antagonist

U. Potočnik[1], *C. E. P. Kozmus*[2], *V. Berce*[3];
[1]*University of Maribor, Faculty of Medicine, Center for Human Molecular Genetics and Pharmacogenomics, Maribor, Slovenia,* [2]*University of Maribor, Faculty of Medicine, Maribor, Slovenia,* [3]*Department of Pediatrics, University Medical Centre Maribor, Maribor, Slovenia.*

Cytotoxic T lymphocyte antigen 4 (CTLA4), an important regulatory molecule in the process of antigen presentation, was previously associated with pathogenesis of autoimmune diseases and asthma. To further evaluate CTLA4 as a potential biomarker, we
have measured the expression of CTLA4 gene isoforms with qPCR in previously untreated children with mild to moderate asthma before and 4-6 weeks after the therapy with inhaled corticosteroids (ICS) or leukotriene receptor antagonist (LTRA).Median relative
expression of full length CTLA4 (flCTLA4) isoform in asthmatics was 0.440 ± 0.425, compared to 1.000 ± 0.738 in healthy controls (p<0.0001), and of soluble CTLA4 (sCTLA4) isoform in asthmatics was 0.580 ± 0.468 compared to 1.040 ± 1.080 in healthy controls (p<0.0001). After ICS treatment, the
sCTLA4 expression in asthmatics increased from 0.435 ± 0.295 to 0.645 ± 0.573 (p=0.049), while after LTRA treatment decreased from 0.480 ± 0.520 to 0.310 ± 0.355 (p=0.008). Our study shows that CTLA4 expression is dysregulated in asthma patients. ICS and LTRA treatments showed opposite effect on sCTLA4 expression which may be a reflection of thedifferent mechanism of action of both drugs in asthma.

Bardet-Biedl syndrome (BBS) is a ciliopathy and pleitropic autosomal recessive disorder characterized by a wide spectrum of clinical signs including progressive retinal degeneration, polydactyly, obesity, learning difficulties, renal tract and genital anomalies as well as other less frequent features such as for instance anosmia, or Hirschrpung disease. Clinical diagnosis was established if at least four major features are present in the patient. The phenotype spectrum of BBS is variable; some manifestations could appear during childhood. BBS is considered as a rare disorder. The aims of this study were to analyze the genetic epidemiology of BBS in Tunisia, further define the genotype- phenotype correlation. **Materials and methods:** Today 50 unrelated families including 75 patients were collected. Molecular analysis was performed using two successive methods, first genome wide scans with microsatellites markers and then exon capture coupled with high-throughput sequencing of thirteen ciliopathies genes. **Results and discussions**: The current prevalence of BBS in Tunisia has been estimated at 1:156 000. Mutations were identified in the 28 analyzed families. Most frequent mutations were described in *BBS1* and *BBS2* genes. This data expands the mutations profile of *BBS* genes in Tunisia and suggests a divergence of the genetic spectrum comparing Tunisian and other populations. Two founder mutations were identified in *BBS2* and *BBS8* genes. **Conclusion**: This study showed the genetic heterogeneity of BBS in Tunisia. Molecular diagnosis of BBS has to be established in the country in order to offer the genetic counseling and prenatal diagnosis for affected families.

Beta-thalassemia is a genetic disease caused by a defect in the production of the beta-like globin chain. More than 200 different mutations are described that can lead to the disease and are mainly found in populations that have been exposed to malaria parasites. We recently described a duplication of 4 nucleotides in the first exon of beta-globin gene in several families of patients originating from Nord-Pas-de-Calais (France). In order to determine if this mutation has arisen there or has been introduced by migrants from regions of the world where thalassemia is endemic, we genotyped 4 unrelated mutation carriers and 32 controls from Nord-Pas-de-Calais for 97 european ancestry informative markers (EAIMs). Using these EAIMs and comparing with population reference panels, we showed that the patients were very similar to the controls and were closer to North European populations than to South European or Middle-East populations. Using the genotypes at 12 microsatellite markers surrounding the beta-globin gene of the 4 mutation carriers plus an additional one recently discovered, we found that they shared a common haplotype that signs a founder effect that was estimated to have taken place 225 years ago (9 generations).
Rare beta-thalassemia mutations have already been described in patients sampled in non-endemic regions but it is the first proof of a founder effect in Northern Europe. How this finding could challenge the hypothesis of a selective advantage of mutation carriers when exposed to malaria would be discussed.

Despites a century-old characterization of biliary atresia (BA), nothing is commonly assumed about heritability of this disease, its onset, its susceptibility factors nor its physiopathology. In this study, we provide the clues to thoroughly revisit BA as a multifactorial disease, related to genetic ancestry. Among the 152,866 children born in French Polynesia between 1979 and 2009, 40 had biliary atresia accounting for an incidence of 26.1/100,000 live births, which is the highest incidence worldwide. Epidemiologic data and follow-up study over 30 years period reveal statistically significant influence of environment with seasonality of births. In all 40 patients, we also studied genealogic and clinical data. Genome-wide analyses of 250,000 SNPs in 24 patients and their parents were performed. Genetic isolate was evidenced by genealogy, inbreeding coefficient calculation (F=0.045) and principal component analysis. Contribution of environmental factors was integrated into an original statistical modeling. While homozygosity mapping revealed no significantly shared region, suggestive linkage to chromosome 2q13.1 was identified in patients with environmental constraint. Transmission disequilibrium test analysis further identified suggestive association with SNPs from 14 loci. Using bioinformatics, we could identify that the majority of genes that were encompassed in those loci were involved in the same highly significant pathway, specific to liver. Our findings provide a novel view of a complex genetic make-up in an isolate population underlying BA. Our study design unveils an approach to study the contribution of both ethnic and environmental factors in a rare disease.

Appraising the clinical validity for pharmacogenetic markers of fluoropyrimidine response in the treatment of colorectal cancer

B. A. Jennings[1], *G. Willis*[2], *J. Skinner*[1], *Y. K. Loke*[1];
[1]*Norwich Medical School, Norwich, United Kingdom,* [2]*Norfolk and Norwich University Hospital, Norwich, United Kingdom.*

Pharmacogenetic tests are not routinely used for fluoropyrimidine treatment stratification despite a high frequency of adverse events leading to significant morbidity and mortality. We have conducted a pharmacogenetic study of early adverse events in a cohort study of 254 colorectal cancer patients treated with 5-fluorouracil or capecitabine. Our objectives were to test the clinical validity of nine previously identified markers of toxicity in a broad clinical setting; and to identify any associations between severe adverse events and six additional candidate variants of proximal enzymes in the pharmacodynamic and pharmacokinetic pathways.
We did not identify any significant associations for variants of the folate metabolizing enzymes and toxicity. However, two pharmacokinetic enzymes were associated with this phenotype. We found a significant association with *TYMP* L471S (adjusted OR = 2.70 [1.23; 5.92], p = 0.01) and a signature of rarer *DPYD* mutations (adjusted OR = 6.76 [1.99; 22.96], p = 0.002).
If a prognostic test for early adverse events analysed the *TYMP* and *DPYD* variants as a signature, the sensitivity would be 45.5 %, with a positive predictive value of just 33.9 %. The poor clinical validity reflects the modest effect size or low allele frequencies of the individual predictive markers considered in this study. The combined effect of risk alleles for a given phenotype may be much larger or indeed smaller than implied by their individual effect sizes but meta-analyses of individualized data sets such as this will be required to identify genetic interactions and prognostic genetic signatures with promising clinical validity.

Genetic analysis of BRCA1 and -2 haplotypes in patients with breast- and/or ovarian cancer in South Tyrol

A. J. Lanthaler, *C. Platzer, H. Heidegger, M. Mitterer, F. D. Vogl;*
General Hospital Merano, Merano, Italy.

Introduction:
The purpose of this study was to determine haplotypes of BRCA1 and BRCA2 for patients with breast and/or ovarian cancer using common single nucleotide polymorphisms (SNPs).
Patients and Methods:
Patients with breast and/or ovarian cancer, unselected for family history, were identified through the local cancer registry. After written informed consent, participants provided a blood sample for genetic analysis. Genomic DNA was extracted by standard technique. Direct sequencing of the complete coding region of BRCA1 and 2 was performed. A set of 12 SNPs in BRCA1 and 16 SNPs in BRCA2 that were repeatedly present in our patient group were selected for genotyping. Haplotypes were designated as in Frosk et al (2007). Rare haplotypes were confirmed by LightCycler PCR and melting curve analysis.
Results:
Blood was obtained of 183 patients. Ten patients (5.5%) with a deleterious BRCA mutation were excluded from haplotype analysis. In the remaining 173 patients, 11 different BRCA1 haplotypes and 12 different BRCA2 haplotypes were found. Of these, 4 BRCA1 haplotypes and 6 BRCA2 haplotypes reached a frequency greater than 5%, representing >93% of all BRCA1 and >84% of all BRCA2 haplotypes, respectively. Four BRCA1 haplotypes were detected only once.
Conclusions:
Common haplotypes in BRCA1/2 can be reliably determined using a limited number of SNPs. Using haplotypes, instead of single polymorphisms, might help to elucidate the impact of genetic variation in BRCA1/2 on cancer risk, since contradictory results in the literature could be due to the use of single polymorphisms only.

Frequency analysis of the CCR5-Delta32 allele in medieval and modern Romanian population

F. Raicu[1,2], *R. Cocos*[1], *S. Schipor*[3], *L. Bohiltea*[1];
[1]*University of Medicine and Pharmacy, Bucharest, Romania,* [2]*Institute of Anthropology „Francisc I. Rainer", Bucharest, Romania,* [3]*"C.I. Parhon" Institute of Endocrinology, Bucharest, Romania.*

The CCR5-delta 32 mutation in human chemokine receptor gene can be considered a rare example of a beneficial mutation. The mutation gives its homozygous carriers complete resistance against HIV infection and has been proposed to provide protection against different lethal epidemics. Although the origin of the mutation indicates prehistoric times, repeated waves of lethal epidemics over medieval centuries strongly modified the European gene pool via bottleneck effect and seem to increase the frequency of CCR5-delta 32 up to 20% as a result of selective advantage.
In order to investigate if the lethal epidemics of the medieval times selected the allele we analyzed the presence of this mutation in aDNA isolated from the skeletons discovered in Piața Universității archeological site and compared them to the frequency in a control group from local modern population. This archaeological site is one of the biggest medieval cemeteries from Romania providing the opportunity to sample the same population at different points during the medieval period and beyond.
The comparisons couldn't reveal strikingly different frequencies of the CCR5-delta 32 allele. Our preliminary results based on 18 aDNA of 150 samples and 74 of 2500 modern DNA indicate that the frequency of the allele in medieval Romanian population is not statistically significant when compared to contemporary one suggesting that lethal epidemics had little effect on its present day frequency. We can conclude based on preliminary data that increase in the allelic frequency of the mutant CCR5-delta 32 allele has been positive selected before the medieval centuries.

Introduction: CD40-CD40 ligand (C40L) signaling pathway is a key way in the cooperation between immune and inflammatory cells. The CD40/CD40L is also involved in a variety of autoimmune and inflammatory disorders caused by a deficiency or abundance of one/both of the receptor-ligand molecules. Some genetic polymorphisms were shown as regulators of protein expression. This study was conducted to investigate the polymorphisms responsible for the CD40L up regulation in blood donors.
Donors and Methods: We genotyped 450 blood donors (200 collected at the French Blood Establishment Auvergne Loire, France and 250 collected at the Blood Banks of Monastir and Sousse, Tunisia).
The studied CD40L polymorphisms are located in the 5'UTR regulatory region, successively rs3092952 SNP A> G and rs201992677 [-/CAAA], an InDel SNP modifying the number of repeats of a CAAA microsatellite.
We performed Denaturing High Performance Liquid Chromatography method and automated sequencing.
Results and discussion: The two studied SNPs are in linkage disequilibrium so they should constitute a haplotype. Surprisingly, all the male donors presenting the G allele rs3092952 were also found to carry seven CAAA repeats (rs201992677) and even 8 CAAA repeats in 2 cases.
A significant difference was observed between the two populations (Tunisian and French).
The next step will be to study whether the CD40L protein up expression is related to the G allele (previously known) or/and to the variable number of tandem CAAA repeats. This could induce a consequence on hyper activation of blood recipients in transfusion.

Functional analysis of Immunochip candidate genes in Celiac Disease

L. PLAZA-IZURIETA[1], *N. Fernandez-Jimenez*[1], *A. Jauregi-Miguel*[1], *T. Lopez-Euba*[1], *C. Wijmenga*[2], *J. C. Vitoria*[1], *J. R. Bilbao*[1];
[1]*BioCruces Research Institute/UPV-EHU, Leioa, Spain,* [2]*University Medical Center Groningen, Groningen, Netherlands.*

Celiac disease (CD) is an immune mediated multigenic disorder caused by intolerance to ingested gluten that develops in genetically susceptible individuals. The major genetic risk factor is HLA DQ2/DQ8 but it is not sufficient to explain all genetic susceptibility to CD. GWAS and IMMUNOCHIP performed in CD identified 39 non-HLA regions associated with CD, and a long list of candidate genes mapping these regions has been proposed.
The aim of this work was to analyze the expression of those genes in the intestinal mucosa of active and treated CD patients and controls, to question their implication in CD development, as well as the influence of the associated SNPs in their expression.
Gene expression analysis was carried out using the Fluidigm BioMark™ HD Real-Time PCR System, in intestinal biopsies of 15 CD children at diagnosis and after >2 years on GFD, and 15 non-celiac controls. Statistical analyses to assess differential expression, genotype effect and correlation were performed.
Ten out of 46 genes were differentially expressed when comparing active and treated patient mucosa, 15 genes showed differences between active disease and controls and 3 of them were constitutively downregulated in patient mucosa, independent of disease status. Correlation was found in the expression of some of the analyzed genes, and in depth studies may be able to clarify these relationships.
Several genes under association peaks seem to have a functional implication in the disease, but other genomic elements, such as miRNA or lncRNAs in the region should not be ruled out.

Autosomal dominant cerebellar ataxias are a group of diseases affecting the cerebellum and its afferent/efferent tracts, characterized by genetic heterogeneity (SCA1 - 34). We studied 1013 index cases and estimated survival in 461 index cases and 224 affected relatives with known mutations. Median age at death (n=461) was 68 years [28-97]. Comparison of 409 subjects with SCA due to CAG expansions (SCA1, 2, 3, 6, 7, 17, DRPLA) and 52 subjects with non-polyglutamine SCAs (SCA 11, 13, 14, 15, 23, 25, 28, 31, 32, 36) showed that survival was significantly shorter in the former (67 years [28-97] versus 83 years [45-95], p< .0001). SCA with polyglutamine expansions died 16 years earlier and have a significantly reduced survival. Among polyglutamine SCA median age at death in SCA1 was 63 years [58-65], significantly earlier than SCA 2, 3, 6 and 7 (Log Rank 34.0, p= .0001). Death occurred 8.1 years earlier in the offspring of polyglutamine SCA (p< .001) indicating anticipation. Despite significantly earlier age at onset in non-polyglutamine SCA (37.8 years ± 13.3 versus 29.0 years ±17.7, p< .001), the disease progression was faster in polyglutamine SCA (duration between age at onset and first examination 21.9± 14.6 years and 8.9± 6.9 years respectively, p< .0001). Duration between age at onset and death was 18 years in index cases with polyglutamine SCA.
Survival and severity among SCAs was significantly different according to the underlying mutational mechanism.

Extensive genetics of Cerebral Cavernous Malformation in Italy

S. Penco, *M. Cigoli, F. Avemaria, P. Primignani, G. Gesu, A. La Camera, A. Citterio, M. Cenzato, L. Tassi;*
Niguarda Ca' Granda Hospital, MIlano, Italy.

Cerebral Cavernous Malformations (CCM) (OMIM 116860; Orpha code: ORPHA 164) are a diffuse cerebrovascular disease characterized by abnormally enlarged and leaky capillaries arranged in mulberry-like structures with no clear flow pattern. The lesion might predispose to seizures, focal neurological deficits or fatal intracerebral hemorrhage. However a CCM can also remain neurologically silent. It might either occur sporadically or as an inherited disorder with incomplete penetrance and variable expressivity.
The Familial form of this disease (FCCM), is defined as the occurrence of CCMs in at least two family members and/or the presence of multiple CCMs and/or the presence of a disease-causing mutation in one of the three genes in which mutations are known to cause familial CCM. Diagnosis is made by clinical history and family history; physical examination including neurological, cutaneous and retinal; brain and/or spinal cord MRI; and when available, histopathologic examination of tissue specimens. The diagnosis of FCCM can be confirmed by molecular genetic testing of the following three genes in which mutations are known to cause FCCM: KRIT1/CCM1, MGC4607/CCM2, and PDCD10/CCM3. Sequencing analysis of the three genes should be integrated by Multiple Ligation Probe Assay (MLPA) to search for genomic rearrangements.
We present here data from 87 Italian FCCM analyzed both by sequence and MLPA analysis. We identified KRIT1/CCM1 mutations in 65.52%, MGC4607/CCM2 mutations in 17.24%, PDCD10/CCM3 in 12.64% and no mutations in 2.3% of the analysed cases.
According to our results, more than 90% of the familial form of the disease present a genetic mutation.

Pulmonary and extrapulmonary parameters are significantly associated with *IL8* polymorphisms in Chronic Obstructive Pulmonary Disease.

R. Baz-Dávila[1], *E. Córdoba-Lanús*[1], *A. Espinoza-Jiménez*[1], *C. Rodríguez*[1], *J. deTorres*[2], *N. Varo*[3], *D. Almeida-González*[1], *C. Casanova*[4];
[1]*Research Unit, Hospital Universitario NS de Candelaria, Santa Cruz de Tenerife, Spain,* [2]*Pulmonary Department, Clínica Universitaria de Navarra, Santa Cruz de Tenerife, Spain,* [3]*Biochemical Analysis Department, Clínica Universitaria de Navarra, Santa Cruz de Tenerife, Spain,* [4]*Research Unit and Pulmonary Department, Hospital Universitario NS de Candelaria, Santa Cruz de Tenerife, Spain.*

RATIONALE: COPD is characterized by airflow limitation and tobacco smoking is its major risk factor. IL8 is a proinflammatory chemokine mainly involved in the initiation and amplification of acute inflammatory reaction. Here we aimed to test the association of *IL-8, CXCR1* and *CXCR2* polymorphisms and susceptibility to disease.
METHODS: 9 tagSNPs were genotyped in 744 caucasian individuals (202 COPD patients, 90 smokers with normal lung function and 452 healthy controls). Clinical variables were measured at baseline and annually over a 2 years period. Pulmonary compromise was measured using lung function, and the extrapulmonary manifestations were determined using the BODE index. We also determined plasma levels of IL-6, IL-8, IL-16, TNF-α, MCP-1, MMP-9, PARC and VEGF in COPD patients.
RESULTS: No significant association was found between gene variants or haplotypes with predisposition to disease when comparing COPD patients with control groups. No relationship was observed between tagSNPs and cytokines levels. Significant associations were found between the rs4073 (T/A), rs2227306 (T/C) and rs2227307 (T/G) in the *IL8* gene and FEV1%, FEV1/FVC and GOLD status (p<0.05) at baseline in COPD patients. The rs4073A, rs2227306C and rs2227307T alleles were significantly associated with patients who scored higher in the BODE index and showed an important decrease in their FVC during the 2 years follow-up period.
CONCLUSIONS: Despite no significant association was found between gene variants and COPD susceptibility, three polymorphisms in the IL8 gene appear to be involved in a worse prognosis of disease, by a reduction in lung capacity and an increased BODE index.

Type and frequency of CNVs in a group of Bulgarian patients with congenital malformations and intellectual disability

S. P. Hadjidekova[1], *D. Avdjieva-Tzavella*[2], *B. B. Rukova*[1], *D. V. Nesheva*[1], *R. Tincheva*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University-Sofia, Sofia, Bulgaria,* [2]*State University Pediatrics Hospital "Queen Evdokia", Medical Faculty, Medical University, Sofia, Bulgaria, Sofia, Bulgaria.*

Introduction: The development of microarray technology revealed an unexpected large number of deletions and duplications in the human genome whose clinical significance is unknown in some cases. This requires a thorough population study of CNVs in healthy individuals and patients.
Methods: Oligo array-CGH (BlueGnome CytoChip oligo 2X105K, v1.1, 35kbp backbone resolution) was applied in 52 patients with developmental delay and multiple congenital anomalies.
Results: A total of 247 CNVs were detected, of which 15 pathogenic, 108 with unknown clinical significance and 124 benign - mean number of CNVs per patient – 4,5.
Unknown CNVs in chromosomal loci 2q37.3, 10q11.22, Xp22.33 (19 variations) were found in over 5% of patients, which were probably not pathogenic.
The most common benign variations were in 15q11.2, 8p11.23, 6p21.32, 3q26.1, 14q11.1 and 12p13.31 loci, occurring in over 10% of the patients.
Conclusion: We determined benign and probably not pathogenic variants in Bulgarian patients. There is an obvious need for large population studies. This would facilitate the interpretation of unknown genomic imbalances in clinical aspect. Besides, it would help the widespread introduction of CGH microarray in diagnostic practices - postnatal and prenatal genetic diagnosis.

Gene-gene interaction between APOE and USF1 for coronary heart disease in TARF study

E. Komurcu Bayrak[1], *M. Poda*[1], *A. Onat*[2], *V. Sansoy*[3], *B. Yuzbasiogullari*[1], *N. Mononen*[4], *T. Lehtimaki*[4], *S. Humphries*[5], *N. Erginel Unaltuna*[1];
[1]*Istanbul University, Institute for Experimental Medicine, Department of Genetics, Istanbul, Turkey,* [2]*Emeritus, Istanbul University, Cerrahpasa Medical Faculty, Department of Cardiology, Istanbul, Turkey,* [3]*Istanbul University, Institute of Cardiology, Department of Cardiology, Istanbul, Turkey,* [4]*Tampere University, Tampere University Hospital, Department of Clinical Chemisty, Tampere, Finland,* [5]*University College London, Center for Cardiovascular Genetics, London, United Kingdom.*

Background: Epistatic gene-gene interactions could contribute to the heritability of coronary heart disease, but limited investigations have been reported. USF1 is a key regulator of several genes involved in lipid and glucose metabolism as a transcription factor. APOE has been identified as a target gene of USF1. APOE gene polymorphisms (SNP) have been shown to associate with plasma apoE concentrations, lipid levels and cardiovascular disease. In this study, we investigated a possible interaction between these two genes on coronary heart disease risk in Turkish Adult Risk Factor (TARF) Study.
Methods: A population-based cross-sectional survey conducted from 1998-2011 included 1874 randomly selected adults (mean age 54.4±11.9 years, 49% men) participating TARF study. 111 of these individuals were diagnosed as coronary heart disease. Genotyping of -219G/T (rs405509), +113G/C (rs440446) and ε2/ε3/ε4 (rs429358 and rs7412) polymorphisms in *APOE* gene and also ex11G/A (rs3737787) and int7C/T (rs2073658) polymorphisms in *USF1* gene was performed using the Taqman technology (ABI 7900HT, Applied Biosystems, CA). Gene-gene interaction effects were analyzed using traditional multiple regression models.
Results: The logistic regression model showed there were significant interactions effect between *APOE* -219G/T and +113G/C polymorphisms and *USF1* int7C/T on coronary heart disease of the Turkish adults (P for interaction =0.009 and =0.01, respectively). After adjustment for age, gender, body mass index and diabetes mellitus, these interactions were also showed (P for interaction =0.004 and =0.02, respectively).
Conclusion: Gene-gene interaction between *APOE* and *USF1* plays an important role in coronary heart disease risk in Turkish population.

Polimorphisms of CYP2B6 and CYP2D6 genes associated with drug metabolism in Roma population samples

R. Szalai, *C. Sipeky, L. Jaromi, L. Magyari, P. Matyas, J. Bene, B. Duga, E. Kovesdi, A. Szabo, B. Melegh;*
University of Pecs, Department of Medical Genetics and Szentagothai Research Centre, Pecs, Hungary.

The human cytochrome P450 B6 and D6 (CYP2B6 and CYP2D6) enzymes, members of the cytochrome superfamily, play major role in the metabolism of several substrates such as drugs and other xenobiotics. These phase I enzymes are known to commonly contribute the biotransformation of clinically important pharmaceuticals, including anticancers (tamoxifen), antidepressants (anandamide), anxiolytics (sertraline), opioid analgesics (methadone). The purpose of this study was to investigate the allelic frequencies of three major functional gene variants, CYP2B6 G516T, CYP2D6 C100T and CYP2D6 G1846A in Hungarian Roma population compared with Hungarian Caucasian controls. A total of 426 Roma cases (151 males, 275 females; mean age 43.3±0.87 years) and 431 Hungarian controls (248 male, 173 females; mean age 37.6±0.61 years) were genotyped for three SNPs using RT-PCR assay and direct sequencing. We found significant differences in the presence of rare variant in case of CYP2B6 G516T ($p \leq 0.001$) and CYP2D6 C100T ($p=0.003$) and G1846T ($p=0.022$) between the Hungarian Roma and Hungarian general population. The 516T allele frequency was 67.1% in the Roma group, 42.7% in controls, whereas the minor CYP2D6 100T allele was present in 53.3% in Romas, while 41.1% in healthy Hungarians. The allele frequency of 1864A was 45.1% in Roma samples and 36.2% in controls. Our results suggest, that both pharmacogenetical and clinical factors including ethnicity can influence the efficacy of individual drug therapy.

P16.022

CFTR gene rearrangements in Argentinean cystic fibrosis patients

L. P. Gravina, *C. Crespo, H. Giugno, C. Castaños, L. Chertkoff;*
Hospital de Pediatría „Prof. Dr. Juan P. Garrahan", Buenos Aires, Argentina.

Introduction: Cystic Fibrosis (CF) is an autosomal recessive disease mainly caused by point mutations and small deletions in the CFTR gene. Besides, more than 30 large deletions that remain undetected when using conventional PCR techniques have been described in CFTR gene. Some of these deletions can reach frequencies up to 6% in certain populations. In Argentina, the study of 32 mutations prevalent in Caucasian population detects about 76% of cystic fibrosis alleles. To date, it is unknown the contribution of CFTR rearrangements in the development of CF in this population.
Objective: To determine the frequency of large deletions in the CFTR gene in Argentinean cystic fibrosis patients with at least one unidentified mutation.
Materials and Methods: The number of copies from all 27 exons in the CFTR gene was studied by Multiplex Ligation-dependent Probe Amplification (MLPA) in 74 CF patients with one or none identified mutation.
Results: CFTR rearrangements were detected in 11 of the 91 alleles studied (12%), 7 as a second mutation and 2 in homozygote form. Six different rearrangements were identified: CFTRdele2, CFTRdele2, 3, Del17a-17b-18, CFTRdele19, Del22-24 and CFTRdele1-24. CFTRdele2, Del17a-17b-18 and CFTRdele19 were found in more than one allele.
Conclusions: The analysis of the CFTR gene deletions allowed increasing the sensitivity of the molecular study. The frequency of CFTR deletions found in this group of CF patients suggests that this methodology should be incorporated into the diagnostic algorithm in Argentinean population.

P16.023

Graphically testing bi-allelic markers for Hardy-Weinberg equilibrium

J. Graffelman;
Universitat Politecnica de Catalunya, Barcelona, Spain.

In genetic association studies markers are usually tested for Hardy-Weinberg proportions (HWP). Such tests are relevant, as deviations from HWP may be the result of genotyping error, can result from population stratification or can be indicative of marker-disease association. The classical test for HWP is the the chi-square test, though nowadays exact test procedures have become increasingly popular. Testing becomes unwieldy if large numbers of markers are tested simultaneously, leading to large amounts of statistics and p-values. In this talk we show that all HWP testing can be done gra-

phically, by simultaneously representing all markers in a de Finetti diagram or ternary plot. Hardy-Weinberg equilibrium traces a parabola inside the ternary plot. Curves that delimit the acceptance region of the HWP test can be traced in the plot as well. For chi-square tests (with or without continuity correction) the limits of the acceptance region are smooth curves. The acceptance region of exact tests can be represented by zigzag lines. In this way the significance status of large databases of markers can be glanced from a single diagram. Systematic heterozygote excess or dearth for the markers under study is then easily detected. Alternative graphical presentations for representing marker data using log-ratio transformations of the genotype counts are also considered. In log-ratio coordinates, the Hardy-Weinberg law is a straight line. Examples of graphical tests with HapMap data and markers involved in colon cancer will be shown. Software for making all diagrams (the R-package HardyWeinberg) will be discussed.

Whole exome sequencing to find de novo causal variants: sample size and significance

C. G. F. de Kovel, *B. P. C. Koeleman;*
UMC Utrecht, Utrecht, Netherlands.

Whole exome sequencing technology enables the detection in patients of de novo variants that might be responsible for their condition. Sometimes, a single trio is investigated in a diagnostics-like setting, while in other studies, large series of patients with the same disorder and their parents are sequenced to find genes with multiple hits. Questions arise about whether particular results can be considered significant and about how many samples are needed to find a significant result. We formulated equations to help answering these questions for specific experiments.
For example, the equations show that in the case of a single average-sized gene and a follow-up cohort, a second missense de novo hit in the gene would be significant with p<0.01, when at least one hit is found in a follow-up sample of up to 300 patients. When a series of patients is sequenced, a more heterogeneous disease will require a larger cohort to find multiple hits in the same gene. At the same time, in a larger cohort, more hits per gene must be found to be considered significant. This trade-off will be demonstrated. Also, the size of the gene matters. For example, finding a double hit in an average-sized gene in a sample of 50 patients occurs with p=0.02 by accident, while finding a double hit in one of the 5% largest genes occurs with p=0.09 by accident, and will therefore not be considered significant.
We will present some guidelines and rule-of-thumb-numbers.

Paternal age explains a major portion of de novo germline mutation rate variability in healthy individuals

S. L. Girard[1], *L. Lemieux Perreault*[2], *A. Barhdadi*[2], *P. A. Dion*[1], *M. Boivin*[3], *M. Dubé*[2], *G. A. Rouleau*[4];
[1]*CRCHUM, Montréal, QC, Canada,* [2]*Institut de Cardiologie de Montréal, Montréal, QC, Canada,* [3]*Université Laval, Québec, QC, Canada,* [4]*Montreal Neurological Institute, Montréal, QC, Canada.*

De novo mutations (DNM) are an important source of rare variants and are increasingly being linked to the development of many diseases. Recently, two studies using individuals with common psychiatric disorders, autism spectrum disorders (ASD) or schizophrenia, have shown a strong link between the fathers' age at time of conception and identified DNM hotspots across the genome1,2. Though they were both revealing, these studies were conducted on cohorts of patients with psychiatric disorders known to result in part from DNM. Using disease-free familial quartets we show for the first time that the overall ratio of somatic:germline DNM is 1:9 and that there is a positive correlation between paternal age and germline DNM in healthy subjects. Interestingly somatic and all CNV DNM did not vary with paternal age. We also found that DNM were not evenly distributed across the genome, which adds support to the possibility of DNM hotspots.

Ammosov North-Eastern Federal University, Yakutsk, Russian Federation,* [8]*Republican Children's Hospital, Kyzyl, Republic of Tuva, Russian Federation.*

Hearing loss is a heterogeneous disorder due to genetic or environmental causes, or both. Congenital (or early onset) sensorineural profound hearing loss is most likely caused by genetic factors. We created the uniform register of 1407 persons with different hearing impairments and conducted genetic epidemiological analysis of hearing loss in the Republic of Tuva located in Southern Siberia and bordered on the south with Mongolia. The total population of the Republic of Tuva is ~310 000 and mainly represented by indigenous people, Turkic-speaking Tuvinians. We revealed 982 patients with severe-profound hearing impairment that is ~ 1 per 300 inhabitants of the Tuva have socially significant hearing loss. Moreover, congenital aural atresia and different ear deformities was found in 55 persons. Then, we analyzed the types of hearing impairments and excluded the patients with conductive and mixed forms of hearing loss as well as patients with presbycusis or sensorineural deafness apparently caused by environmental factors. As a result, a group of patients with congenital (or early onset) sensorineural severe-profound hearing loss included 542 individuals. Mutation screening of the GJB2 gene entire coding region in 173 patients (mostly Tuvinians, and a few Russians) from this group revealed mutations p.W172C, c.235delC, p.V37I, c.299_300delAT, and c.35delG (only in Russian patients) in 24.3% of all examined patients. The p.W172C mutation makes the largest contribution to deafness in Tuvinian patients. Carrier frequency of p.W172C in normal hearing Tuvinians (N=117) was found to be 4.3%.
The study was supported by RFBR grants #11-04-01221-a, #12-04-98520.

P16.027

Prevalence of Mutations in the GJB2 and GJB6 Genes in patients with Non-syndromic Deafness in UAE population

A. A. Mahasneh[1], *A. S. Doudin*[1], *M. Alkasimi*[2], *M. Bin Surour*[2];
[1]*Dept. of Aplied Biology, University of Sharjah, Sharjah, United Arab Emirates,* [2]*Zayed Higher Organization for Humanitarian Care and Special Needs, Abu Dhabi, United Arab Emirates.*

Hearing loss, affecting millions of people, is the most common form of sensory impairment. It is a genetically heterogeneous disorder. The various deafness forms so far studied appear as monogenic disorders. They are all rare with the exception of one, caused by mutations in the gene encoding the gap junction protein connexin26, which accounts for about 1/3 to 1/2 of the cases of prelingual inherited deafness in Caucasian populations. This study focuses on two of the most common genes which cause autosomal recessive deafness, GJB2 and GJB6, to determine the frequency for common mutations in these genes. We specifically aim to estimate the prevalence of 35delG, 167delT, and 235delC in the GJB2 gene and D13S1830 deletion mutation in the GJB6 gene in individuals with nonsyndromic hearing loss and in healthy individuals in the population of United Arab Emirates. Common mutations were screened for in extracted genomic DNA using PCR-RFLP and multiplex PCR techniques. Eighty-eight patients with non-syndromic hearing loss participated in the study from Sharjah, Abu Dhabi, and Al-Ain centers. The 35delG mutation was the most common in our patients, and was the only one detected in 8 (homozygous for 35delG) out of 88 patients (9%). None of our tested patients were positive for the 167delT or 235delC mutations. Using multiplex PCR assay, the results showed a homozygous wild type genotype for the del (GJB6-D13S1830) mutation in both deaf and normal subjects alike. In addition, none of the seventy-four tested healthy individuals carried a mutation in 35delG, 167delT, or 235delC.

Effect modification of SNPs in predicted milk rich miRNA target sites on the association between breastfeeding and diarrhea

M. Bustamante[1,2,3], *J. C. Kiefte-de Jong*[4,5], *E. Kreiner-Møller*[6,7], *M. Marinelli*[1,2,8], *A. Espinosa*[1,2], *M. Montfort*[3], *H. M. Moll*[4,5], *F. Ballester*[9], *H. Bisgaard*[6,7], *V. W. V. Jaddoe*[4,5], *J. Sunyer*[1,2,8], *X. Estivill*[3,2];

[1]*Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain,* [2]*CIBER Epidemiologia y Salud Pública (CIBERESP), Barcelona, Spain,* [3]*Center for Genomic Regulation (CRG), Barcelona, Spain,* [4]*Generation R Study Group, Erasmus University Medical Center, Rotterdam, Netherlands,* [5]*Department of Pediatrics, Erasmus University Medical Center, Rotterdam, Netherlands,* [6]*COPSAC, The Copenhagen Prospective Studies on Asthma in Childhood, Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark,* [7]*The Danish Pediatric Asthma Center, Copenhagen University Hospital, Gentofte, Denmark,* [8]*Hospital del Mar Research Institute (IMIM), Barcelona, Spain,* [9]*University of Valencia, CSISP-FISABIO and CIBERESP, Valencia, Spain.*

Breastfeeding is a well known protection factor for diarrhea. Recently, several studies have shown that immune related miRNAs are present in mammal milk and colostrums. To indirectly test the function of milk miRNAs on diarrhea susceptibility, we explored the effect modification of SNPs in predicted milk rich miRNA target sites on the association between breastfeeding and diarrhea.

SNPs that might modify the binding of the 32 most abundant milk miRNA based on *in silico* predictions were retrieved from the PolymiRTS v2.0 database. After filtering for SNP functionality, around 600 SNPs were available in INMA (Infancia y Medio

Ambiente) birth cohort (N=719). The effect modification of these SNPs on the association between breastfeeding (any and predominant >=16 weeks) and diarrhea at age 1 year, was tested using PLINK. The four top SNPs (rs7467, rs940774, rs216463 and rs8053471) based on arbitrary p interaction values were selected for replication in two European cohorts: Generation R (N=2457) and COPSAC (N=345).

The most consistent result was for rs8053471. In particular, any breastfeeding and predominant breastfeeding decreased the risk of diarrhea in children with the rs8053471 minor allele [combined OR (95%CI) for any breastfeeding >=16 weeks: AA 1.10 (0.85;1.42), AG 0.62 (0.44;0.90), GG 0.45 (0.22;0,93)]. Rs7467 and rs940774 showed some trend of replication for predominant and any breastfeeding, respectively.

In summary, these preliminary results suggest that the relationship between breastfeeding practices and diarrhea protection might be, in part, mediated by milk miRNAs. Further investigations are needed to validate these results.

Polymorphism in maternal gene *RFC-1* A80G can increase the risk of Down syndrome pregnancies: a systematic review and meta-analysis

D. B. Victorino*, M. F. Godoy, E. M. Goloni-Bertollo, E. C. Pavarino;*
Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil.

First described in 1866, Down syndrome (DS) is resulting from a failure of chromosome 21 segregation during maternal meiosis in about 95% of cases. Maternal polymorphisms linked to folate metabolism have been studied as a risk factor for DS. A80G is a common polymorphism related to the folate transporting protein (RFC-1). It has been associated with DS, but inconsistent results have emerged from studies that investigated such association. Therefore, we performed this meta-analysis to derive a more precise estimation of this association. Studies were identified by searching the PubMed database for relevant articles in English published before january 2013 using the following criterion: (reduced-folate carrier or RFC-1 or A80G) and (Down syndrome or Trisomy 21). Case reports, editorials and review articles were excluded. The meta-analysis examined the association between gene polymorphism and maternal risk of DS for the dominant and recessive models of the mutant allele. The associations were indicated as a pooled odds ratio (OR) with the corresponding 95% confidence interval (CI) and significance level was considered for $p < 0.05$ values. Data from 11 case-control studies were included in the meta-analysis. The meta-analysis of dominant and recessive models showed a significant association between *RFC-1* A80G polymorphism and the birth of children with DS [random effects pooled OR = 1.28 (CI: 1.002-1.645) P= 0,0475] and [random effects pooled OR = 1.24 (CI: 1.029-1.512) P= 0,0241], respectively. Our study has demonstrated that there is a significant association between *RFC-1* A80G polymorphism and the risk for a DS pregnancy.

Polymorphism g.37190613G>A of the ELMO1 gene related with diabetic nephropathy in Mexican Mestizos.

N. O. Dávalos-Rodríguez[1], *S. A. Ramirez-Garcia*[2], *L. R. Topete-Gonzalez*[1], *C. Charles-Niño*[1], *M. A. Mazariegos-Rubi*[1], *I. P. Dávalos-Rodríguez*[3], *N. Villa-Ruano*[2], *A. R. Rincón-Sánchez*[1], *D. Garcia-Cruz*[1], *L. Cortes-Sanabria*[1];

[1]*UNIVERSIDAD DE GUADALAJARA, GUADALAJARA JALISCO, Mexico,* [2]*UNIVERSIDAD DE LA SIERRA SUR, Oaxaca, México, Mexico,* [3]*División de Genética, CIBO, IMSS., GUADALAJARA JALISCO, Mexico.*

Introduction. ELMO1 gene encodes a protein involved in cytoskeleton organization. Variations in this gene have been associated with diabetic nephropathy, as the case of the polymorphism g.37190613G>A. In Mexican population there is no previous report on this issue Aim: To analyze the distribution of alleles and genotypes frequency from polymorphism g.37190613G>A in Mexican population. Methods: Genomic DNA of 103 mestizos from Northwest and 50 Half Breeds (with ancestry Yoruba and Zapoteca) of the Southern Lowlands, of Oaxaca, was extracted of peripheral blood leukocytes by the Miller method. The polymorphism was determined by PCR-PASA. The Hardy Weinberg test was validated by a X2. Results: This study population shows the presence of ancestral (G) and the reference (A) allele. The MAF rate, as well as heterozygosity index was estimated. The allele and genotype distribution is in Hardy Weinberg equilibrium, beging similar to the European and Asian populations. The populations here studied differs of native Africans, which ancestral allele is the most frequent. No carriers were found with homozygote G genotype. However northwestern mestizos show the expected distribution, having more Spanish ancestry. Conclusions. This study suggests that the ancestral allele from g.37190613G>A polymorphism, was lost during miscegenation of the different ethnic groups after the conquest of México. The allele A is now cosidered as a wild-type, transmitted by Negroid Asians and Spanish whose arrived in the Costa Chica and Southern Lowlands, in the 16th and 17th century as well as its a relationship with an increased risk of diebetic nephropathy in Mexican population.

Genetics of sphingolipids in hypertension

M. Fenger[1], *A. Linneberg*[2], *J. Jeppesen*[2];

[1]*University of Copenhagen, Hvidovre, Denmark,* [2]*University of Copenhagen, Glostrup, Denmark.*

Several attempts to decipher the genetics of essential hypertension have been done, but only a few genes have been identified. Unsolved population heterogeneity and the insufficiency of the prevailing monogenic approach to capture genetic effects in a polygenic condition are the main reasons for the modest results obtained. The physiologically heterogeneity of diastolic and systolic blood pressures was resolved by partition of the study population by combined latent class analysis and structural equation modelling into an ensemble of 14 physiological more homogeneous subpopulations. Two-gene interactions were evaluated for the sphingolipid metabolic network, and he phosphatidate and redox metabolic networks by variance decomposition and by a information theory approach. On average more than 5,000 highly significant interactions were detected by variance decomposition in each of the subpopulations including 160 single nucleotide polymorphisms (SNP) in 82 genes. The number of interactions were reduced to less than 0.5% by only including interactions with significant mutual information. The analysis suggests that acid ceramidase and sphingosine kinase-1 to be functional hubs in blood pressure regulation.

Of the 675 interactions with significant weighted mutual information 38 increased the prevalence of hypertension (diastolic and/or systolic), while 27 decreased the prevalence of hypertension in the study population. These interactions included genes from the networks mentioned above in a complex pattern of specific genotypes. Thus, the sphingolipid metabolic network was established to be of significance in regulating the blood pressure by itself and by integrated interaction with the phosphatidate and redox genetic networks.

Comparison of multi- and single-sample variant calling in high-coverage exome data

J. A. B. Floyd, *A. Hendricks, L. Crooks, K. Walter, S. McCarthy, C. A. Anderson;*
Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Genetic variants are typically ascertained on a 'per sample' basis following high-coverage exome sequencing,. However, calling variants simultaneously across all sequenced individuals better captures shared genetic variants and yields more accurate genotype calls at these sites. As a result, this approach has recently been proposed for calling genotypes following exome sequencing. However, when studying rare phenotypes the focus is typically not on shared genetic variation but on very rare or private mutations. The utility of multi-sample calling for the ascertainment of such variants remains unclear.

Using data from the UK10K project, we make direct comparisons across almost 1,000 exomes called using both single-sample (SAMtools and GATK) and multi-sample calling (SAMtools). We compare how well each method identifies variants across the minor allele frequency spectrum (including singletons) in terms of the number of called variants (sensitivity), and the quality of these calls (specificity) (using the Ti/Tv ratio as a proxy for quality). Comparisons between the two approaches are performed across a range of variant quality score recalibration (VQSR) filtering thresholds

Preliminary analyses suggest that while multi-sample calling provides three to four times more variants unique to this method (depending on the VQSR threshold), the quality of these variants is considerably lower (Ti/Tv ~1.6) than those variants unique to single-sample calling (Ti/Tv ~2). In addition, single-sample calling provides around 5% more singleton variants per sample. Analyses are still ongoing with aim of ascertaining the best approach for accurately calling very rare or private mutations following exome sequencing.

Heterozygosity in familial Mediterranean fever is not causal but represents a susceptibility factor for clinically-similar complex disorders

I. Jéru[1,2,3], *E. Cochet*[3], *G. Le Borgne*[1,2], *P. Duquesnoy*[1], *E. Grimprel*[3,2], *K. Stankovic Stojanovic*[4], *S. Karabina*[1,2], *G. Grateau*[4,2], *V. Hentgen*[5], *S. Amselem*[1,2,3];
[1]*INSERM UMRS_933, Paris, France,* [2]*Université Pierre et Marie Curie-Paris6, UMR_S933, Paris, France,* [3]*Assistance Publique Hôpitaux de Paris, Hôpital Trousseau, Paris, France,* [4]*Assistance Publique Hôpitaux de Paris, Hôpital Tenon, Paris, France,* [5]*Centre Hospitalier de Versailles, Service de Pédiatrie, Le Chesnay, France.*

Background. Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disorder due to *MEFV* mutations and one of the most frequent Mediterranean genetic diseases. The observation of many heterozygous patients in whom a second mutated allele was excluded led to propose that heterozygosity could be causal; however, this might often be coincidental due to high rate of mutations in Mediterranean populations.

Objective. To better delineate the pathogenicity of heterozygosity in order to help genetic counselling and better manage the disease.

Methods. Complementary statistical approaches were used: genotype comparison in siblings from 24 familial forms, estimation of FMF prevalence at population levels, genotype study in 557 patients from four Mediterranean populations.

Results. Nearly all affected siblings of probands carrying two *MEFV* mutations also carry two mutated alleles. At population level, we did not observe any contribution of heterozygosity to the disease prevalence. However, patients are more prone to be heterozygous as shown by the higher ratio heterozygous carriers/non carriers in patients than in healthy individuals ($p<10^{-7}$-$p<0.003$). The risk for heterozygotes to develop FMF was estimated between 5.10^{-3} and 2.10^{-2} and the relative risk between 4.6 and 8.4. Finally, heterozygous patients were frequently part of families displaying a complex mode of disease inheritance.

Conclusions. This is the first statistical demonstration that heterozygosity is not responsible for classical Mendelian FMF, but constitutes a susceptibility factor for clinically-similar complex conditions. We also provide a first estimate of the risk for heterozygotes to develop FMF.

The Mutation Analysis of the *MEFV* Gene in Patients With Familial Mediterranean Fever in Turkey

F. A. Pinarli, *A. Yesilyurt, N. Eyerci, D. Erdogan, Z. Firat, M. Caliskan;*
Dışkapı Yıldırım Beyazıt Traning and Research Hospital, Ankara, Turkey.

Purpose: Familial Mediterranean Fever (FMF) is a chronic inflammatory disease with otosomal recessive inheritance characterized by recurrent acute periods of fever, abdominal pain, rash and polyserositis. The mutations of the gene encoding pyrin protein play an important role in the etiology of the disease. In this study, we analyzed the MEFV mutations the patients referred to our center with a diagnosis of FMF according to the criteria of Tel- Hashomer.

Materials and Methods: We screened the mutations of the most frequently affected exons (2, 3, 5, 10) of the MEFV gene with DNA sequence analysis in 217 patients referred in Diskapi Yıldırım Beyazit Training and Research Hospital ,The Center of Genetic Diagnosis, Ankara, Turkey. The demographic and clinical data with pedigree analyses of the patients were performed with chi-square and fisher exact tests.

Results: Total 31 different mutations were found in the screened exons of 207 patients. The most frequent mutations were M694V, V726A, E148Q, and M680I. The most common clinical symptoms were abdominal pain, fever, and joint pain. Conclusion: FMF, occurring most commonly in Jewish, Turkish, Arabic and Armenian people, is a disease with a difficult differential diagnosis. The disease has an increasing frequency in Turkish people and is a candidate for important health problem in near future. The settling of diagnostic algorithms, the correct use of molecular methods and the exact definition of genotype-phenotype correlations will all help to reduce the number of patients with FMF waiting for the correct diagnosis.

P16.035

Origin of the Manouche gypsies in France - how did it all begin: lesson learnt from a founder mutation associated with Glanzmann thrombasthenia

M. Fiore[1], *X. Pillois*[1], *P. Nurden*[1], *A. T. Nurden*[1], *F. Austerlitz*[2];
[1]*Centre de Référence des Pathologies Plaquettaires, Plateforme Technologique d'Innovation Biomédicale, Hôpital Xavier Arnozan, Pessac, France,* [2]*Laboratoire d'Eco-Anthropologie et Ethnobiologie, UMR 7206 CNRS/MNHN/Universite Paris 7, Museum National d'Histoire Naturelle, Paris, France.*

The c.1544+1G>A substitution at the 5′ splice donor site of intron 15 of the ITGA2B gene, called the French Gypsy mutation, causes Glanzmann thrombasthenia, an inherited hemorrhagic disorder transmitted as an autosomal recessive trait and characterized by an altered synthesis of the platelet αIIbβ3 integrin. So far, this mutation has only been found in affected individuals originating from French Manouche families, strongly suggesting a founder effect. Our goal was to investigate the origin of the French Gypsy mutation. We estimated the age of the mutation by a likelihood-based method that uses the length of the shared haplotypes among a set of patients. For this, we genotyped 23 individuals of Manouche origin; consisting of 9 Glanzmann thrombasthenia patients homozygous for the French Gypsy mutation, 6 heterozygous carriers and 8 homozygous wild-type individuals. They were genotyped for four single-nucleotide polymorphisms using high-resolution melting curve analysis, and for two CA repeats in the BRCA1 and THRA genes at chromosome 17, using fragment analysis gels. We found that a haplotype of five polymorphic loci covering a 4-cM region was strongly associated with the French Gypsy mutation, suggesting a founder effect. The estimated age of this founder mutation was 300-400 years (range 255-552 years). Thus, all carriers of the French Gypsy mutation c.1544+1G>A at intron 15 descended from a common ancestor 300-400 years ago. Finally, on the basis of our results, we will also detail in this work the possible migration history of the Manouche gypsies in France.

Phospholamban p.Arg14del mutation causes arrhythmogenic cardiomyopathy

*P. A. van der Zwaag[1], I. A. W. van Rijsingen[2], R. de Ruiter[1], **E. A. Nannenberg**[2], J. A. Groeneweg[3], J. G. Post[3], R. N. W. Hauer[3], I. C. van Gelder[1], M. P. van den Berg[1], P. van der Harst[1], A. A. M. Wilde[2], J. P. van Tintelen[1];*
[1]UMCG, Groningen, Netherlands, [2]AMC, Amsterdam, Netherlands, [3]UMCU, Utrecht, Netherlands.

Background. Recently, we showed that the c.40_42delAGA (p.Arg14del) mutation in the phospholamban (PLN) gene can be identified in 10-15% of Dutch patients with dilated cardiomyopathy or arrhythmogenic cardiomyopathy. The arrhythmogenic burden of the p.Arg14del mutation was illustrated by the high rate of appropriate ICD discharges and a positive family history for sudden cardiac death.
Methods. Our goal was to evaluate the geographical distribution and the origin of this mutation and to estimate the prevalence in a Dutch population cohort. We investigated the postal codes of the places of residence of p.Arg14del mutation carriers and places of birth of their ancestors. In addition, a large population-based cohort (PREVEND) was screened for this mutation.
Results. By April 2012, we had identified 101 probands carrying the PLN p.Arg14del mutation. A total of 358 family members were also identified, resulting in a total of 459 mutation carriers. The majority of mutation carriers live in the northern part of the Netherlands and analysing their grandparents' places of birth indicated that the mutation likely originated in the eastern part of the province of Friesland. In the PREVEND cohort we identified six heterozygous PLN p.Arg14del mutation carriers out of 8,267 subjects (0.07%).
Conclusion. The p.Arg14del mutation in the PLN gene is the most frequently identified mutation in Dutch cardiomyopathy patients. The mutation that arose 575-825 years ago is likely to have originated from the northeastern part of the province of Friesland and is highly prevalent in the general population in the northern part of the Netherlands.

P16.037

Characterization of CCG repeats in *FMR1* gene and risk for Fragile X syndrome (FXS) among Ashkenazi population.

*K. Weiss[1], A. Orr-Urtreger[1,2], T. Naiman[1], E. Bardugo[1], Y. Yaron[1,2], **S. Ben-Shachar**[1];*
[1]Tel Aviv Medical Center, Tel Aviv, Israel, [2]Tel Aviv University, Tel Aviv, Israel.

Introduction: FXS is the most common cause of inherited intellectual disability. FXS is usually caused by CGG trinucleotide expansion in *FMR1* gene. Normal alleles have < 55 CGG repeats. Premutation alleles (55-200 repeats) may expand to full mutations (>200 repeats) in female meiosis. In addition, interspersed AGG repeats decrease the risk while un-interrupted CGG repeats are associated with allele instability and expansion. FXS carrier rate varies in different populations. This study describes the carrier rate and stability of *FMR1* alleles in a large cohort of Ashkenazi women.
Methods: 4344 Ashkenazi and 4985 non-Ashkenazi females without a family history of FXS or intellectual disability were analyzed for CGG repeats using Southern-blotting and PCR. AGG interruptions were evaluated in 326 Ashkenazi and 298 non-Ashkenazi using Amplidex® kit.
Results: Both populations showed two major peaks of 30 and 29 repeats. Ashkenazim had higher frequency of 30 repeats, and lower frequency of other peaks (P <0.0001). Significant higher rate of premutation allels was detected among Ashkenazi, only in 55-59 repeats' range (1:114 versus 1:277 in non-Ashkenazi). Loss of AGG interruptions (<2) was less common in Ashkenazi with normal alleles compared to non-Ashkenazim (9% versus 19% , p= 0.0002).
Discussion: While Ashkenazi females have high carrier rate of FXS, most Ashkenazi carriers have a low-range premutation allele, that carries a low risk of expansion to a full mutation. In addition, normal size allele have increased stability in Ashkenazim compare with non-Ashkenazim. Thus the risk for offspring with FXS may be lower than expected in Ashkenazim.

P16.038

The FTO gene polymorphisms are associated with body composition and bone mineral content in the Chinese postmenopausal women

M. Lin[1,2], *H. Wu[3], L. Chen[1], L. Hsiao[4], C. Hwu[4];*
[1]Institute of Public Health, National Yang-Ming University, Taipei, Taiwan, [2]Department of Medical Research and Education, Taipei Veterans General Hospital, Taipei, Taiwan, [3]Department of Radiology, Taipei Veterans General Hospital, Taipei, Taiwan, [4]Section of Endocrinology and Metabolism, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Genome-wide association studies have identified *FTO*, *ACACB*, *SEC16B*, *MC4R*, and *CDKAL1* genes that can contribute specifically to the risk of abdominal adiposity. However, it is unknown whether these genetic factors affect relative body fat distribution in the abdominal visceral and subcutaneous compartments. To investigate the association between *FTO*, *ACACB*, *SEC16B*, *MC4R*, and *CDKAL1* gene polymorphisms and body composition in the Chinese postmenopausal women, five hundred and fifteen post-menopausal women were recruited and 99 of them were followed-up within duration of 2 years. Body composition and fat distribution were measured by dual-energy x-ray absorptiometry (DEXA). Three SNPs of the *FTO* gene and five SNPs from *ACACB*, *SEC16B*, *MC4R*, and *CDKAL1* genes were selected for genotyping on these post-menopausal women. We found that post-menopausal women carrying TT genotype of FTO rs14211085 increased their BMI by 0.67, while those carrying CC+CT genotype decreased BMI by 0.59 during a period of two years (p=0.017). We also found that the waist circumference of women carrying CT+TT genotype of *ACACB* rs2239607 was significantly increased by 3.48 cm compared with their counterparts (0.30 cm) during a period of two years (p=0.012). We further observed that post- menopausal women carrying GA+GG genotype of *FTO* rs9930506 had significantly higher total lean tissue as well as bone mineral content compared with their counterpart (p<0.05). Moreover, women bearing CC+CT genotype of *FTO* rs14211085 had significantly higher bone mineral content compared with their counterpart. Our findings provide initial evidence that the FTO may contribute to body composition and bone mineral content.

P16.039

Use of genetic data in Europe: balancing informed consent and research freedom

E. Rial-Sebbag[1], *G. Chassang[1], E. S. Dove[2], A. Cambon-Thomsen[1];*
[1]INSERM UMR 1027, Toulouse, France, [2]Centre of Genomics and Policy, Department of Human Genetics, Faculty of Medicine, McGill University, Montreal, QC, Canada.

The EU Commission proposal for a Regulation revising the protection of individuals with regards to the processing of personal data (Com (2012) 11 final) (the "Regulation"), was launched in early January 2012 in order to remedy the legal uncertainty stemming from fragmentation in the way personal data protection was implemented across Member States. Another key issue was to increase the Regulation's ambit to better cover emerging fields resulting from rapid technological developments. Since January 2012, the Council of the EU and the European Parliament (December 2012) have proposed amendments that will have important consequences for medical research, especially since they concern data processing "for historical, statistical and scientific research purposes" (art.83) and notably in the context of health (art.81). Also, the Regulation now separately defines and regulates "genetic data" by including it as sensitive data having new legal ramifications for the way researchers can conduct their studies. Moreover, informed consent ("IC") procedures have been reinforced as they are seen as the only way to protect the autonomy of research participants. Consequently, IC has to be "freely given specific, informed and explicit"; which may nullify most of the current exceptions designed for research, ignoring the specific, unique nature of long term genetic research. An emphasis on IC to protect autonomy ignores many other available governance mechanisms (e.g. information disclosure, transparency, etc.). Indeed, transparent information exchange better balances informed consent and research freedom and should therefore be considered the best option for promoting and protecting fundamental human rights.

P16.041

Frequencies of the GJB2 gene mutations in genetic non syndromic hearing loss patients from Eastern Sicily .

M. Amorini, *S. Romeo, P. Romeo, C. Di Bella, F. Pugliatti, S. Cara, V. Procopio, C. Liuzzo, C. Salpietro, L. Rigoli;*
Department of Pediatrics, Medical School, Messina, Italy.

Genetic nonsyndromic hearing loss (NSHL) is a pathological condition present in 1-2/1000 neonates. The inheritance pattern is autosomal recessive (80%) (DFNB), autosomal dominant (17%) (DFNA), X-linked (2-3%) (DFN) and mitochondrial (<1%). In Caucasian and European populations, NSHL are attributable to mutations in the *GJB2* gene that encodes connexin 26 protein (CX26). In the cochlea, CX26-containing gap-junctions are proposed to maintain K^+ homeostasis between outer hair cells and endolymphatic space during the auditory transduction.
The aim of our study was to determine the prevalence and the spectrum of the *GJB2* mutations in NSHL patients from Eastern Sicily.
In this study, a group of 196 unrelated NSHL patients (age range, 4-40 years) (43 females and 110 males) was enrolled and was age-sex matched with 196 healthy subjects. All patients underwent age-specific audiological evaluation. DNA samples were analyzed for allelic variants in the coding exon of the *GJB2* gene by PCR amplification and direct sequencing. The sequencing samples were compared with a wild type sequence obtained from the site http://www.ncbi.nlm.nih.gov/gene/2706 (NG_008358.1 RefSeqGene).
In our patients, the molecular analysis of the *GJB2* gene showed different mutations: the 35delG deletion (16%), the R184W (6%) and 167delT (4%) genetic variants. Moreover, V153I, W24X, E47X and M163V mutations encountered with a frequency of 2%. The frequency of the 35delG was significantly different from the control group (p<0.001), as well as the other mutations (p<0.01). We also found the M163V mutation, a very rare variant that we here described for the third time in the world literature.

P16.042

Interaction of a genetic risk score of triglyceride risk variants and measures of insulin sensitivity on fasting serum triglyceride levels in a Danish population

J. M. Justesen[1], *C. H. Sandholt*[1], *K. H. Allin*[1], *A. Borglykke*[2], *N. T. Krarup*[1], *T. Sparsø*[1], *T. Jørgensen*[2,3,4], *T. Hansen*[1,5], *O. Pedersen*[1];
[1]*The Novo Nordisk Foundation Center for Basic Metabolic Research, Section of Metabolic Genetics, Copenhagen, Denmark,* [2]*Research Centre for Prevention and Health, Glostrup University Hospital,, Glostrup, Denmark,* [3]*Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [4]*Faculty of Medicine, University of Aalborg, Aalborg, Denmark,* [5]*Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark.*

Background: Thirty-two susceptibility loci have in meta-analyses been shown to associate with serum triglyceride at genome-wide significance levels. To test the hypothesis that the impact of a genetic risk-score (GRS) of validated triglyceride risk variants may be modulated by the level of whole-body insulin-sensitivity or specific environmental factors we constructed an unweighted (uw-GRS) and a weighted GRS (w-GRS).
Methods: A total of 31 variants were genotyped in 6,784 individuals from the Inter99 study-population. Individuals receiving lipid-lowering medication were removed (n=80). In a cross-sectional design, we investigated whether BMI, measures of insulin sensitivity (HOMA-IR, $ISI_{matsuda}$ and BIGG-SI) or lifestyle factors (alcohol consumption, physical activity, diet and smoking) interact with the effect of the GRS on fasting serum triglyceride levels.
Results: Fourteen risk variants associated with increased triglyceride levels (p<0.05), having per allele effect sizes ranging from 1.8%-14.9%. The uw-GRS and w-GRS associated with triglyceride levels with a per allele increase of (OR[95%CI]) 2.6%(2.2-3.0), $p=2.1\times10^{-42}$ and 0.7%(0.6-0.8), $p=3.9\times10^{-78}$, respectively. We demonstrated an interaction between the w-GRS and BMI ($p=6.5\times10^{-3}$), HOMA-IR ($p=2.6\times10^{-4}$), $ISI_{matsuda}$ ($p=2.0\times10^{-4}$), and BIGG-SI ($p=3.3\times10^{-3}$) in relation to triglyceride levels. Hence, the GRS had a stronger effect among individuals who were insulin resistant. We found no interaction with any of the lifestyle factors. Similar results were obtained for the uw-GRS.
Conclusion: Our findings suggest that individuals who are insulin resistant may be more susceptible to the cumulative genetic burden of the triglyceride variants. Therefore, these genetically-destined at-risk individuals may benefit more from targeted interventions that aim at increasing insulin sensitivity.

P16.043

Impact of a genetic risk score on incidence of coronary artery disease and myocardial infarction and fasting serum lipids in a prospective population-based cohort of 6,127 Danish individuals

N. T. Krarup[1], *A. Borglykke*[2], *K. H. Allin*[1], *C. H. Sandholt*[1], *E. A. Andersson*[1], *J. M. Justesen*[1], *T. Jørgensen*[2,3,4], *O. Pedersen*[1], *T. Hansen*[1,5];
[1]*University of Copenhagen, Center for Basic Metabolic Research, Copenhagen, Denmark,* [2]*Research Centre for Prevention and Health, Glostrup, Denmark,* [3]*Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark,* [4]*Faculty of Medicine, University of Aalborg, Aalborg, Denmark,* [5]*Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark.*

Abstract
Background: Genome-wide association studies have identified genetic risk-variants of coronary artery disease (CAD). We aimed to estimate the effect of a genetic risk score on 1) incidence of CAD and myocardial infarction (MI), and 2) baseline fasting serum lipid traits.
Methods: Data on genotype and quantitative traits was available in the population-based Inter99 study (n_{total}=6,127). Information on CAD (n_{cases}=374) and MI (n_{cases}=124) was obtained from national registries (mean follow-up=11.6 years). Participants were array-genotyped with the HumanCardio-Metabo- or Humanexome-chip for 34 CAD risk-variants. A genetic risk score (GRS) was calculated as sum of risk-variants. Risk of MI and CAD were calculated using a Cox regression-model automatically adjusted for age.
Results: The sex-adjusted GRS associated with incidence of MI and CAD (effect per GRS tertile HR[95%CI]= 1.27[1.01 - 1.59], p=0.04, and 1.19[1.05 - 1.36], p=0.007, respectively). Adjustments for sex, BMI and smoking-status showed association (HR[95%CI])= 1.28 [1.02 - 1.60], p=0.03 and 1.20[1.06 - 1.37], p=0.005, respectively). For the same model, the GRS associated with total cholesterol (β[95%CI]: 11.6%(8.3 - 14.9), $p=7.58\times10^{-13}$), serum triglycerides (2.7%(1.2 - 4.2), $p=4.2\times10^{-4}$), LDL-cholesterol (9.2%(5.0 - 13.5), $p=2.25\times10^{-5}$), triglyceride/HDL ratio (3.6%(1.7 - 5.6), $p=2.1\times10^{-4}$) and remnant cholesterol (3.2%(1.2-5.2), p=0.002). The GRS showed a nominal association with HDL-cholesterol (-1.1%(-2.24 -0.01), p=0.053). Finally, association of GRS on MI- and CAD-incidence was adjusted for total cholesterol and systolic blood-pressure (1.26[1.01-1.59], p=0.04 and 1.19[1.05-1.36], p=0.008, respectively).
Conclusion: A CAD GRS influences classical MI-risk factors suggesting that observed increased risk of CAD and MI could partly be mediated through altered lipid levels.

Multiple Endocrine Neoplasia syndrome type 1 (MEN1) is a rare disease secondary to mutations in MEN1 and predisposes to endocrine tumours. Although genotype-phenotype studies failed to identify a statistical correlation, some families harbour recurrent tumoral patterns. This is the first genotype-phenotype correlation study in MEN1 disease considering a time dependent statistical analysis, testing intra-familial correlation and evaluating the impact of the mutation localization in MENIN interacting domains in a large cohort. We report on the MEN1 cohort from the GTE network. Patients with MEN1 mutation and clinical follow up were included, i.e. 262 families, 806 patients. Mutations type, localization and 9 interacting factors of the MENIN protein were compared to occurring tumor types and death ages. The genotype-phenotype study was performed using a frailty Cox model

with gender adjustment and FDR correction procedure. The intra-familial correlation was assessed using a dedicated statistical method. There was no significant correlation between mutation type or localization and the different phenotypes. Overall survival was significantly reduced when mutations affected the JunD interacting domain (HR=2.13 (CI-95%[1.26; 3.60]). Patients had a higher risk of death from cancer of the MEN1 spectrum (HR=2.44 (CI-95%[1.25; 4.77]). Intra-familial correlation was demonstrated and completed with estimates of the heritability coefficients for tumor types. This result suggests that loss of interaction between JunD and MENIN ought to be a modifying factor of the disease expressivity and might result in the development of more aggressive tumors. This study highlighted the intrafamilial correlation, and helps follow up and care for MEN1 families.

How diverse is GJB2 in Portugal?

J. R. Chora[1], *A. C. Gonçalves*[1], *T. D. Matos*[1], *H. Simões-Teixeira*[1], *G. Fialho*[1], *H. Caria*[1,2];
[1]*Centre for Biodiversity, Functional, and Integrative Genomics (BioFIG), Faculty of Science, University of Lisbon, Lisboa, Portugal,* [2]*School of Health, Polytechnic Institute of Setúbal, Setúbal, Portugal.*

To anyone acquainted with the genetics of deafness, GJB2 is the most familiar and well known gene, in which novel mutations are still being found. From the beginning it became clear that some GJB2 mutations are more prevalent in certain world regions or ethnicities and nowadays, with more than 200 different mutations, polymorphisms and novel variants described, population specificity is even more evident. Thus, when faced with probands requiring GJB2 diagnosis or genetic counseling, it is very helpful to have full knowledge of mutation prevalence in their region of origin.
Previous studies concerning deafness genetics in Portugal, and focusing on GJB2, have suggested that mutation spectrum of this gene in our population it's not exactly like other Mediterranean or western European countries. Portuguese history may explain part of this specificity.
In this study we set out to extend the investigation on GJB2 mutation prevalence in the general population by screening about 900 random neonates from different Portuguese regions in a thorough representation of our country's population. Screening of GJB2 gene was performed by sequencing the entire coding region. GJB6 deletions del(GJB6-D13S1830) and del(GJB6-D13S1854) were tested by multiplex PCR.
A great variability of GJB2 variants was observed and some interesting regional differences were found, supporting our previous studies. The prevalence and distribution of those variants will be discussed in detail, and compared with the rest of Europe and other world populations.

The Malta BioBank and the Maltese Genome Project

J. Vella[1], *A. Fiott*[1], *C. Mizzi*[1], *J. Borg*[2], *M. Bugeja*[1], *R. Galdies*[1], *W. Cassar*[1], *J. Scerri*[1], *C. Scerri*[1], ***A. Felice***[1];
[1]*University of Malta, Laboratory of Molecular Genetics, Faculty of Physiology & Biochemistry, Msida, Malta,* [2]*University of Malta, Faculty of Health Sciences, Msida, Malta.*

The Malta BioBank is the first national archive of biological samples. It houses a population bank and a clinical bank with specific collections. The population bank has a very large collection of random Maltese neonates, pooled neonatal samples, multiple births and senior citizens. The clinical bank has specific collections such as the Globin Bank, the Coeliac collection, the Parkinson's collection, the Diabetes collection and a small collection of rare diseases e.g. cystic fibrosis.
The two main projects of the biobank are: 1) the Globin Bank which includes abnormal haemoglobins (Hb) and thalassaemia in the Mediterranean and genetic control of globin gene expression; and 2) the Maltese Genome Project which includes origins, mobility and genetic epidemiology of the Maltese population for gene discovery research.
The Globin Bank currently holds more than 250 Hb F Malta I ($p.\alpha_2G\gamma_2117Arg$) carrier samples and other samples with haemoglobin variants such as Hb F Sardegna ($p.\alpha_2A\gamma_275Thr$). The F Malta I variation has been found to be in tight linkage disequilibrium with the adult Hb variant Hb Valletta ($p.\alpha_2\beta_287Pro$).
A unique family with HPFH was found to be haplo-insufficient in the transcription factor KLF1 (p.K288X) on chromosome 19.

From GWAS to WGS: a whole-genome association study in 250 trios of the Genome of the Netherlands Project.

J. van Setten[1], *S. L. Pulit*[1], *L. C. Francioli*[1], *A. Menelaou*[1], *P. Deelen*[2], *L. Karssen*[3], *E. Slagboom*[4], *D. I. Boomsma*[5], *C. M. van Duijn*[3], *C. Wijmenga*[2], *M. Swertz*[2], *P. I. W. de Bakker*[1], *Genome of the Netherlands Consortium;*
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*University Medical Center Groningen, Groningen, Netherlands,* [3]*Erasmus Medical Center, Rotterdam, Netherlands,* [4]*Leiden University Medical Center, Leiden, Netherlands,* [5]*VU University Amsterdam, Amsterdam, Netherlands.*

Introduction: The Genome of the Netherlands Project (GoNL) was set up to characterize genomic variation in 250 pedigrees of Dutch ancestry. 231 trios and 19 quartets were sequenced at medium depth of coverage (>12x) by BGI (Shenzhen, China). We explored how this whole-genome sequencing data set could be used for an association analysis with height, weight, body mass index (BMI), and lipid traits (LDL-C, HDL-C, triglycerides, and total cholesterol).
Methods: We included 748 samples in the association analysis and called 19,763,454 bi-allelic SNPs. We excluded SNPs based on Hardy-Weinberg equilibrium ($P < 1 \times 10^{-6}$) and minor allele frequency < 1%, leaving 8,337,919 SNPs for further analysis. We used FaST-LMM to incorporate family structure in the association testing.
Results: No SNPs reached genome-wide significance ($P \leq 5 \times 10^{-8}$) for any trait. There was no evidence of population stratification or inflated type 1 error rate. Testing loci previously associated with the traits studied, we observed a clear excess of significant associations with the expected direction of effect. We also tested various gene-based tests, and explored how to correct effectively for the correlated test statistics.
Discussion: Power to test for association is limited with a small sample size. Nevertheless, we were able to replicate a bulk association signal for known loci of all phenotypes studied. We expect that the primary value of the GoNL whole-genome sequencing panel will be for imputation in much larger samples already genotyped in the GWAS era.

TWB1802, the first release of GWA control samples from Taiwan BioBank

C. Chen, *C. Hsiung, P. Wu, J. Wu, C. Shen;*
Taiwan BioBank, Academia Sinica, Taipei, Taiwan.

A population-specific reference is essential for hunting disease genes and developing personalized medicine. About 2% of the 23 million Taiwan residents population are the aboriginal peoples, belonging to the Austronesian family, while the majority is of Han-Chinese ancestry. Taiwan BioBank aims to build a national-wide biomedical research database that integrates genomic profiles, life styles and environment information of 300,000 Taiwan residents. Currently, Taiwan BioBank targets on disease gene-mapping using a genome-wide association (GWA) study approach. This study is set to conduct a population-specific reference that may serve as a global control sample for future GWA studies of diseases in the Taiwan population. A total of 2090 DNA samples, including 158 replicates, are randomly selected from a cohort study of the Taiwan BioBank and genotyped using the TWB array, which is designed for the Taiwan population by Taiwan BioBank. After removing replicates and samples with cryptic kinships, 1802 un-related samples are compiled as the first TWB release (TWB1802), including 899 males and 903 females. A total of 623,190 SNPs pass QC filters. Population structure analysis shows that all TWB1802 samples are clustered with the HapMap Asian groups (CHB, CHD, and JPT). Admixture analysis shows that the majority of TWB1802 may have southern or northern Han Chinese origins while some individuals show signals of admixture of Han Chinese and Austronesian origins. A publically-accessible web-based calculation platform, Taiwan View (http://taiwanview.twbiobank.org.tw/taiwanview/twbinfo.do) is built to perform on-line GWA analysis using TWB1802 as a control group. Further expansion with more than 20,000 Taiwanese samples is undergoing.

Genetic and environmental factors involved in normal hearing function and age-related hearing loss

G. Girotto[1], *D. Vuckovic*[1], *A. Buniello*[2], *M. Lewis*[2], *K. P. Steel*[2], *P. Gasparini*[1];
[1]*Dept of Developmental and Reproductive Sciences;IRCCS-Burlo Garofolo-Children Hospital-University of Trieste, Trieste, Italy,* [2]*FMedSci, FRS, Wolfson Centre for Age-Related Diseases, King's College London, Guy's Campus, London, London, United Kingdom.*

The vast majority of genetic and environmental/lifestyle factors underlying normal hearing function and age-related hearing loss (ARHL) remain to be identified. To reach this goal we decided to run 1) a series of Genome Wide Association Studies (GWAS) on hearing traits and ARHL, 2) expression studies by immunohistochemistry and confocal microscopy in wildtype mice on a list of 24 genes identified by GWAS, 3) a search for environmental/lifestyle factors (i.e. degree of education, smoking and drinking habits) by epidemiological studies.
Up to now, using a series of isolated populations/communities coming from Europe, Caucasus and Central Asia for an overall number of 3815 individuals, two GWAS for hearing quantitative traits (one sex separated), and one GWAS for ARHL have been performed. By meta-analyzing data some significant and suggestive loci (p≈10-8,10-7) have been found. As regards expression studies, 5 genes (Arsg, Slc16a6, Dclk1, Gabrg3, Csmd1) out of the 24 selected ones show strikingly specific expression in the cochlea, while additional 8 (Ptprd, Grm8, Kiaa056/GlyBP, Evi5, Irg1, Rimbp2, Ank2, Cdh13) display expression in multiple cell types of the cochlea. As regards environmental/lifestyle factors, the epidemiological analyses revealed that among all the investigated variables, coffee consumption was associated at low and high frequencies (p=0.006) while the intake only at high frequency (p=0.003) in 4 out of 10 countries investigated. Moreover, a statistical significant association between ARHL and level of education was detected (p=0.0003) confirming previously reported data. Additional studies are in progress to further confirm and expand present results.

Thresholds for significance in GWAS used in practice: a systematic analysis

A. Jannot[1], *G. Ehret*[2], *T. Perneger*[1];
[1]*CRC & Division of clinical-epidemiology, Department of health and community medicine, University of, Geneva, Switzerland,* [2]*Cardiology Center, University Hospitals of Geneva, Geneva, Switzerland.*

Background: In genome-wide association studies (GWAS), an association is considered as significant if its p-value is below the genome-wide threshold of significance. The choice of a threshold requires a fine balance between power and the risk of false positives and the current practice for this choice has not been systematically described. We conducted a systematic analysis to describe genome-wide significance thresholds in published GWA studies.
Materials and methods: We identified all GWASs published during the first half of 2011 and retrieved the genome-wide threshold of significance as stated by the authors. Most GWAS were followed by a replication stage in an independent sample, and we also systematically extracted the threshold for a SNP to be included in the replication stage.
Results: We identified 167 published GWASs over the study period. One third of studies (56) did not cite any significance threshold for their results. Sixty-seven studies (40%) considered $5x10^{-8}$ as genome-wide significant threshold. For the remaining 44 studies, the thresholds were more liberal (median 10^{-7}). A replication stage was performed in 122 GWASs. Thresholds to include SNPs in a replication stage were liberal (median 10^{-5}), varied considerably between studies, and were justified in only 14 studies (11%).
Conclusion: The most commonly used genome-wide threshold was 5x10-8, although reported in less than half of the manuscripts. No consensus emerged for the choice of the threshold to include SNPs in a replication stage. Establishing recommendations for thresholds would increase the interpretability of positive signals reported in the literature.

A meta-analysis of genome-wide association studies identifies a novel locus associated with thrombin generation potential

A. Rocanin-Arjo[1], *L. Carcaillon*[2], *W. Cohen*[3], *N. Saut*[3], *M. Germain*[1], *L. Letenneur*[4], *M. Alhenc-Gelas*[5], *A. Dupuy*[6], *M. Bertrand*[7], *P. Amouyel*[8], *P. Scarabin*[2], *D. Trégouët*[1], *P. Morange*[3];
[1]*INSERM, Paris, France,* [2]*INSERM, Villejuif, France,* [3]*AP-HM, Marseille, France,* [4]*INSERM, Bordeaux, France,* [5]*AP-HP, Paris, France,* [6]*INSERM, Montpellier, France,* [7]*UPMC, Paris, France,* [8]*Institut Pasteur, Lille, France.*

High thrombin generation levels have been associated with the risk of venous thrombosis and ischemic stroke. In order to investigate the genetic architecture underlying the inter-individual variability of thrombin generation, we measured three quantitative biomarkers for thrombin generation, the Endogeneous Thrombin Potential (ETP), the Peak height and the Lag-time in two independent samples, the Three City Study and MARTHA, with genome-wide genotype data. By applying an imputation strategy based on the 1000 Genomes project to these two samples totalling 2,100 individuals inferred for ~6,6M markers, genome-wide significant associations were observed for ETP and Peak at the F2 gene ($p = 4.62\ 10^{-22}$ and $p = 1.05\ 10^{-8}$, respectively), a well-established susceptibility locus for thrombin generation. Further conditional analysis on the F2 signal revealed suggestive evidence ($p < 10^{-6}$) at 6 additional independent single nucleotide polymorphisms (SNPs) for at least one of the three phenotypes. These 6 SNPs were tested for replication in a third independent sample of 800 individuals part of the MARTHA12 study. For one SNP located on chromosome 9, the association with Lag-time was highly significant ($p = 3.26\ 10^{-7}$). When the results of the three data sets were combined, the overall evidence for association of the chr. 9 locus with Lag-time reached $p = 1.35\ 10^{-11}$. This locus has never been reported associated to thrombin generation, paving the way for novel mechanistic pathways in the aetiology of thrombotic disorders.

Replication of GWAS identification of Kawasaki disease susceptibility genes and a functional study affirm a role for BLK in disease susceptibility

Y. C. Lee[1], *C. J. Chang*[2], *H. C. Kuo*[3], *J. K. Lee*[4], *C. C. Khor*[5], *Y. T. Chen*[2], *C. H. Chen*[2], *J. Y. Wu*[2];
[1]*National Tsing Hua Univeristy, Hsinchu, Taiwan,* [2]*Academia Sinica, Taipei, Taiwan,* [3]*Kaohsiung Chang Gung Memorial Hospital, Kaohsing, Taiwan,* [4]*University of Ulsan College of Medicine,, Seoul, Korea, Democratic People's Republic of,* [5]*Genome Institute of Singapore,, Singapore, Singapore.*

SNPs in *BLK* gene, which encodes B-lymphoid tyrosine kinase, showed the most significant associations with Kawasaki disease in two recent genome-wide association studies (GWAS) of Han Chinese and Japanese populations. In this reports, we conducted a meta-analysis to combine the evidence regarding *BLK* from these two previous GWAS and further replicated the associations in Korean and European populations. A top SNP identified in Han Chinese, rs2736340 in BLK, provided compelling evidence for associations in our meta-analysess of studies in Han Chinese and Japanese ($P = 3.97\times10^{-25}$) populations, all Asian populations ($P = 4.741\times10^{-31}$), and overall population samples ($P = 1.032\times10^{-24}$). Moreover, we showed that *BLK* expression was significantly induced in white blood cells in Kawasaki disease patients at the acute stage, and the risk allele of rs2736340 expressed lower levels of BLK in lymphoblastoid cell lines. These results provide clues about the involvement of BLK in Kawasaki disease pathogenesis.

P16.053

Power comparison study of association tests with a general regression model

M. Dizier[1], *A. Philippi*[2], *C. Julier*[2], ***F. Mathieu***[2];
[1]*CEPH, UMR-S946, Paris, France,* [2]*Inserm UMR-S 958, Faculté de Médecine Denis-Diderot, Paris, France.*

Introduction: In most GWAS in the absence of information on the underlying model, the additive model is used for association studies. This may result in significant lack of power in case of strong departure from additive effect. In this case, a General regressive Model (GM), allowing to test for both additive effect and dominance deviation from additive effect, may be more appropriate for association tests.
Aims: to compare the power of GM to other classical association tests under a large panel of models.
Method: Powers were estimated by simulating 1 million replicates of 300 cases and 300 controls for 3 disease prevalence (1%, 5% and 10%), various SNP frequencies (between 0.1 and 0.5), various risk allele's genetic effect (Odds-Ratio between 1.2 and 4) and different transmission modes (recessive, dominant, additive). Four association tests: general, recessive, dominant

and additive models were applied to all replicates to estimate their respective powers to detect association.
Results: Although GM has one supplementary degree of freedom, its power to detect association is close to the power obtained by analysis under the true (simulated) model. Furthermore, GM is much more powerful than the additive model when the true genetic model is recessive. The test on dominance deviation parameter was able to estimate the correct model in more than 95% of replicates.
Conclusion: We recommended applying GM model instead of the additive model for GWAS. Reanalysis of GWAS data of multifactorial diseases using GM is likely to detect new variants that have been missed by classical methods.

Region-based association analysis of human quantitative traits in related individuals

N. M. Belonogova, *G. R. Svishcheva, Y. S. Aulchenko, T. I. Axenovich;*
Institute of Cytology & Genetics SD RAS, Novosibirsk, Russian Federation.

Regional-based association analysis instead of individual testing of each SNP was introduced in genome-wide association studies to increase the power of gene mapping, especially for rare genetic variants. For regional association tests, the kernel-machine-based regression (KMBR) approach was recently proposed as more powerful alternative to collapsing-based methods. However, the vast majority of existing methods for KMBR are applicable only to unrelated samples. We propose a new method for KMBR association analysis of quantitative traits in samples of relatives. The method is based on the GRAMMAR+ transformation of phenotypes followed by using existing KMBR software for unrelated samples (for example, SKAT). GRAMMAR+ transformation can be calculated with the 'polygenic' procedure in the GenABEL package v 1.7-2 (http://www.genabel.org/). We compared the performance of kernel-based association analysis on the material of the GAW17 by using our transformation, the original untransformed trait, and environmental residuals. We demonstrated that the distribution of the test statistic under the null hypothesis does not correspond to the declared distribution when original traits or environmental residuals are analyzed by SKAT. Only the GRAMMAR+ transformation produced type I errors close to the nominal value and had the highest empirical power. Therefore, the new method can be applied to the analysis of related samples by using existing software for KMBR association analysis developed for unrelated samples. GRAMMAR+ transformation is a computationally efficient alternative to other methods, including correction on relative structure in KMBR analysis via covariance matrix, because our trait transformation allows the use of KMBR methods with smaller computational complexity.

Searching for Hashimoto's missing heritability using Canine Lymphocytic Thyroiditis: a mission "possible"?

M. Bianchi[1], *K. Sundberg*[2], *J. Hanson*[3], *G. Andersson*[2], *Å. Hedhammar*[3], *K. Lindblad-Toh*[1,4], *G. Pielberg*[1];
[1]*Science for Life Laboratory, Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden,* [2]*Department of Animal Breeding and Genetics, Swedish University of Agricultural Sciences (SLU), Uppsala, Sweden,* [3]*Department of Clinical Sciences, Swedish University of Agricultural Sciences (SLU), Uppsala, Sweden,* [4]*Broad Institute of Harvard and Massachusetts Institute of Technology (MIT), Cambridge, MA, United States.*

Dogs are not only man's best friends in our daily life, but also in the long-term challenge of unravelling the genetics behind complex diseases. Canine lymphocytic thyroiditis (CLT), shares similarities in etiology, clinical signs and disease progression with Hashimoto's thyroiditis (HT), one of the most common autoimmune diseases in humans. The aim of our study is to identify genetic risk factors associated with canine autoimmune hypothyroidism, and to investigate these in human HT patients.
We performed a genome-wide association study using 115 Swedish Giant Schnauzer dogs (71 cases and 44 controls), considering presence of autoantibodies against thyroglobulin, increased levels of thyroid stimulating hormone (≥40 mU/l) and decreased levels of thyroxine (≤5 pmol/l) in the definition of the disease phenotype. We used kinship matrix and manual pedigree check in order to control for relatedness and applied a mixed model in the association analysis. An association on CFA11 was consistently confirmed ($p<10^{-5}$), spanning a 7 Megabase region of extensive linkage disequilibrium. An additional association, with a potentially really intriguing biological meaning, was found on CFA 18 ($p<10^{-4}$).
Once we have confirmed the associations by including more samples and identified haplotypes and genetic variants associated with the disease, we will be able to evaluate them in Hashimoto´s patients as well. Studying CLT may help solve a piece of the intricate puzzle behind the development of Hashimoto's disease, and possibly unravel a fraction of its missing heritability.

Evaluation of SNP's in promoter region of Gγ-globin gene and their relation with fetal hemoglobin in healthy individuals and sickle cell anemia patiens in Colombia.

Y. Mendoza, ***C. J. Fong****, G. Barreto;*
Universidad del Valle, Cali, Colombia.

The sickle cell anemia (SCA) is a genetic disease (autosome recessive) caused by a mutation in β-globin gene that provoke a structural change in hemoglobin. There are modulators of SCA, once is fetal hemoglobin (HbF). The HbF is a complex character, but have been identified several mutations in promotor region of Gγ-globin associated to increasing of HbF levels. The objective of this survey was evaluate SNP's in proximal promotor of Gγ-globina gene to establish markers associated to HbF expression both in sickle cell patients and healthy people in Colombia. 163 Blood samples were taken of individuals of Atlantic and Pacific colombian coasts: 49 blood samples from sickle cell patients and 114 from healthy people. 15 SNP's were evaluated, neither showed relation with modulation of HbF expression in sickle cell anemia patients, but two SNP's, -309 (A→G) and -16 (C→G) were associated to HbF in healthy people. Is possible that regulation factors in cis could be different between sickle cell patients and healthy people and therefore the SNP's evaluated here were not present in important transcriptions elements in these patients meanwhile in healthy people do.

Most association studies omit chromosome X. Here we show the benefit of testing for the associations of a dense set of chromosome X variants with metabolic and anthropometric traits.
We imputed 1,250,369 non-pseudoautosomal X chromosome markers in 19,563 individuals in seven Northern European cohorts and investigated the contribution of these variants to the levels of twelve quantitative traits (BMI, height, WHR, insulin, glucose, CRP, HDL-C, LDL-C, TC, TG, systolic and diastolic blood pressure) for which multiple associated autosomal loci have been previously identified. Using a linear mixed model we estimate that the genotyped and well-imputed chromosome X markers (MAF>1%) together account for up to 2% (for height, CRP and systolic BP) of variance in these traits. In a chromosome X-wide association analysis we identified two associations ($p<5\times10-8$): Common SNPs in two independent ($r2<0.02$) loci in Xq21.1 were associated with height. Given the potentially incomplete dosage compensation in some loci in X we evaluated gender differences in the associations: in the other height locus the effect was considerably larger in women (explained variance 0.55% and 1.09 cm difference between homozygotes in 31-year-old women) in a manner consistent with both X chromosomes being active in this locus. The associated variants have a who-

le-blood-cis-eQTL with ITM2A, a gene implicated in early cartilage development. Supporting our observations, ITM2A has been previously shown to variably escape from X-inactivation.
Our results show that chromosome X contributes to the variability of many complex traits with potential sexually dimorphic associations and hence support including it in future GWAS.

Hemophilia B is 6 times less frequent than hemophilia A and characterization of deleterious mutation is less reported. We present here the result of molecular studies performed in 400 hemophilia B unrelated patients.
The functional region of *F9* gene, including the 8 exons with the flanking splice junction, the promoter and part of the 3'untranslated region surrounding polyadenylation site were studied by DNA sequencing. In all patients negative after complete gene sequencing, search for duplication was performed using quantitative fluorescent multiplex-PCR (QFM-PCR). A causative mutation was identified in 368/400 (95%) patients, mainly point mutations, a whole *F9* gene deletion in 6 patients, a large *F9* gene deletion encompassing one or several exons in 12 patients, a LINE sequence insertion in one patient and a mutation located in the Leyden region in 15 patients. For the first time a *F9* gene duplication was identified in 3 unrelated families. Thirty-eight (11%) of the identified mutations have not been reported so far. The strategy used to predict the deleterious consequences of these new variations will be presented. Collection on the international database of the mutations responsible for all hemophilia B cases, whatever the severity is particularly helpful to improve genetic counselling, especially for pregnant women with low FIX:C level, no family history of hemophilia and discovery of unknown mutation.
To conclude, only 5% of the patients had no mutation identified after extensive gene analysis. Next generation sequencing will probably help us to solve these cases.

‚Estimation of genetic diversity in NS3-protease region of hepatitis C virus using 454 pyrosequencing'

O. Kulkarni[1], *O. François*[1], *P. Morand*[2], *M. G. B. Blum*[1], *S. Larrat*[2];
[1]*UJF-Grenoble 1 / CNRS / TIMC-IMAG UMR 5525, Grenoble, F-38041, France,* [2]*Virology Laboratory / UMI 3265 UJF-EMBL-CNRS, CHU Grenoble, Michallon Hospital, 38043, Grenoble, France.*

Viruses are highly diverse in their genetic constitution, both within and between infected hosts. They adapt to the host's environment with a high mutation rate and can make efficient treatment very difficult. Hepatitis C virus (HCV), which causes nearly 200 million chronic infections worldwide is curable with treatments which comprise immunoregulator and direct antiviral agents. Our analysis is a case study in which viral samples from 40 patients with chronic HCV are being sequenced using a 454 Roche GS Junior at different stages of treatment. Using variant callers, we obtain the frequency of the variants that are found in the viral population during the course of the treatment. We study the viral diversity during the treatment to assess whether the treatment actually decreases the viral diversity. Our main objective is to test if the viral diversity at the onset of the treatment is an important determinant of the treatment outcome. This would ultimately help in understanding the evolution of the virus and provide further insights into drug design and personalized treatment of HCV.

GWAS Identifies Novel Susceptibility Loci on 6p21.32 and 21q21.3 for Hepatocellular Carcinoma in Chronic Hepatitis B Virus Carriers

W. Zhao[1], *J. Liu*[1], *S. Li*[2], *J. Qian*[3], *Y. Yang*[4];
[1]*Human Genetics, Genome Institute of Singapore, Singapore, Singapore,* [2]*Department of Hepatobiliary Oncology, State Key Laboratory of Oncology in South China, Sun Yat-Sen University Cancer Center, Guang Zhou, China,* [3]*State Key Laboratory of Genetic Engineering, Center for Fudan–VARI Genetic Epidemiology and MOE Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan University, Shanghai, China,* [4]*Eastern Hepatobiliary Surgery Hospital, Second Military Medical University, Shanghai, China.*

Genome-wide association studies (GWAS) have recently identified KIF1B as susceptibility locus for hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC). To further identify novel susceptibility loci associated with HBV-related HCC and replicate the previously reported association, we performed a large three-stage GWAS in the Han Chinese population. 523,663 autosomal SNPs in 1,538 HBV-positive HCC patients and 1,465 chronic HBV carriers were genotyped for the discovery stage. Top candidate SNPs were genotyped in the initial validation samples of 2,112 HBV-positive HCC cases and 2,208 HBV carriers and then in the second validation samples of 1,021 cases and 1,491 HBV carriers. We discovered two novel associations at rs9272105 (HLA-DQA1/DRB1) on 6p21.32 (OR = 1.30, P = 1.13×10^{-19}) and rs455804 (GRIK1) on 21q21.3 (OR = 0.84, P = 1.86×10^{-8}), which were further replicated in the fourth independent sample of 1,298 cases and 1,026 controls (rs9272105: OR = 1.25, P = 1.71×10^{-4}; rs455804: OR = 0.84, P = 6.92×10^{-3}). We also revealed the associations of HLADRB1*0405 and 0901*0602, which could partially account for the association at rs9272105. The association at rs455804 implicates GRIK1 as a novel susceptibility gene for HBV-related HCC, suggesting the involvement of glutamate signaling in the development of HBV-related HCC.

P16.061
Association of hypoxia inducible factor-1 alpha gene polymorphism with physical performance in Lithuanian athletes

V. Ginevičienė[1], *A. Jakaitienė*[1], *K. Milašius*[2], *L. Tubelis*[2], *V. Kučinskas*[1], *A. Utkus*[1];
[1]*Department of Human and Medical Genetics, Vilnius, Lithuania,* [2]*Lithuanian Educological University, Vilnius, Lithuania.*

A nonsynonymous coding single-nucleotide polymorphism (Pro582Ser, c.C1772T, rs11549465) of the hypoxia inducible factor-1 alpha (*HIF1A*) gene has been shown to be associated with changes of maximal oxygen consumption (VO_2max) during training. Given this evidence and the impact of *HIF1A* on oxygen metabolism in muscle activities, we hypothesized that variant of the *HIF1A* gene might be associated with Lithuanian elite athletes status and their VO_2max level. A total of 249 Lithuanian elite athletes (112 endurance-oriented, 50 power-oriented, 87 "mixed group") and 266 healthy unrelated individuals (controls) were genotyped(PCR-RFLP). Anthropometric measurements, anaerobic muscle strength (short-term explosive muscle power, anaerobic alactic maximum power) and aerobic VO_2max test were evaluated. The results revealed that the frequencies of the *HIF1A* genotypes were different in the athletes compared to controls (Pro/Pro 74.7%; Pro/Ser 24.9%; Ser/Ser 0.4% *vs.* Pro/Pro 75.2%; Pro/Ser 21.4%; Ser/Ser 3.4%; P=0.038). The frequency of the *HIF1A* Ser allele was higher in the power-orientated (18%) athletes compared to endurance-oriented (12%), "mixed group" (10.9%) and controls (14.1%). Muscle strength phenotypic indexes did not differ between athletes depending on their *HIF1A* genotype ($P>0.05$). Interestingly, we found that athletes carrying the Pro/Ser genotype exhibited significantly higher VO_2max (69.5*vs*.60.3 ml/kg/min, $P<0.05$) than those carrying the Pro/Pro genotype. Based on these findings, we conclude that *HIF1A* variation may be associated with Lithuanian elite athletes' status and athletes carrying the *HIF1A* Pro/Ser genotype with higher aerobic capacity. Of course, further studies will be needed to fully understand the mechanisms underlying the putative association between the *HIF1A* polymorphism and endurance performance.

Human leucocyte antigen G (HLA-G) is a tolerogenic molecule which plays a crucial role in protecting the fetus from maternal immune attack. Besides, HLA-G expression can be induced in numerous pathological conditions where its immunosuppressive properties render it an efficient means of escape from immune recognition for pathogens and tumors. In contrast to classical class I HLA molecules which display extensive variability in the coding region, *HLA-G* rather exhibits a higher degree of variation in regulatory regions. In this study, we aimed to characterize the sequence variation and haplotype structure of the *HLA-G* promoter region to investigate the evolutionary history of the *HLA-G* promoter and shed some light into the mechanisms that may underlie *HLA-G* expression control. The 1.4-kb upstream regulatory region of *HLA-G*, which includes all of the known promoter elements, was sequenced in three new African populations (Serere from Senegal, Tori from Benin, Yansi from Congo) and these data were combined with the available sequence data from the 1000 Genomes project and the literature. Patterns of sequence variation, frequency spectrum and genetic differentiation of *HLA-G* promoter strongly supported a history of balancing selection at this region. An extended analysis of a 300-kb region surrounding *HLA-G* revealed that this region is the direct target of selection and is not involved in a hitchhiking effect. These results suggests that there might be a fine balance between optimal levels of expression from fetal to adult life, allowing both fetal tolerance and appropriate intrauterine defense against pathogens.

Founder Mutation for Huntington Disease in Caucasus Jews

H. N. Baris[1,2], *O. Melamed*[1], *D. M. Behar*[1,3], *N. Magal*[1], *E. Pras*[4,2], *H. Reznik-Wolf*[5], *Z. U. Borochowitz*[5], ***B. Davidov***[1], *R. Mor-Cohen*[6,2], *C. Bram*[7,8];

[1]*The Recanati Genetic Institute, Beilinson Hospital, Petah Tikva, Israel,* [2]*Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel,* [3]*Molecular Medicine Laboratory, Rambam Health Care Campus, Haifa, Israel,* [4]*The Danek Gartner Institute of Human Genetics, Sheba Medical Center, Tel Hashomer, Israel,* [5]*The Simon Winter Institute for Human Genetics, Bnai-Zion Medical Center, Rappaport Faculty of Medicine and Research Institute, Technion-Israeli Institute of Technology, Haifa, Israel,* [6]*Amalia Biron Research Institute of Thrombosis and Hemostasis, Sheba Medical Center, Tel-Hashomer, Israel,* [7]*Van Leer Institute, Jerusalem, Israel,* [8]*University of Florida, Gainesville, FL, United States.*

Huntington disease (HD) is an autosomal dominant disorder characterized by chorea, psychiatric illness and cognitive decline caused by expansion of the trinucleotide CAG repeat within the *HTT* gene. The prevalence of HD is well known among Europeans, but not in Jewish communities. We analyzed the clinical and demographic data of our HD patients and carried out haplotype analysis in order to look for and date a founder mutation. Between 2006 and 2011, 1,400 patients were evaluated in our adult genetics clinic. Eleven patients from 10 different families were diagnosed with HD; nine families are Caucasus Jewish (CJ) and one is Ashkenazi. Of the nine CJ, eight shared a 3.74 Mb haplotype, which is compatible with the HD-susceptible A1 haplogroup. We calculated the coalescence age of the mutation using the DMLE+2.0 software program to be between 4 and 10 generations, which correspond to around 80-200 years ago. In our clinic 90% of HD patients are CJ, although the CJ comprise only 1.4% of the Israeli population. These findings suggest a higher prevalence of HD among CJ compared to the general Israeli population and are consistent with a recent founder mutation in this group.

This should raise the index of suspicion for HD in CJ, thereby allowing for earlier diagnosis so that prenatal testing can be offered when desired, and treatment once it is available.

Risk scores derived from known lipid variants improve identification of individuals at increased risk of hypercholesterolemia

S. M. Willems[1], *E. J. G. Sijbrands*[2], *A. Dehghan*[3], *A. Hofman*[3], *B. A. Oostra*[1], *O. H. Franco*[3], *A. Isaacs*[1], *C. M. van Duijn*[1];

[1]*Genetic Epidemiology Unit, Department of Epidemiology, Erasmus MC, Rotterdam, Netherlands,* [2]*Department of Internal Medicine, Erasmus MC, Rotterdam, Netherlands,* [3]*Department of Epidemiology, Erasmus MC, Rotterdam, Netherlands.*

Background Hypercholesterolemia (HC; total cholesterol > 6.5 mmol/l and/or use of lipid lowering medication) is a well-established modifiable cardiovascular disease risk factor. We determined the ability of genotypic risk scores to identify individuals at increased risk of hypercholesterolemia.

Methods and Results We calculated TC, LDL-C, HDL-C and TG risk scores in the Rotterdam Study (RS, n=10,072) and Erasmus Rucphen Family Study (ERF, n=2,715), using 157 SNPs discovered in recent meta-analyses of ≥100,000 individuals. Adding the TC score to a clinical model based on age, sex and BMI improved the prediction of HC (c-index in RS increased from 0.64 to 0.68 (P=2.1x10^{-31}) and in ERF from 0.71 to 0.75 (P=2.9x10^{-9})). The LDL-C, HDL-C and TG scores combined improved prediction similarly. In RS, Kaplan-Meier curves showed an approximately doubled cumulative incidence of HC in the highest TC risk score quartile compared to the lowest. In both cohorts, overall and in age strata, prevalence of HC increased with TC risk score quartile (P_{trend}=1.3x10^{-96} to 0.002). Odds ratios also increased with quartile, from 1.62 for the second to 3.5 for the highest quartile compared to the lowest in the total sample. Maximum OR was 3.9 for the highest quartile in the 65-74 years stratum (P=2.4x10^{-32}).

Conclusion Our results show that genetic risk scores can be useful in identifying individuals at increased risk of hypercholesterolemia. Our findings also suggest that a genetic risk score can help identify individuals that would benefit from earlier and more intensive monitoring of cholesterol levels.

Genetic Predisposition to Left Ventricular Dysfunction: A Multigenic and Multi-analytical Approach

A. Mishra, *A. Srivastava, T. Mittal, N. Garg, B. Mittal;*

Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Lucknow, India.

Background: Left ventricular dysfunction (LVD) is a complex, multifactorial condition, caused by mechanical, neurohormonal, and genetic factors. The present study was undertaken to identify the combination of genetic variants of renin-angiotensin-aldosterone system (RAAS), matrix metalloproteinases (MMPs) and inflammatory pathway genes and their possible interactions contributing towards genetic susceptibility to LVD in the background of coronary artery disease (CAD).

Methods and Results: The study included 510 consecutive patients with angiographically confirmed CAD. Among them, 162 with reduced left ventricle ejection fraction (LVEF≤45%) were categorized as having LVD. We analysed 11 polymorphisms in 9 genes of RAAS, MMPs and inflammatory pathways. Single locus analysis showed that AT1 A1166C (p value<0.001; OR=3.67), MMP9 R668Q (p value=0.007; OR=3.48) and NFKB1 -94 ATTG ins/del (p value=0.013; OR=2.01) polymorphisms were independently associated with LVD. A combined G-score consisting of risk alleles of associated polymorphisms showed much higher significance as compared to individual variations (p-value<0.001). High-order gene-gene interaction using Classification and Regression Tree analysis (CART) and Multifactor dimensionality reduction (MDR) approaches revealed AT1 A1166C and NFKB1 -94 ATTG ins/del polymorphisms jointly increased the risk of LVD to great extent (p-value=0.001; OR=8.55) and best four-factor interaction model consisted of AT1 A1166C, MMP7 A-181G, MMP9 R668Q and NFKB1 ATTG ins/del polymorphisms with an improved testing accuracy of 0.566 and CVC=9/10 with permutation p<0.001) respectively.

Conclusion: The AT1 A1166C independently and in combination with MMP9 R668Q and NFKB1 -94 ATTG ins/del polymorphisms plays important role in conferring genetic susceptibility to LVD in CAD patients.

Association study of TOLL and CARD with leprosy susceptibility in Chinese population

A. Irwanto[1,2], *H. Liu*[3,4,5], *F. Bao*[3,5], *F. Zhang*[3,4,5], *J. Liu*[1,2,6];
[1]*Human Genetics, Genome Institute of Singapore, Singapore, Singapore,* [2]*Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore,* [3]*Shandong Provincial Institute of Dermatology and Venereology, Shandong Academy of Medical Sciences, Jinan, China,* [4]*Shandong Provincial Hospital for Skin Diseases, Shandong University, Jinan, China,* [5]*Shandong Provincial Key Lab for Dermatovenereology, Jinan, China,* [6]*School of Life Sciences, Anhui Medical University, Hefei, China.*

Background: Previous genome-wide association studies (GWAS) identified multiple susceptibility loci that have highlighted the important role of *TLR* (Toll-like Receptor) and *CARD* (caspase recruitment domain) genes in leprosy.
Methods: A large three-stage candidate gene-based association study of 69 *TLR* and *CARD* genes was performed in the leprosy samples of Chinese Han.
Results: Of 4,363 SNPs investigated, eight SNPs showed suggestive association (P<0.01) in our previously published GWAS datasets (Stage 1). Of the eight SNPs, rs2735591 and rs4889841 showed significant association (P<0.001) in an independent series of 1,504 cases and 1,502 controls (Stage II), but only rs2735591 (next to *BCL10*) showed significant association in the second independent series of 938 cases and 5,827 controls (Stage III). Rs2735591 showed consistent association across the three stages (P>0.05 for heterogeneity test), significant association in the combined validation samples ($P_{corrected}=5.54\times10^{-4}$ after correction for 4,363 SNPs tested), and genome-wide significance in the whole GWAS and validation samples ($P=1.03\times10^{-9}$, OR=1.24). In addition, we demonstrated the lower expression of *BCL10* in leprosy lesions than normal skins and the formation of a highly significant gene network by *BCL10* and the eight previously identified genes ($P=1\times10^{-19}$) that regulates the activity of NFκB, a major regulator of downstream inflammatory responses, which provides further biological evidence for the association.
Conclusion: We have discovered a novel susceptibility locus on 1p22, which implicates *BCL10* as a new susceptibility gene for leprosy. Our finding highlights the important role of both innate and adaptive immune responses in leprosy.

LITGEN project has been launched in 2011. The aim is to determine genetic diversity and structure of the population of Lithuania using informative variable genetic markers such as SNPs, CNVs, STRs of Y chromosome, mtDNA, autosomes, exome and whole genome for future extensive wide scale human genome studies in Lithuania.
First stage of LITGEN project was to collect samples from different ethno-linguistic groups of Lithuanians. Questionnaires and informed consent forms were obtained and signed by all participants. Phenotypic data such as diet, physical activity, genealogy and anamnesis were collected by questionnaires. About 1000 samples were collected and current database contains 259 triads. 150 triads were assigned to particular ethno-linguistic group as all members originated from the same region. Analysis of biochemical phenotype associated with cardiovascular diseases has been performed for all participants. Attention is paid to particular groups of genes or pathways involved in cardiovascular diseases, nutrigenomics, pharmacogenetic response, autosomal recessive diseases identifying genomic variants specific to the population of Lithuania. Data from questionnaires and biochemical phenotype are managed using BC|GENE data management platform. Y chromosome haplotype consisting of 17 STR markers was determined for male participants using commercial AmpFlSTR® Yfiler™ kit. Large scale genotyping was performed using HumanOmniExpress-12 v1.0. Further bioinformatical analysis is performed from the obtained data.
LITGEN project (VP1-3.1-ŠMM-07-K-01-013) is funded by Global Grant.

Local interactions capture both known and novel loci and provide new insights into eight human metabolic traits

W. Wei[1], *A. Gyenesei*[2], *C. A. M. Semple*[1], *C. S. Haley*[1];
[1]*MRC Human Genetics Unit, University of Edinburgh, Edinburgh, United Kingdom,* [2]*Finnish Microarray and Sequencing Centre, Turku Centre for Biotechnology, University of Turku and Åbo Akademi University, Turku, Finland.*

Local interactions between neighbouring SNPs are hypothesized to be able to capture variants missing from genome-wide association studies (GWAS) via haplotype effects but have not been thoroughly explored. Aided by recent improvements in software we were able to perform full pair-wise genome scans and conventional GWAS in eight metabolic traits in the Northern Finland Birth Cohort 1966 (NFBC1966) and the Atherosclerosis Risk in Communities study cohort (ARIC). Genome-wide significant interactions were detected in ARIC for systolic blood pressure between *PLEKHA7* (a known GWAS locus for blood pressure) and *GPR180* (which plays a role in vascular remodelling), and also for triglycerides as local interactions within the 11q23.3 region (replicated significantly in NFBC1966), which notably harbours several loci (*BUD13*, *ZNF259* and *APOA5*) contributing to triglyceride levels. Tests of the local interactions within the 11q23.3 region conditional on the top GWAS signal suggested the presence of two independent functional variants, each with supportive evidence for their roles in gene regulation. Local interactions captured 9 additional GWAS loci identified in this study (3 significantly replicated) and 73 from previous GWAS (24 in the eight traits and 49 in related traits). We conclude that the detection of local interactions requires adequate SNP coverage of the genome and that such interactions are only likely to be found between weakly linked SNPs. Analysing local interactions is a potentially valuable complement to GWAS and can provide new insights into the biology underlying variation in complex traits.

A frequency based approach for discriminating between causative and rare genetic variations in LQTS

V. Novelli[1], *A. Malovini*[2], *M. Cerrone*[3], *C. Napolitano*[4], *S. Priori*[5];
[1]*Division of Molecular Cardiology, Maugeri Foundation, Pavia, Italy,* [2]*Fondazione S. Maugeri, Pavia, Italy,* [3]*Langone Medical Center, New York University, NYC, NY, United States,* [4]*Division of Cardiology and Molecular Cardiology, Maugeri Foundation, Pavia, Italy,* [5]*Division of Cardiology and Molecular Cardiology, Maugeri Foundation-University of Pavia, Pavia, Italy.*

Long QT syndrome (LQTs) is a Mendelian disease characterized by delayed ventricular repolarization manifest with prolongation of the corrected QT (QTc) interval on the electrocardiogram. Genetic testing on LQT syndrome led to the worldwide identification of hundreds of genetic variations in 13 different genes. Interpreting and validating the effects of these mutations is still challenging especially in absence of functional studies that can confirm their deleterious effect. In this context, using NHLBI genetic frequency regarding 23 LQTS mutations supported by functional studies we estimated a Minor Allele Frequency (MAF) threshold to discriminate between a causative rare genetic and a low frequency variation.To assess the validity of our model we applied the estimated threshold 0.04% to a population of 337 LQTS probands carrying 204 unique single-nucleotide variations.Results showed that the median value of the QTc distribution was significantly higher for patients with rare mutations (MAF < 0.04%) comparing with those having common variants (p < 0.05). In addition, using data regarding 79 functionally validated variations, we tested the performances of the two bioinformatic tools Polyphen2 and SIFT in predicting the deleterious effects of the genetic variation.
Our data provided a validated frequency cut-off value to discriminate between causative mutations and low frequency variations in absence of in vitro or in vivo studies.

Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [4]Department of Hematology, Ampang Hospital, Selangor, Malaysia.

Methylenetetrahydrofolate reductase (MTHFR) is a critical enzyme in folate metabolism. This enzyme is involved in DNA synthesis, DNA repair and DNA methylation. Several studies have shown that MTHFR C677T gene polymorphism is associated with susceptibility to lymphoproliferative disorders (LPD). The objective of this case-control study was to determine the association between MTHFR C677T gene polymorphism and risk of LPD in the Malaysian population. The C677T polymorphism was genotyped in 1,246 participants (524 lymphoid malignancy patients and 722 healthy individuals) using the Sequenom iPLEX MassARRAY platform. A total of 524 (42%) LPD patients and 722 (58%) controls participated in this study. Of the LPD patients, 32%, 9%, 42%, and 17% were diagnosed with diffuse large B cell lymphoma (DLBCL), follicular lymphoma (FL), other non-Hodgkin lymphoma (NHL), and Hodgkin's lymphoma (HL) subgroups respectively. No statistically significant differences were observed for different genotypes between patients and controls in the pooled LPD group (p>0.05). Overall, there was significant association between C677T polymorphism and risk of FL (p =0.006). Subgroup analysis by ethnicity in patients with FL as compared with controls showed significant association in Malaysian Malays (p=0.016). However, sample size in this subgroup was small. This study suggests that C677T polymorphism might be a risk factor for susceptibility to FL in the Malaysian Malays. However, due to the small sample size of patients with FL, false positive finding cannot be ruled out.

Prevalence and diversity of monogenic hereditary pathology among the children of Rostov region (Russia)

M. Amelina[1], *T. Ponomareva*[2], *N. Vetrova*[2], *S. Amelina*[2], *A. Petrin*[3], *R. Zinchenko*[4]; [1]*Scientific Research Institute of Obstetrics and Pediatrics, Rostov-on-Don, Russian Federation,* [2]*Scientific Research Institute of Biology „Southern Federal University", Rostov-on-Don, Russian Federation,* [3] *Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [4]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Results of prevalence and nosologycal forms of a monogenic hereditary pathology (MHP) among the children's of twelve investigated Districts of Rostov Region (Russia) was submitted. The total size of investigated populations was made 497460 people, including 97345 (19.57%) children. The ethnic structure of considered sample on more that 90 % is presented by Russian population. The study was conducted on the original protocol examined by standard protocol of medical genetic research elaborated in laboratory of genetic epidemiology, Research Centre for Medical Genetics. About 3000 MHP and syndromes of OMIM could be identified by this research. Clinical investigations were performed by pediatricians, clinical geneticists, neurologists, ophthalmologists, orthopedists, audiologist, and dermatologists, focused on diagnostic of MHP. The spectrum of MHP detected in the twelve Districts comprises 166 nosologycal forms - 95- autosomal dominant (AD), 57- autosomal recessive (AR) and 14- X-linked. The prevalence rate (for 1000 children) of children's population by all types MHP - AD, AR, and X-linked, separately for urban (1.86±0.21, 1.82±0.21, 0.53±0.16, respectively) and rural (4.38±0.28, 3.39±0.25, 1.30±0.22, respectively) populations was calculated. In rural populations, the prevalence is higher in 2 times higher than in urban. The total prevalence of MHP was 6.49±0.28/ 1000 children. Given that this study can detect only half of hereditary diseases, the total prevalence of hereditary disorders in children more than 1%. In this study, we studied the prevalence of hereditary diseases among children Republics Bashkortotan, Udmurtia and Chuvashia, in which the burden of hereditary diseases was 1.4%, 1.2%, and 1.1%, respectively

Mitochondrial DNA diversity in medieval and modern Romanian population

R. Cocos[1], *L. Bohiltea*[1], *S. Schipor*[2], *F. Raicu*[1,3]; [1]*"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania,* [2]*" C.I.Parhon" National Institute of Endocrinology, Bucharest, Romania,* [3]*Institute of Anthropology „Francisc I. Rainer", Bucharest, Romania.*

Ancient DNA population studies may yield interesting results in cases where are indications from archaeology and history that a population demographic modification has taken place and significantly reduce the genetic diversity via bottleneck effect.

We analyzed mtDNA variation using aDNA samples from Piata Universității archaeological site and modern DNA to study nature and extent of temporal changes in genetic variation in Bucharest region during 16th-19th centuries. The archaeological site of Piata Universității cemetery unearthed about 676 graves with 900 skeletons. We have analyzed by now 18 aDNA samples out of a total of 150 dental pieces recovered from the skeletons excavated from the cemetery and 74 out of 250 modern DNA samples collected. Standard contamination precautions and authentication criteria were applied. Hypervariable regions I and II of ancient mtDNA were amplified and sequenced using twelve overlapping fragments, each with a length of approximately 100 base pairs. The majority of the ancient and modern mtDNA samples analyzed by now falls into the common West Eurasian mitochondrial haplogroups.

In conclusion, to fully assess the dynamics of the historical population composition by comparing genotypes in a temporal context we have to complete the comparative analysis of all aDNA and modern DNA samples. Moreover, in order to reveal possible genetic data changes caused by a possible population bottleneck corresponding to the waves of lethal epidemics, in which an almost one-third of the population was lost, we will also investigate a set of 17 fast evolving short tandem repeat loci (STR).

Cardiometabolic risk factors are correlated epidemiologically and share common genetic predisposition, as confirmed by single-trait genome-wide association studies. A large-scale multi-phenotype analysis can be a valuable tool to dissect independence of effects of a genetic variant on metabolic traits and disease risk, e.g. pleiotropy. We aimed to a) evaluate the multi-phenotype analysis method using an *FTO* variant known to exert its action via body mass index (BMI) and b) explore multi-phenotype effects at *FADS1* and *GIPR*, both associated with a range of metabolic traits. We implemented a method that utilizes multiple logistic regression with SNP genotypes as the outcome and phenotypes as explanatory variables. Model selection was based on Bayesian Information Criterion scores summed across studies from derived multi-phenotype likelihoods. Analysis was performed in up to 167,984 individuals of European ancestry from 26 studies. Consistent with previous reports, the multi-phenotype meta-analysis confirmed that BMI drives associations with other traits at *FTO*, suggesting absence of pleiotropy. Variants at *FADS1* have an effect on lipids, fasting glucose and resting heart rate among others. At *FADS1*, the best models within multi-phenotype sets underscored independent effects for triglycerides and total cholesterol (P_{LRT}=1.3x10^{-102}). Variants at *GIPR* are associated with BMI, type 2 diabetes and 2-hour post load glucose and insulin. We were not able to detect pleiotropy at *GIPR*, possibly due to a smaller number of individuals with 2-hour glucose measurements in this study. The multi-phenotype method confirmed mediation effects for a known *FTO* variant and shows promise for dissecting pleiotropic associations.

A two-stage genome-wide association study identifies germline predisposition loci for myeloproliferative neoplasms

A. S. Harutyunyan[1], *T. Berg*[1], *T. Klampfl*[1], *J. D. Milosevic*[1], *A. Puda*[1], *B. Gisslinger*[2], *M. Penka*[3], *A. M. Vannucchi*[4], *M. Cazzola*[5], *H. Gisslinger*[2], *R. Kralovics*[1,2];
[1]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria, [3]University Hospital Brno, Brno, Czech Republic, [4]University of Florence, Florence, Italy, [5]University of Pavia, Pavia, Italy.

Myeloproliferative neoplasms (MPN) are chronic hematological malignancies characterized by excessive production of terminally differentiated blood cells. Genome-wide association (GWA) studies in recent years have become the main tool for identification of common polymorphisms predisposing to diseases. So far a strong susceptibility haplotype spanning JAK2 gene has been identified for MPN. We aimed to find more loci conferring risk to develop MPN by performing a GWA study comparing MPN samples with healthy controls. Genotype data obtained by Affymetrix Genome-Wide Human SNP Array 6.0 for all samples was used for the analysis.
We used 372 Austrian MPN cases and 1757 German controls (KORA-gen) for initial GWA. The strongest association was detected for JAK2 locus (allelic association P=1.4x10-28, OR=2.59). To overcome the limitation of small sample size we designed a second stage of association validation for which we used four smaller independent cohorts which were also genotyped by the same SNP array platform: three cohorts from Italy (n=98, n=76, n=56) and one cohort from Czech Republic (n=37). All the SNPs that showed P value <10-3 in initial GWA were selected and the allele frequencies were compared to those of the four validation cohorts and their respective control groups. The analysis revealed three haplotypes on chromosomes 7p12.1 (P=9.06x10-6, OR=1.53), 13q12.11 (P=2.42x10-5, OR=0.69) and 15q26.2 (P=1.33x10-4, OR=1.44) that had similar frequencies in all validation cohorts and are thus candidates for common MPN predisposition. The current study also demonstrates the usefulness of multi-stage GWA analysis using SNP array data for validation.

Resolution of the paradoxical excess of duplications over deletions at the DPY19L2 locus in the general population

P. F. Ray[1,2], *C. Coutton*[3,2], *T. Karaouzene*[1,2], *V. Satre*[3,2], *P. Jouk*[3], *C. Arnoult*[2], *N. Thierry-Mieg*[4];
[1]CHU de Grenoble, Département de DBTP, Grenoble, France, [2]Université Joseph Fourier, Centre National de la Recherche Scientifique, Laboratoire AGIM, FRE3405, Equipe „Génétique, Infertilité et Thérapeutiques", Grenoble, France, [3]CHU de Grenoble, Département de Génétique et Procréation, Grenoble, France, [4]Université Joseph Fourier, Centre National de la Recherche Scientifique, Laboratoire TIMC-IMAG UMR 5525, Grenoble, 38041, France, Grenoble, France.

We demonstrated previously that 75% of infertile men with round acrosomeless spermatozoa (globozoospermia) had a homozygous 200 Kb deletion removing the totality of DPY19L2. We showed that this deletion occurred by Non Allelic Homologous Recombination (NAHR) between two homologous 28 Kb Low Copy Repeats (LCRs) located on each side of the gene. The accepted NAHR model predicts that inter-chromatid and inter-chromosome NAHR create a deleted and a duplicated recombined allele, while intra-chromatid events only generate deletions. Therefore more deletions are expected to be produced de novo. Surprisingly, array CGH data show that in the general population, DPY19L2 duplicated alleles are approximately three times as frequent as deleted alleles. In order to shed light on this paradox, we measured the rates of de novo deletions and duplications at this locus on the sperm of three control donors. We achieved this by developing a digital PCR assay amplifying specifically the deleted and duplicated alleles. We measured that the average rate of de novo deletion was 8.9x10-6 (95% CI: 7.1x10-6; 1.1x10-5) whereas that of duplication was 3.9x10-6 (95% CI: 3.1x10-6; 4.9x10-6) showing an approximate two fold excess of de novo deletions over duplications, concordant with the NAHR theoretical model. We calculated that the excess of de novo deletions was compensated by evolutionary loss whereas duplications, not subjected to selection, increased gradually. We conclude that the purifying selection against sterile, homozygous deleted men, accounts partly for this compensation, but heterozygously deleted men also likely suffer a small fitness penalty.

Whole-genome sequencing of the Val Borbera cohort highlights low frequency variants associated with several complex traits

M. Traglia[1,2], *M. Cocca*[1,3], *Y. Memari*[4], *L. Bomba*[4], *C. F. Sala*[1], *C. Masciullo*[1], *C. Barbieri*[1], *N. Soranzo*[4], *D. Toniolo*[1];
[1]Division of Genetics and Cell Biology, San Raffaele Research Institute, MILANO, Italy, [2]Institute for Maternal and Child Health–IRCCS "Burlo Garofolo"– University of Trieste, Trieste, Italy, [3]Institute for Maternal and Child Health–IRCCS "Burlo Garofolo"–Trieste, University of Trieste, Trieste, Italy, [4]Human Genetics Wellcome Trust Sanger Institute Genome Campus Hinxton, CB10 1HH, United Kingdom.

Next-generation sequencing approaches allow the identification of population-specific low-frequency variants. A random sample of 110 individuals from the genetic isolate Val Borbera cohort (VBI) from Italy were whole-genome sequenced at low-coverage (6.5X).
After genome refinement, quality control and filtering steps, a total of 11,446,954 single nucleotide variants (SNV) and 812,109 INDELs were detected on autosomal chromosomes, and 372,230 SNVs and 29,671 INDELs were detected on the X-chromosome. Of these, 4,695,640 SNVs (about 39%) were at low frequency (MAF<=5%), whereas 2,603,184 (about 22%) were private to VBI when compared to two large-scale sequencing projects (UK10K and 1000 Genomes Project).
Prior to genotype imputation, the whole set of 1664 participants having genome-wide SNP array data were pre-phased using SHAPEIT2[1] . Imputation into the GWAS sample was based on a combined reference panel including the set of variants discovered in the pilot phase of the 1000 Genomes Project and the VBI WGS dataset. The final dataset includes 36,648,992 imputed SNVs and 1,380,736 INDELs.
We tested associations of individual SNPs at a large set of hematological, lipid and anthropometric quantitative traits [2], identifying several several suggestive signals driven by low-frequency variants. Replication experiments in other European sequenced populations are ongoing.

P16.077

Inferring negative selection from mutation genealogies

M. Jeanpierre;
Université Paris Descartes, Paris, France.

Mendelian diseases are rare because natural selection prevents the dissemination of the disease-causing allele. Inferences about negative selection can provide important information about the probability of a given variant being the cause of a genetic disease. This is particularly important for non-coding variants, for which it is difficult to carry out functional tests.
The reconstruction of mutation genealogies from present-day chromosomes can provide us with information about past events. It is difficult to define the signature of negative selection from inferred genealogies and to quantify the probability of a given allele being a disease-causing variant, because the history of a variant reflects demographic history, the random transmission of alleles over generations and natural selection.
The relationship between branch length and ancestral haplotype size is purely statistical and the challenge is to develop simplifications with a minimal loss of information, because the precision of the reconstruction depends on the dimensionality of the graph. Most pathological variants are the product of recent mutations, and this assumption underlies allele frequency-based methods. Negative selection is therefore taken into account, albeit indirectly, through allele frequency, for the evaluation of variants of unknown significance. The analysis of graphs representing the genealogy of a variant may be viewed as an extension of this widely used method.
As haplotype decay is essentially stochastic, simple geometric structures that can be described unambiguously in mathematical terms can provide the algebraic framework for untangling the forces shaping the genealogy of a single allele.

[1]*Department of Medical Genetics, Faculty of Medical Sciences, University of Campinas – Unicamp, Campinas, SP, Brazil,* [2]*Medical Genetics Service, Hospital de Clinicas de Porto Alegre, Porto Alegre, RS, Brazil,* [3]*Medical Genetics Sector, State University of Alagoas, Maceió, AL, Brazil,* [4]*Clinical Genetics Service, University Hospital, Federal University of Alagoas, Maceió, AL, Brazil,* [5]*Centro de Atendimento Integral ao Fissurado Labiopalatal (CAIF), Curitiba, PR, Brazil,* [6]*Department of Molecular Biology, Medicine School of São José do Rio Preto (FAMERP-FUNFARME), São José do Rio Preto, SP, Brazil,* [7]*Genetics Service of Albert Sabin Childhood Hospital, Fortaleza, CE, Brazil,* [8]*Center for Research and Rehabilitation of Lip and Palate Lesions (CRRLPL), Centrinho Prefeito Luiz Gomes, Joinville, SC, Brazil.*

Nonsyndromic cleft lip with cleft palate (NSCLP) is a congenital malformation with a prevalence of 0.2% to 0.04% among live births. Environmental factors and pathogenic mutations in several genes have been described, as well as association studies between polymorphisms in candidate genes and NSCLP. Considering this, the aim of our study was to investigate the association between NSCLP and 39 candidate genes, which were selected based on NSCLP mutations and association studies and expression patterns during facial development. We evaluated 140 patients with NSCLP and 350 control individuals without NSCLP from Brazilian sample. A total of 251 tagging SNPs selected by Haploview software were used in the analysis, which screened the candidate genes. These SNPs were genotyped using the OpenArray™ TaqMan system. Logistic regression analysis was performed to analyze allele and genotype association. Seven SNPs in six different genes were statistically associated with NSCLP, even after correction for multiple testing [*MSX1* rs12532*GG (p=0.037); *BMP4* rs17563*AA (p=0.046); *JAG2* rs9972231*TT (p=0.030) and rs11621316*AA (p=0.027); *WNT9B* rs1443311*GG (p=0.025); *AXIN2* rs11655966*AA (p=0.010); *LHX8* rs12409145*AA (p=0,034)]. In addition, four SNPs showed an increased risk for NSCLP [*MSX1* rs12532*GG (OR=1.84, 95%CI=1.11-3.03); *BMP4* rs17563*AA (OR=1.71, 95%CI=1.11-2.63); *JAG2* rs11621316*AA (OR=1.88 95%CI=1.22-2.88); *LHX8* rs12409145*AA (OR=6.13, 95%CI=1.59-23.56)]. Interestedly, three SNPs presented a decreased risk for NSCLP [*WNT9B* rs1443311*GG (OR=0.20 95%CI=0.05-0.75); *AXIN2* rs11655966*AA (OR=0.50, 95%CI=0.33-0.76); *DVL2* rs2074222*GG (OR=0.52, 95%CI=0.34-0.81); *JAG2* rs9972231*TT (OR=0.34, 95%CI=0.14-0.80)]. This data suggests that these genes could be associated with formation and/or fusion of the facial processes and could predispose or protect to NSCLP.

Does Haplotype Tests Gain Power than Collapsing Tests in General Pedigree-based Association Studies for Detecting Rare Variants

Y. Yao*, W. Guo;*
National Insititute of Mental Health, Bethesda, MD, United States.

Recently, rare variants have received more attention with the advent of next-generation sequence technology. Some rare variants have been found to play a causal role in human disorders including psychiatric disorders. The established strategy is to collapse the rare variants as in the burden tests while analyzing the rare variants. In this study, we focus on the detection of the rare variants using pedigree data. A weighted haplotype test was considered in case-control design by Li et al which showed greater power than the collapsing tests through simulations. The haplotype-based approach has become attractive because haplotypes may carry some information of ungenotyped rare variants. Therefore, we aimed to investigate the performance of haplotype collapsing tests in family data. As the Pedigree-Disequilibrium-Test (PDT), the proposed haplotype based PDT test (hPDT) evaluates the difference in the counts of the transmitted and un-transmitted haplotypes from parents to affected siblings and the difference in the counts of haplotypes between affected and unaffected sibs.
In this study, ForSim is used to simulate sequence data in pedigrees. 200 families are randomly selected. To investigate the power, we randomly select 50% of the rare variants in the causal region to be causal. We further assume that r% (r% ranges from 5%, to 100%) of rare variants increase disease risk, whereas the remaining (100 - r)% decrease disease risk. As a comparison, the rare variants based PDT test (rvPDT) is also considered. Results indicated that when r=0.8, the power is 0.85 and 0.75 for hPDT and rvPDT, respectively.

Frequency of mutations in the *PAH* gene in PKU patients in Rostov Region

N. Vetrova[1], *M. Amelina*[2], *S. Amelina*[1], *O. Senyuta*[1], *R. Zinchenko*[3];
[1]*Scientific Research Institute of Biology „Southern Federal University", Rostov-on-Don, Russian Federation,* [2]*Scientific Research Institute of Obstetrics and Pediatrics, Rostov-on-Don, Russian Federation,* [3]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moskow, Russian Federation.*

Phenylketonuria (PKU) is an autosomal recessive inherited disorder arising from the deficiency of phenylalanine hydroxylase (PAH). In the majority of cases, PKU is caused by mutations in the *PAH* gene. More than 500 mutations have been described world-wide and the PAH enzyme has been fully characterized. Frequency and occurrence of mutations characterized by significant between-population differences. The most common mutation for Europeans is a missense mutation in exon 12 of the gene PAH - R408W.
DNA was extracted and examined by standard procedures from 77 patients with PKU. Were determined 8 mutations (R408W, P281L, IVS10nt546, R261Q, IVS12nt1, R158Q, R252W, I65T).
There are 3 mutations are the most frequently then others: R408W, IVS10nt546 and IVS12nt1. The frequency of these mutations is 72.73% in all patients and 77.60 % in Russian patients. R408W mutation makes up 62.34% in all patients (72.42% in Russian patients). About 25% of patients with R408W are heterozygous. 7.14% of patients had IVS10nt546 mutation. 90% of these patients were Turkish, Azerbaijani, Georgian and Armenian. IVS12nt1 mutation was detected in 4.31% Russian patients and 3.25 % in all PKU-patients. P281L, R252W, R261 and R158Q mutation frequencies in the PKU patients were 2.60% 1.95%, 1.95% and 1.29% respectively. There is no patient with I65T mutation.
All PKU patients in Rostov Region have a classic form, caused by the mutation in the *PAH* gene. There is no patient with BH4-deficient hyperphenylalaninemia in Rostov Region. The most common mutation for PKU patient in Rostov Region is R408W.

Population isolates have well-documented characteristics that can aid to identify rare variants associated with complex traits, namely reduced phenotypic, environmental and genetic heterogeneity. Besides, alleles that are rare in general populations may have become more frequent in those isolated populations, which could facilitate their identification. However, the cost of sequencing technology is still too high to allow the study of rare variants through the sequencing of the whole genome or exome for all individuals from an isolated population. To overcome this technical bottleneck, a cost-effective strategy consists in the sequencing of a limited number of previously genotyped individuals from the population followed by the imputation of the discovered variants onto the rest of the population.
Imputation involves a phasing process which can be performed using approaches that can be divided into two groups: local phasing and long-range phasing. The former family of approaches is based on linkage disequilibrium (LD) while the latter is based on Identity-By-Descent (IBD) and was designed to take advantage of relatedness between samples from isolated population. Here, we compare the performance of two recently published phasing approaches – SHAPEIT2 (Delaneau et al, 2013), a local phasing approach, and SLRP (Palin et al, 2011), a model-based long-range phasing approach - on samples from an isolated population from the Cilento region in Italy. This population is composed of three villages totaling about 2,000 genotyped individuals. Comparison is performed through simulations based on the genealogical structure of this isolated population.

Worldwide population differentiation of genes involved in drug response

B. Patillon[1,2,3], *P. Luisi*[4], *E. Génin*[5], *A. Sabbagh*[1,2];
[1]*IRD, UMR216, Paris, France,* [2]*PRES Sorbone Paris Cité, Université Paris Descartes, Faculté de Pharmacie, Paris, France,* [3]*Université Paris Sud, Kremlin-Bicêtre, France,* [4]*Institute of Evolutionary Biology, CEXS-UPF-PRBB, Barcelona, Spain,* [5]*Inserm U1078, Brest, France.*

Human adaptation to spatially and temporally varying chemical environments has greatly influenced the present-day distribution of variants involved in xenobiotic response, including drug response. Documenting the general population differentiation patterns at pharmacogenetic genes and studying them in relation with natural selection can help us to better understand the genetic basis of drug response. In this study, we systematically investigated worldwide population differentiation and potential signals of natural selection in a comprehensive list of 45 genes with a known role in the pharmacokinetics or pharmacodynamics of drugs, identified as Very Important Pharmacogenes (VIP) by investigators of the Pharmacogenetics Research Network. To this end, we used frequency data from the 1000 Genomes Project, involving 14 worldwide populations, and estimated the degree of population differentiation, as measured by the fixation index FST, for all SNPs identified in VIP genes. Using genome-wide SNP data, we constructed several empirical distributions according to SNP physical position and function (non genic, genic, 5'-UTR, 3'-UTR, intronic, splice site, coding synonymous and coding non synonymous). An outlier approach based on these distributions allowed to identify highly differentiated variants in ADH1A, ADH1B, CYP3A4, CYP3A5, DRD2, P2RY1 and VKORC1 genes, reflecting the action of diversifying selection, while low levels of genetic differentiation were observed for the P2RY12 and SULT1A1 genes, reflecting homogenizing selection. Our results provide insights into the interethnic genetic differences in VIP genes and provide new candidates for putative functional variants that may contribute to the current variability in drug response within and among human populations.

Genomewide linkage scan for principal components of phospho- and sphingolipids level in blood

I. Zorkoltseva[1], *N. Belonogova*[1], *A. Demirkan*[2], *N. Amin*[2], *A. Kirichenko*[1], *Y. Aulchenko*[1], *C. M. van Duijn*[2], *T. Axenovich*[1];
[1]*Institute of Cytology and Genetics, Novosibirsk, Russian Federation,* [2]*Erasmus University Medical Center, Rotterdam, Netherlands.*

Phospho- and sphingolipids are a complex class of molecules involved in a number of important cellular functions. They influence membrane structure, intracellular signaling and interaction with the extracellular environment. The purpose of this study was to identify quantitative trait loci underlying variations in the lipids level in plasma.
One hundred and twenty eight species of phospho- and sphingolipid were measured in 821 individuals from an extended pedigree from the Erasmus Rucphen Family study. All individuals were genotyped using Illumina 6k linkage chip. Because many lipid levels were highly intercorrelated we redefined phenotypes in terms of principal components composed of linear combinations of the original traits. Linkage analysis was performed using MERLIN.
We identified two significant loci: 11q12.3 (LOD = 5.26) and 19q13.3-q13.4 (LOD = 4.14). The first peak included well known genes *FADS1* and *FADS2*. The second region has not been identified before although the potential candidate genes *TOMM40/APOE* were located on the boundary of the linkage interval. Our linkage peak was not explained by *TOMM40/APOE*, because the linkage signal was not decreased after conditioning on genotypes of rs2075650 and rs157580 in this locus. The next local association analysis of the linkage region demonstrated 33 SNPs with FDR-based q-value <0.05. Three of them (rs1167351, rs4802810, rs736574) demonstrated q-value 0.000135 – 0.000797. GWAS for these SNPs showed p-values 2.78×10^{-8} – 4.93×10^{-7}.
These results indicate the presence of new genes involved in the control of the lipids level in 19q13.3-q13.4 region. Identification of these genes may become possible after exome sequencing.

Population isolates can enhance the power to detect association at low-frequency and rare sequence variation, because of potentially increased allele frequency and extended linkage disequilibrium. We have collected samples from two isolated populations in Greece (HELlenic Isolated Cohorts study, www.helic.org). All samples (n~3000) have information on a wide array of anthropometric, cardiometabolic, biochemical, haematological and diet-related traits. All individuals have been typed on the Illumina OmniExpress and exome-chip platforms, and 250 individuals have been whole-genome sequenced (WGS) at 4x depth. We are in the process of whole-genome sequencing all individuals at 1x depth. We have assessed the degree of relatedness compared to the general Greek population by calculating IBS. We find that 80% of subjects have at least one "surrogate parent" in the isolates, compared to 1% in the outbred Greek population. Using the GWAS and exome-chip data, we find that all of the 14 established fasting glucose level-associated variants (binomial $p=6.1\times10^{-5}$) and 23 of 30 BMI loci (p=0.002611) have the same direction of effect as published studies. Next generation association studies using the HELIC resource have the potential to address study design/methodological questions relating to very low depth WGS, characterise for the first time the population genetics of these populations, and link phenotype to genotype for traits of medical relevance.

Population diversity and history of the Indian subcontinent: Uncovering the deeper mosaic of sub-structuring and the intricate network of dispersals

A. Basu[1], *N. Sarkar Ray*[1], *P. P. Majumder*[1,2];
[1]*National Institute of BioMedical Genomics, Kalyani, India,* [2]*Indian Statistical Institute, Kolkata, India.*

Past genomic studies have provided a broad picture of the peopling of the India: proposing a southern exit route through western coastline and migration from west and central Asia, through north-western corridor. We undertook a genome-wide study (Illumina 1M SNP chip) comprising 367 individuals, drawn from 20 ethnic groups of India representing all geographic regions, linguistic groups and social hierarchies, including hunter-gatherers from Andaman&Nicobar(A&N) Islands.
Our analysis corroborated with previous studies on the existence of deep rooted population structure in India, as evidenced by a high average pairwise FST ~0.04. The average pairwise FST was extremely high (>0.1) between A&N and the mainland Indian populations, indicating the high differentiation.
Unlike Europe, geography alone is a poor predictor of genetic diversity and/or ancestry, as indicated by PCA, ADMIXTURE and MANTEL test indicating complex local histories. There was poor correlation between pairwise genetic distance and geographical distance (0.33).
Our results of admixture estimation and hierarchical clustering reveal that genetically the populations of mainland India form four ancestry clusters (cross validation error minimum (0.52) compared to other competing models).
- TibetoBurman speaking populations of the northeast region
- Upper Caste groups of both northern(IE) and southern(DR) regions
- Austro-Asiatic(AA) speakers of central and eastern region
- DR speaking lower caste and tribal groups of southern region.

On inclusion of the Human Genome Diversity Panel (HGDP) data, we show that the A&N are close to the Polynasian populations, indicating early dispersal routes to Polynasia, Melanasia and Australia.

P16.086

Ascertaining the effect of common and rare copy number variation in primary biliary cirrhosis risk

S. Ji[1], *N. Kumasaka*[1], *C. Shtir*[2], *C. The UK PBC Consortium*[3], *D. J. Gaffney*[1], *C. A. Anderson*[1];
[1]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom,* [2]*Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom,* [3]*Various affiliations, UK, United Kingdom.*

Primary biliary cirrhosis (PBC) is an autoimmune disease of the liver, characterized by immune-mediated destruction of intrahepatic bile ducts. Recent SNP-based association studies have identified 25 independent risk loci, but the role of copy number variants (CNVs) in disease susceptibility has, thus far, not been investigated. Here, we present the first large-scale CNV-based association study of PBC using 2,981 cases from the UK PBC Consortium and 8,970 UK population controls, genotyped using the Immunochip. To accurately call CNV genotypes at both common (minimum aneuploid haplotype frequency (MAF)>1%) and rare CNVs (MAF≤1%) we used two different algorithms. PlatinumCNV, which performs 'per SNP' across sample CNV calling was used to ascertain common CNVs. In contrast, PennCNV, which takes a 'per individual' across SNP approach was used to call rare CNVs. We devised an extensive quality control (QC) pipeline to remove artefacts associated with potential confounding factors such as genotyping centre and DNA source, and performed a number of post-calling QC steps to reduce false-positive CNV calls. In our preliminary analyses to date we have identified one genome-wide significant common CNV (rs9611142: $P=1.30\times10^{-9}$, MAF=0.23) in high linkage disequilibrium (LD) with a known GWAS hit (rs2267407, $r^2=0.76$). Four common CNVs of suggestive significance ($10^{-8}<P<10^{-6}$) were also identified, one of which is not tagged by a known SNP association (maximum $r^2<0.01$). Further analyses of both common and rare CNVs are currently underway and validation and replication analyses are planned. Both CNV and SNP genotypes will be incorporated into our fine-mapping analyses.

Pierre et Marie Curie, Cellule Pasteur UPMC, Paris, France,* [3]*University of British Columbia, Centre for Molecular Medicine and Therapeutics, Child and Family Research Institute, Vancouver, BC, Canada,* [4]*CNRS, MNHN, Université Paris Diderot, Sorbonne Paris Cité, UMR7206 Eco-Anthropologie et Ethnobiologie, Paris, France,* [5]*IRD, MNHN, UMR208 Patrimoines locaux, Paris, France,* [6]*ISH, UMR5596, Laboratoire Dynamique du Langage, Lyon, France,* [7]*Sainte-Justine Hospital Research Centre, Department of Pediatrics, University of Montreal, Montreal, QC, Canada,* [8]*Department of Anthropology, Pennsylvania State University, University Park, PA, United States,* [9]*University of British Columbia, Centre for Molecular Medicine and Therapeutics, Child and Family Research Institute and Department of Medical Genetics, Vancouver, BC, Canada.*

Over the past years, studies have suggested that epigenetic patterns, on top of playing an important role in the fine-tune regulation of gene expression, can also result from both inherited profiles and complex interactions with environmental factors. Epigenetic modifications could then allow fast and transient adaptation to new environments. We hypothesize that variations in epigenetic patterns may exist between populations, depending on their genetic background, their lifestyle and the environment to which they are exposed. To test these hypotheses, we will study 191 individuals from four populations: two African Pygmy populations historically relying on hunter-gathering: the Baka of Western Africa and the Batwa of Eastern Africa; and their respective neighbouring agriculturalist populations: the Nzime and Nzebi of Western Africa, and the Bakiga of Eastern Africa. Pygmy and non-Pygmy populations differ in their genetic background, lifestyle, environment, exposure to pathogens and cultural practices. We will focus on the study of their DNA methylation profile, as being the most accessible and characterized component of the epigenome. To this end, for each sample, we have obtained the genome-wide DNA methylation profile of >450,000 sites, and we genotyped one million SNPs genome-wide. These data will allow us to study the population variation in genetic and epigenetic profiles, and to map common and population-specific methylation quantitative trait loci. By integrating all these results with functional information from existing databases and natural selection information obtained by analyzing genotyping data, we hope to better understand the interaction between genetic diversity, environment, lifestyle and epigenetic modifications in humans.

P16.088

Detection of population stratification on rare variant association studies for nicotine dependence

A. Hsieh, *Y. Li, C. Fann;*
Academia Sinica, Taipei, Taiwan.

To date, rare variants (MAF < 1 % or 5 %) have a proven role in complex diseases. The discovery of these genetic variants and their contribution to the development of diseases lead to several research issues in genetic studies. One of the research issues is that the prevalence of risk alleles varies across populations. Therefore, we considered population stratification based on principal components analysis to explicitly model ancestry differences between cases and controls and applied it into two rare variant detecting methods, i.e., combined multivariate and collapsing (CMC) and weighted sum statistic (WSS) methods. We used the latest publicly available dataset of the Genetic Architecture of Smoking and Smoking Cessation downloaded from the database of Genotypes and Phenotypes. This study includes 3,564 samples across populations (White and Black) genotyped on the Illumina HumanOmni2.5. We identified the specific ethnic association between nicotine dependence and CHRNA7 (p-value =4.25×10-10) in Black and THSD4 (p-value =3.45×10-11) in White which were originally implicated by bioinformatics studies using other nicotine dependence related data sets. The CHRNA7 gene included 113 SNPs (31 were rare) and THSD4 included 775 SNPs (133 were rare). Although these SNPs were not significant (p-value >10-5) by using a Trend test, they were detected by CMC and WSS methods while considering population stratification. In this study, we showed that considering population stratification in rare variant analysis could help gain more insight into identifying genetic risk factors for nicotine dependence.

P16.089

Proteins network involved in Familial Hypercholesterolaemia

A. C. Alves[1,2], *M. Bourbon*[1,2];
[1]*Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal,* [2]*Center for Biodiversity, Functional & Integrative Genomics (BioFIG), Lisbon, Portugal.*

Familial Hypercholesterolemia (FH) is an autossomal dominant disorder characterized by high levels of LDLc and premature cardiovascular disease. In the Portuguese FH Study 60% of clinical FH patients do not present any mutation in FH associated genes (LDLR, APOB, PCSK9, LDLRAP1), so the cause of hypercholesterolemia in these families should be in another gene of lipid metabolism.
The main aim of this project was the analysis of alterations, found by exome sequencing, in genes present in the protein networks of FH associated genes/proteins in order to identify the genetic cause of the hypercholesterolemia in these patients.
The exome sequencing of 5 index patients with clinical diagnosis of FH was performed in an Illumina sequencer and data analysis was performed by annovar software.
The networks of proteins associated with FH have identified 26 genes previously described in several studies as interacting with these genes. A total of 27 variants were found; a large number are synonymous alterations and the vast majority have been previously described in dbSNP. Eleven nonsynonymous alterations have been identified in 5 genes of lipid metabolism (LRPAP1, SORT1, LPA, LRP2 and EGFR) and one has not been described before in dbSNP. Family studies are being conducted to observe co-segregation of the alteration with the phenotype and determine if these variants can be alterations causing disease.
Identification of novel genes causing FH will improve patient identification and prognosis and can lead to the identification of novel lipid lowering drugs.

Background. Wolfram, Alström and Bardet-Biedl (WABB) syndromes are rare diseases, which are characterized by presence of diabetes and visual involvement with significantly shorten life expectancy. There are no treatments available, and no access to well characterized cohorts of patients. The lack of specific health policies and the scarcity of expertise, translate into delayed diagnosis and difficult access to care. Genetic testing centres are concentrated in a few member states with unequal access to testing across the EU.

Methods/Design. EURO-WABB is an international multicentre large-scale observational study capturing longitudinal clinical and outcome data for patients with WABB diagnoses. Comprehensive clinical, genetic and patient experience data are collated into an anonymised and web-based disease registry. 700 participants will be recruited over 3 years from sites throughout Europe.

Discussion. The registry data will be used to increase the understanding of the natural history of WABB diseases, to serve as an evidence base for clinical management, and to aid the identification of opportunities for intervention to stop or delay the progress of the disease processes. The detailed clinical characterization will allow inclusion of patients into studies of novel treatment interventions or multi-national clinical trials. The registry will also support wider access to genetic testing, provide information for affected families and health professionals; and encourage international collaborations for patient benefit. It is hoped that the registry will create a more supportive environment and improved quality of life for WABB patients achieved through earlier diagnosis, prompt identification and management of complications and increased healthy life years.

P16.091

A novel SVM-based approach for detecting rare variants of complex diseases

*Y. Fang, **Y. Chiu**;*
National Health Research Institutes, Zhunan, Taiwan.

Several strategies for the identification of rare variants (RVs) contributing to disease susceptibility have been proposed thus far. The most important feature of several recent proposed new statistical methods is pooling or collapsing multiple rare single nucleotide variants (SNVs) together such that collectively they would have a reasonable high frequency and effect. However, if the pooled RVs are associated with the trait in different directions or if some RVs are non-causal (i.e. they are not associated with the traits), pooling may weaken the signal in associated RVs and thus reduce statistical power. It is therefore helpful to determine whether a RV should be pooled by considering its association effect (including the association direction). Here, we propose a novel support vector machine (SVM) based approach to identify RVs associated with the disease based on the RVs' association effects. The disease may involve both common and rare variants with protective, deleterious or neutral effects. Environmental or gene-gene interactions can be accounted for in this approach. Simulation studies under a wide variety of scenarios and a data example showed the proposed approach outperformed other available approaches.

Background Rheumatoid arthritis (RA) patients rate pain relief as the highest priority in treatment. Interestingly, recent research indicates that inflammation and pain pathways are important, but partly independent, targets of anti-tumour necrosis factor (TNF-inhibitor) therapy. Therefore, identification of genetic factors predicting pain relief is important in efforts to personalize treatment.

Objective We performed a genome-wide association study (GWAS) to identify genetic factors predicting pain reduction during anti-TNF treatment in RA patients.

Methods We conducted a GWAS including 919 RA patients treated with TNF-inhibitor. Association analysis using the relative pain change on a visual analogue scale (VASpain) 14 weeks after treatment initiation as outcome was performed under additive genetic model with adjustment for baseline VASpain. Pathway analysis was performed in Ingenuity.

Results 2,557,253 single nucleotide polymorphisms (SNPs) and 868 patients passed quality control. No findings reached the threshold for genome-wide significance (p-value $\leq 1x10^{-8}$) and lowest p-value identified was $7.27x10^{-7}$. Pathway analysis using all SNPs with a p-value<0.001 identified three canonical pathways to be overrepresented in our dataset. All three show a direct link to pain (processing): neuropathic pain signaling in dorsal horn neurons ($p=1.68x10^{-7}$), synaptic long term depression ($p=4.83x10^{-7}$) and glutamate receptor signaling ($p=5.97x10^{-7}$).

Conclusions We show that pain change after TNF-inhibitor treatment is associated with pain related genes. These genes do not show overlap with previous studies focusing on TNF-inhibitor treatment outcome based on the disease activity score. Identified pathways will be replicated in an independent cohort. Confirmed biomarkers can be used to personalize medication for the individual patient.

Genetic variation underlying common hereditary hyperbilirubinemia (Gilbert's syndrome) and the relationship with respiratory function in the UK 1946 birth cohort.

***L. J. Horsfall**[1], R. Hardy[2], A. Wong[2], D. Kuh[2], D. Swallow[1];*
[1]University College London, London, United Kingdom, [2]MRC Unit for Lifelong Health and Ageing, London, United Kingdom.

Background: Bilirubin has potent antioxidant properties and raised serum levels have been linked with lower rates of respiratory disease. It is currently unknown whether the genetic variation underlying common hereditary hyperbilirubinemia (Gilbert's syndrome) is associated with differences in respiratory function.

Objectives: To examine whether the genetic variation of uridine diphosphate glucuronosyltransferase (*UGT1A1*), which has a major influence on serum bilirubin levels, also influences respiratory function.

Methods: Two functional variants of the *UGT1A1* regulatory region; rs8175347 (TA)n and rs4124874 c.-3279T>G were typed in 2,132 members of 1946 British birth cohort and regression models were fitted to examine the relationship with respiratory function.

Results: The frequency of the low activity variants of rs8175347 and rs4124874 associated with raised bilirubin levels were 0.30 and 0.44 respectively. There was a statistically significant association between *UGT1A1* (TA)n genotypes and lung function at age 43, and an interaction with smoking status at age 53. Mean FEV1 and FVC at age 53 for heavy smokers (≥20 cigarettes per day) with *UGT1A1* (TA)n alleles underlying Gilbert's syndrome was 472 ml (95%CI: 228 to 715) and 580 ml (95%CI: 280 to 881) higher respectively compared with heavy smokers without these alleles. The odds of moderate to severe COPD by age 53 were less than half in those with the *UGT1A1* (TA)n alleles underlying Gilbert's syndrome (odds ratio 0.48 [95%CI: 0.26 to 0.88])

Conclusions: Alleles of *UGT1A1* that cause raised serum bilirubin are associated with increased lung function in adults.

REL and PADI4 polymorphisms and rheumatoid arthritis in the Tunisian population

H. Ben Hassine[1], *O. Khalifa*[1], *E. Chabchoub*[1], *H. Ben Fradj*[2], *A. Attig*[1], *H. Dridi*[1], *I. Boussaid*[1], *A. Boumiza*[1], *A. Achour*[1], *H. Zeglaoui*[2], *N. Mahfoudh*[3], *F. B. H. Slama*[1], *R. Zemni*[1];
[1]*Department of Immunogenetics, Faculty of Medecine, University of Sousse, Sousse, Tunisia,* [2]*Department of Rheumatology, University Hospital Farhat Hached, Sousse, Tunisia,* [3]*Department of Genetics, University hospitak Hedi Chekir, Sfax, Tunisia.*

Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by autoimmunisation against citrulline, potentially leading to severe disability and premature mortality. Citrulline is generated by enzymes called peptidylarginine deiminase (PADs). Both genetic and environmental factors contribute to RA pathogenesis. PADI4 gene (1p36) has been mapped by linkage analysis in RA families. In addition, genome wide association studies (GWAS) had incriminated lately REL as a RA susceptibility locus. Considering these data, we investigated in the Tunisian population four single nucleotide polymorphisms (SNPs) mapping to PADI4 gene (PADI4 94 (rs2240340), PADI4 96 (rs1748032)) and REL gene (rs13031237, and rs6727504).
Two hundred and nineteen RA patients and 300 matched controls were enrolled. Genotyping was determined by Restriction Fragment Length Polymorphism-Polymerase Chain Reaction (PCR-RFLP) and confirmed by Mutagenically Separated PCR (MS-PCR). Frequencies of alleles and genotypes were analyzed using the khi-square test. Statistical significance was assumed at $P < 0.05$.
GT genotype (Rs13031237, REL gene) was significantly associated with the disease (OR = 1.71 (IC95%: 1.26-2.32), P = 0.018). Although, no evident association with anti-CCP or erosion was found. Rs6727504 was not polymorphic in the Tunisian population. In addition, we found no association between PADI4-94 and PADI4-96 SNPs and RA occurrence.
Our study is the first to examine the potential role of REL and PADI4 gene polymorphisms in the Tunisian and the North African populations. Our preliminary results should be confirmed by a larger cohort to validate our conclusion that SNP rs13031237 is in linkage disequilibrium with another polymorphism to identify.

No major impact of insertion/deletion polymorphism of the angiotensin-converting enzyme gene on susceptibility to rheumatoid arthritis in Serbian patients

T. M. Damnjanovic[1], *B. Jekic*[1], *N. Maksimovic*[1], *V. Milic*[2], *L. Lukovic*[1], *V. Bunjevacki*[1], *M. Krajinovic*[3], *I. Novakovic*[1];
[1]*Institute of Human Genetics, Faculty of Medicine, Belgrade, Serbia,* [2]*Institute of Rheumatology, Faculty of Medicine, Belgrade, Serbia,* [3]*Research Center, CHU Sainte-Justine, Montreal, QC, Canada.*

Angiotensin-converting enzyme (ACE) is upregulated in synovial stroma in rheumatoid arthritis (RA). Increased tissue ACE may potentiate synovial hypoxia and proliferation in RA. ACE gene insertion/deletion (I/D) polymorphism has consistently been associated with the variance of serum ACE concentrations.
The aim of this study is to determine genotypes of ACE gene I/D polymorphism in rheumatoid arthritis (RA) patients and to study the correlation between gotten genotypes and susceptibility to RA. A group of 260 RA patients and 101 healthy subjects were included in this study. Patients and controls were gender- and age-matched. DNA was extracted from peripheral blood leukocytes, and I/D polymorphism genotypes of the ACE gene was determined using polymerase chain reaction.
The distribution of ACE I/D genotypes in RA patients (DD 51.9%, ID 31.2 % and II 16.9%) were not significantly different from healthy controls (DD 45.6%, ID 33.6%; and II 20.8%). We have found a higher frequency of D allele in RA patients compared to the controls (67.5 % versus 62.3%) ($\chi 2=1.704$, p=0.191, OR=1, 25, and 95%: 0,892-1, 757) but without significant association. Also, comparison between ACE genotypes in subgroups of patients with RA made by gender, disease duration, values DAS28 and rheumatoid factor positive significant association was not observed.
Our data suggest that ACE gene I/D polymorphism is not a risk factor for RA in Serbian population.

Increased autoimmune diseases prevalence in Sardinian population explained by runs of homozygosity and genomic regions under positive selection

G. Fiorito[1,2], *C. Di Gaetano*[1,2], *F. Rosa*[1], *S. Guarrera*[1], *B. Pardini*[1], *F. Frau*[3,4], *C. Barlassina*[3], *C. Troffa*[4], *G. Argiolas*[4], *R. Zaninello*[4], *F. Ortu*[4], *D. Cusi*[3], *N. Glorioso*[4], *A. Piazza*[1,2], *G. Matullo*[1,2];
[1]*HUGEF - HUman GEnetics Foundation, Turin, Italy,* [2]*Department of Medical Sciences, University of Turin, Turin, Italy,* [3]*Department of Health Sciences, University of Milan, Milan, Italy,* [4]*Hypertension and Related Diseases Center, AOU, University of Sassari, Sassari, Italy.*

Sardinia population is one of the European genetic outliers because of its historical and geographical isolation, characterized by an increased prevalence of certain disorders like type 1 diabetes or multiple sclerosis.
The objective of this study was to provide a plausible explanation of the increased autoimmune diseases prevalence in the Island, analyzing Runs of Homozygosity (ROH) and genetic regions showing signatures of positive selection.
About 1.2M Single Nucleotide Polymorphism (SNP) genotyped in 1077 Sardinian individuals were used to investigate the genetic population structure, as well as to estimate ROH and Extended Haplotype Homozygosity (EHH) regions.
Fixation index (F_{st}) values, λ inflation factors and Multidimensional Scaling analyses supported a high level of homogeneity in the Sardinian population.
Several short ROH (0.5Mb-2Mb), characteristic of the island population were identified. These regions contain genes already described as involved in the onset of several autoimmune diseases. Moreover, by means of EHH analysis, we identified various genomic regions showing footprint of positive selection and, once again, harbor genes associated with autoimmune diseases.
In conclusion, we confirmed the high genetic homogeneity of Sardinia, making this population very useful for association studies. Moreover, we showed that the high prevalence of certain diseases may be explained by the shared ancestry combined with the action of evolutionary forces. Therefore, estimation of ROH and EHH are efficient techniques to explain disease variability in isolated population.

Genetic structure of Romani populations in Croatia - analysis of autosomal STR loci

K. Pokupcic[1], *A. Baresic*[2], *A. Galov*[3], *B. Janicijevic*[2], ***M. Pericic Salihovic***[2];
[1]*Forensic Science Centre „Ivan Vucetic", Zagreb, Croatia,* [2]*Institute for Anthropological Research, Zagreb, Croatia,* [3]*Faculty of Science, University of Zagreb, Zagreb, Croatia.*

Roma population is the largest transnational minority in Europe, made of numerous endogamous groups which share common Indian origin. Based on the history of early migrations to Europe, they might be classified into the Balkan Roma, the Vlax Roma, and the Northern/Western European Roma. In order to capture genetic variation of Roma population in Croatia we analysed 15 autosomal STR loci (AmpFlSTR Identifiler) on 536 Roma belonging to two major migration categories: Balkan and Vlax. Vlax Roma samples comprise individuals from two different linguistic groups (Munteni and Ardeleni). Diversity indices pointed to the lowest diversity among Ardeleni Vlax Roma. Moreover, Fst and Rst genetic distances show closer relationship between Balkan and Munteni Vlax populations than between two Vlax Roma populations. STRUCTURE program analysis revealed the highest deltaK for K=2, assigning Ardeleni Vlax individuals separately. Although it would be expected that Vlax Roma groups cluster together according to migration data, the clustering of Munteni Vlax population closer to Balkan Roma suggests that despite of common migration history the gene pool of Vlax Roma population shows pronounced differentiation, probably due to strict socio-cultural rules of the endogamous groups within migration category. High level of endogamy in Ardeleni Vlax group is also confirmed with our socio-cultural data collected in regard to this population. Due to extremely polymorphic nature of analysed loci further analyses are needed to entirely resolve genetic relations among endogamous Roma groups.

Investigating the Effect of Sequencing Depth on Low Coverage Next Generation Sequencing Association Studies

T. S. Shah, *J. Z. Liu, Y. Luo, M. O. Pollard, C. A. Anderson;*
Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Whole-genome and exome sequencing will allow researchers to probe the role of rare genetic variation in disease susceptibility. Low coverage sequencing with multi-sample calling has made large-scale case-control sequencing association studies feasible. However, cases and controls will often be sequenced at different depths, possibly as a result of using common controls. In this preliminary work we investigate how changes in depth affect variant discovery, genotype accuracy and power to detect association. Initial analysis was performed on whole-genome sequence data from 1,754 Crohn's disease cases sequenced at a mean coverage of 4X. In a series of simulations, sequencing reads were randomly downsampled from 4X to a mean depth of 2X. SNP genotypes were called for downsampled and original read depths using a combination of Samtools, GATK and Beagle. 37% of variants detected in the 4X data were missing after downsampling. The majority of these missing variants were rare (mean MAF 0.027 in 4X data), around half being either singletons or doubletons. For SNPs appearing in both 2X and 4X sets, genotype comparisons between depths showed rare (MAF < 0.005) and low-frequency (MAF between 0.005 and 0.05) SNPs had lower mean R-squareds (0.811 and 0.837 respectively) than common ones (SNPs with MAF > 0.05 had mean R-squared 0.954).
To extend our analysis we will investigate a wider range of sequencing depths. We will report how differences in sequencing coverage between cases and controls affect power to detect association compared to balanced designs where cases and controls are sequenced at identical depths.

Developing the Polygenic Model for Schizophrenia

E. Hannon, *P. Holmans, A. Pocklington;*
Cardiff University, Cardiff, United Kingdom.

Genetic risk for schizophrenia is thought to comprise of thousands of variants including common single nucleotide polymorphisms (SNPs) of small effect. This is known as a polygenic effect and has been demonstrated through the polygenic model. Based on genome-wide association study results, the total number of associated risk alleles, weighted by their odds ratios, is counted for each individual in an independent sample and shown to be significantly different between cases and controls. Here we present three developments of this effective yet simple model; allowing for multiple populations, inclusion of linkage disequilibrium (LD) and inclusion of interactions.
In the original application, population stratification was controlled for in the association test to produce a single odds ratio for each SNP. The model was reformulated to include multiple odds ratios for the different populations, which were then weighted for each individual by the likelihood of them coming from that population. In the current polygenic framework stringent pruning is applied to ensure SNPs are independent, thus losing information from the SNPs that are removed. An alternative method is proposed that allows for LD at the association analysis stage, meaning more SNPs can be retained. Finally the model was extended to include interactions between independently associated SNPs. For each model odds ratios were calculated in the International Schizophrenia Consortium study, and fitted with data from the Molecular Genetics of Schizophrenia study. Each adaptation was compared to the original formulation.

Looking for a fine-scale genetic structure in Western France human populations

C. DINA[1,2], *N. Duforêt-Frebourg*[3], *F. Simonet*[1], *S. Lecointe*[1], *F. Gros*[1], *H. Le Marec*[1,2], *R. Redon*[1,2], *J. Schott*[1,2], *M. Blum*[3], *M. Karakachoff*[1,4];
[1]*institut du Thorax - Inserm UMR 1087 / CNRS UMR 6291, Nantes, France,* [2]*CHU de Nantes, Nantes, France,* [3]*Unité Mixte de Recherche CNRS Université Joseph Fourier UMR 5525, TIMC-IMAG, Grenoble, France,* [4]*Istituto di Fisiologia Clinica, Pisa, Italy.*

The Common Variant Common Disease hypothesis was only partly verified through effective discovery of statistical associations. This empirical observation led the research community to reconsider the importance of rare variants.
The rare alleles of recent origin are likely to cluster geographically in communities with limited migration rates, like French rural populations before 20th century. Where these rare alleles strongly increase the risk of disease, we'd expect outbreaks of disease prevalence and enhanced power to establish the variant-phenotype relationship.
This work aims to assess whether the demographical history of some regions of Western France lends itself to a fine-scale population structure. This analysis was performed considering patients enrolled at Western France hospitals as having a Calcific Aortic Valve Stenosis (CAVS) diagnosis. Geographical location of individuals was defined according to the declared place of birth. This group of patients was genotyped genome-wide using Affymetrix Axiom chip.
In the preliminary Principal Components Analysis, the first two principal components revealed an important correlation with geography ($p < 1e-04$). There is a clear clustering of people from Brittany and people from Vendée, two regions geographically close.
These preliminary results show that population stratification can be observed even at a very low level in populations usually considered as open and panmictic. This strongly suggests that recent rare alleles are likely to cluster geographically even in these populations. Therefore, identification of rare variants inducing disease susceptibility can benefit from a strategy focusing on small geographic units.

P16.101

Statistical Prioritization of Sequence Variants

W. Li[1,2], *L. J. Strug*[2,1];
[1]*Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada,* [2]*Child Health Evaluative Sciences, Hospital for Sick Children, Toronto, ON, Canada.*

Association studies with sequence data require prioritizing variants for follow-up experiments. Statistical information contributes to this prioritization. Standard statistical methods rank sequence variants using exact p-values. However, one-sided and two-sided p-values can rank the same set of variants differently, suggesting problems in ranking sequence variants using exact p-values. Summarizing the disease-variant distribution into 2x2 tables, here we propose to rank sequence variants using the maxLRc, defined as the ratio of the conditional likelihoods evaluated at the maximum conditional likelihood estimate of the odds ratio versus at an odds ratio of 1. We have shown analytically that, under the best-case scenario when the disease-variant distribution is in quasi-complete (one empty cell) or complete separation (two diagonal empty cells), the maxLRc always results in the same rankings as one-sided exact p-values when the alternative hypothesis is specified in the "correct" direction (directional p-values). Under the more common case of overlap (no empty cell), there is no general agreement among two-sided p-values, directional p-values and maxLRc. However, using simulated data, we show that when the number of controls is greater than the number of cases, rankings assigned by maxLRc correlate better with the true rankings than p-values. We also illustrate our approach in a study of Rolandic Epilepsy. The maxLRc ranks variants using only information obtained from the observed data, whereas p-values incorporate the probability of more extreme observations that could have been observed. A more extreme observation is defined by the investigator's a priori belief in the direction of the association.

P16.103

A "population-based approach" to study the link between TAS2R genes, taste perception and food liking

A. Robino[1], *M. Mezzavilla*[1], *N. Pirastu*[1], *B. Tepper*[2], *P. Gasparini*[1];
[1]*Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", University of Trieste, Trieste, Italy,* [2]*Department of Food Science, School of Environmental and Biological Sciences, Rutgers University, New Brunswick, NJ, United States.*

Variations at the TAS2R38 gene account for the major portion of differences in PROP (6-n-propylthiouracil) taste perception, which have been shown to influence food preferences and dietary behaviour. We examined the link between PROP taste responses, food preferences and TAS2R genes in six different populations of the Caucasus and Central Asia, located along the Silk Road. We reported, for the first time, genotypic frequencies of the TAS2R38 gene and PROP phenotype distribution in these populations. We found a strong relationship between PROP tasting and food preferences (r=0.67, p-value=0.009) using a "population-based approach", in which we exploit phenotypic differences between populations comparing a distance matrix based on PROP taste responses and a matrix based on food preferences. No

evidence of correlation was found between the distance matrix of food preference and the matrix of genetic distance based on TAS2R38 or the matrix based on the whole genome. Preliminary results of candidate gene analysis allowed us to identify others TAS2R genes that could cooperate with TAS2R38 in the modulation of PROP perception and as consequence food liking.
Besides increasing the knowledge of worldwide TAS2R38 prevalences and bitter taste, our results show that differences in food preferences among populations correlate with PROP status but not with the TAS2R38 gene, suggesting that PROP status is probably a marker for general taste sensitivity and as such is a major driver of food preferences. In addition, our work represent a starting point to study the involvement of multiple genes in bitter perception and food liking.

P16.104

Molecular screening of δ- globin chain gene in a population from Eastern Sicily (Italy).

C. Di Bella, *S. Cara, F. Pugliatti, M. La Rosa, V. Procopio, M. Amorini, P. Romeo, C. Liuzzo, C. Salpietro, L. Rigoli;*
Department of Pediatrics, Medical School, Messina, Italy.

In β-thalassemia carriers, a deficit of δ-globinic chain could mitigate the haematological phenotype with an increase of HbA2 (α2δ2) milder compared to the expected values. Therefore, a β-thalassemia carrier could not be identified. In Eastern Sicily (Italy), the Yalousa (δcd27) mutation is the most frequent variant (81%) of the δ- globin chain gene. It is localized at codon 27 and causes a δ+ thalassemia.
In our study, we selected 50 subjects from the Eastern Sicily (Italy), with values of HbA2 between 2.1% and 1.6%, associated with a normal haematological phenotype. Moreover, we recruited 4 **α**-thalassemia carriers, and 5 β-thalassemia carriers. DNA samples were analyzed by ARMS-PCR to detect the δcd27 mutation. To identify other mutations, we performed an automatic sequencing of the δ- globinic chain gene and GAP-PCR to detect the δ-Corfù hemoglobin.
We found the δcd27 mutation in 31/50 (62.0%) subjects and in the 5 β-thalassemia carriers. In the
4 α-thalassemic carriers, we found 2 subjects with δcd12 (Asn>Lys) (Hb Nyu) mutation at the heterozygous state (δ+ thalassemia), and 1 heterozygote subject for the δcd4 (Thr>Ile) genetic variant (δ+thalassemia).
Our study showed that there is a considerable heterogeneity of δ- globinic chain gene mutations.
Therefore, we conclude that the screening of δ- globinic chain gene is important for a complete typing of the β-thalassemia carriers. Indeed, the coheredity of several molecular defects of the globin genes may modify the phenotypic paintings so as to make them silent and hide conditions of great importance in genetic counseling of couples.

Rationale: Telomere length is recognized as a marker of biological age. Previous studies reported decreased telomere length in patients with chronic obstructive pulmonary disease (COPD), suggesting premature aging due to environmental exposure and/or chronic inflammation. Since the lungs are continuously exposed to environmental hazards, lung function per se may be a surrogate marker for biological age in light of the large inter-individual variability observed.
Objectives: We investigated the association of telomere length with respiratory disease (COPD and asthma), and spirometric indices: forced expiratory volume in one second (FEV1), forced vital capacity (FVC) and FEV1/FVC.
Methods: Our meta-analysis of 14 studies included 1,189 COPD cases with 16,115 controls, 2,834 asthma cases with 28,195 controls and spirometric parameters of 13,100 individuals. Associations were tested by linear regression, adjusting for age, sex, and smoking status.
Measurements and Main Results: We observed negative associations between telomere length and COPD (β=-0.0676, p=0.018) as well as asthma (β=-0.0452, p=0.024) with stronger effects in women compared to men. The investigation of spirometric indices showed positive associations between telomere length and FEV1 (p=1.62x10-7), FVC (p=2.38x10-4), and their ratio FEV1/FVC (p=6.13x10-3). The associations were weaker in apparently healthy subjects compared to COPD or asthma patients.
Conclusions: Our results indicate that lung function may reflect biological aging primarily due to intrinsic processes which are likely to be aggravated in lung diseases. Shortened telomeres in lung disease suggest that aging processes are involved in the pathogenesis of COPD and asthma.

Rare Variant Extensions of the Transmission Disequilibrium Test Detects Associations with Autism Exome Sequence Data

Z. He[1], *B. O'Roak*[2], *J. Smith*[2], *G. Wang*[1], *S. Hooker*[1], *B. Li*[1], *M. Kan*[1], *N. Krumm*[2], *D. Nickerson*[2], *E. Eichler*[2], *S. M. Leal*[1];

Many population-based rare variant association tests have been developed to analyze sequence data. A drawback of these methods is that it is difficult to adequately control for population substructure and/or admixture and spurious associations can occur. For rare variants this problem can be substantial, because the spectrum of rare variation can differ greatly between populations. A solution is to perform analysis using the transmission disequilibrium test (TDT), which was developed to analyze trio data and is robust to population substructure/admixture. Sequence data is being generated on trios to detect de Novo events, and is also useful to detect association with transmitted variants. We extended the TDT to test for rare variant (RV) associations using four commonly used rare variant association methods. We demonstrate that for all RV-TDT tests type I error is well controlled even when there are high levels of population substructure or admixture. The power of the RV-TDT tests was evaluated using a number of population genetic and disease models. The RV-TDT was used to analyze exome data from 199 Simons Simplex Collection (SSC) autism trios. Using the RV-TDT an association was found between autism and rare variants in the *ABCA7* gene. Given the problem of adequately controlling for population heterogeneity in rare variant association studies and the growing number of sequenced based trio studies the RV-TDT is extremely beneficial to elucidate the involvement of rare variants in the etiology of complex traits.

Aims: We had noted preferential transmission of mutant alleles in Long QT syndrome (LQTS) families, which suggested a survival advantage for affected gametes. To determine whether this phenomenon depends on LQTS mutations or gene loci (LQT1, *KCNQ1* in 11p15.5; LQT2, *KCNH2* in 7q36.1; LQT3, *SCN5A* in 3p22.2), we studied parental and grandparental origins of alleles transmitted in LQTS and control families and the role of channel dysfunction in the transmission distortion.

Methods and Results: We studied 3782 genotyped members from 679 European and Japanese LQTS families (2748 carriers). We determined grandparental and parental origins of mutant alleles in 1892 children and 619 grandchildren, and grandparental origin of normal alleles in healthy children from 44 three-generation control CEPH families. In families from Europe and Japan, mutant alleles were significantly more frequently maternal than paternal in origin (61%, 1155 vs. 737 alleles,p<0.001). The ratio of maternal alleles in LQT1 (66%) was significantly higher than in LQT2 (56%, p<0.001) and LQT3 (57%, p=0.01). Unlike control families' Mendelian distribution of grandparental alleles, mutant grandparental LQT1 and LQT2 alleles in grandchildren showed excess maternal grandmother alleles. For LQT1, maternal origin mutant alleles bore a significant relationship to the level of dysfunction (dominant negative 67%, non-dominant 58%, p<0.03), however for LQT2 or LQT3 this association was not significant.

Conclusion: An excess of mutant alleles of maternal origin, most pronounced in LQT1, is homogeneous across ethnic groups. This is not linked to a locus-specific grandparental origin allele transmission distortion, but to potassium channel dysfunction.

Only a small fraction of individuals infected with *Mycobacterium tuberculosis* develop clinical tuberculosis (TB) in their lifetime. Genetic epidemiological evidence suggests a genetic determinism of pulmonary TB (PTB), but the molecular basis of genetic predisposition to PTB remains largely unknown. We used a positional-cloning approach to carry out ultrafine linkage-disequilibrium mapping of a previously identified susceptibility locus in chromosomal region 8q12-13 by genotyping 3,216 SNPs in a family-based Moroccan sample including 286 offspring with PTB. We observed 44 PTB-associated SNPs (p < 0.01), which were genotyped in an independent set of 317 cases and 650 controls from Morocco. A single signal, consisting of two correlated SNPs close to *TOX*, rs1568952 and rs2726600 (combined p = $1.1x10^{-5}$ and $9.2x10^{-5}$, respectively), was replicated. Stronger evidence of association was found in individuals who developed PTB before the age of 25 years (combined p for rs1568952 = $4.4x10^{-8}$; odds ratio of PTB for AA versus AG/GG = 3.09 [1.99-4.78]). The association with rs2726600 (p=0.04) was subsequently replicated in PTB-affected subjects under 25 years in a study of 243 nuclear families from Madagascar. Stronger evidence of replication in Madagascar was obtained for additional SNPs in strong linkage disequilibrium with the two initial SNPs (p=0.003 for rs2726597), further confirming the signal. We thus identified around rs1568952 and rs2726600 a cluster of SNPs strongly associated with early-onset PTB in Morocco and Madagascar. SNP rs2726600 is located in a transcription-factor binding site in the 3' region of *TOX*, and further functional explorations will focus on CD4 T lymphocytes.

Distribution of eight SNPs of lipid level modifier genes in healthy Roma and Hungarian population samples

J. Bene[1], *K. Sumegi*[1,2], *L. Jaromi*[1,2], *L. Magyari*[1,2], *E. Kovesdi*[1,2], *B. Duga*[1], *R. Szalai*[1,2], *P. Matyas*[1], *A. Szabo*[1], *Z. Banfai*[1], *B. Melegh*[1,2];

[1]University of Pécs, Department of Medical Genetics, Pécs, Hungary, [2]Szentagothai Research Centre, Pécs, Hungary.

The role of triglyceride metabolism in various diseases, such as cardiovascular or cerebrovascular diseases is still in the focus of numerous extensive investigations. Several polymorphisms associated with plasma lipid level changes are published in genome-wide association studies. Here we report the results of the genetic analysis of eight variants, rs12130333 at the ANGPTL3, rs16996148 at the CILP2, rs17321515 at the TRIB1, rs17145738 and rs3812316 of the MLXIPL, rs4846914 at GALNT2, rs1260326 and rs780094 residing at the GCKR loci. We genotyped 399 Roma and 404 Hungarian samples with PCR-RFLP method. Significant differences were found between Roma and Hungarian population samples in the allele frequency of ANGPTL3 variant (T allele frequency of rs1213033: 12.2% vs. 18.5% in Romas vs. Hungarians, p<0.025), of both MLXIPL variants (C allele frequency of rs17145738: 94.1% vs. 85.6%, C allele frequency of rs3812316: 94.2% vs. 86.8% in Romas vs. in Hungarians, p<0.025), and of GALNT2 variant (G allele frequency of rs4846914: 46.6% vs. 54.5% Romas vs. in Hungarians, p<0.025), while no differences could be verified in the remaining SNPs and the known minor alleles showed no correlation with triglyceride levels in any population samples. Our results suggest that these SNPs may be considered as risk factors for metabolic or cardio-cerebrovascular diseases in different population samples. The current study revealed fundamental differences of triglyceride modifying SNPs in Roma populations, although here we cannot associate the changes with triglyceride levels, the minor alleles still can have clinical implication as disease susceptibility.

P16.110

Type 2 diabetes risk alleles near BCAR1 and in ANK1 associate with decreased β-cell function whereas risk alleles near ANKRD55 and GRB14 associate with decreased insulin sensitivity in the Danish Inter99 cohort

M. N. Harder;

Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark.

Context: Recently, ten novel type 2 diabetes (T2D) susceptibility single nucleotide polymorphisms (SNPs) in *ZMIZ1*, *ANK1*, *KLHDC5*, *TLE1*, *ANKRD55*, *CILP2*, *MC4R*, *BCAR1*, *HMG20A* and *GRB14* loci were discovered in Metabochip-genotyped populations of European ancestry.

Objective: The present study aimed to characterize pre-diabetic quantitative traits underlying these SNP associations and to calculate the amount of inter-individual variation in glycemic traits explained by these and previous T2D susceptibility variants.

Design and Participants: 5,739 Danish individuals naïve to glucose-lowering medication were included in quantitative trait studies, while case-control

analyses were performed in 1,892 T2D patients and 6,603 normoglycemic controls. Participants without known T2D underwent an oral glucose tolerance test (OGTT), and measures of insulin release and sensitivity were estimated from insulinogenic, disposition, BIGTT and Matsuda indexes.
Results: We confirmed associations of *ZMIZ1*, *KLHDC5*, *CILP2*, *HMG20A*, *ANK1*, *ANKRD55* and *BCAR1* with T2D. The risk T-allele of *BCAR1* rs7202877 associated with decreased disposition index (*P*=0.02). The C-allele of *ANK1* rs516946 associated with decreased insulinogenic (*P*=0.005) and disposition (*P*=0.002) indexes. The G-allele of *ANKRD55* rs459193 associated with decreased Matsuda index (*P*=0.02) adjusted for waist circumference. The C-allele of *GRB14* rs13389219 associated with both increased insulinogenic (*P*=0.04) and decreased Matsuda (*P*=0.05) indexes. All validated European T2D variants still only explained a few percentages of glycemic trait variation.
Conclusion: If replicated in independent samples *BCAR1* rs7202877 may mediate its diabetogenic impact through impaired β-cell function. In addition, we substantiate previous evidence that *ANK1* rs516946 confers impaired insulin release and *ANKRD55* rs459193 and *GRB14* rs13389219 associate with insulin resistance.

M.N. Harder: None.

Mediation of Genetic Effects

A. Ulgen[1], *J. Hjelmborg*[2], *W. Li*[3];
[1]*Faculty of Medicine, Eastern Mediterranean University, Famagusta, Cyprus,* [2]*Dept of Biostatistics, University of Southern Denmark, Odense, Denmark,* [3]*Robert S Boas Center for Genomics and Human Genetics, Feinstein Institute for Medical Research, Manhasset, NY, United States.*

We apply a genetic modeling via simulation to twin data from Nordic Twin Registry for obesity and cancer related measurements. For obesity, we use both BMI and other quantities derived from BMI to measure the weight growth. More specifically, the log(BMI) at baseline is regressed over other factors: ln(BMI_ij)= beta_i + alpha_i *j +gamma*age_i+epsilon_ij, for individual i and timepoint j (time since the baseline, in years). The alpha_i is then the log-weight growth rate (Hjelmborg et al. Obesity, 16(4), 2008). For cancer data, we use phenotypes available in the registry.
We follow the genetic modeling of twin data proposed by (Dite et al. and Stone et al; Cancer Epidemiol Biomarkers Prev; 17(12), 2008 and 21(7), 2012, respectively). In this modeling, the phenotype of a twin in a twin pair is regressed over both twins' co-variates. If the two twins in a twin pair are labeled as 1 and 2, Y denotes phenotype and X co-variate, then E(Y)= alpha + beta1 X1 +beta2 X2. It was shown that by varying a covariate experimentally, the expected value of the phenotype measure would change.
In our analysis, we assume a bivariate normal distribution for both (Y1,Y2) and (X1,X2). We treat phenotype measurements such as BMI, growth rate, at the baseline time as X, and that at the later time as Y. This approach would incorporate measurements at two points along a time course, thus enhance the power to detect the genetic component. We also introduce a random effects model for the stratification effects.

P16.112
Association between *USF1* and type II diabetes in Turkish adults.

M. Poda[1], *S. E. Humphries*[2], *A. Onat*[3], *G. Can*[4], *N. Erginel–Unaltuna*[1];
[1]*Department of Genetics, Institute of Experimental Medicine (DETAE), Istanbul University, Istanbul, Turkey,* [2]*Center for Cardiovascular Genetics, Royal Free and University College London Medical School, Rayne Institute, London, United Kingdom,* [3]*Emeritus, Department of Cardiology, Cerrahpasa, Medical Faculty, Istanbul University, Istanbul, Turkey,* [4]*Department of Public Health, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey.*

Background: Upstream stimulatory factor 1 (*USF1*) belongs to the basic helix-loop-helix leucine zipper family. *USF1* controls expression of genes involved in lipid and glucose homeostasis and the gene has been linked with familial combined hyperlipidemia (FCHL). USF1 haplotypes have shown to be associated with glucose and lipid parameters in the EARSII study. We therefore evaluated the association of two *USF1* SNPs (rs3737787 and rs2073658) with type 2 diabetes (T2DM) in the adult Turkish population.
Methods: We genotyped 1831 subjects (895 males of mean age 52.91+/-11.80 and 936 females of mean age 52.5+/-11.82) and analyzed clinical data.
Results: The genotype (rs2073658; CC: 0.54, CT: 0.39, TT: 0.068; rs3737787; GG: 0.54, GA: 0.38, AA: 0.74) and haplotype (CG: 0.7, CA: 0.038, TG: 0.034, TA: 0.228 at D'=0.824) frequencies were determined. We observed an excess of TA haplotype and the two variants were in LD with each other. T2DM was more prevalent in males carrying the T (11.2% vs. 15.9% (p=0.036)) allele of rs2073658 compared to homozygotes for the C allele. After adjustment for confounding factors including age, physical activity, BMI, smoking and alcohol consumption logistic regression models revealed that male carriers of the T allele of the this polymorphism had higher risk of having T2DM (OR=1.81 [95%CI 1.20-2.74], p=0.005).
Conclusion: In this study we detected an association between the rare allele of the *USF1* gene and T2DM risk in Turkish adults for the first time.

P16.113
Contribution of rs7756992 of CDKAL1 and rs4402960 of IGF2BP2 to the risk of type 2 diabetes in the Tunisian population.

K. Lasram[1,2], *N. Ben Halim*[1,2], *S. Hsouna*[1,2], *I. Arfa*[1,2], *H. Jamoussi*[1,3], *A. Abid*[1,3], *S. Abdelhak*[1,2], *R. Kefi*[1,2];
[1]*Institut Pasteur de Tunis, Laboratory of Biomedical Genomics and Oncogenetics, Tunis, Tunisia,* [2]*Université Tunis El Manar, Tunis, Tunisia,* [3]*National Institute of Nutrition and Food Technology, Department of external consultation,, Tunis, Tunisia.*

Aims: The insulin-like growth factor 2 mRNA-binding protein 2 (IGF2BP2) and the cyckin-dependent kinase 5 regulatory subunit-associated protein 1-like 1 (CDKAL1) identified through GWAS studies have been shown to be associated with type 2 diabetes in various ethnic groups. The study aim was to investigate the association of the rs7756992 of CDKAL1 and rs4402960 of IGF2BP2 with T2D and diabetic complications (nephropathy and retinopathy).
Methods: We performed a case-control association study including 200 T2DM Tunisian patients (WHO criteria) with diabetic nephropathy (33%), diabetic retinopathy (41.5%) and 208 controls (age ≥40; fasting plasma glucose <6.1 mmol/l; without first degree family history of diabetes). Genotyping was performed using TaqMan technology. Statistical analyses were carried out using Stata 11 software (StataCorp, College Station, TX, USA).
Results: We found a significant association between the rs4402960 of IGF2BP2 and T2DM (p < 10-4). Furthermore, the rs7756992 of CDKAL1 was associated with the reduced risk of diabetic nephropathy in patients with diabetes (p = 0.001).
Conclusion: The present study confirms that the rs4402960 of IGF2BP2 gene is a strong candidate for type 2 diabetes susceptibility across different ethnicities. Interestingly, our study is the second one that described the rs7756992 of CDKAL1 gene as associated with diabetic nephropathy.

Cysteinyl leukotriene 1 and cysteinyl leukotriene 2 receptors are associated with atopic asthma in a founder population

M. D. Thompson[1], *V. Capra*[2], *J. Stankova*[3];
[1]*University of Toronto, Department of Pharmacology, Toronto, ON, Canada,* [2]*University of Milan, Department of Pharmacological Sciences, Milan, Italy,* [3]*Université de Sherbrooke, Department of Pediatrics, Sherbrook, QC, Canada.*

The atopy phenotype underlies many cases of asthma. The cysteinyl leukotriene receptor 1 (cysLT1) and 2 (cysLT2) genes have been important subjects of study because they are functionally and pharmacologically implicated in the atopy phenotype affecting many asthma subjects. In a founder population, we reported that the G300S variant of the cysLT1 receptor gene and the M201V variant of the
CysLT2 receptor gene are implicated in atopic asthma. In this report, we discuss the statistical association of both variants with the atopy phenotype - a phenomenon that may suggest that the interaction of
cysLT1 and cyLT2 gene variants gives rise to atopy in some populations. In vitro analysis has shown that cysLT1 and cysLT2 proteins directly interact within the
cell: representing a putative mechanism for the etiology of atopy in certain asthmatic populations.

P17.1

Segmenting the human genome based on states of neutral genetic divergence

K. Makova, *P. Kuruppumullage Don, G. Ananda, F. Chiaromonte;*
Penn State University, University Park, PA, United States.

Many studies have shown that levels of divergence generated by different mutation types vary and co-vary across the human genome. However, this phenomenon has been neither characterized simultaneously for multiple mutation types nor anchored to specific regions of the genome. A complete understanding of its mechanistic basis has also been lacking. Here we fit Multivariate Gaussian Hidden Markov Models to insertion, deletion, nucleotide substitution and microsatellite human-orangutan divergence estimates inferred in neutrally evolving regions of the human genome. We segment the genome into contiguous segments forming six divergence states, each characterized by a specific divergence profile, and associate these states with 35 genomic landscape features, parsing the contributions of different biochemical processes to mutagenesis. High divergence states inhabit GC-rich, highly recombining sub-telomeric regions, while low divergence states cover inner parts of autosomes. Chromosome X forms its own, lowest divergence state. The state of elevated microsatellite mutability is interspersed across the genome. This characterization is echoed in a segmentation based on human diversity data (from the 1,000 Genomes Project). Deviations from these general trends highlight the evolutionary history of primate chromosomes. We further demonstrate that genes and non-coding functional marks (ENCODE annotations) localize in the genome according to the underlying divergence states. In particular, functional elements are enriched in states with elevated divergence. These segmentations allow screening personal genome variants, including those associated with cancer and other diseases, and provide a framework for accurate computational predictions of non-coding functional elements. Therefore, our results provide a powerful resource for biomedical data analysis.

High impact of genetic drift on the isolated population of Rab Island - evidence from mitochondrial DNA diversity

D. Havaš Augustin[1], *N. Jeran*[1], *N. Novokmet*[1], *J. Šarac*[1], *T. Šarić*[1], *E. Metspalu*[2], *B. Vojniković*[3], *R. Villems*[2], *P. Rudan*[1,4];
[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Estonian Biocentre and Institute for Molecular and Cell Biology, Tartu, Estonia,* [3]*Eye Clinic "Dr. B. Vojniković", Rijeka, Croatia,* [4]*Anthropological Center of the Croatian Academy of Sciences and Arts, Zagreb, Croatia.*

The Croatian Island of Rab is situated in the Northern Adriatic Sea. Evidence of human presence are seen from the Neolithic period and ever since this Island has been inhabitated by many ethnically different populations. After Illyrians and Romans, one of the most genetically and historically important periods was arrivals of Slavic tribes from 8th until 10th century. Here we present the evidence of high impact of the genetic drift on the genetic diversity and structure of the contemporary Rab Islanders. Analysis of mitochondrial DNA haplogroups of 163 autochthonous inhabitants from 5 settlements revealed relatively high level of haplogroup and haplotype diversity in the overall sample due to dynamic gene flow throughout history. On the other hand, only four haplogroups (H6, HV, J1c and U4) encompass more than one half of total maternal gene pool of this Island. Even so, every fourth contemporary Islander has one particular haplotype of U4d2 haplogroup. This is so far the most frequent finding of this haplogroup ever reported in any population (24.5 %). One possible explanation of such high deviation from average European frequency could be due to several epidemics of plague in 15th and 16th century when a vast majority of population died, in some cases almost 90 % of some settlements were devastated. The results of this study gave insight into microevolutionary processes that shaped the current maternal gene pool of this northern Adriatic Island.

Geographical Substructuring on Eastern Adriatic Islands

T. Šarić[1], *J. Šarac*[1], *N. Jeran*[2], *D. Havaš Augustin*[1], *N. Novokmet*[1], *E. Metspalu*[3], *N. Vekarić*[4], *S. Missoni*[1], *R. Deka*[5], *R. Villems*[3], *P. Rudan*[1,6];
[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Institute for Anthropological Research; at the time of research, Zagreb, Croatia,* [3]*Estonian Biocenter and Institute for Molecular and Cell Biology, Tartu, Estonia,* [4]*Institute for Historical Sciences of the Croatian Academy of Sciences and Arts, Dubrovnik, Croatia,* [5]*Departament of Environmental Health, College of Medicine, University of Cincinnati, Cincinnati, OH, United States,* [6]*Anthropological Center of Croatian Academy of Sciences and Arts, Zagreb, Croatia.*

This poster shortly portrays an analysis of the matrilineal legacy of two Eastern Adriatic islands, Hvar and Korčula. Both islands fit into a southern group of Eastern Adriatic islands, belonging to the cities of Split and Dubrovnik municipalities, respectively. We have analysed a total of 250 mtDNAs based on high resolution analysis of SNPs from the control and coding region. Results show a relatively high diversity of haplogroups: 7 haplogroups and 37 subhaplogroups, altogether. Despite a relatively small population (11103 on Hvar, 16182 on Korčula) and sample size (161 from Hvar, 89 from Korčula) of both Islands, the analysis showed a tendency of population substructuring depending on the geographical region of the island, when mitochondrial DNA haplogroup distribution is concerned. While Hvar islanders are divided into an Eastern and Western group, the Korčula islanders show a three-way distribution into Northern, Eastern and Western group. Also, two unexpected and rare haplogroups were discovered, L2a3 in a single individual on the island of Korčula, and F1b haplogroup in 10 individuals on the island of Hvar. Both lineages have been completely sequenced, and presented in a form of phylogenetic tree. We wanted to emphasize events such as founder effect, bottleneck, isolation and various historical, geographical and sociocultural factors that acted upon the maternal genetic landscape of contemporary populations on Eastern Adriatic islands.

P17.4

Mitochondrial DNA Analysis of the Southeast European Genetic Variation Reveals a New, Local Subbranching in Hg X2

J. Šarac[1], *T. Šarić*[1], *D. Havaš Augustin*[1], *N. Jeran*[2], *S. Cvjetan*[2], *E. Metspalu*[3], *M. Reidla*[3], *N. Novokmet*[1], *S. Missoni*[1], *R. Villems*[3], *P. Rudan*[4];
[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Institute for Anthropological Research (at the time of research), Zagreb, Croatia,* [3]*Estonian Biocenter and Institute for Molecular and Cell Biology, Tartu, Estonia,* [4]*Institute for Anthropological Research and Anthropological Center of the Croatian Academy of Sciences and Arts, Zagreb, Croatia.*

High mtDNA variation in Southeastern Europe is a reflection of the turbulent and complex demographic history of this area, influenced by gene flow from various parts of Eurasia and a long history of intermixing. Our results of 1035 samples from four SEE populations (Croatians, Slovenians, Bosnians, Herzegovinians) show that their maternal genetic diversity fits within a wider European maternal genetic landscape, but in spite of the geographical proximity of sampled populations, certain differences can be observed in mtDNA haplogroup composition and variation. Also, we observed five new samples in the Bosnian population and one new Herzegovinian sample designated as X2* individuals, that could not be asigned to any of its sublineages (X2a'k) according to the existing X2 phylogeny. Subhaplogroup X2 is highly diversificated and spread over a wide geographic area, but usually at low frequencies (<5%). A detailed picture of X2 migrations across Europe, Asia and North America is still unrevealed and therefore intriguing. In attempt to clarify the phylogeny of our X2 samples, their mitochondrial DNA has been completely sequenced and no matching sequences have been found among over 18 000 mtDNAs in the updated mtDNA phylogenetic tree. We suppose that these lineages present SEE variants of the X2 clade and that they are signs of one or several local micro-differentiation processes that occured in a relatively recent demographic past. Additional sequencing of X2* individuals in this area is in progress and we expect our new insights will contribute to further resolution of the X2 phylogeny.

Y chromosome haplogroup analysis to estimate genetic origin of Balts

A. Puzuka[1], *L. Pliss*[2], *L. Piekuse*[1], *S. Limborska*[3], *A. Krumina*[2];
[1]*Riga Stradins University, Laboratory of Molecular Genetics, Riga, Latvia,* [2]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [3]*Institute of Molecular Genetics, Russian Academy of Sciences, Moscow, Russian Federation.*

Background. To obtain a more accurate portrait of ancestry of Balts Y chromosome haplogroupe (Y-hg) structure was determined in Russian individuals that inhabit historical regions of Baltic tribes and compared with incidence of Y-hg in Latvian population.

Material and methods. A study comprised 192 men - representatives of four

Northern-Western Russian regions (Mezen, Ustyuzhna, Sychevka, Starista) and 153 men representing Latvian subpopulations. To establish Y haplogroups DNA samples were hierarchically genotyped (using appropriate PCR followed by RFLP or sequencing) by 13 Y chromosomal binary markers (M9, SRY-1532, M17, Tat, M178, M170, P37, M253, M223, M172, YAP, M35, M201).
Results and discussion. It was found that distribution of major Y-hg's was relatively homogenous among analysed Russian and Latvian subpopulations. Only Russian subpopulation Mezen (Archangelsk district) showed the lowest frequency of the Slavic component
representing R1a haplogroup (22.5%) in comparison to other Russian (~55%) and Latvian (~40%) subpopulations. On the other hand the Fino-Ugric speaking population representing haplogroup N1c was the most common in Mezen (51%) in comparison to other Russian (~15%) and Latvian (~45%) subpopulations. Principal component analysis revealed that haplogroup N1c links Mezen with Eastern Latvian subpopulations Semigalians and Letigalians in one cluster, representing the hypothesis that the genetic history of N1c Y chromosomes in Baltic-speaking populations is distinct from that of the Uralic speakers.
Conclusion: Findings indicate that there are no significant differences in common Y-hg distribution among analysed Russian and Latvian subpopulations; however the analysis of Y-Hg genofund in Mezen indicates possible Fino-Ugric or Baltic ancestry.

P17.6
Diverse functions of titin in non-muscle cells

A. Mikelsaar;
University of Tartu, Institute of Biomedicine, Tartu, Estonia.

Introduction. Previously we have reported on the development of a new mouse anti-titin-A- band monoclonal antibody, named MAb Titl 5H1.1, using the synthetic peptide N- AVNKYGIGEPLESDSVVAK-C. In the human skeletal muscles, this antibody reacts specifically with titin in the A-band of the sarcomere and in different non-muscle cell types with nucleus and cytoplasm, including centrioles (Mikelsaar et al, 2010). We have specified the epitope area of MAb Tit1 5H1.1 to the hexapeptide N-AVNKYG-C which is highly conserved in the evolution and is related to Fn3 domains of the titin molecule. Our immunohisto- and cytochemical studies with MAb Tit1 5H1.1 in human, mouse and zebrafish tissues and cell cultures showed a striated staining pattern in muscle cells and also staining of centrioles, cytoplasm and nuclei in non-muscle cells (Mikelsaar et al, 2012). We have further studied the expression of titin in non-muscle cells and tissues of different organisms.
Results. Our immunohisto- and cytochemical studies with MAb Tit1 5H1.1 performed so far have shown the expression of titin in some cell types of nervous system of human and mouse organism. The study is in progress.
Conclusions. Our data show that titin may have in addition to the known roles in muscle cells and in non-muscle cells as a centriole associated protein also other roles in non-muscle cells to be specified. Acknowledgements. This work was partly supported by target financing SF0188096s08 of the Estonian Ministry of Science.

Hereditary diseases with specific mutations in Yakuts

N. R. Maximova[1,2]***;***
[1]*Yakutsk Science Center of Complex Medical Problems of Russian Academy of SD of Medical Sciences, Yakutsk, Russian Federation,* [2]*North Eastern Federal University, Yakutsk, Russian Federation.*

Several forms of pathologies, referred to as Yakut hereditary diseases, have been distinguished on the basis of the results of genetic epidemiological studies and molecular genetical analysis of Mendelian diseases in the population of the Republic of Sakha (Yakutia): spinocerebellar ataxia type I, myotonic dystrophy, oculopharyngeal muscular dystrophy, hereditary enzymopenic methemoglobinemia, and 3-M syndrome, SOPH syndrome, hereditary loss deafness 1A type. These diseases are characterized by a high prevalence among Yakuts as compared to their global incidence in the world and some of them have a specific mutations in Yakut population (oculopharyngeal muscular dystrophy, hereditary enzymopenic methemoglobinemia, and 3-M syndrome, SOPH syndrome, hereditary loss deafness 1A type). That results show that Yakut population is a genetical isolate and can be used in wide genetical studies for identify new genes.

P18.02
Difficulties in genetic counselling and prenatal diagnosis: An Omani consanguineous couple at risk for two distinct genetic syndromes

Z. Bruwer*, U. Achandira, K. Al Kharusi, A. Al-Kindy;*
Genetics and Developmental Medicine Clinic, Sultan Qaboos University Hospital., Muscat, Oman.

We report on a female infant with multiple congenital anomalies including cardiac defects, dysplastic multicystic kidney, hypotonia, developmental delay and dysmorphic features. Parents are first cousins and of Arab descent with a history of primary infertility and one second trimester miscarriage. Karyotyping and FISH for 4p deletion revealed a normal result. On performing array-CGH non-contiguous interstitial deletions within the long arm of chromosome 6 [6q14.1 to 6q14.3 (deletion ~1.9Mb) and 6q15 (~1.6Mb)] were identified. Heterozygous deletions of this interval have been reported to cause developmental delay, dysmorphism, cardiac anomalies and hypotonia. Follow-up array-CGH studies did not identify the presence of the deletion in either parent confirming the abnormality to be of de novo origin. Cytogenetic testing was undertaken to rule out the possibility of a balanced translocation. The mother's result revealed a normal karyotype while the father showed a whole short arm translocation of chromosome 3 onto chromosome 13. It was explained to the parents that the translocation was not the cause of the 6q deletion and although the recurrence risk for the microdeletion syndrome would be low they were still at risk for unbalanced products of conception arising from the translocation. The couple, of Islamic belief, was five months pregnant at the time of counselling and declined amniocentesis (termination of pregnancy has to occur prior to ensoulment of the fetus at 19 weeks). This report highlights the counselling difficulties experienced and the challenges faced with the time constraints for prenatal diagnosis and consideration of termination in the Arab population.

P18.03
Three peculiar families with alpha thalassaemia

A. RAVANI[1]*, A. Venturoli*[1]*, P. Rimessi*[1]*, B. Dolcini*[1]*, M. Taddei Masieri*[1]*, C. Trabanelli*[1]*, S. Bigoni*[1]*, S. Fini*[1]*, C. Borgna Pignatti*[2]*, A. Ferlini*[1]*;*
[1]*U.O e Sezione di Genetica Medica, Ferrara, Italy,* [2]*Clinica Pediatrica, Ferrara, Italy.*

Molecular characterization of alpha globin genes is of increasing interest. Due to the massive immigration phenomenon, to diagnose alpha thalassaemia is essential, especially in people from Asia (high frequency of large deletions, resulting in a procreative risk of Hb Bart's Hydrops Foetalis and HbH disease). Also in the Italian autochthonous population the definition of alpha globin genes structure is necessary in order to clarify many cases of thalassaemia intermedia.
We report here three peculiar Italian cases.
1)Two siblings from Veneto Region with Thalassaemia Intermedia. The clinical phenotype is mild with intrafamilial variability. In the family we identified heterozygous Beta°Cod.39
and two different triplicate alpha with different extension.
2)A family from Toscana Region, in which father and son present a severe form of Thalassaemia Intermedia (with apparent dominant transmission). In both we found heterozygous Beta°Cod. 39 mutation and a large duplication, involving the entire alpha globin gene cluster and including the regulatory region HS40
3)A young girl from the Veneto Region with a haemoglobin variant (50% of total haemoglobin; the haematological parameters are abnormal and the percentage of HbA2 is below the normal range.
The girl is a compound heterozygote for the deletion -alpha3.7 and the point mutation alpha2IVS1[-5nt]. By Direct Sequencing of fusion gene -alpha3.7 we identified Hb Hasharon (50% of total haemoglobin, one variant gene of two active alpha genes).
The given examples highlight that the alpha globin gene cluster analysis can help to clarify different scenarios in thalassaemia: intrafamilial clinical variability, unexpected inheritance pattern and misleading haematological results.

Screening relatives for familial abdominal aortic aneurysm: don't forget the women

K. M. Van de Luijtgaarden, *S. E. Hoeks, F. Bastos Gonçalves, E. V. Rouwet, T. Valentijn, R. J. Stolker, H. J. M. Verhagen, D. Majoor-Krakauer;*
Erasmus University Medical Center, Rotterdam, Netherlands.

Targeted screening of women and men with a genetic risk for abdominal aorta aneurysm (AAA) may add to population screening in reducing mortality from rupture. In order to identify individuals with a genetic risk for AAA, we performed a family history study of AAA patients and calculated the risk for individual relatives of having an aneurysm. Furthermore, we estimated the prevalence of familial AAA, and we investigated if specific clinical characteristics could help to distinguish familial AAA.
Family histories of 568 AAA patients were obtained by semi-structured questionnaires. Patients were classified as familial AAA when at least one first-degree relative was reported with an aortic aneurysm. Multivariable logistic regression analysis was performed to identify discriminative characteristics between familial and sporadic AAA.
Aneurysms were reported in 5% of all first-degree relatives (parents, siblings and offspring). Affected relatives occurred in 128 families, indicating a prevalence of 23% of familial AAA. Male and female patients had a similar prevalence of familial AAA. In patients with familial AAA, 17% of the first-degree relatives were affected, 26% of male relatives and 11% of female relatives. Index patients with familial AAA were younger at diagnosis and fewer had diabetes mellitus and hypertension.
The increased risk in male and female relatives in familial AAA showed that family screening - in contrast to population screening- should include women. Family history taking is important to recognise familial AAA and identify and inform relatives about their risk and offer relatives screening for AAA.

French Agence de la biomédecine annual report on genetic testing: a useful tool for public health

P. Lévy[1], *B. Belloir*[2], *V. Lanneau*[2], *A. Deshayes*[1], *A. Cohen-Akenine*[1], *D. Royère*[1];
[1]*Agence de la biomédecine, SAINT DENIS LA PLAINE, France,* [2]*INSERM, US14 - Orphanet, Paris, France.*

The French Agence de la biomédecine is a public organization under the supervision of the Health Ministry created by the law on Bioethics in 2004. Its missions aim to guarantee quality, safety and transparency and anticipate technological developments regarding activities under its responsibility among which genetic diagnoses.
Evaluation of the activities at a national level is a key element of the expertise and regulations that must be managed by the Agency. In order to collect and analyze genetic laboratory activities the Agency has established a partnership with INSERM (Orphanet) to develop an online access to Orphanet's thesaurus.
This enabled us to harmonize the disease nomenclature for which genetic testing was performed by the laboratories. With over than 240 laboratories and more than 1,000 various disorders, this partnership was the best way to analyze the different tests performed by French laboratories.
This report communicates only diagnostic activities related to routine patient's results excluding research genetic testing. (Summary of the 2012 postnatal diagnostic genetic activities results will be available in March).
This annual report is public and available on the Biomedicine Agency website: www.agence-biomedecine.fr
The report provides critical information to support rare diseases plan decision process at national level. It gives a complete overview of genetic labs practice and technological evolutions and to some extent encourages genetic labs networking.
In conclusion, the French Agence de la biomédecine annual national report is a useful tool for public health.

P18.06

Managing extreme anxiety in a mother preoccupied with a perceived physical defect in her normal infant

C. A. Shalhoub[1], *G. Betts*[2], *A. M. Turner*[1];
[1]*Medical Genetics Department, Sydney Children's Hospital, Randwick NSW, Australia,* [2]*Psychology Department, Sydney Children's Hospital, Randwick NSW, Australia.*

Anxiety is a normal emotion experienced by parents facing potential diagnosis of a genetic condition in their child. Genetic counsellors are trained in assisting patients manage their anxieties and anxiety usually diminishes following reassurance from clinicians and receipt of normal results. It is important however, that we are aware of our limitations and able to recognise when further support beyond genetic counselling is required. A mother presented in a highly anxious state following the suggestion that her baby had features of a skeletal dysplasia. Several clinical examinations and investigations deemed the baby normal. During these months, we engaged with the mother regularly as her anxiety escalated following each normal result. We were challenged by her persistence that her child was abnormal. Her anxiety appeared extreme and we feared for her, and consequently the baby's, well-being. Referral to a psychologist and later to a psychiatrist ensued. The mother's anxiety proved intractable and ultimately resulted in a devastating outcome. Many challenging issues were presented, including managing excessive concern and preoccupation with a perceived physical defect in a normal individual. This is in contrast to the more common scenario of assisting families adapt to a new diagnosis in their sometimes perceived perfect child. We have reflected on our roles as genetic counselling professionals and questioned our practice, as standard counselling strategies appeared ineffectual. This case has emphasised the breadth of human emotions and reactions and has allowed us to consider the nature of such extreme anxiety in this unique counselling situation.

P18.07

CNVs involving the dystrophin gene detected incidentally in female patients referred for routine array-CGH

S. Sigaudy[1], *T. Busa*[1], *D. Heron*[2], *S. Whalen*[2], *C. Popovici*[1], *C. Missirian*[1], *B. Keren*[2], ***N. Philip***[1];
[1]*Hopital d'Enfants de la Timone, Marseille, France,* [2]*Hopital Pitie Salpetrière, Paris, France.*

Molecular karyotyping has progressively replaced conventional karyotype for investigating intellectual deficiency (ID). This technology has significantly improved the rate of diagnoses in ID but raises the possibility of unexpected but clinically significant findings. These variants cannot explain intellectual disability but may predict adult-onset disorders or have an impact on relatives. The problems raised by the incidental finding of CNV affecting cancer predisposing genes have been debated and some authors have proposed that the possibility of such a finding should be discussed during the pre-test counselling session and explicitly mentioned on the informed consent form. We raise the question of finding CNVs in X-linked genes in girl and consequences on genetic counseling. Dystrophinopathies are among the most frequent X-linked disorders. Intragenic deletions or duplications account for approximately 60% of mutations and are thus accessible to routine array-CGH. We report four cases of CNV involving the dystrophin gene detected on CGH-array in female patients without any family history of dystrophinopathy who were referred for developmental delay. There were three deletions and one duplication. The rearrangement was de novo in two and inherited in two. A deletion identified in a girl was found in her asymptomatic father. In case of maternal inheritance, prenatal diagnosis for dystrophinopathy was proposed, whereas the cause of developmental delay in the index case remained unsolved. Furthermore, information of at-risk relatives proved difficult in the absence of precise knowledge of the condition.

P18.08

Clarifying assent

N. A. A. Giesbertz, *A. L. Bredenoord, J. J. M. van Delden;*
UMC Utrecht, Julius Center, Utrecht, Netherlands.

Assent is a relatively young term in research ethics, but became an often mentioned ethical requirement in current pediatric research guidelines. Also the European Society of Human Genetics considers assent an important condition for the inclusion of children in biobanks. Although many emphasize the importance of assent, few explain how they understand the concept. In this paper we will discuss the concept of assent and its different

underlying ethical principles.
In the first category, assent appears to be a substitute for informed consent, grounded in respect for autonomy and protection against harm. We conclude that this interpretation of assent is not of added value as a majority of children cannot be considered competent to make autonomous decisions. In addition, other safeguards are more appropriate to protect children against harm. The grounds from the second category can be classified as engagement grounds. These grounds do justice to the specifics of childhood and are of added value.
Furthermore, we argue that it follows that both the content and the process of assent should be adjusted to the individual child and the study at hand. This can be referred to as personalized assent. Personalized assent is an appeal to the moral responsibility and integrity of the researcher. We will illustrate our interpretation of assent by means of case studies we conducted on pediatric biobanks.

P18.09
Inheritance of autoinflammatory diseases: shifting paradigms and nomenclature

I. Touitou;
UMAI laboratoire de génétique, Montpellier, France.

Over 15 years have passed since the discovery of the first autoinflammatory gene, MEFV, responsible for familial Mediterranean fever. The identification of another gene, TNFRSF1A, in 1999 led to the concept of autoinflammation which characterizes rheumatologic conditions triggered by a defective innate immunity. Substantive progress has been made since then, with the identification of 18 autoinflammatory genes accounting for up to 24 disease entities showing overlapping symptoms. The accumulation of studies reporting patients with missing or excess mutations as compared to expected numbers, favors the hypothesis that these diseases are distributed along a continuum ranging from monogenic to multifactorial conditions, rather than featuring only classical modes of inheritance. Moreover, the probable interactions of environmental and epigenetic factors further obscure our understanding of the mechanisms underlying the phenotypic expression of patients.
This review explores the history of autoinflammatory gene discovery, discusses the nosological disparities stemming from the clinical vs pathophysiological definition of autoinflammatory diseases, and summarizes various inheritance patterns. This review calls for a consistent disease nomenclature and presents a reconciling hypothesis which places different sequence variants within the autoinflammatory disease continuum. Integrating these new concepts should help to facilitate communication between health professionals and promote personalized patient care.

P18.10
Targeted preconception carrier screening aimed at high-risk populations

L. Henneman[1], *P. Lakeman*[2], *M. C. Van Maarle*[2], *L. P. Ten Kate*[1], *M. C. Cornel*[1], *E. J. Meijers-Heijboer*[1,2];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands.*

Autosomal recessive disorders cause serious morbidity and mortality in at least 25/10,000 children. Most affected children (>80%) are born unexpectedly without recognized family history of the condition. Preconception carrier screening aims to identify carrier couples with 1-in-4 risk of having an affected child, enabling informed reproductive choices before pregnancy. Many countries do not have population-based carrier screening programmes, and even for subpopulations at higher risk, testing is often not available.
In the Netherlands, in the absence of a nation-wide screening programme, we have taken the initiative to start offering carrier testing to high-risk populations: 1) An isolated community having high prevalent disorders due to founder effects; 2) Ashkenazi Jewish population (e.g. Tay Sachs disease); 3) Consanguineous couples; 4) People with African, Asian or Mediterranean ancestry (haemoglobinopathies); and 5) Caucasian people (cystic fibrosis). Each population requires a different approach, preferably embedded in a broad preconception care setting. A multidisciplinary approach is required, including, eg. primary care providers, clinical/molecular geneticists, and patients organizations. Possibilities and barriers for the implementation of screening will be studied. The psychological impact, stigmatisation/discrimination and informed choice will be monitored.
A great advantage is that services can be developed based on community needs, and can thus be delivered more effectively. New technologies allow simultaneous analyses of carrier status of multiple recessive disorders, potentially changing the screening landscape, but obviously raises new ethical and societal issues. By using a step-wise integrated approach targeting specific high-risk groups, an infrastructure for responsible genetic screening services (potentially even genome-wide) can be developed.

P18.11
First case of Hb Randwick and beta-thalassemia in an Italian family

G. Ivaldi[1], *G. Barberio*[2], *D. Leone*[1], *S. Bigoni*[3], *S. Carturan*[3], *M. Taddei Masieri*[3], *A. Ravani*[3], *A. Citana*[1], *D. A. Coviello*[1];
[1]*Laboratory of Human Genetics, E.O. Ospedali Galliera, Genoa, Italy,* [2]*Laboratorio Analisi Chimico Cliniche, Ospedale di Oderzo- Azienda ULSS 9, Treviso, Italy,* [3]*Laboratorio di Genetica Molecolare – U.O.Genetica Medica, A.O.Universitaria S.Anna, Ferrara, Italy.*

When two or more globin gene defects are co-inherithed the results is quite often a production of complex hemoglobin asset not always easy to diagnose. In particular the laboratory evaluation at the protein level, in these cases, the bichemical assay could be very tricky and the diagnosis can be missed.
Very indicative is the case presented in this report: a girl, 10yo, presenting frequent episodes of anemia. One episode occurred during an infection by a parvovirus at 5yo. The child and her mother showed a very similar chromatographic profile (Variant II - Beta Thal Dual Kit, Bio-Rad) with an increased Hb A2 and moderate microcytosis in the child. The first level screening by biochemical test was in favour of a beta thalassemia trait in the child, but with the possibility to investigate additional defects.
The molecular analysis of beta genes identified in the proband the presence of beta thalassemia (beta° IVSI-1 at heterozigous state) and one additional T>G mutation at codon 15 on the second allele, corresponding to the rare variant "Hb Randwick" already described in 1988 in an Italian family living in Australia. This same defect was present also in the mother. Hb Randwick has been described as an unstable variant oh Hb because "in vitro" shows fenomeni di precipitation events by oxidative agents, tested in our laboratoty. Hb Randwick was never described before associated with beta thalassemia; the case presented is a new combination of two beta globin genes and indicate the possibility to better evaluate Hb instability.

Biobanking for genetic research: ethical, legal and social issues

K. A. Melham;
University of Oxford, Oxford, United Kingdom.

Biobanks are fundamental resources for biomedical research. They are particularly useful for research requiring large sample sizes, such as genetic studies. This paper addresses core ethical, legal and social (ESLI) issues that arise in biobanking for genetic research. Delving more deeply into the usual – and still necessary – considerations of consent, withdrawal, privacy, feedback, benefit sharing and governance, this paper addresses the particular issues raised by the very intersection of biobanking and genetics within the regulatory oversight of medical research. While not claiming exceptional status for either, it argues that both biobanks and genetic research represent specific instances where the established ethical norms and practice of medical research may not be fit for their purposes. From the fiction of anonymity to the conflation of requirements for banking with those for invasive or interventional research, this paper reassesses the ethical, legal and social requirements – and possibilities – of biobanking for genetic research.

Genetic discrimination in life insurance could be ethically acceptable.

S. Côté[1,2], *V. Ravitsky*[3], *H. Pavel*[1,4];

Genetic discrimination (GD) is a complex phenomenon that may have social, personal, familial and economic implications for individuals and populations. In Canada, there is currently a legal vacuum regarding the protection of individuals against GD. Concerns regarding GD by insurance companies are currently being expressed by both patients and professionals. These concerns can create barriers to genetic counselling and testing. They may also encourage individuals to resort to direct-to-consumer (DTC) companies for genetic testing outside the healthcare system.
This study explored ethical arguments regarding justifications of GD in the context of life insurance. Our analysis concluded that GD would be ethically acceptable if allowed only for amounts that exceed a minimal coverage (based on actuarial data) necessary for the promotion of equality of opportunity, as in the case of property and business start-up insurance. For example, in England and Wales, there is a moratorium prohibiting GD regarding minimal coverage (in life insurance the threshold is currently 500 000 £). Beyond this amount, differential treatment is permitted only if actuarial data exists to justify such treatment on the basis of customers' genetics. In Canada, similar protection against DG could promote access to genetic services and prevent the use of DTC testing, which currently does not ensure informed consent nor provides appropriate counselling. Appropriate protection can thus promote access to proper medical care and allow healthcare professionals to be less reluctant when referring their patients to genetic testing.

Cardiac conditions as an example of a new public health approach to genetic testing

C. Skrzynia*, J. S. Berg, J. P. Evans;*
University of North Carolina, Chapel Hill, NC, United States.

Public health genetics is facing a new, technology-driven challenge. Massive parallel sequencing (MPS) offers the opportunity of detecting mutations throughout the genome, thereby potentially allowing population screening for a wide range of conditions characterized by serious morbidity and mortality. Cardiac diseases offer an important opportunity to explore this challenge due to extensive knowledge about genes underlying serious but preventable genetic cardiac conditions. The first public health endeavor in the US, newborn screening, began in the 1960's to ascertain treatable conditions not evident in newborns. The criteria necessary for screening included preventable or treatable conditions with sufficiently high population frequency; significant morbidity and/or mortality and the availability of inexpensive and effective screening.Advances in technology such as tandem mass spectroscopy eventually allowed detection of many metabolic conditions from the same sample with little increased cost. That advance has generated debate regarding whether the classic criteria above are too restrictive and whether newborn screening should be expanded. Now our field faces the possibility of further expanding screening by using MPS to screen adults for high risk from undetected, highly penetrant mutations. If such a screening program were to be implemented, what criteria should be fulfilled? We propose to consider the following criteria: clinical severity; penetrance; and efficacy and acceptability of intervention. Using the example of cardiac conditions such as LQTS, HCM, DCM and others, we discuss these potential criteria and develop a scoring system to guide a new public health approach to genetic testing.

A nurse-led cardiogenetic follow-up clinic is highly appreciated by the family members at risk for DCM/HCM.

K. Berkenbosch-Nieuwhof[1], *E. Birnie*[1], *M. Van den Berg*[1], *P. Van Haelst*[2], *J. Van Tintelen*[1], *I. Van Langen*[1];
[1]*University Medical Center Groningen, Groningen, Netherlands,* [2]*Antonius Hospital, Sneek, Netherlands.*

Purpose: A growing number of first degree family members at risk for developing dilated/hypertrophic cardiomyopathy (DCM/HCM) are advised to be routinely followed up, but available health care resources are increasingly scarce. We compared a novel nurse-led cardiogenetic follow-up clinic with conventional follow-up by cardiologists.
Methods: First degree family members eligible for DCM/HCM follow-up were invited at the nurse-led FU clinic or attended the cardiologist's FU clinic randomly. Care consisted of ECG, echocardiography, assessment of his/her - and family's health and provision of information on DCM/HCM. Uptake and resource use were recorded. Patient satisfaction was collected using a validated questionnaire.
Results: 164 of 225 eligible family members (73%) participated (range 16-78 years, 47% men). 50% were mutation carriers and 50% had a positive family history of DCM/HCM. The uptake of the nurse-led clinic was higher than the cardiologist's clinic (72% vs. 55%, p=0.02). A follow-up consult took equal amounts of time (mean 15min, range 13-17min). The maximum patient satisfaction score was more often reached at the nurse-led clinic (85% vs. 48%, p<0.01). Family members at the nurse-led clinic more frequently reported that the caregiver appreciated his/her opinion (91% vs. 61%, p<0.01) and that they appreciated the caregiver's time highly (94% vs. 72%, p<0.01). Personal perceived control was equal.
Conclusions: Follow-up at a nurse-led cardiogenetic clinic results in larger uptake and more patient satisfaction whereas caregiver's time and perceived personal control are equal and costs are lower. A nurse-led cardiogenetic clinic can be considered an optimal alternative for conventional follow-up by cardiologists.
